Executive Summary

This report summarizes the energy efficiency potential analysis performed by the Pennsylvania Statewide Evaluator (SWE) Team from 2016 to 2025. This report presents the results of technical, economic, and achievable potential over 10 years (starting on June 1, 2016) for the residential, commercial, and industrial sectors. In addition, program potential for electric energy efficiency programs was calculated over five years.

STUDY OBJECTIVES AND SCOPE

This study examines the potential to reduce electric consumption and peak demand through the implementation of energy efficiency technologies and practices in residential, commercial, and industrial facilities, as well as associated activities in Pennsylvania.¹ This study assesses electric energy efficiency potential throughout the seven Pennsylvania investor-owned electric distribution company (EDC)² service areas over 10 years, from June 1, 2016 through May 31, 2025.

The main objectives of the study include:

- Evaluating the electric energy efficiency technical, economic, achievable, and program potential savings throughout the Commonwealth of Pennsylvania, and more specifically within the seven largest EDC service areas;
- Calculating the Total Resource Cost Test (TRC) benefit-cost ratio for the achievable potential savings for electric energy efficiency measures and programs, and determining the electric energy efficiency economic potential savings for Pennsylvania homes and businesses.

TYPES OF POTENTIAL ESTIMATED

The scope of this study distinguishes four types of energy efficiency potential: (1) technical, (2) economic, (3) achievable, and (4) program.

- **Technical Potential** is the theoretical maximum amount of energy use that could be displaced by efficiency, disregarding all non-engineering constraints such as cost-effectiveness and the willingness of end users to adopt the efficiency measures. Technical potential is constrained only by factors such as technical feasibility and applicability of measures. Under technical potential, the SWE Team assumed that 100% of new construction and burnout measures are adopted as those opportunities become available, while retrofit and early retirement opportunities are replaced incrementally (10% per year) until 100% of homes (residential) and square footage stock (nonresidential) are converted to the efficient measures over 10 years.
- **Economic Potential** refers to the subset of the technical potential that is economically cost-effective as compared to conventional supply-side energy resources. Economic potential follows the same adoption rates as technical potential. In addition, similar to technical potential, the economic scenario ignores market barriers to ensuring actual implementation of efficiency. Finally, economic potential only considers the costs of efficiency measures themselves, ignoring

¹ The residential sector analysis includes an estimation of low income potential. Similarly, the nonresidential sector analysis examines the potential from institutional facilities.

² EDCs evaluated within this study include Duquesne Light and Power, PPL Energy, PECO Energy, and the four First Energy Companies: Met-Ed, Penelec, PennPower, and West Penn Power.

any programmatic costs (e.g., marketing, analysis, administration) that would be necessary to capture them.³

- **Achievable Potential** is the amount of energy use that efficiency can realistically be expected to displace, assuming the most aggressive program scenario possible (e.g., providing end users with payments for the entire incremental cost of more efficient equipment). This is often referred to as *maximum achievable potential*. Achievable potential takes into account real-world barriers to encouraging end users to adopt efficiency measures, the non-measure costs of delivering programs (for administration, marketing, tracking systems, and monitoring and evaluation), and the capability of programs and administrators to boost program activity over time.⁴ In addition to the maximum achievable scenario, this analysis includes a *base achievable potential* scenario that is based on historical incentive levels and the corresponding program adoption rates observed from the Pennsylvania EDCs and other regional utility demand-side management (DSM) programs. The base achievable potential scenario also uses willingness-to-participate surveys conducted for the 2014 Pennsylvania (PA) Public Utility Commission (PUC) residential and nonresidential baseline studies.
- **Program Potential** refers to the efficiency potential possible given specific program funding levels and designs. Program potential studies can consider scenarios ranging from a single program to a full portfolio of programs. A typical potential study may report a range of results based on different program funding levels. For this study, the SWE Team has opted to utilize a simple-scaling approach to estimate program potential given the available DSM budgets stipulated under Act 129⁵. More information on this calculation approach can be found in Section 1.10, “Program Potential,” below.

APPROACH SUMMARY

The SWE Team used a “bottom-up” approach to estimate energy efficiency potential in the residential sector. Bottom-up approaches begin with characterizing the eligible equipment stock, estimating savings and screening for cost-effectiveness first at the measure level, then summing savings at the end-use and service-territory levels. In the commercial and industrial sectors, the SWE Team utilized the bottom-up modeling approach to first estimate measure-level savings and costs as well as cost-effectiveness, and then applied cost-effective measure savings to all applicable shares of energy load. Further details of the market research and modeling techniques utilized in this assessment are provided in Section 1, “Analysis Approach,” below.

INCREMENTAL ANNUAL VS. CUMULATIVE ANNUAL SAVINGS

It is important to note the distinction between incremental annual savings and cumulative annual savings. Incremental annual savings are those that occur in a given year due to participation in energy efficiency programs in that given year. Cumulative annual energy savings are those that accumulate in any given year due to participation in energy efficiency programs in that given year, as well as participation in prior years, to the extent that participation in prior years continues to yield savings. Cumulative annual energy savings account for the fact that measures installed in prior years may have useful lives longer than one year, and therefore produce savings that persist into the future for some

³ National Action Plan for Energy Efficiency, “Guide for Conducting Energy Efficiency Potential Studies” (November 2007), page 2-4.

⁴ National Action Plan for Energy Efficiency, “Guide for Conducting Energy Efficiency Potential Studies” (Nov. 2007), page 2-4.

⁵ Act 129 EE&C Phase II Implementation Order – Entered Aug. 3, 2012. The Act 129 Phase 2 EE&C Program Implementation Order. From the Public Meeting of August 2, 2012. Docket Nos. M-2012-2289411 and M-2008-2069887

time. However, cumulative annual energy savings also reflect savings decay – that is, savings that can no longer be counted in a given year once a measure is no longer operational or has “burned out.”

One particularly important distinction between incremental annual savings and cumulative annual savings is that the sum of the incremental annual savings may be greater than the cumulative annual savings over an extended time frame due to measure savings decay. A detailed example of the potential difference between incremental annual savings and cumulative annual savings is discussed in Section 1.4, “Incremental Annual vs. Cumulative Annual Savings.”

STUDY LIMITATIONS

As with any assessment of energy efficiency potential, this study necessarily builds on various assumptions and data sources, including the following:

- Energy efficiency measure lives, savings, and costs
- The discount rate for determining the net present value (NPV) of future savings
- Projected penetration rates for energy efficiency measures
- Projections of electric generation avoided costs for electric capacity and energy as defined in the 2009, 2011, and 2013 Pennsylvania PUC TRC Orders⁶
- Projections of transmission and distribution (T&D) avoided costs
- Future changes to codes and standards
- EDC load forecasts and assumptions on their disaggregation by sector, segment, and end use
- End-use saturations and fuel shares

While the SWE Team has sought to use the best and most current available data, there are assumptions for which a reasonable alternative would yield slightly different results. Furthermore, while the lists of energy efficiency measures examined in this study represent most commercially available measures, these measure lists are not exhaustive. Finally, the SWE Team did not attempt to place a dollar value on some difficult-to-quantify non-energy benefits arising from the installation of some measures, such as increased comfort or increased safety. These non-energy benefits may affect some customers’ choices to implement one or more measures that may otherwise have been less cost-effective or only marginally cost-effective.

ENERGY EFFICIENCY POTENTIAL

Table ES-1 and Figure ES-1 summarize the achievable potential across all sectors as well as total annual program costs. Total maximum achievable potential for the region of the seven EDCs covered by Act 129 in 2020 and 2025 for energy efficiency is 7.5% and 13.2%, respectively, of 2010 kilowatt-hour (kWh) sales.⁷

⁶ The PA PUC TRC Test Orders can be found on the PA PUC 129 website.

⁷ For purposes of this study, the baseline period sales are forecast kWh sales for each EDC for the period June 1, 2009 through May 31, 2010. The SWE Team has selected the load for this year to be consistent with Act 129 of 2008, which required the EDCs to reduce electric consumption at least 1% by May 31, 2011, and 3% by May 31, 2013, relative to their forecast load for the period June 1, 2009 through May 31, 2010. All energy and demand savings are presented in this report at the end-consumer (meter) level unless specifically noted otherwise.

The SWE Team estimates that with the current annual spending cap,⁸ the seven EDCs can achieve a combined annual savings equal to 0.8% to 1.0% of 2010 load per year. After accounting for measure savings decay and annual savings adjustments for codes and standards, the cumulative annual program potential in 2020 is 5,092,433 megawatt hours (MWh) or 3.5% of the baseline load.

Without a budget cap, annual savings could achieve roughly 1.2% to 2.0% of 2010 load in the base achievable and maximum achievable scenarios, respectively. On a cumulative annual basis, the base achievable potential is 4.6% of the baseline load in 2020 and the maximum achievable potential is 7.5% of baseline load in 2020.

| EDC Program Costs - Million \$ | | | | | | |
| Maximum Achievable | \$581.8 | \$601.9 | \$619.9 | \$638.5 | \$607.0 | \$642.6 |
| Base Achievable | \$302.1 | \$316.2 | \$329.3 | \$342.6 | \$325.7 | \$361.6 |
| Program | \$228.7 | \$239.2 | \$249.1 | \$259.2 | \$246.4 | n/a* |
| <i>*Program potential was only estimated for five years to be consistent with a Phase III of Act 129. Program potential in 2025 would be part of Phase IV of Act 129</i> | | | | | | |

⁸ Program potential is estimated based on funding levels of 2% of 2006 utility electric revenues, as specified in Act 129 legislation.

Figure ES-1: Cumulative Annual Energy (MWh) Savings by Scenario by Year

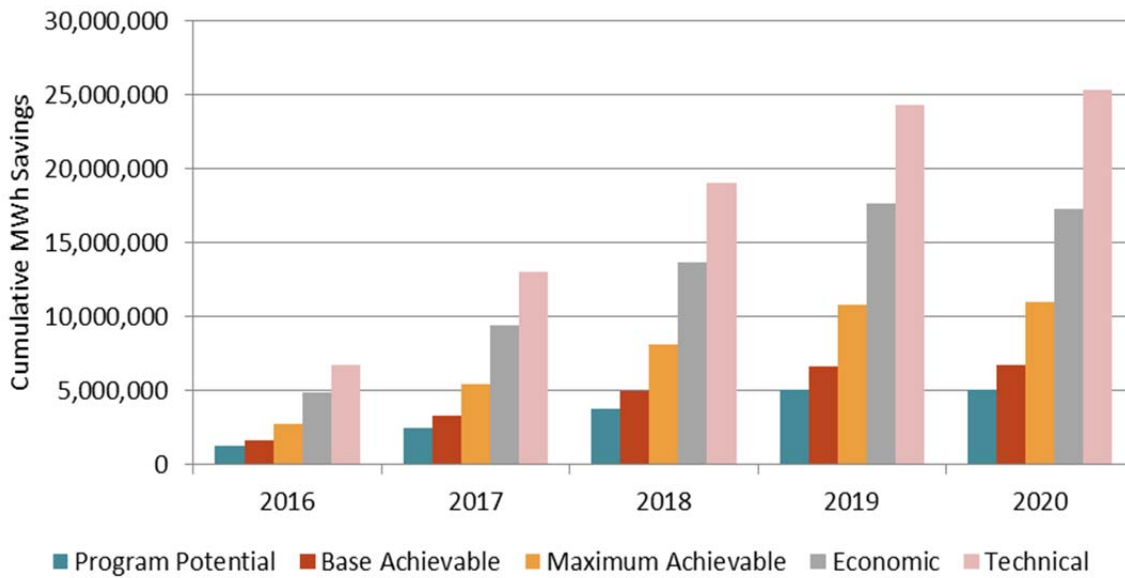

Figure ES-2 shows the cumulative annual energy (MWh) savings impacts for each potential scenario relative to the combined EDC load forecast for 2016 through 2025. The projected energy savings are estimated to be achieved through EDC program efforts and exclude savings due to codes and standards, which are incorporated in the EDCs’ forecasts.⁹

Figure ES-2: 2016-2025 Statewide Energy (MWh) Forecast and Potential Savings Projections by Scenario

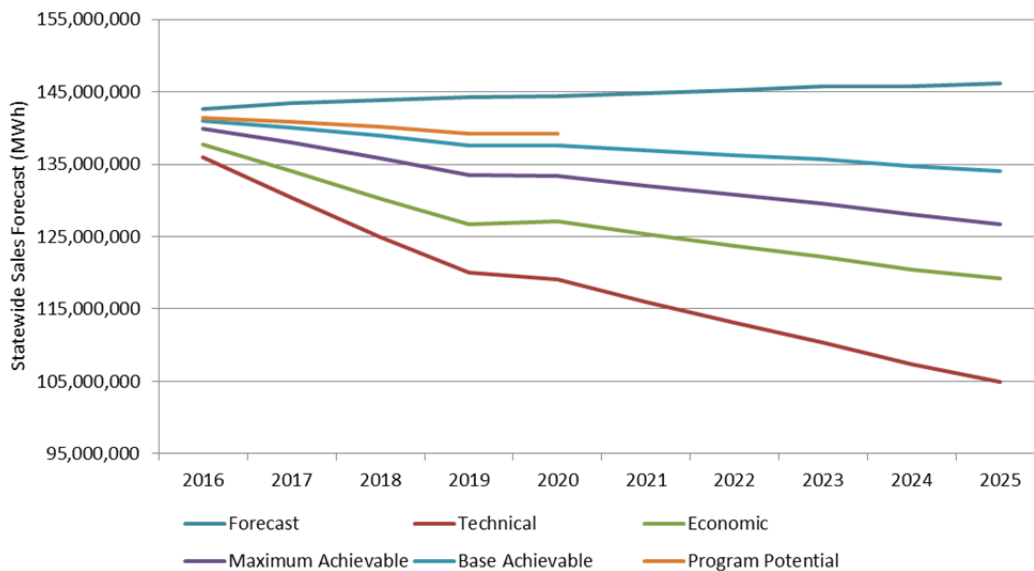

Table ES-2 presents the cumulative annual base achievable potential by customer class. Residential-sector savings represent 2.5% of the baseline load after five years and 4.5% after 10 years.

⁹ Note that the lack of apparent growth in energy savings potential between 2019 and 2020 is not a result of reduced market adoption of efficient technologies, but the estimated impacts of the general service lighting backstop provision in Energy Independence and Security Act (EISA) of 2007 and the analysis’ adjustment that the general service lighting baseline shifts to the compact fluorescent light (CFL) bulb in 2020. The shift in baseline technology impacts all installed bulbs, resulting in modest overall growth in potential from 2019 to 2020.

Nonresidential sector savings represent 2.1% of the baseline load after five years and 3.8% of the baseline in 2025.

Table ES-2: Statewide Cumulative Annual Potential by Customer Sector by Year

| Base Achievable Potential | 2016 | 2017 | 2018 | 2019 | 2020 | 2025 |
|--|---------|-----------|-----------|-----------|-----------|-----------|
| Cumulative Savings Potential - MWh | | | | | | |
| Residential | 953,810 | 2,005,954 | 3,087,372 | 4,149,256 | 3,722,120 | 6,587,083 |
| Commercial | 408,759 | 791,076 | 1,173,748 | 1,550,571 | 1,853,605 | 3,205,776 |
| Industrial | 248,169 | 488,254 | 719,423 | 949,338 | 1,173,082 | 2,319,030 |
| Cumulative Savings Potential - % of 2010 Load | | | | | | |
| Residential | 0.7% | 1.4% | 2.1% | 2.8% | 2.5% | 4.5% |
| Commercial | 0.3% | 0.5% | 0.8% | 1.1% | 1.3% | 2.2% |
| Industrial | 0.2% | 0.3% | 0.5% | 0.6% | 0.8% | 1.6% |

Figure ES-3 shows the cumulative annual base achievable potential in 2020. The residential sector accounts for 55.2% of the base achievable savings in 2020. The commercial- and industrial-sector savings account for 27.5% and 17.4%, respectively, of the total base achievable potential in 2020.

Figure ES-3: Statewide 2020 Cumulative Annual Potential by Customer Sector

Table ES-3 shows the cumulative annual maximum achievable, base achievable, and program potential by EDC. Additional details of electric energy efficiency potential by EDC can be found in Sections 3.4, “Residential Potential by EDC;” 4.4, “Commercial Potential by EDC;” and 5.4, “Industrial Potential by EDC”.

Table ES-3: Portfolio Cumulative Annual Energy (MWh) Savings Potential by EDC by Year

| Energy Savings (MWh) | 2016 | 2017 | 2018 | 2019 | 2020 | 2025 |

| <i>Program Pot. % of 2010 Load</i> | 0.8% | 1.7% | 2.6% | 3.4% | 3.5% | - |

This study concludes that continuing electric energy efficiency programs in a Phase III of Act 129 will continue to be cost-effective for Pennsylvania ratepayers. Table ES-4 shows the TRC benefit-cost ratios for the maximum achievable, base achievable, and program potential based on a five-year implementation period beginning June 1, 2016. The TRC ratio statewide for the program potential scenario is 1.88.

Table ES-4: Statewide TRC Cost-Effectiveness Results by Scenario for 2016-2020

| | NPV ¹⁰ Costs (Million \$) | NPV Benefits (Million \$) | NPV Net Benefits (Million \$) | TRC BC Ratio ¹¹ |
|---------------------------|---|------------------------------|----------------------------------|-------------------------------|
| Maximum Achievable | \$3,412.7 | \$6,235.1 | \$2,822.4 | 1.83 |
| Base Achievable | \$2,233.3 | \$4,185.7 | \$1,952.4 | 1.87 |
| Program | \$1,692.0 | \$3,184.2 | \$1,492.3 | 1.88 |

Table ES-5 shows the five-year EDC costs to acquire the potential; the sum of the first-year MWh savings over the five-year period; and the estimated acquisition costs (\$/MWh) for the maximum achievable, base achievable, and program potential scenarios. The program potential energy savings in Table ES-5 are therefore the sum of the incremental annual savings achieved in each of the years spanning 2016 through 2020. This total is different than the cumulative annual program potential savings estimate of 5,092,433 MWh shown in Tables ES-1 and ES-3 due to the differences in incremental annual savings and cumulative annual savings described above.

For the purposes of determining statewide acquisition costs from the base achievable costs and savings data, the SWE Team concludes that it is correct to divide the sum of the incremental annual savings data across the timeframe by the sum of the annual costs. This method maintains the integrity of the definition of an acquisition cost and aligns with actual EDC budgeting and planning practices. The differences in the sum of the incremental annual and cumulative annual program potential savings should be carefully considered when using this report to inform the establishment of future savings targets for Phase III of Act 129.

Table ES-5: Statewide Acquisition Costs by Scenario for 2016-2020

| | 2016-2020 Program Costs (Million \$) | 2016-2020 Program Savings (MWh) | Acquisition Cost (\$/1 st -YR MWh Saved) |
|---------------------------|---|------------------------------------|--|
| Maximum Achievable | \$3,644.3 | 14,332,129 | \$254.3 |
| Base Achievable | \$1,615.9 | 8,782,160 | \$184.0 |
| Program | \$1,222.5 | 6,629,460 | \$184.4 |

The five-year program potential energy savings and budget values are found in Table ES-6 for each EDC and the Commonwealth of Pennsylvania.

Table ES-6: Five-Year Program Potential Savings and Budget by EDC

| | Portfolio Spending Ceiling (Million \$) | Program Acquisition Costs (\$/1 st -YR MWh Saved) | 2016-2020 Potential Savings (MWh) | % of 2010 Forecast |
|--|---|---|--------------------------------------|-----------------------|
| 2016-2020 – Five-Year Program Potential | | | | |
| Duquesne | \$97.7 | \$186.9 | 522,837 | 3.7% |
| FE: Met-Ed | \$124.3 | \$182.2 | 682,474 | 4.6% |
| FE: Penelec | \$114.9 | \$191.9 | 598,704 | 4.2% |
| FE: Penn Power | \$33.3 | \$176.1 | 189,107 | 4.0% |
| FE: West Penn | \$117.8 | \$181.0 | 650,760 | 3.1% |
| PECO | \$427.0 | \$184.7 | 2,311,387 | 5.9% |
| PPL | \$307.5 | \$183.7 | 1,674,191 | 4.4% |
| Statewide | \$1,222.5 | \$184.4 | 6,629,460 | 4.5% |

¹¹ BC ratio: Benefit-cost ratio

ORGANIZATION OF THE REPORT

The remainder of this report is organized in seven sections as follows:

Section 1 Analysis Approach details the methodology used to develop the estimates of technical, economic, achievable, and program potential for electric energy efficiency savings.

Section 2 Characterization of Pennsylvania Service Areas provides an overview of the Pennsylvania EDC service areas and a brief discussion of the historical and forecasted electric energy sales by sector as well as peak demand.

Section 3 Residential Energy Efficiency Potential provides a breakdown of the technical, economic, and achievable potential in the residential sector.

Section 4 Commercial Energy Efficiency Potential provides a breakdown of the technical, economic, and achievable potential in the commercial sector.

Section 5 Industrial Energy Efficiency Potential provides a breakdown of the technical, economic, and achievable potential in the industrial sector.

Section 6 Portfolio Level Results and Program Energy Efficiency Potential Estimates provides detailed information on the program potential in the residential, commercial, and industrial sectors over the five-year period of June 2016 through May 2020.

Section 7 Conclusions and Recommendations presents the final discussion regarding the potential for energy efficiency savings in Pennsylvania.

1 Analysis Approach

This section describes the overall methodology the SWE Team utilized to conduct the Pennsylvania statewide electric energy efficiency potential study. The main objectives of this energy efficiency potential study is to estimate the technical, economic, achievable, and program potential for energy efficiency statewide for periods of five and 10 years beginning June 1, 2016; and to provide potential kWh and kW savings estimates for each level of energy efficiency potential (technical, economic, achievable, and program). This study does not examine potential peak load reduction and energy reductions from demand response programs, but rather will estimate demand savings and peak load reductions¹² associated with different types of energy efficiency potential.¹³

This electric energy efficiency potential study will provide results that are both statewide and specific to each of the seven Pennsylvania EDCs. To accomplish this objective, the SWE Team created a series of unique energy efficiency potential models for each of the seven EDCs and for each primary market sector (residential, commercial, and industrial).¹⁴

1.1 OVERVIEW OF APPROACH

The SWE Team used a bottom-up approach to estimate energy efficiency potential in the residential sector. Bottom-up approaches begin with characterizing the eligible equipment stock, estimating savings and screening for cost-effectiveness first at the measure level, then summing savings at the end-use and service area levels. In the commercial and industrial sectors, the SWE Team utilized the bottom-up modeling approach to first estimate measure-level savings and costs as well as cost-effectiveness, and then applied cost-effective measure savings to all applicable shares of energy load. Further details of the market research and modeling techniques utilized in this assessment are provided in the following sections.

1.2 FORECAST DISAGGREGATION

This analysis of the potential for energy efficiency savings begins with utilizing the most recent and available electricity sales forecasts from Pennsylvania EDCs for a period of 10 years beginning June 1, 2016, which reflects annual energy reductions from Act 129 Phases I and II.

Disaggregated forecast data provides the foundation for the development of energy efficiency potential estimates for the commercial and industrial sectors. The SWE Team applied the measure-level savings factors discussed in the Technical Potential section below to the corresponding share of the EDC's energy load by sector (commercial, industrial, and government/nonprofit/institutional (GNI)), segment (building type), end use, and equipment type.

For the commercial and industrial sectors, the SWE Team disaggregated each EDC's baseline 2016-2025 load forecast using a top-down/bottom-up calibration analysis. The SWE Team conducted the top-down forecast disaggregation by applying EDC-specific segment and end-use consumption shares derived from

¹² Estimated peak load reductions will be estimated, to the extent practicable, consistent with the coincident summer peak period as defined in the 2014 TRM, (i.e., "...the period between the hour ending 15:00 Eastern Prevailing Time (EPT) and the hour ending 18:00 EPT during all days from June 1 through August 31, inclusive, that is not a weekend or federal holiday.")

¹³ The SWE Team conducted a Demand Response (DR) Potential Study in parallel with the Energy Efficiency MPS. The SWE Team issued a separate report detailing the findings from the DR Potential Study. The PA PUC will provide guidance to the SWE Team on the allocation of the spending cap budget between energy efficiency (EE) and DR programs for Phase III.

¹⁴ To the extent possible, modeling input assumptions for the potential study will be based on the results and findings from studies with statistically valid sampling designs and acceptable precision levels.

the 2014 Pennsylvania Non-Residential End-Use and Saturation Study to each EDC's load forecast. In this exercise, the SWE Team:

- Determined energy consumption per customer sector and segment in baseline year (2016).
- Disaggregated customer segment loads into end-use loads such as space cooling.
- Forecasted the 10-year end-use energy consumption by sector and segment through 2025.

The SWE Team then constructed a bottom-up commercial and industrial forecast of consumption by equipment type, calibrating the forecast to the top-down disaggregated forecast by end use for each sector and segment. The SWE Team conducted this calibration by calculating the available stock (square feet) in the base year for each EDC, then multiplying stock against equipment energy use intensities EUIs after applying an end-use fuel share, end-use saturation, and equipment type saturation values derived from the 2014 Pennsylvania Baseline Study¹⁵ and other regional sources as needed. The SWE Team calibrated this bottom-up estimate of energy consumption to the top-down energy consumption values by altering the equipment EUIs and/or available stock as needed.

The commercial sector, as defined in this analysis, was comprised of the following business segments:¹⁶

- Institutional
 - Education
 - Healthcare
 - Government/Public Service
 - Non-profit
 - Other Institutional
- Grocery
- Lodging
- Office
- Restaurant
- Retail
- Warehouse
- Miscellaneous

The industrial sector, as defined in this analysis, was comprised of the following industrial segments:¹⁷

- Manufacturing
 - Chemicals
 - Computers and Electronics
 - Food
 - Metals
 - Paper
 - Plastics
 - Other
- Mining
- Other Non-Manufacturing

¹⁵ Two baseline studies (residential and nonresidential) were performed. *Pennsylvania Statewide Act 129 2014 Non-Residential End Use & Saturation Study*. April 2014 submitted by Nexant; and *2014 Pennsylvania Statewide Act 129 Residential Baseline Study*. April 2014 submitted by GDS Associates.

¹⁶ These designations may fall into "small C&I" or "large C&I" rate schedules and Act 129 customer sectors for EDCs. Some of these segments may also qualify as "GNI."

¹⁷ These designations may fall into "small C&I" or "large C&I" rate schedules and Act 129 customer sectors for EDCs. Some of these segments may also qualify as "GNI." In addition, some "agricultural" customers may have a residential rate schedule for some EDCs.

Although it is not necessary to develop a disaggregated residential sales forecast for each EDC based on the approach utilized in the residential sector, the SWE Team attempted to calibrate any building energy modeling outputs and end-use baseline energy consumption estimates so that total estimated residential energy consumption aligns with the EDC residential sector load forecasts.

1.3 MEASURE ANALYSIS

1.3.1 Summary

Energy efficiency measures considered in the study include all measures in the 2015 Pennsylvania Technical Reference Manual (TRM), as well as other energy efficiency measures based on the SWE Team’s knowledge and current databases of electric end-use technologies and energy efficiency measures in other jurisdictions. The study includes measures and practices that are currently commercially available as well as emerging technologies. The commercially available measures are of the most immediate interest to energy efficiency program planners in Pennsylvania. Emerging technology research was focused on measures that are either commercially available but currently not widely accepted, or are not currently available but expected to be commercialized over the analysis timeframe.¹⁸

1.3.2 Number of Measures Evaluated

In total, the SWE Team analyzed 400 measure types. Many measures required multiple permutations for different applications, such as different building types, efficiency levels, decision types, and EDC. The SWE Team developed a total of 95,025 measure permutations for this study across the seven EDCs, and tested all measures for cost-effectiveness under the TRC. The parameters for cost-effectiveness under the TRC are discussed in detail later in Section 1.7.1, “Total Resource Cost Test.” Of the permutations analyzed, roughly 50% or 46,634 measures had a measure TRC benefit-cost ratio of 1.0 or higher.¹⁹

Approximately 70% of all measures types included in this study are included in the 2015 Pennsylvania TRM. The SWE Team included 119 additional measure types to offer a more robust analysis of electric energy efficiency savings potential in Pennsylvania.

Table 1-1: Number of Measures Evaluated

| | # of Measures | Total # of Measure Permutations | # with TRC ≥ 1 |
|--------------------|---------------|---------------------------------|----------------|
| By Sector | | | |
| Residential | 69 | 5,306 | 3,021 |
| Commercial | 209 | 76,636 | 34,912 |
| Industrial | 122 | 13,083 | 8,701 |
| Total | 400 | 95,025 | 46,634 |
| By Source | | | |
| PA TRM | 281 | 63,652 | 30,824 |
| Secondary | 119 | 31,373 | 15,810 |
| Total | 400 | 95,025 | 46,634 |

¹⁸ For example, ENERGY STAR recently created a rating system for clothes dryers. High efficiency clothes dryers were included as an emerging technology.

¹⁹ The residential included some low income-specific measures with a TRC ratio less than 1.0 in the economic and achievable potential analysis. Low income-specific measures with a TRC ratio of 0.25 or greater were retained in the residential analysis of economic and achievable potential.

1.3.3 Measure Characterization

A significant amount of data is needed to estimate the kWh and kW savings potential for individual energy efficiency measures or programs across the entire residential, commercial, and industrial sectors in Pennsylvania. The SWE Team utilized data specific to Pennsylvania when it was available and current. The SWE Team used the 2015 TRM, the SWE 2014 incremental cost database, and the SWE 2014 baseline study as the main sources of data for measure assumptions.²⁰ For measures not listed in the TRM or SWE 2014 incremental cost database, the SWE Team conducted secondary research to develop reasonable and supportable assumptions.

Measure Savings: The SWE Team utilized the 2015 TRM to inform calculations supporting estimates of annual measure savings as a percentage of base equipment usage. For custom measures and measures not included in the TRM, the SWE Team estimated savings from a variety of sources, including:

- Mid-Atlantic TRM and other existing deemed savings databases
- Building energy simulation software (such as BEopt or EQuest) and engineering analyses
- Scheduled changes in federal codes and standards
- Secondary sources such as the American Council for an Energy-Efficient Economy (ACEEE), Department of Energy (DOE), Energy Information Administration (EIA), ENERGY STAR[®], and other technical potential studies
- Program evaluations conducted by Pennsylvania EDCs as well as other utilities and program administrators

Measure Costs: Measure costs represent either incremental or full costs, and typically include the incremental cost of measure installation. For purposes of this study, nominal measure costs were escalated by the general rate of inflation over time. One exception to this assumption will be an assumed decrease in costs for light emitting diode (LED) bulbs, and to a lesser extent, compact fluorescent light (CFL) bulbs over the study horizon. LED bulb consumer costs have been declining rapidly over the last several years and future cost projections predict a continued decrease in bulb costs.²¹ The SWE Team's treatment of LED bulb costs and market penetration are discussed in greater detail in Section 1.3.5, "Review of LED Lighting Assumptions."

When available, the SWE Team obtained measure cost estimates from the 2014 PA Incremental Cost Database. For measures not in this database, the SWE Team used the following data sources:

- Secondary sources such as the ACEEE, ENERGY STAR, National Renewable Energy Lab (NREL), California Public Utility Commission (PUC) Incremental Cost Database, Northeast Energy Efficiency Partnership (NEEP) Incremental Cost Study, and other technical potential studies
- Retail store pricing (such as websites of Home Depot, Lowe's, and Grainger) and industry experts
- EDC program evaluation and market assessment reports
- EDC annual reports to the PA PUC
- RS Means Commercial Construction Materials

Measure Life: Measure life represents the number of years that energy using equipment is expected to operate. Pennsylvania's Act 129 caps the measure's life, when used in the TRC calculation, at a

²⁰ This analysis also incorporates the results of the 2014 residential and nonresidential lighting metering study. The results of this analysis were not available for inclusion in the 2015 TRM, but are to be reflected in the market potential estimates of Phase III EE and DR potential.

²¹ 2014 DOE SSL Multi-Year Program Plan & NEEP Residential Lighting Strategy Report.

maximum of 15 years.²² The SWE Team obtained measure life estimates from the 2015 PA TRM, and used the following data sources for measures not in the TRM:

- Manufacturer data
- Savings calculators and life-cycle cost analyses
- The California Database for Energy Efficient Resources (DEER) database
- Evaluation reports
- Surveys conducted by the EDCs
- Other consultant research or technical reports

Baseline and Efficient Technology Saturations: In order to assess the potential electric energy efficiency savings available, estimates of the current saturation of baseline equipment and energy efficiency measures are necessary. The SWE Team primarily obtained up-to-date measure or end-use and equipment saturation data from the following recent studies:

- 2014 PA PUC residential and nonresidential baseline studies (based on site surveys conducted by the SWE Team in the fall of 2013)
- Other recently completed home energy and appliance saturation surveys completed in Pennsylvania or similar regions, including EDC research studies
- EDC end-use fuel share forecasts
- Latest (2009) EIA Residential Energy Consumption Survey (RECS)
- Latest (2010) EIA Manufacturing Energy Consumption Survey (MECS)
- Latest (2003) EIA Commercial Buildings Energy Consumption Survey (CBECS)

Documentation for the development of energy efficiency measure assumptions in the residential, commercial, and industrial sectors is provided in the appendices of this report.

1.3.4 Treatment of Codes and Standards

Although this analysis does not attempt to predict how energy codes and standards will change over time, the analysis does account for the impacts of several known improvements to federal codes and standards. Although not exhaustive, key adjustments include:

- General Service lighting baselines reflect the minimum efficiency standards and schedule established in the Energy Independence and Security Act of 2007 (EISA 2007). As a result, the baseline efficiency for most general lighting was assumed to be a halogen bulb through May 31, 2020. Beginning in June 2020, the analysis reflects the adjustments included in the EISA 2007 backstop provision, and the general service lighting baseline shifts to the CFL bulb. This shift in baseline impacts all bulbs, including those installed prior to 2020.
- The baseline efficiency for air source heat pumps (ASHP) is anticipated to improve to 14 SEER/8.2 HSPF²³ in 2015. As the existing stock of ASHPs was estimated to turn over, the baseline efficiency was assumed to be the new federal standard.
- In 2015, the DOE makes amended standards effective for residential water heaters that required updated energy factors (EF) depending on the type of water heater and the rated storage volume. For electric storage water heaters with a volume greater than 55 gallons, the standards effectively require heat pumps for electric storage products. For storage tank water heaters with a volume of 55 gallons or less, the new standard (EF=0.948) becomes essentially the equivalent of today's efficient storage tank water heaters.

²² Estimates of the natural replacement cycle of equipment with measure lives greater than 15 years were not capped in the potential modeling.

²³ SEER: Seasonal Energy Efficiency Ratio; HSPF: Heating Seasonal Performance Factor.

- In March 2015, the DOE will amend the standards for residential clothes washers. The new standards will require the Integrated Modified Energy Factor (MEF) (ft³/kWh/cycle) to meet certain thresholds based on the machine configurations. The ENERGY STAR specifications for residential clothes washers will also be amended to increase the efficiency of units that can earn the ENERGY STAR label. Version 7.0 of the ENERGY STAR specification is scheduled to go into effect in March 2015. These amended federal and ENERGY STAR standards have been factored into the study.
- In January 2015, the DOE will amend the standards for residential clothes dryers. The new standards will require the EF (pounds/kWh) to meet certain thresholds based on the machine configurations. There is also an ENERGY STAR specification in development for residential clothes dryers. Version 1.0 of the ENERGY STAR specification for residential clothes dryers is scheduled to go into effect in January 2015. The DOE-amended standards and the ENERGY STAR specification for residential clothes dryers have been factored into the study.
- In line with the phase-in of 2005 EPA regulations, the baseline efficiency for general service linear fluorescent lamps was moved from the T12 light bulb to a T8 light bulb effective June 1, 2016, in PA Act 129.

1.3.5 Review of LED Lighting Assumptions

Although the SWE Team has partially discussed the treatment of general service screw-in LED lighting, it is important to review the various assumptions that were tailored throughout this analysis given the emerging market for LEDs and the overall importance of lighting to the EDCs' energy efficiency portfolios.

Savings: Screw-in LED bulbs were assumed to replace the current federal code baseline according to the EISA 2007. For the initial four years of the analysis (June 2016 through May 2020), LED bulb savings are calculated relative to a halogen bulb. For the final six years of the analysis, the SWE Team assumes the CFL bulb becomes the code baseline, and LED savings are calculated against the CFL bulb.

Costs: LED bulb costs are widely projected to decrease significantly over the next decade. Current estimates project standard LED screw-in bulbs at \$4.00 by 2020 and \$2.40 by 2030.²⁴ Similarly, LED reflector bulbs are assumed to decline to \$7.00 in 2020 and \$5.00 by 2030. Based on these declining projections, as well as the current price of LED bulbs and estimated interim price points, the SWE Team developed annual cost projections for standard and reflector screw-in LED bulbs. Table 1-2 shows the annual projections for a standard 60-watt equivalent LED screw-in bulb and a 65-watt equivalent LED reflector.

Table 1-2: Price Projections for Residential LED Lighting

| Bulb Technology | 2016 | 2017 | 2018 | 2019 | 2020 | 2025 |
|----------------------|---------|---------|--------|--------|--------|--------|
| LED Screw-In | \$7.00 | \$6.00 | \$5.00 | \$4.38 | \$4.00 | \$3.20 |
| LED Reflector | \$13.60 | \$11.40 | \$9.20 | \$7.80 | \$7.00 | \$6.00 |

Market Acceptance: In an effort to recognize the increasing market adoption of LED bulbs and the increased focus on LED technologies in EDC energy efficiency programs, the SWE Team's potential analysis also projected an increasing focus on LED screw-in bulb technologies over CFL bulbs. Table 1-3

²⁴ Energy Information Administration. Technology Forecast Updates – Residential and Commercial Building Technologies, Reference Case. The 2014 DOE SSL Multi-Year Program Plan, NEEP Residential Lighting Strategy, and IMS Research (Does LED Lighting Have a Tipping Point?) all estimate the \$4.00 LED standard screw-in bulbs price point in 2020.

shows the annual applicability of LED vs. CFL bulbs assumed in the residential sector.²⁵ For example, in 2017, 83% of all assumed efficient screw-in bulb installations will be LED. As noted above, the screw-in lighting baseline shifts to the CFL bulb in 2020, and all assumed efficient installations shift to LEDs at that time.

Table 1-3: Assumed Annual Applicability of LED Bulbs

| Bulb Technology | 2016 | 2017 | 2018 | 2019 | 2020 |
|-----------------|------|------|------|------|------|
| CFL Bulb | 30% | 17% | 7% | 7% | 0% |
| LED Bulb | 70% | 83% | 93% | 93% | 100% |

1.4 INCREMENTAL ANNUAL VS. CUMULATIVE ANNUAL SAVINGS

It is important to note the distinction between incremental annual savings and cumulative annual savings. Incremental annual savings are those which occur in a given year due to participation in energy efficiency programs in that given year. Cumulative annual energy savings are those which accumulate in any given year due to participation in energy efficiency programs in that given year, as well as participation in prior years, to the extent that participation in prior years continues to yield savings. Cumulative annual energy savings account for the fact that measures installed in prior years may have useful lives longer than one year, and therefore produce savings that persist into the future for some time. However, cumulative annual energy savings also reflect savings decay – that is savings that can no longer be counted in a given year once a measure is no longer operational or has “burned out.”

One particularly important distinction between incremental annual savings and cumulative annual savings is that the sum of the incremental annual savings may be greater than the cumulative annual savings over an extended time frame due to measure savings decay. Consider the example in Table 1-4 below. In the example, an energy efficiency program is offering rebates for the purchase of high efficiency televisions. The program runs for five years and obtains one participant per year. Each participant yields 100 kWh in savings a year and it is assumed that the television measures have a useful life of four years. Each year, the new participants in the program provide 100 kWh in incremental annual savings in the year in which they participate and the savings from these participants persist in subsequent years for the life of the television. A participant in Year 1 will yield 100 kWh incremental annual savings in Year 1. This participant will also continue to yield 100 kWh of savings in Years 2 through Year 4. Then, in Year 5, the 100 kWh savings from the first year participant will disappear as it will be assumed that the efficient television will burn out after four years. However, because there is a participant in Year 5, the cumulative annual savings will stay at 400 kWh – what was lost to equipment decay is being replaced by a new participant. The sum of the incremental annual savings in Year 5 is 500 kWh because it is the sum of the savings introduced in each year by the five total participants. The year-by-year incremental annual data and cumulative annual data are provided in the table below.

Table 1-4: Incremental Annual vs. Cumulative Annual Savings Example

| Television Example | Year 1 | Year 2 | Year 3 | Year 4 | Year 5 |
|---------------------------|---------|---------|---------|---------|---------|
| Incremental Annual | 100 kWh | 100 kWh | 100 kWh | 100 kWh | 100 kWh |
| Sum of Incremental Annual | 100 kWh | 200 kWh | 300 kWh | 400 kWh | 500 kWh |
| Cumulative Annual | 100 kWh | 200 kWh | 300 kWh | 400 kWh | 400 kWh |

²⁵ Annual applicability factors based on the NEEP Residential Lighting Strategy. 2013-2014 Update. Table 6. Rate of In Program Bulbs.

1.5 POTENTIAL SAVINGS OVERVIEW

Potential studies often distinguish between several types of energy efficiency potential: technical, economic, achievable, and program. However, because there are often important definitional issues between studies, it is important to understand the definition and scope of each potential estimate as it applies to this analysis.

The first two types of potential, technical and economic, provide a theoretical upper bound for energy savings from energy efficiency measures. Still, even the best-designed portfolio of programs is unlikely to capture 100% of the technical or economic potential. Therefore, achievable potential and program potential attempt to estimate what savings may realistically be achieved through market interventions, when it can be captured, and how much it would cost to do so. Figure 1-1 illustrates the four most common types of energy efficiency potential.

Figure 1-1 Types of Energy Efficiency Potential²⁶

| | | | | |
|--------------------------|----------------------------|----------------------------|--|--------------------------|
| Not Technically Feasible | Technical Potential | | | |
| Not Technically Feasible | Not Cost-Effective | Economic Potential | | |
| Not Technically Feasible | Not Cost-Effective | Market & Adoption Barriers | Achievable Potential | |
| Not Technically Feasible | Not Cost-Effective | Market & Adoption Barriers | Program Design, Budget, Staffing, & Time Constraints | Program Potential |

1.6 TECHNICAL POTENTIAL

Technical potential is the theoretical maximum amount of energy use that could be displaced by efficiency, disregarding all non-engineering constraints such as cost-effectiveness and the willingness of end users to adopt the efficiency measures. Technical potential is only constrained by factors such as technical feasibility and applicability of measures. Under technical potential, the SWE Team assumed that 100% of new construction and burnout measures are adopted as those opportunities become available (e.g., as new buildings are constructed they immediately adopt efficiency measures), while retrofit and early retirement opportunities are replaced incrementally (10% per year) until 100% of homes (residential) and stock (commercial and industrial) are converted to the efficient measures over a period of 10 years.

1.6.1 Core Equation for the Residential Sector

The core equation used in the residential sector energy efficiency technical potential analysis for each individual efficiency measure is shown in Equation 1-1 below.

²⁶ Reproduced from "Guide to Resource Planning with Energy Efficiency." November 2007. US Environmental Protection Agency (EPA). Figure 2-1.

Equation 1-1: Core Equation for Residential Sector Technical Potential

Where:

Base Case Equipment End-Use Intensity = the electricity used per customer per year by each base-case technology in each market segment. In other words, the base case equipment end-use intensity is the consumption of the electrical energy using equipment that the efficient technology replaces or affects.

Saturation Share = the fraction of the end-use electrical energy that is applicable for the efficient technology in a given market segment. For example, for residential water heating, the saturation share would be the fraction of all residential electric customers that have electric water heating in their household.

Remaining Factor = the fraction of equipment that is not considered to already be energy efficient. To extend the example above, the fraction of electric water heaters that is not already energy efficient.²⁷

Applicability Factor = the fraction of the applicable units that is technically feasible for conversion to the most efficient available technology from an engineering perspective (e.g., it may not be possible to install CFLs in all light sockets in a home because the CFLs may not fit in every socket).²⁸

Savings Factor = the percentage reduction in electricity consumption resulting from the application of the efficient technology.

1.6.2 Core Equation for the Nonresidential Sector

The core equation utilized in the nonresidential sector technical potential analysis for each individual efficiency measure is shown in Equation 1-2 below. The SWE Team developed a forecast of nonresidential square footage information for each building type for each EDC, sourced primarily from the 2014 Non-Residential End Use & Saturation Study.

Equation 1-2: Core Equation for Nonresidential Sector Technical Potential

²⁷ For purposes of this study, the remaining factor for replace-on-burnout measures was 100%. This assumes that all measures, regardless of current efficiency, are eligible to revert back to the code baseline at the time of replacement. This is uniquely different from the prior market potential study completed by the SWE Team which removed installed measures that were already energy efficient from the analysis pool. The assumption used in this analysis results in increased potential, but more closely aligns with the EDCs' ability to track savings at the gross savings level.

²⁸ In instances where there are two (or more) competing technologies for the same electrical end use, such as heat pump water heaters, water heater efficiency measures, high-efficiency electric storage water heaters and solar water heating systems, an applicability factor aids in determining the proportion of the available population assigned to each measure. In estimating the technical potential, measures with the most savings are given priority for installation. For all other types of potential, measures with the greatest TRC ratio are assigned installation priority.

Where:

Total Stock Square Footage by Building Type = the forecasted square footage level for a given building type (e.g., office buildings).

Base Case Equipment End-Use Intensity = the electricity used per square foot per year by each base-case equipment type in each market segment. In other words, the base case equipment end-use intensity is the consumption of the electrical energy using equipment that the efficient technology replaces or affects. The SWE Team obtained this end-use consumption data from such sources as the US EIA CBECS & MECS, Pennsylvania EDC data, the Pennsylvania TRM, and others.

Saturation Share = the fraction of the EDC equipment electrical energy that is applicable for the efficient technology in a given market segment. For example, for room air conditioners, the saturation share would be the fraction for a specific EDC of all space cooling kWh in a given market segment that is associated with room air conditioner equipment.

Remaining Factor = the fraction of the equipment or practice that is technically feasible for conversion to the efficient technology from an engineering perspective (e.g., it may not be possible to install VFDs on all motors in a given market segment).

Applicability Factor = the fraction of equipment that is not considered to already be energy efficient. For example, the fraction of electric water heaters that is not already energy efficient.

Savings Factor = the percentage reduction in electricity consumption resulting from the application of the efficient technology.

1.7 ECONOMIC POTENTIAL

Economic potential refers to the subset of the technical potential that is economically cost-effective (based on screening with the TRC) as compared to conventional supply-side energy resources. The SWE Team calculated the TRC benefit-cost ratios for this study according to the Pennsylvania PUC's TRC Orders.

The SWE Team pre-screened possible energy efficiency technologies and practices based on an understanding of which measures were likely to be cost-effective and in the interest of conserving time and effort for other aspects of the analysis. Measure screening allowed the SWE Team to remove measures that were not commercially available, were already at current code, or were not applicable to Pennsylvania. All measures that were not found to be cost-effective based on the results of the TRC were excluded from further analysis. The SWE Team then readjusted and applied allocation factors to the remaining measures that were cost-effective.

1.7.1 Total Resource Cost Test

The SWE Team utilized the 2009 and 2011 Pennsylvania PUC TRC Orders to determine the cost-effectiveness for energy efficiency measures in this potential study. The TRC measures the net costs of a DSM or energy efficiency measure or program as a resource option based on the total costs of the measure/program, including both the participants' and the utility's costs.

In general, the benefits calculated in the TRC usually include the avoided electric supply costs for the periods when there is an electric load reduction; savings of other resources such as fossil fuels and water; and applicable federal and state energy efficiency tax credits. However, consistent with Act 129

and the 2013 PA TRC Order, only the electricity savings and avoided operation and maintenance costs will be used to calculate the benefits for the PA TRC.²⁹

Costs in the TRC (incremental or full cost depending on whether the measure was replaced on burnout or is an early replacement/retrofit) are the program costs paid by the utility (or program administrator) and the participants. Thus, all incremental equipment costs, installation, operation and maintenance, cost of removal, and program administration costs are included in this test regardless of who pays for them. In an effort to be consistent with the National Action Plan for Energy Efficiency's definition of economic potential, the SWE Team will not include marketing; analysis; administration; and evaluation, measurement, and verification (EM&V) costs for the measure cost-effectiveness screening conducted to develop the estimates of economic potential.³⁰ Although excluded from economic potential, these non-incentive costs will be included in the development of program acquisitions costs and estimates of the program costs related to achievable and program potential savings.

The PA TRC Order limits measure lives to a maximum of 15 years when calculating the TRC. Although select energy efficiency measures may have longer effective useful lives (EUL), the measure lives for purposes of cost-effectiveness calculations are capped at a maximum of 15 years.

1.7.2 Avoided Costs

The SWE Team based the avoided cost forecasts utilized for measure cost-effective screening and for reporting potential benefits on the Pennsylvania PUC's 2013 TRC Order and each EDC's avoided cost structure, including energy, transmission, distribution, and generation capacity avoided costs. Each EDC provided the latest available electric generation avoided cost projections, while the SWE Team developed the transmission and distribution (T&D) avoided cost projections used in this study. According to the latest PUC TRC Order, the discount rate used in the calculation of the Pennsylvania TRC is the utility's after-tax weighted average cost of capital. Avoided energy costs were differentiated by time and season where possible.

1.8 ACHIEVABLE POTENTIAL

Achievable potential is the amount of energy that can realistically be saved given various market barriers. Achievable potential takes into account real-world barriers to encouraging end users to adopt efficiency measures; the non-measure costs of delivering programs (for administration, marketing, analysis, and EM&V); and the capability of programs and administrators to boost program activity over time. Barriers include financial, customer awareness and willingness to participate in programs, technical constraints, and other barriers the "program intervention" is modeled to overcome. Additional considerations include political and/or regulatory constraints. The potential study evaluated two achievable potential scenarios:

- **Maximum Achievable** estimates achievable potential on paying incentives equal to 100% of measure incremental costs.
- **Base Achievable** estimates achievable potential on EDCs paying incentive levels (as a percent of incremental measure costs) comparable to those in effect from Program Year (PY) 1 through PY5 along with incentive-rate trends from other regional utilities. As discussed later in Section 2.3, "Phase I/II EDC Performance Benchmarking," incentives have historically been roughly

²⁹ Tax credits, while traditionally a benefit in the TRC are treated as a reduction to costs in the PA TRC, according to the TRC Order.

³⁰ National Action Plan for Energy Efficiency: Understanding Cost-Effectiveness of Energy Efficiency Programs.

57.5% of measure costs in the residential sector, and approximately 25% of measure costs in the commercial and industrial sectors.

While many different incentive scenarios could be modeled, the number of achievable potential scenarios was limited to the two scenarios described above due to the available budget for this potential study. The SWE Team analyzed the two selected achievable potential scenarios with different anticipated penetration curves or market acceptance models for each incentive level. In the maximum achievable scenario, the penetration curve is based on a maximum penetration assuming 100% funding of the measure incremental costs. Previous studies and actual program experience suggest that this curve can reach an asymptote not greater than 85% to 90% over a period of 20 years from the beginning of DSM programs in Pennsylvania under Act 129, as 100% of customers will not accept or adopt energy efficiency measures for various reasons.³¹ The SWE Team also incorporated data collected in the recent Pennsylvania baseline studies on customer willingness to participate at various incentive levels (discussed in more detail below).

The base achievable potential scenario analyzed reflects the expected market adoption associated with the percentage of incremental costs reflected in current EDC incentive levels. Base achievable incentives were set at a percentage of incremental measure costs grounded upon an analysis of Program Year (PY) 1 through PY5 annual report data from the EDCs, as well as other utility regional trends. These two scenarios include forecasts of market penetration that take into account uncertainty based on consumers' willingness to participate in programs.

For new construction, energy efficiency measures can be implemented when each new home or building is constructed, thus the rate of availability will be a direct function of the rate of new construction. For existing buildings, energy efficiency potential in the existing stock of buildings will be captured over time through two principal processes:

- 1) As equipment replacements are made normally in the market when a piece of equipment is at the end of its effective useful life (referred to as "replace-on-burnout" or "turnover" vintage).
- 2) At any time in the life of the equipment or building (referred to as "retrofit" or "early replacement" vintage).

For the replace-on-burnout measures, the opportunity to replace existing equipment with high efficiency equipment is when equipment fails beyond repair or if the consumer is in the process of building or remodeling. Using this approach, only equipment that needs to be replaced in a given year will be eligible to be upgraded to energy efficient equipment.

For the retrofit measures, savings can theoretically be captured at any time; however, in practice, it takes many years to retrofit an entire stock of buildings, even with the most aggressive of energy efficiency programs.

1.9 ACHIEVABLE POTENTIAL MARKET PENETRATION RATES

In an effort to inform estimates of market adoption, the SWE Team analyzed both the historical achievements of the EDCs in prior Phase I and Phase II program years relative to estimates of economic potential, as well as willingness-to-participate research collected as part of the SWE baseline studies. The historical benchmarking estimated an initial "ground floor" market adoption rate while the willingness-to-participate research assisted in the development of long-term market adoption values.

³¹ Driving Demand for Energy Efficiency: Hood River Conservation Project Case Study. LBNL. Additional examples suggesting high levels of program participation are included as an appendix.

1.9.1 Initial Year Market Adoption Rate

The SWE Team compared the historical achievements of the EDCs in PY3, PY4, and PY5 to the economic potential estimated by the 2012 SWE Market Potential Study (MPS) to derive an estimate of what percentage of the SWE-estimated economic potential was actually achieved by the EDCs in these years. The process of completing this comparison consisted of several steps. First, the SWE Team compiled the PY3, PY4, and PY5 kWh savings of each EDC as reported by the EDCs to calculate the total statewide gross verified savings for each year. Then, the SWE Team derived an estimate of economic potential for PY 5 based on the cumulative annual economic potential estimates from the 2012 SWE MPS. As PY3 and PY4 pre-dated the years included in 2012 SWE MPS, the SWE Team also generated an estimate of the economic potential in those years.

Once the SWE Team gathered the statewide PY3, PY4, and PY5 kWh savings and derived estimates of statewide economic potential in those years, the SWE Team was able to calculate the statewide gross verified savings as a percentage of economic potential. The SWE Team then took a simple average of these percentages across PY3, PY4, and PY5 to generate an assumption of the percentage of the economic potential that was actually achieved by the EDCs across the three-year timeframe. In the residential sector, the SWE Team found that the EDCs achieved 30% of the economic potential during that timeframe, while the nonresidential sector achieved 32% of economic potential, according to the methodology detailed above. The SWE Team used this estimate as a starting point for the first year in the market adoption ramp rates used in the base achievable scenario.

For the maximum achievable scenario, the initial year market adoption was adjusted higher based on the assumption that incentives were equal to 100% of the measure cost as well as research findings from the willingness-to-participate research. For example, in the nonresidential sector, the willingness-to-participate findings showed that customers were 2.25 times more likely to adopt an energy efficiency measure with a 100% incentive compared to a 25% incentive. The SWE Team then used this 2.25 multiplier against the base achievable first-year adoption value of 34% for nonresidential to come up with a maximum achievable initial year adoption rate of 76.5%.

1.9.2 Long-Term Market Adoption Rates

Estimating future market adoption of energy efficient technologies is a difficult and uncertain practice. In an effort to inform these estimates, the SWE Team conducted customer likelihood and willingness-to-participate research as part of the statewide baseline studies completed in 2014.³² This research included questions to residential homeowners and nonresidential facility managers regarding their perceived willingness to purchase and install energy efficient technologies across various end uses and incentive levels. Although homeowners were asked about a limited number of specific technologies within end uses, the SWE Team extended these results across whole end uses. By contrast, facility managers were asked about a range of lighting technologies within the lighting end use.

Once the SWE Team established historical market adoption rates for the initial year of the analysis, the SWE Team utilized likelihood and willingness-to-participate data to estimate the long-term (10-year) market adoption potential for both the maximum and base achievable scenarios. Figure 1-2 presents the long-term market adoption rates assumed for the residential sector. When incentives are assumed to

³² For a more complete description of this research, reference the 2014 statewide baseline studies completed for both the residential and nonresidential sectors.

be 100% of the measure cost, long-term market adoption ranged from 80% to 85%.³³ For the base achievable potential scenario (incentives assumed to be 57.5% of the measure cost), the long-term market adoption rates ranged from 40% for building shell measures (insulation) to 85% for appliances (refrigerators). The SWE Team assumed a linear ramp rate over 10 years from the initial year market adoption rate (30%) to the various long-term market adoption rates for each specific end use.

Figure 1-2: Long-Term Market Adoption Rates based on Residential Willingness-to-Participate Survey Results

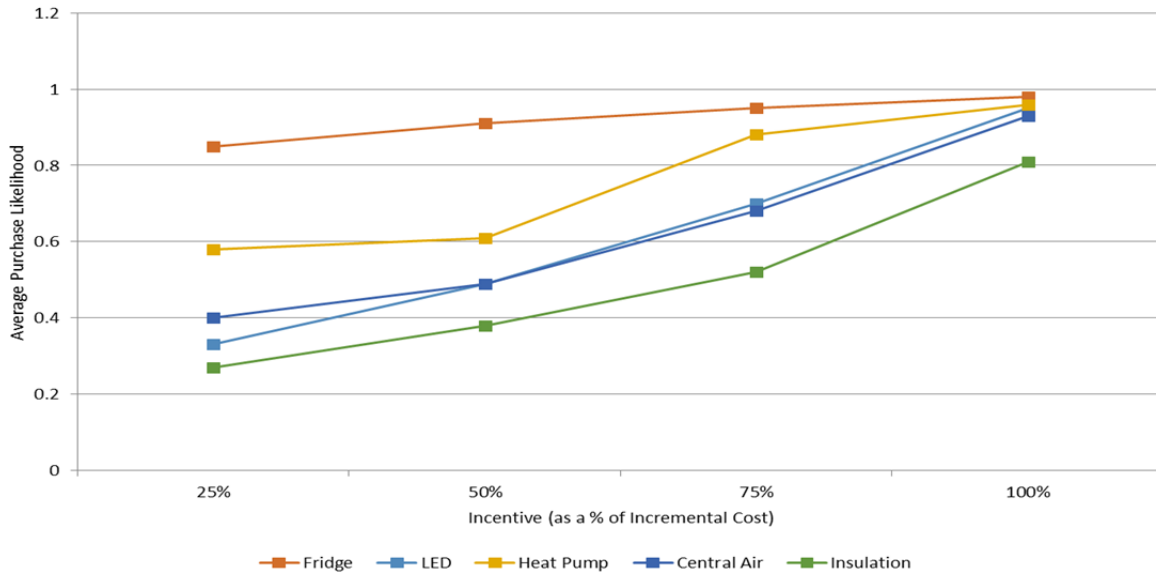

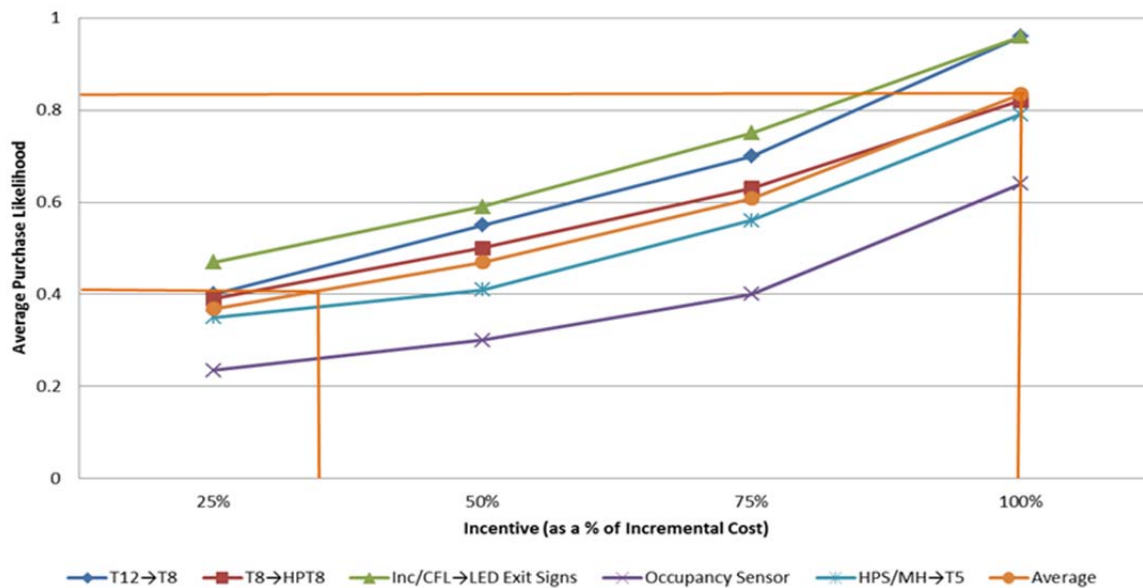

Figure 1-3 shows the willingness-to-participate survey results and long-term market adoption rate for the nonresidential sector. The average long-term adoption rate for the base achievable scenario (which assumes a 35% incentive rate) was estimated to reach 41% at the end of the 10-year period, while the maximum achievable scenario (with a 100% incentive rate) was estimated to reach an average adoption rate of 83% after 10 years. The SWE Team then applied a linear growth rate from the analysis’ first-year adoption rate of 34% to reach the 10-year long-term adoption rate of 41% under the base achievable scenario, while the maximum achievable scenario achieved 83% adoption in the tenth year.

³³ Although the willingness to participate research indicated willingness levels above 85% at the 100% of incremental cost incentive level, the SWE capped long term market adoption rates at 85%.

Figure 1-3: Long-Term Market Adoption Rates based on Nonresidential Willingness-to-Participate Survey Results

1.10 PROGRAM POTENTIAL

While the identified achievable potential includes energy efficiency potential available in the marketplace, it was vital to isolate the portion that could be realistically acquired through EDC programs. It is important to recognize that there are program constraints such as available program funding (cost caps), how much time is available to deliver programs or reach a compliance target, NTG factors, consumer willingness to participate in programs or adopt measures, and the possibility of specific “set-asides” for the low income and institutional sectors.

The SWE Team analyzed program potential using an achievable-to-program potential “scaling” analysis based on Act 129 funding caps. This approach had the added benefit of not imposing any direct program design decisions on the EDCs. Act 129 set the annual funding levels for DSM at no more than 2% of 2006 Pennsylvania utility electric revenues (for the EDCs subject to Act 129). Therefore, the SWE Team calculated the program potential estimate for the five-year period ending in 2020 as follows:

- a) First, the SWE Team calculated technical potential.
- b) Then, the SWE Team calculated economic potential (TRC benefit-cost testing was applied at this step).
- c) Next, the SWE Team calculated achievable potential (penetration rate forecasts were applied to economic potential to arrive at achievable potential). The achievable potential estimates are based on forecasts of kWh and kW savings estimates from 2016 through 2025 for all cost-effective energy efficiency measures. The achievable potential estimates are provided for each individual energy efficiency measure, and for all measures combined. Based on the savings associated with the measures included in the base achievable potential scenario, the SWE Team then developed portfolio acquisition costs (by summing the five-year annual incremental administrative plus incentive costs, divided by the five-year sum of incremental annual energy savings).

- d) Finally, the SWE Team calculated program potential based on a target annual utility energy efficiency budget that is 2% of annual utility revenues in the year 2006. The calculated kWh and kW base achievable potential estimates were scaled up or down across the board with a single factor until the utility costs for the program potential scenario were equal to 2% of annual utility revenues in 2006. When the budget and the savings are scaled to the 2% utility spending target, the development of the program potential estimate is complete.

2 Characterization of Pennsylvania Service Areas & Phase I/II Program Offerings

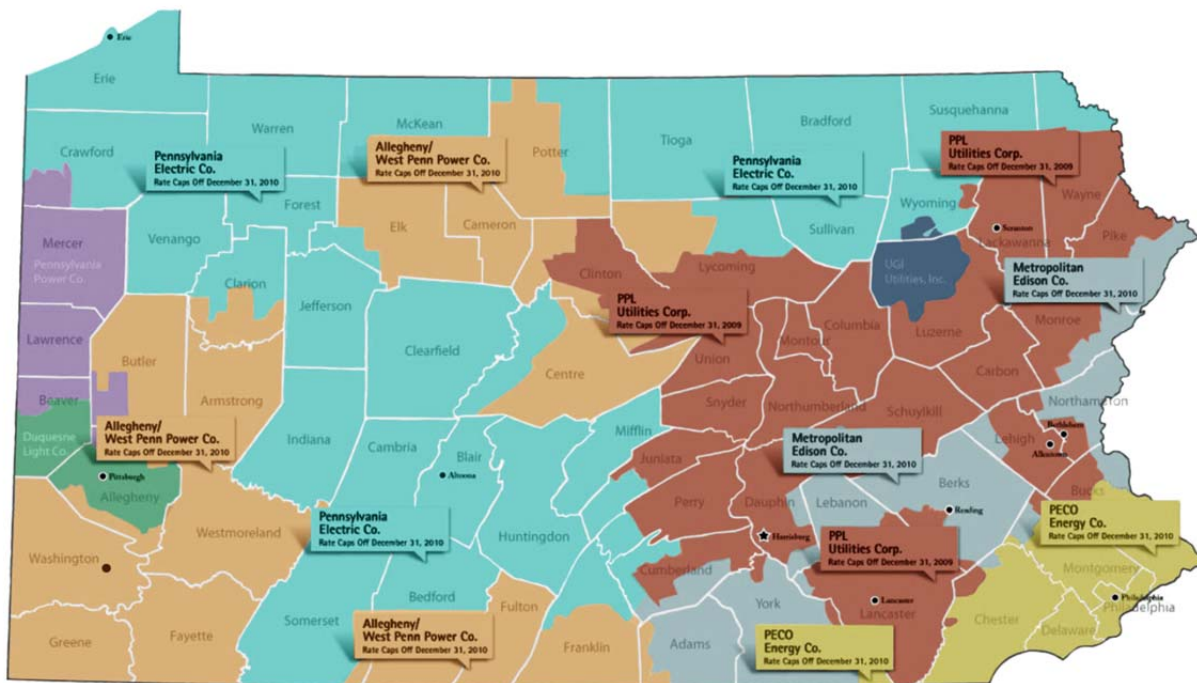

The following section provides a brief overview of the seven EDC service areas included under Act 129, their forecasted load, and a brief overview of their performance for Phase I and Phase II to date (i.e., PY1 through PY5).

2.1 EDC AREAS

There are currently eleven EDCs that provide energy to Pennsylvania customers. The focus of this analysis is on the seven largest EDCs, including: Duquesne Light Company (Duquesne), Metropolitan Edison Company (Met-Ed), Pennsylvania Electric Company (Penelec), Pennsylvania Power Company (Penn Power), West Penn Power Company (West Penn), PECO Energy Company (PECO), and PPL Electric Utilities Corporation (PPL).

Figure 2-1 shows the service areas for each of the seven Pennsylvania EDCs included in this study. Each EDC’s service area varies in size and demographics.

Figure 2-1: Pennsylvania EDC Service Area Map

2.2 2010 HISTORICAL LOAD & STATEWIDE LOAD FORECAST

2.2.1 2010 Historical Load

Table 2-1 presents the forecasted energy (MWh) sales by EDC and customer class for the period beginning June 2009 and ending May 2010. The SWE Team has selected the load of this year to be consistent with Act 129 of 2008, which required the EDCs to reduce electric consumption at least 1% by May 31, 2011, and 3% by May 31, 2013, relative to their forecast load for the period June 1, 2009 through May 31, 2010. Savings targets for Phase II of Act 129 were also established based on the

2009/2010 forecast load. Consequently, the savings potential estimates in this report have also been compared to the 2009/2010 forecast load for each EDC.

Table 2-1: 2009/2010 Energy (MWh) Forecast Sales by EDC and Customer Sector

| EDC | Residential | Commercial | Industrial | Total |
|-----------------------|-------------------|-------------------|-------------------|--------------------|
| Duquesne | 4,188,344 | 7,081,429 | 2,815,727 | 14,085,500 |
| FE: Met-Ed | 6,199,448 | 4,126,943 | 4,538,643 | 14,865,033 |
| FE: Penelec | 4,882,328 | 4,261,919 | 5,255,052 | 14,399,300 |
| FE: Penn Power | 1,845,141 | 1,162,174 | 1,765,619 | 4,772,933 |
| FE: West Penn | 7,931,627 | 5,533,913 | 7,473,127 | 20,938,667 |
| PECO | 14,009,363 | 20,961,102 | 4,415,535 | 39,386,000 |
| PPL | 15,136,306 | 12,829,784 | 10,248,276 | 38,214,367 |
| Statewide | 54,192,558 | 55,957,264 | 36,511,978 | 146,661,800 |

2.2.2 Statewide Load Forecast

As discussed earlier, a critical first step in the modeling process is to disaggregate each EDC's load by sector. As shown in Figure 2-2, the statewide annual MWh sales are distributed fairly evenly among the residential, commercial, and industrial sectors, with approximately 35% of annual MWh sales from 2016 through 2025 in each of the residential and commercial sectors, and 30% of annual MWh sales in the industrial sector. The MWh sales forecast grows at a compound annual growth rate of 0.24% per year across all sectors over the 10-year forecast.

Figure 2-2: Statewide Energy (MWh) Sales Forecast by Sector from June 2016-May 2025

2.3 PHASE I/II EDC PERFORMANCE BENCHMARKING

The SWE Team conducted an extensive review of all available information pertaining to the EDCs' Phase I and Phase II energy efficiency program performance. The SWE Team reviewed each of the EDC's filed annual reports (PY1 through PY5) and collected various data points including verified savings, EDC expenditures, and participant costs to establish benchmarking data on EDC performance through the first five years of their DSM programs under Act 129. Metrics tracked include the following:

- 1) Incentive expenditures as a percentage of incremental costs
- 2) Administrative costs (\$/kWh saved)
- 3) Acquisition costs (\$/kWh saved)
- 4) Savings as a percentage of 2010 load

The purpose of this step was to understand historical program delivery and performance, and to help inform estimates of achievable and program potential. Because this study focuses on energy efficiency potential only, demand management programs, renewable energy programs, conservation voltage reduction (CVR) programs, and other programs not involving energy efficiency savings were excluded from this analysis. Only the costs and savings for the applicable energy efficiency programs were captured when rolling up the metrics discussed below.

Table 2-2 shows the average statewide incentive rate for PY1 through PY5 as 57% of incremental costs for residential, 24% for nonresidential, and 33% across the entire portfolio. In addition, the EDCs are spending an average of \$0.069 for each kWh saved in non-incentive costs across their portfolios. The SWE Team used these numbers to help inform the achievable base incentive rate in the potential modeling, as well as the administrative cost per kWh saved when calculating the acquisition costs associated with the achievable base scenario.

Table 2-2: Statewide Cumulative Five-Year Program Savings and Costs by Sector

| Sector | Verified Impact (MWh) | Total Incentive \$ | Total Admin \$ | Participant \$ | Incentive Rate | Admin Cost \$/1 st -YR kWh-saved |
|-----------------------|-----------------------|----------------------|----------------------|------------------------|----------------|---|
| Residential | 3,210,689 | \$177,832,506 | \$244,418,083 | \$309,659,924 | 57% | \$0.076 |
| Nonresidential | 2,829,403 | \$206,874,090 | \$170,480,829 | \$853,868,453 | 24% | \$0.060 |
| Portfolio | 6,040,092 | \$384,706,596 | \$414,898,912 | \$1,163,528,376 | 33% | \$0.069 |

Table 2-3 shows the acquisition costs per first-year kWh saved by sector by year across all EDCs. Throughout the first five years of program offerings, the EDCs are acquiring each first-year kWh of energy efficiency savings for roughly \$0.16/kWh.

Table 2-3: Statewide Annual Incremental Acquisition Costs by Sector, by Program Year (\$/1YR kWh saved)

| Sector | PY1 | PY2 | PY3 | PY4 | PY5 |
|-----------------------|----------------|----------------|----------------|----------------|----------------|
| Residential | \$0.114 | \$0.123 | \$0.149 | \$0.111 | \$0.161 |
| Nonresidential | \$0.172 | \$0.134 | \$0.140 | \$0.129 | \$0.169 |
| Portfolio | \$0.126 | \$0.128 | \$0.144 | \$0.121 | \$0.164 |

Table 2-4 shows the annual incremental savings by sector as a percentage of 2010 load in each sector. As the programs have matured, the EDCs have increased their savings from 0.21% of 2010 sales in PY1 to 1.25% of 2010 sales in PY4. However, savings as a percent of 2010 load declined in the first year of Phase II.

Table 2-4: Statewide Annual Incremental Savings as a % of 2010 load by Sector by Year

| Sector | PY1 | PY2 | PY3 | PY4 | PY5 |
|-----------------------|--------------|-------------|-------------|-------------|-------------|
| Residential | 0.5% | 1.6% | 1.4% | 1.5% | 1.2% |
| Nonresidential | 0.1% | 0.7% | 0.8% | 1.1% | 0.5% |
| Portfolio | 0.21% | 1.1% | 1.0% | 1.3% | 0.7% |

While these performance metrics are informative and point to successes on the part of the EDCs to capture large amounts of energy efficiency at reasonable costs, they also reflect savings associated with “low-hanging fruit” such as CFLs and linear fluorescent T8 lamps. The savings percentage and acquisition costs are also indicative of lighting savings (which accounted for the majority of PY1 through PY5 savings) with a lower baseline. That is, the savings were obtained before federal lighting standards raised the efficiency of a large share of the residential and commercial lamps, including the phase-out of standard incandescent bulbs and T12 linear fluorescent lamps and magnetic ballasts. These improved codes and standards are not only expected to erode savings potential in these lighting programs, but also increase the cost for lighting programs and drive EDCs to deeper DSM savings in other non-lighting end uses.

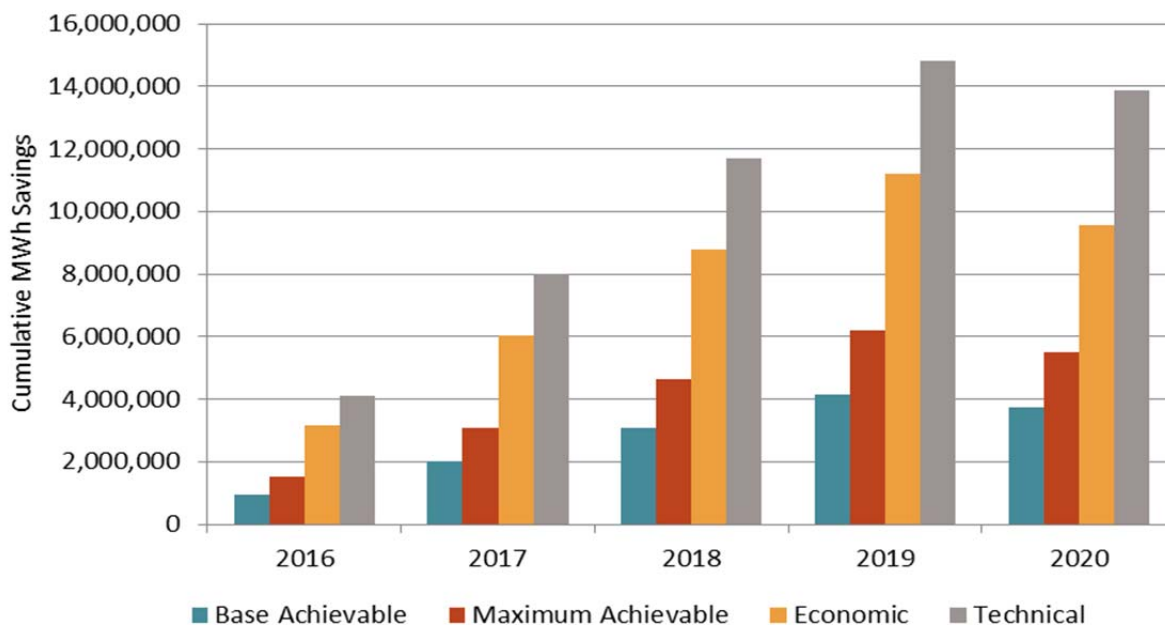

3 Residential Energy Efficiency Potential

This section of the report presents the estimates of electric technical, economic, and achievable potential for the Commonwealth of Pennsylvania as well as for each EDC service area. Program potential is discussed separately in Section 6 of this report. Electric energy efficiency savings, cost estimates, and benefit-cost estimates are presented in this section.

3.1 SUMMARY

Figure 3-1 summarizes the electric energy efficiency savings potential for the residential sector for all seven EDCs combined across the state. The five-year cumulative annual energy savings potential under the base achievable scenario amounts to 3,722,120 MWh and 506 MW by 2020, representing a possible 6.9% reduction of 2010 load in the residential sector.

Figure 3-1: Residential Cumulative Annual Savings Potential by Scenario by Year

The slight decrease in potential from 2019 to 2020 is a result of a significant baseline shift in residential lighting efficiency from a halogen bulb in 2019 to a CFL bulb in 2020, and the associated decrease in savings opportunities for LED technologies. This shifting efficiency baseline assumption was discussed earlier in Section 1.3.4, “Treatment of Codes and Standards.”

Table 3-1 also presents the same estimates for electric energy efficiency savings potential for the residential sector, but includes a look at 10-year cumulative energy savings as well as demand savings potential resulting from the implementation of energy efficiency measures.

Technical potential, which reflects the adoption of all energy efficient technologies, is a theoretical upper bound on savings. The five-year technical potential is 13.9 million MWh on a cumulative annual basis (2,398 MW).

Economic Potential, which reflects the savings when all cost-effective measures are implemented, is 9.6 million MWh on a cumulative annual basis (1,324 MW) in 2020.

Maximum Achievable Potential is a subset of economic potential and represents the attainable savings assuming incentive levels are set at 100% of measure incremental costs and the long-term market penetration of high efficiency electric equipment reaches 85% in any given year. Maximum achievable potential is 5.5 million MWh (755 MW) in 2020, or 10.1% of 2010 residential load.

Base Achievable Potential is also a subset of economic potential and represents the SWE Team's best estimate of attainable savings potential assuming comprehensive implementation of all cost-effective measures and no restrictions on budget. The base achievable potential scenario assumes incentive levels are set at 57.5% of measure incremental costs. Base achievable is estimated at 953,810 MWh in the first year (2016). Base achievable potential savings are 3.7 million MWh (506 MW) in 2020, or 6.9% of 2010 residential load.

Table 3-1: Residential Cumulative Annual Energy (MWh) and Demand (MW) Savings Potential by Scenario by Year

| | 2016 | 2017 | 2018 | 2019 | 2020 | 2025 |

3.2 RESIDENTIAL POTENTIAL BY MARKET SEGMENT

Figure 3-2 shows the five-year cumulative annual savings potential by home type under the base achievable potential scenario. Single family detached homes account for the largest share of the statewide residential market, and accordingly, represent the housing type with the largest potential for electric energy efficiency savings. According to US Census and existing demographic data supplied by the EDCs, single family detached homes represent 59.5% of the residential housing market (weighted by population across the seven EDCs) and 72.5% of 2020 energy savings potential.³⁴

³⁴ Housing market segmentation is discussed in the Pennsylvania Statewide Act 129 2014 Residential Baseline Study.

Figure 3-2: 2020 Residential Base Achievable Energy Savings Distribution by Housing Type

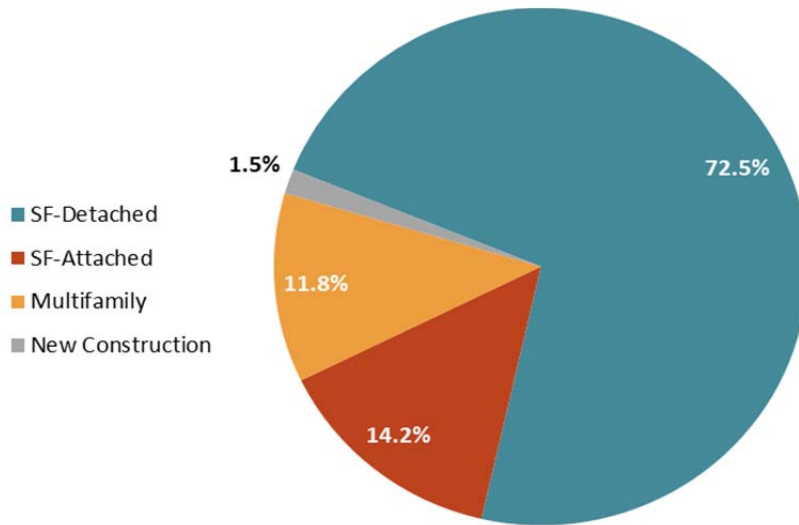

Table 3-2 details the same five-year findings and summarizes the varying savings potential under each scenario. Table 3-2 also provides the summer five-year cumulative annual demand savings potential.

Table 3-2: 2020 Residential Cumulative Annual Energy (MWh) and Demand (MW) Savings Potential by Housing Type

| | Existing SF-Detached | Existing SF-Attached | Existing Multifamily | New Construction |
|--|----------------------|----------------------|----------------------|------------------|

| Base Achievable | 5.0% | 1.0% | 0.8% | 0.1% |
| 2020 Demand Savings Potential - Summer Peak MW | | | | |
| Technical | 1,574.7 | 388.6 | 396.9 | 38.2 |
| Economic | 913.2 | 207.1 | 187.5 | 16.4 |
| Max Achievable | 520.2 | 118.5 | 107.6 | 9.1 |
| Base Achievable | 347.1 | 79.3 | 73.7 | 6.3 |

The SWE Team also analyzed residential energy efficiency potential between low income and non-low income consumers.³⁵ Low income potential includes savings stemming directly from low income-specific measures as well as additional savings attributed to low income participants in non-low income-specific programs. Low income-specific measures include those offerings where EDCs are expected to pay 100% of the measure cost to low income-qualified customers.³⁶ Savings attributed to the low income sector

³⁵ The percent of the population estimated to be low income was derived from the US Census: 2011 American Community Survey, Three-Year Estimates.

³⁶ The threshold for cost-effectiveness for low income specific measures was below the traditional screening level of 1.0. Low income-specific measures were retained in the economic and achievable potential if they had a TRC ratio of 0.25 or higher.

from non-low income measures do not assume any additional incentives above and beyond the standard offering.

The SWE Team developed the list of low income-specific measures included in this analysis based on the historical low income offerings of the seven EDCs and included CFL/LED lighting installation, appliance upgrades, and heating, ventilation and air conditioning (HVAC) equipment and shell improvements. The percent of savings attributed to the low income sector from non-low income measures was estimated at 15%, and was based on the average reported values in the EDCs' most recent annual reports (PY5) to the Commission.

As Table 3-3 shows, in total, the 2020 base achievable savings from low income participants is 825,104 MWh, or approximately 1.5% of 2010 residential load. Savings from non-low income participants are 2.9 million MWh, or roughly 5.3% of 2010 residential load.

Table 3-3: 2020 Residential Cumulative Annual Energy (MWh) and Demand (MW) Savings Potential Estimates by Income Type

3.3 RESIDENTIAL POTENTIAL BY END USE

Figure 3-3 shows the residential cumulative annual energy and demand savings by end use for the base achievable scenario in 2020. Lighting represents the greatest share of the residential base achievable potential energy savings (35.6%), despite higher baseline conditions with CFLs in place of EISA-compliant halogens starting in 2020. The “Cross-Cutting” end use, consisting primarily of behavioral energy efficiency measures that provide energy consumption feedback to consumers in an effort to encourage reduced energy use, represents the third largest for potential savings due to its widespread applicability to nearly all households. Savings from the water heating, HVAC equipment, and building envelope end uses, although also substantial, are limited due to cost-effectiveness concerns and/or applicability of electric space and/or water heating across the EDCs.

Lighting also represents the greatest opportunity for demand savings in 2020 from energy efficient improvements. However, improvements to HVAC equipment and the building envelope are also opportunities for significant demand reductions.

Figure 3-3: 2020 Base Achievable Savings Potential Distribution by End Use

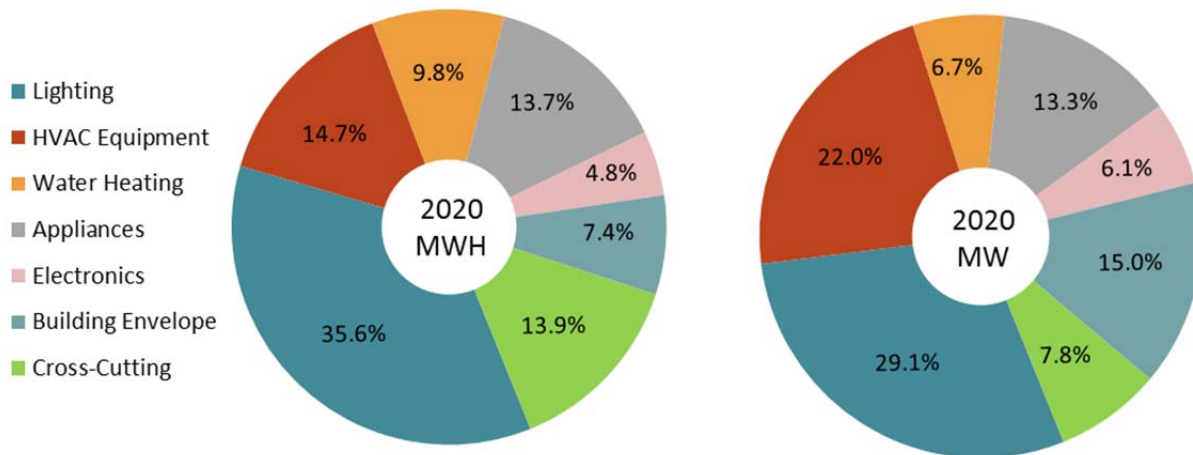

Table 3-4 provides the residential cumulative annual energy savings potential by end use for 2016 through 2020 as well as 2025. The annual look at estimated electric energy efficiency potential depicts the anticipated decrease in lighting potential from 2019 to 2020 as a result of the 2007 EISA backstop provision going into effect. However, lighting remains the end use with the greatest electric efficiency potential due to the high saturation of sockets eligible to be converted to LEDs.

Table 3-4: Residential Cumulative Annual Energy (MWh) Savings Potential by End Use by Scenario

| Energy (MWh) | 2016 | 2017 | 2018 | 2019 | 2020 | 2025 |

* Cross-cutting refers to behavioral measures. Efficient pool pumps were not cost-effective and were only included in estimates of technical potential.

3.4 RESIDENTIAL POTENTIAL BY EDC

The SWE Team calculated electric energy efficiency potential for each EDC individually to produce a cumulative estimate of energy efficiency savings potential.

Table 3-5 provides the cumulative annual energy (MWh) savings and percentage of 2010 load. Across the EDCs, the base achievable potential ranges from 6.0% to 7.6% of 2010 residential load over a five year period. The five-year cumulative annual energy savings potential for all seven EDCs combined is estimated at 3.7 million MWh, or 6.9% of 2010 residential sector load.

3.5 RESIDENTIAL BENEFITS AND COSTS

Table 3-6 provides the economic impacts by EDC for the residential achievable scenarios. Overall, capturing the estimated program potential would result in an NPV of nearly \$2.25 billion in lifetime benefits for an investment of \$1.25 billion (NPV) in the base achievable potential scenario. The Commonwealth of Pennsylvania would capture about \$997 million in present value net benefits and a TRC ratio of 1.8.

Table 3-6: 2020 Residential TRC Benefit-Cost Ratios by Achievable Scenario by EDC

| | NPV Costs (Million \$) | NPV Benefits (Million \$) | NPV Net Benefits (Million \$) | TRC BC Ratio |
|-------------------------------------|------------------------|---------------------------|-------------------------------|--------------|
| Maximum Achievable Potential | | | | |
| Duquesne | \$176.5 | \$346.0 | \$169.5 | 2.0 |
| FE: Met-Ed | \$196.0 | \$376.7 | \$180.7 | 1.9 |
| FE: Penelec | \$194.2 | \$316.0 | \$121.9 | 1.6 |
| FE: Penn Power | \$51.4 | \$83.7 | \$32.3 | 1.6 |
| FE: West Penn | \$282.4 | \$493.9 | \$211.5 | 1.7 |
| PECO | \$474.7 | \$842.5 | \$367.8 | 1.8 |
| PPL | \$524.4 | \$918.5 | \$394.1 | 1.8 |

| | NPV Costs (Million \$) | NPV Benefits (Million \$) | NPV Net Benefits (Million \$) | TRC BC Ratio |
|----------------------------------|------------------------|---------------------------|-------------------------------|--------------|
| Statewide | \$1,899.6 | \$3,377.4 | \$1,477.8 | 1.8 |
| Base Achievable Potential | | | | |
| Duquesne | \$117.6 | \$231.6 | \$114.0 | 2.0 |
| FE: Met-Ed | \$129.2 | \$250.7 | \$121.5 | 1.9 |
| FE: Penelec | \$129.7 | \$212.8 | \$83.1 | 1.6 |

| PPL | \$344.2 | \$609.6 | \$265.4 | 1.8 |
| Statewide | \$1,250.1 | \$2,246.9 | \$996.9 | 1.8 |

Table 3-7 represents the total program expenses paid by the EDCs to realize five-year achievable savings estimates under the maximum and base achievable scenarios. For the residential sector, the per first-year MWh acquisition cost is between \$256/MWh in the maximum achievable scenario assuming 100% incentives for all measures, and \$203/MWh in the base achievable scenario. The estimated EDC acquisition costs include both incentive costs as well as non-incentive costs to include marketing, incentive fulfillment, and EM&V.

Table 3-7: Five-Year Residential Acquisition Costs (TRC) by Achievable Scenario by EDC

| EDC | 2016-2020 Program Costs (\$Million) | 2016-2020 Program Savings (MWh) | Acquisition Costs (\$/1 st -YR MWh Saved) |

4 Commercial Energy Efficiency Potential

This section of the report presents the commercial sector estimates of electric technical, economic, and achievable potential for the Commonwealth of Pennsylvania as well as for each EDC service area. Program potential is discussed separately in Section 6 of this report. Electric energy efficiency savings, cost estimates, and benefit-cost estimates are presented in this section.

4.1 SUMMARY

Figure 4-1 summarizes electric energy efficiency savings potential for the commercial sector for all seven EDCs combined across the state. The five-year cumulative energy savings potential under the base achievable scenario amount to 1,853,605 MWh and 319.2 MW, representing a possible 3.3% reduction of 2010 load in the commercial sector. Details on each of the four scenarios are discussed in more detail below.

Figure 4-1: Commercial Cumulative Annual Energy (MWh) Savings Potential by Scenario, by Year

Table 4-1 presents the same estimates for electric energy efficiency savings potential for the commercial sector for all seven EDCs combined across the state by scenario. Details on the findings for each scenario are presented below.

Technical potential, which reflects the adoption of all energy efficient technologies, is a theoretical upper bound on savings. The 5-year cumulative energy efficiency technical potential is 6,716,920 MWh.

Economic Potential, which reflects the savings when all cost-effective measures are implemented, is just over 4,078,690 MWh during the same five-year period.

Maximum Achievable Potential is a subset of economic potential and represents the attainable savings assuming incentive levels are set at 100% of measure incremental costs and the long-term market penetration of high efficiency electric equipment reaches 85% of available stock in any given

year. Maximum achievable potential is 739,695 MWh in 2016. By 2020, the cumulative maximum achievable potential savings is 3,225,158 MWh, representing 5.8% of 2010 statewide commercial sales.

Base Achievable Potential is also a subset of economic potential and represents the SWE Team's best estimate of attainable savings potential assuming comprehensive implementation of all cost-effective measures and no restrictions on budget. The base achievable potential scenario assumes incentive levels are set at 35% of measure incremental costs. Base achievable potential is estimated at 408,759 MWh in 2016. By 2020, the cumulative base achievable potential savings are estimated to be 1,853,605 MWh, representing 3.3% of 2010 statewide commercial sales.

Table 4-1: Commercial Cumulative Annual Energy (MWh) and Demand (MW) Savings Potential by Scenario by Year

| Maximum Achievable | 138.4 | 264.5 | 389.1 | 509.0 | 596.7 | 1,022.3 |
| Base Achievable | 71.7 | 138.0 | 204.4 | 269.2 | 319.2 | 560.8 |

4.2 COMMERCIAL POTENTIAL BY MARKET SEGMENT

Figure 4-2 shows the five-year cumulative savings potential distribution by commercial building segment under the achievable base scenario. The office segment is the single building type with the largest share of potential savings, representing 18.9% of achievable potential in 2020. Healthcare represents the second largest opportunity for savings at 13.4% of achievable potential. The miscellaneous segment at 19.6% of achievable potential consists of various building types from movie theaters and bowling alleys to mixed-use buildings and service buildings such as gas stations, among many others.

Figure 4-2: 2020 Commercial Energy Savings Distribution by Building Type, Achievable Base

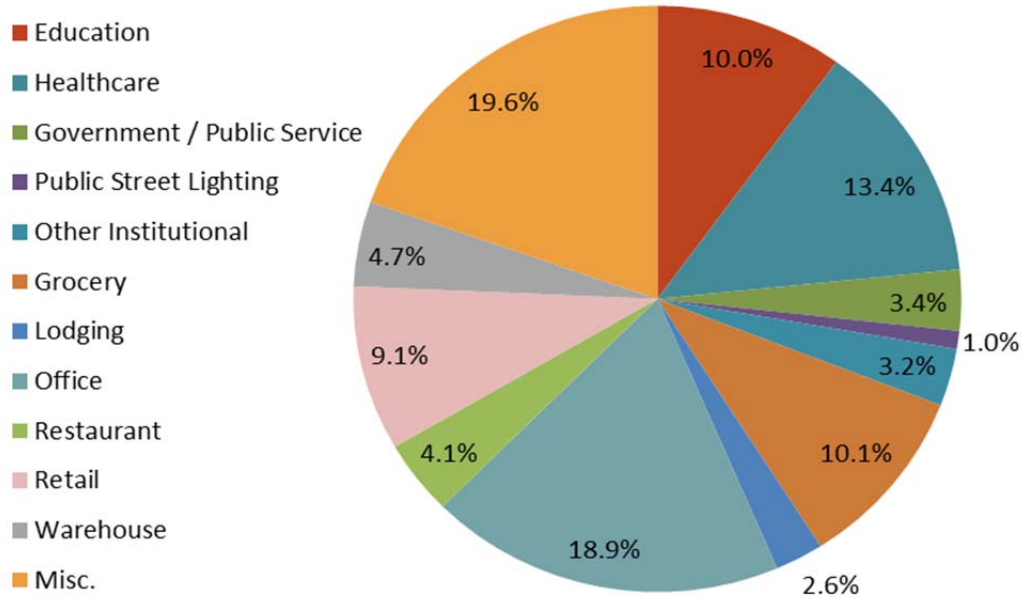

Table 4-2 details the same five-year findings, but summarizes the varying savings potential under each scenario. While the office segment shows the largest magnitude for savings potential at 350,791 MWh, the grocery segment is estimated to have the highest share of potential as a percentage of 2010 load at 5.1% (compared to 3.1% for office). The healthcare segment also shows a high percentage of potential (4.3%) compared to 2010 load, while government/public service has the lowest percentage at 2.2%.

| NOTES: | | | | | | | | | | | | |
| •2010 energy load data not available for Public Street Lighting | | | | | | | | | | | | |

Table 4-3 and Figure 4-3 show the savings potential broken out between segments that reside in the commercial sector and segments that could contribute to the GNI carve-out³⁷. Under the base achievable scenario 1,280,734 MWh (69.1%) of energy savings potential resides in the commercial sector, while 521,871 MWh (30.9%) of energy savings potential is estimated to reside in the GNI sector.

4.3 COMMERCIAL POTENTIAL BY END USE

Figure 4-4 summarizes the distribution of cumulative five-year savings potential by commercial end use under the base achievable scenario, while Table 4-4 details the estimated savings potential by commercial end use by scenario by year. The lighting end use (including linear fluorescents, high bay

³⁷ While the SWE was able to identify government and institutional buildings in the EDCs customer databases, no reliable data was available to identify nonprofit customers since nonprofits cut across multiple building types. Therefore, the SWE team used education and healthcare buildings as a proxy for nonprofit customers since many of these buildings types are occupied by nonprofits.

lighting, other interior, and exterior lighting) accounts for the largest share of potential savings by end use with 744,277 MWh by 2020, representing 40.0% of achievable potential in 2020 – despite higher baseline conditions with T8 linear fluorescent lamps in place of T12s. The SWE Team found the next largest share of energy savings potential in the refrigeration end use (18.2%), followed by HVAC (space cooling, space heating, and heat pumps) and plug loads.

4.4 COMMERCIAL POTENTIAL BY EDC

This section details the commercial energy efficiency savings potential for each of the seven EDCs included in this assessment. Table 4-5 summarizes the SWE Team's findings. The SWE Team estimates the available energy savings potential to be roughly equal between EDCs when compared on a percentage of 2010 load basis, though some variance can be noted. PPL and Penn Power showed the largest share of five-year cumulative energy savings potential under the base achievable scenario at 3.9% and 3.7% of their 2010 load, respectively. Met-Ed and PECO showed the smallest share of five-year cumulative energy savings potential under the base achievable scenario at 2.8% of its 2010 load. The five-year cumulative energy savings potential for all seven EDCs combined is estimated at 1,853,605 MWh under the base achievable scenario, representing 3.3% of 2010 commercial sector load.

4.5 COMMERCIAL BENEFITS AND COSTS

Table 4-6 provides the economic impacts by EDC for the commercial base achievable and maximum achievable scenarios. Overall, the SWE Team found there to be a significant amount of cost-effective energy efficiency savings potential still attainable in Pennsylvania between 2016 and 2020. The SWE Team estimates that the NPV of the cost to attain all energy efficiency savings under the base achievable scenario at \$623.6 million from 2016 to 2020, while the benefits amount to almost \$1.4 billion during the same time period resulting in \$770 million in net benefits and a TRC ratio of 2.2.

Table 4-6: 2020 Commercial TRC Benefit-Cost Ratios by Achievable Scenario by EDC

| | NPV Costs (Million \$) | NPV Benefits (Million \$) | NPV Net Benefits (Million \$) | TRC BC Ratio |
|-------------------------------------|---------------------------|------------------------------|----------------------------------|--------------|
| Maximum Achievable Potential | | | | |
| Duquesne | \$131.5 | \$295.6 | \$164.0 | 2.2 |
| FE: Met-Ed | \$47.5 | \$107.9 | \$60.4 | 2.3 |
| FE: Penelec | \$60.3 | \$133.0 | \$72.7 | 2.2 |
| FE: Penn Power | \$16.4 | \$32.8 | \$16.3 | 2.0 |
| FE: West Penn | \$77.1 | \$160.2 | \$83.2 | 2.1 |
| PECO | \$254.1 | \$582.3 | \$328.1 | 2.3 |
| PPL | \$251.7 | \$494.1 | \$242.4 | 2.0 |
| Statewide | \$838.6 | \$1,805.9 | \$967.3 | 2.2 |
| Base Achievable Potential | | | | |
| Duquesne | \$86.3 | \$207.3 | \$121.1 | 2.4 |
| FE: Met-Ed | \$39.3 | \$90.2 | \$50.9 | 2.3 |
| FE: Penelec | \$47.8 | \$106.9 | \$59.0 | 2.2 |
| FE: Penn Power | \$13.1 | \$26.9 | \$13.8 | 2.1 |
| FE: West Penn | \$61.5 | \$131.8 | \$70.3 | 2.1 |
| PECO | \$209.6 | \$480.0 | \$270.5 | 2.3 |
| PPL | \$166.1 | \$350.5 | \$184.4 | 2.1 |
| Statewide | \$623.6 | \$1,393.6 | \$770.0 | 2.2 |

Table 4-7 summarizes the total estimated program expenses³⁸ that would be paid by the EDCs to realize the five-year cumulative energy savings estimates under the base achievable and maximum achievable scenarios. For the commercial sector, the per-MWh acquisition cost is between \$139/MWh and \$150/MWh among the EDCs under the base achievable scenario. The total estimated five-year programmatic costs for all seven EDCs is estimated at \$280.7 million to achieve the 1,910,733 MWh of commercial sector savings under the base achievable scenario, resulting in a statewide average acquisition cost of \$147/MWh.

³⁸ Program costs include administrative costs and incentive costs incurred by EDCs to obtain the sum of the five-year annual incremental savings.

Table 4-7: Five-Year Commercial Acquisition Costs (TRC) by Achievable Scenario by EDC

| EDC | 2016-2020 Program Costs (\$Million) | 2016-2020 Program Savings (MWh) | Acquisition Costs (\$/1 st -YR MWh Saved) |

5 Industrial Energy Efficiency Potential

This section of the report presents the industrial sector estimates of electric technical, economic, and achievable potential for the Commonwealth of Pennsylvania, as well as for each EDC service area. Program potential is discussed separately in Section 6 of this report. Electric energy efficiency savings, cost estimates, and benefit-cost estimates are presented in this section.

5.1 SUMMARY

Figure 5-1 summarizes electric energy efficiency savings potential for the industrial sector for all seven EDCs combined across the state. The five-year cumulative energy savings potential under the base achievable scenario amount to 1,173,082 MWh and 151.4 MW, representing a possible 3.2% reduction of 2010 load in the industrial sector. Details on each of the four scenarios are discussed in more detail below.

Figure 5-1: Industrial Energy (MWh) and Demand (MW) Savings Potential by Scenario by Year

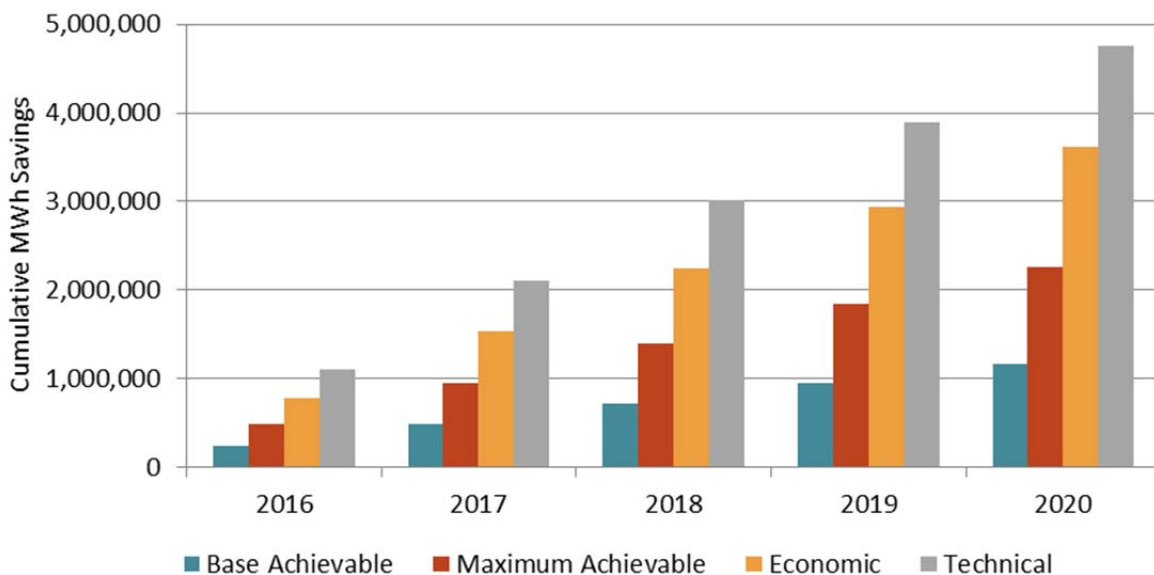

Table 5-1 presents the same estimates for electric energy efficiency savings potential for the commercial sector for all seven EDCs combined across the state by scenario. Details on the findings for each scenario are presented below.

Technical potential, which reflects the adoption of all energy efficient technologies, is a theoretical upper bound on savings. The five-year technical potential is 4,762,249 MWh (708.3 MW).

Economic Potential, which reflects the savings when all cost-effective measures are implemented, is 3,613,522 MWh during that same five-year period.

Maximum Achievable Potential is a subset of economic potential and represents the attainable savings assuming incentive levels are set at 100% of measure incremental costs and the long-term market penetration of high efficiency electric equipment reaches 85% of available stock in any given

year. Maximum achievable potential is 483,986 MWh in 2016. By 2020, the cumulative maximum achievable potential savings is 2,262,661 MWh, representing 6.2% of 2010 statewide industrial sales.

Base Achievable Potential is also a subset of economic potential and represents the SWE team's best estimate of attainable savings potential assuming comprehensive implementation of all cost-effective measures and no restrictions on budget. The base achievable potential scenario assumes incentive levels are set at 35% of measure incremental costs. Base achievable potential is estimated at 248,169 MWh in 2016. By 2020, the cumulative base achievable potential savings are estimated to be 1,173,082 MWh, representing 3.2% of 2010 statewide industrial sales.

Table 5-1: Industrial Cumulative Annual Energy (MWh) and Demand (MW) Savings Potential by Scenario by Year

5.2 INDUSTRIAL POTENTIAL BY MARKET SEGMENT

Figure 5-2 shows the five-year cumulative savings potential distribution by industrial building segment under the achievable base scenario. The Manufacturing (Mfg): Other segment accounts for the largest share of potential savings, representing 33.2% of achievable potential in 2020. This segment includes the manufacturing of automobiles, aircraft, furniture, and other miscellaneous materials. Mfg: Metals represents the second largest opportunity for savings at 15.2% of achievable potential.

Figure 5-2: 2020 Industrial Base Achievable Cumulative Annual Energy Savings Distribution by Industry Type

Table 5-2 details the same five-year findings, but summarizes the varying savings potential under each scenario. Mfg: Other has the largest magnitude for savings potential at 389,529 MWh, and also has the highest share of potential as a percentage of 2010 load at 19.1%. The Mfg: Other segment is comprised of several, smaller miscellaneous manufacturing industry types in Pennsylvania. Some of the industries types included in this bundled industrial segment include apparel, machinery, textile, transportation equipment, printing, furniture and stone/clay/concrete manufacturing facilities, to name a few. Mfg: Food has the next highest share of potential as a percentage of 2010 load at 4.0%.

Table 5-2: Industrial Cumulative Energy (MWh) & Demand (MW) Savings Potential by Scenario, by Industry Type

5.3 INDUSTRIAL POTENTIAL BY END USE

Figure 5-3 summarizes the distribution of cumulative five-year savings potential by industrial end use under the base achievable scenario, while Table 5-3 details the estimated savings potential by industry end use by scenario by year. The Motors end use accounts for the largest share of the potential savings by end use with 449,568 MWh by 2020, representing 38.3% of achievable potential in 2020. The SWE Team found the next largest share of energy savings potential in the HVAC end use (19.5%), followed by Process (18.7%).

5.4 INDUSTRIAL POTENTIAL BY EDC

This section details the industrial energy efficiency savings potential for each of the seven EDCs included in this study. Table 5-4 summarizes the SWE Team's findings. The SWE Team estimates the available energy savings potential to be roughly equal between EDCs when compared on a percentage of 2010 load basis, though some variance can be noted. PECO shows the largest share of five-year cumulative energy savings potential under the base achievable scenario at 5.5% of its 2010 load. Penn Power showed the smallest share of five-year cumulative energy savings potential under the base achievable scenario at 2.3% of its 2010 load. The five-year cumulative energy savings potential for all seven EDCs combined is estimated at 1,173,082 MWh under the base achievable scenario, representing 3.2% of 2010 industrial sector load.

5.5 INDUSTRIAL BENEFITS AND COSTS

Table 5-5 provides the economic impacts by EDC for the industrial base achievable and maximum achievable scenarios. Overall, the SWE Team found there to be a significant amount of cost-effective energy efficiency savings potential still attainable in Pennsylvania between 2016 and 2020. The SWE Team estimates that the NPV of the cost to attain all energy efficiency savings under the base achievable scenario at \$359.6 million from 2016 to 2020, while the benefits amount to over \$545 million during the same time period resulting in more than \$185 million in net benefits and a TRC ratio of 1.5.

Table 5-5: 2020 Industrial TRC Benefit-Cost Ratios by Achievable Scenario by EDC

| | NPV Costs (Million \$) | NPV Benefits (Million \$) | NPV Net Benefits (Million \$) | TRC BC Ratio |
|-------------------------------------|---------------------------|------------------------------|----------------------------------|--------------|
| Maximum Achievable Potential | | | | |
| Duquesne | \$49.9 | \$85.0 | \$35.1 | 1.7 |
| FE: Met-Ed | \$89.0 | \$143.1 | \$54.1 | 1.6 |

| FE: Penn Power | \$22.9 | \$31.9 | \$9.0 | 1.4 |
| FE: West Penn | \$102.5 | \$157.1 | \$54.6 | 1.5 |
| PECO | \$143.8 | \$224.2 | \$80.3 | 1.6 |
| PPL | \$169.9 | \$257.8 | \$87.9 | 1.5 |
| Statewide | \$674.5 | \$1,051.8 | \$377.3 | 1.6 |

| | NPV Costs (Million \$) | NPV Benefits (Million \$) | NPV Net Benefits (Million \$) | TRC BC Ratio |
|----------------------------------|---------------------------|------------------------------|----------------------------------|--------------|
| Base Achievable Potential | | | | |
| Duquesne | \$26.7 | \$43.8 | \$17.1 | 1.6 |
| FE: Met-Ed | \$46.9 | \$73.5 | \$26.6 | 1.6 |
| FE: Penelec | \$51.9 | \$79.6 | \$27.7 | 1.5 |
| FE: Penn Power | \$11.8 | \$16.2 | \$4.4 | 1.4 |
| FE: West Penn | \$55.0 | \$81.7 | \$26.7 | 1.5 |
| PECO | \$76.6 | \$116.3 | \$39.7 | 1.5 |
| PPL | \$90.7 | \$134.1 | \$43.4 | 1.5 |
| Statewide | \$359.6 | \$545.2 | \$185.6 | 1.5 |

Table 5-6 summarizes the total estimated program expenses that would be paid by the EDCs to realize the five-year cumulative energy savings estimates under the base achievable and maximum achievable scenarios. For the industrial sector, the per-MWh acquisition cost is between \$148/MWh and \$159/MWh among the EDCs under the base achievable scenario. The total estimated five-year programmatic costs for all seven EDCs is estimated at \$188.2 million to achieve 1,214,609 MWh of industrial sector savings under the base achievable scenario, resulting in a statewide average acquisition cost of \$155/MWh.

Table 5-6: Five-Year Industrial Acquisition Costs (TRC) by Achievable Scenario by EDC

| EDC | 2016-2020 Program Costs (Million \$) | 2016-2020 Program Savings (MWh) | Acquisition Costs (\$/1 st -YR MWh Saved) |
|------------------------------------|---|------------------------------------|---|
| Maximum Achievable Scenario | | | |
| Duquesne | \$39.8 | 169,398 | \$235.0 |
| FE: Met-Ed | \$71.2 | 301,964 | \$235.7 |
| FE: Penelec | \$76.2 | 337,636 | \$225.8 |

6 Portfolio-Level Results and Energy Efficiency Program Potential Estimates

This section presents the total³⁹ technical, economic, and achievable potential and then presents the estimates of electric program potential for the Commonwealth of Pennsylvania as well as each EDC service area for 2016 through 2020. Program potential is an estimate of energy savings that can be achieved through programs within a specific planning constraint. This study estimates program potential for a scenario where annual program spending is capped at 2% of 2006 EDC revenues.

Program potential is only determined for the first five years of the study horizon, as the purpose of this analysis is to inform decision making on the next Phase of PA Act 129, expected to be the period from June 1, 2016 through May 31, 2020.

6.1 TOTAL TECHNICAL AND ECONOMIC POTENTIAL

Table 6-1 summarizes the total cumulative annual technical and economic potential. Total cumulative annual technical potential across all customer classes and EDCs is 25.3 million MWh after five years and 41.2 million MWh after 10 years. These numbers are equivalent to 17.3% and 28.1% of the baseline load, respectively. After excluding measures that were not cost-effective based on the TRC, potential decreases to 11.8% of the baseline load after five years, and 18.4% of the baseline load after 10 years.

Table 6-1: Total Cumulative Annual Technical and Economic Energy (MWh) Potential across all EDCs

| | 2016 | 2017 | 2018 | 2019 | 2020 | 2025 |
|--|-----------|------------|------------|------------|------------|------------|
| Cumulative Savings Potential - MWh | | | | | | |
| Technical | 6,707,085 | 13,016,622 | 18,973,644 | 24,294,903 | 25,336,859 | 41,190,328 |
| Economic | 4,895,392 | 9,387,083 | 13,662,316 | 17,628,245 | 17,253,764 | 26,944,933 |
| Cumulative Savings Potential - % of 2010 Load | | | | | | |
| Technical | 4.6% | 8.9% | 12.9% | 16.6% | 17.3% | 28.1% |
| Economic | 3.3% | 6.4% | 9.3% | 12.0% | 11.8% | 18.4% |

6.2 TOTAL ACHIEVABLE POTENTIAL

Table 6-2 shows the cumulative annual and incremental annual achievable savings potential. Incremental annual savings could achieve roughly 1.2% to 2.0% of 2010 load in the base achievable and maximum achievable scenarios, respectively. On a cumulative annual basis, the base achievable potential is 4.6% of the baseline load in 2020 and maximum achievable potential is 7.5% of baseline load in 2020. Without a spending cap, the EDC costs to acquire base achievable potential would range from \$300 million to \$360 million annually. In the maximum achievable scenario, assuming incentives equal to 100% of the measure cost, EDC costs would range from \$582 million to \$642 million annually.

Table 6-2: Total Cumulative Annual Achievable Energy (MWh) Potential across all EDCs

| | 2016 | 2017 | 2018 | 2019 | 2020 | 2025 |
|--|-----------|-----------|-----------|------------|------------|------------|
| Cumulative Savings Potential - MWh | | | | | | |
| Maximum Achievable | 2,761,211 | 5,438,518 | 8,133,238 | 10,772,462 | 10,983,129 | 19,357,092 |

| Maximum Achievable | \$581.8 | \$601.9 | \$619.9 | \$638.5 | \$607.0 | \$642.6 |
| Base Achievable | \$302.1 | \$316.2 | \$329.3 | \$342.6 | \$325.7 | \$361.6 |

6.3 TOTAL PROGRAM POTENTIAL

As noted above, program potential estimation considered an annual spending ceiling that limits the annual program spending to 2% of 2006 annual revenue. This program spending constraint is the same as currently implemented within Phase II of Act 129. The ceiling was determined for each EDC and is summed to the state level, as each EDC has a unique rate and customer structure. The 2006 spending for each EDC was obtained from the PA PUC. Figure 6-1 summarizes the annual spending ceiling and the spending ceiling for a five-year implementation phase for each EDC.

Figure 6-1 One-Year and Five-Year Program Potential Budgets

Estimation of program potential for Phase III of Act 129 (estimated to be a five-year cycle) utilizes both residential and nonresidential potential savings. Because the base achievable potential scenario is based on historical incentive levels in Phase I and Phase II, the SWE Team utilized this achievable scenario as a foundational piece in the determination of program potential. In calculating expected program costs, incentive and non-incentive, the SWE Team utilized economic and performance metrics from the Phase I and Phase II implementation of EDC programs, as described in Section 2.3, “Phase I/II EDC Performance Benchmarking,” of this report.

The first step in the program potential calculation is to compile the sum of the incremental annual five-year (2016-2020) residential and nonresidential sector estimates for energy efficiency savings potential and the associated costs in the base achievable potential scenario. The next step in the program potential calculation compares the sum of the residential and nonresidential program costs to the five-year budgets ceilings at the EDC and state levels. The final step to calculate program potential is to scale the respective EDC base achievable potential energy savings to the five-year spending ceiling value while holding the acquisition cost constant. Using this scaling approach, the SWE Team found that the total five-year program potential for energy efficiency savings to be 6.6 million MWh, representing 4.5% of the 2010 baseline load.

The five-year program potential energy savings and budget values are found in Table 6-3 for each EDC and the Commonwealth of Pennsylvania.

Table 6-3: Five-Year Program Potential Savings and Budget by EDC

| | Portfolio Spending Ceiling (Million \$) | Program Acquisition Costs (\$/1 st -YR MWh Saved) | 2016-2020 Potential Savings (MWh) | % of 2010 Forecast |
|--|---|--|-----------------------------------|--------------------|
| 2016-2020 – Five-Year Program Potential | | | | |
| Duquesne | \$97.7 | \$186.9 | 522,837 | 3.7% |
| FE: Met-Ed | \$124.3 | \$182.2 | 682,474 | 4.6% |
| FE: Penelec | \$114.9 | \$191.9 | 598,704 | 4.2% |
| FE: Penn Power | \$33.3 | \$176.1 | 189,107 | 4.0% |
| FE: West Penn | \$117.8 | \$181.0 | 650,760 | 3.1% |
| PECO | \$427.0 | \$184.7 | 2,311,387 | 5.9% |
| PPL | \$307.5 | \$183.7 | 1,674,191 | 4.4% |
| Statewide | \$1,222.5 | \$184.4 | 6,629,460 | 4.5% |

6.4 PROGRAM POTENTIAL BENEFITS AND COSTS

Table 6-4 provides the economic impacts for the program potential scenario. Overall, the SWE Team found that the costs incurred to acquire the estimated energy efficiency savings in the program potential scenario would have an NPV of \$1.7 billion. The lifetime benefits those energy savings would provide are estimated to equal more than \$3 billion, providing more than \$1.49 billion in net benefits for the Commonwealth of Pennsylvania.

Table 6-4: Five-Year Program Potential Benefit-Cost Results and TRC Ratios

| | NPV Costs (Million \$) | NPV Benefits (Million \$) | Net NPV Benefits (Million \$) | TRC BC Ratio |
|--|------------------------|---------------------------|-------------------------------|--------------|
| 2016-2020 – Five-Year Program Potential | | | | |
| Duquesne | \$143.7 | \$300.9 | \$157.2 | 2.1 |

| FE: Penelec | \$159.7 | \$277.8 | \$118.1 | 1.7 |
| FE: Penn Power | \$43.0 | \$72.5 | \$29.4 | 1.7 |
| FE: West Penn | \$153.5 | \$275.0 | \$121.5 | 1.8 |
| PECO | \$600.1 | \$1,162.9 | \$562.8 | 1.9 |
| PPL | \$423.0 | \$770.1 | \$347.1 | 1.8 |
| Statewide | \$1,692.0 | \$3,184.2 | \$1,492.3 | 1.9 |

7 Conclusions & Recommendations

The final section of this report provides a brief summary of the overall potential findings and general conclusions and recommendations stemming from the SWE Team analysis.

7.1 SUMMARY

In summary, the remaining potential for cost-effective electric energy efficiency in the service areas of the seven EDCs bound under Act 129 is significant. The statewide estimated electricity savings attainable under the program potential scenario for the five-year time period (2016-2020) amount to 6,629,460 MWh (a 4.5% reduction in the projected 2010 baseline MWh sales) based on the sum of first-year savings over the five-year period. These values are based on an estimated weighted average portfolio acquisition cost among all EDCs of \$184/MWh saved.

The NPV costs to acquire the savings over the five-year period are equal to \$1.7 billion, yet yield NPV benefits during the same timeframe in excess of \$3 billion resulting in net benefits of \$1.49 billion and a TRC ratio of 1.9. The results of this study demonstrate that cost-effective electric energy efficiency resources can play an important role in Pennsylvania's energy resource mix during the next five years.

7.2 FINAL OBSERVATIONS

This energy efficiency potential study was designed as an update to the 2012 potential study and is intended to assess the remaining cost-effective electric energy efficiency potential in Pennsylvania over the possible implementation of Phase III of Act 129 (2016-2020). There are several important facts about the data and assumptions used in this electric energy efficiency potential study, including:

- The forecasts of program potential are based on many assumptions, including EDC-forecasted sales, avoided costs, measure costs and expected savings, the SWE Team's experience and industry knowledge, among others. A significant change to these assumptions can affect the applicability of the SWE Team's estimates (e.g., due to a large change in economic conditions).
- As discussed in Section 6, the SWE Team utilized a "scaling" approach to scale the base achievable savings potential to program potential given the estimated acquisition cost of obtaining the mix of measures adopted within the base achievable scenario. Given the budget ceiling for each EDC under Act 129, actual achieved savings could be higher or lower depending on the actual mix of "expensive" measures vs. "cheap" measures offered by EDCs in their DSM programs.
- Currently, Phase II of Act 129 has specific targets for two "set-asides" sectors: residential low income and government, nonprofit and institutional (GNI). This analysis considers the market opportunity for these "set-aside" sectors based on specific residential and commercial segments, but does not directly recommend whether targets should be established for the set-asides in Phase III or what those targets should be.
- The SWE Team estimated savings from the low income sub-sector in this analysis based on historical program offerings and experience as well as current market conditions. Any significant increases to these offerings might impact overall potential, likely with the effect of reducing program potential. For instance, residential low income programs often utilize 100% incremental measure cost incentives. Higher budgets for either set-aside program would have the consequence of reducing the overall budget for the broader portfolio, leading to reduced program potential savings.
- The scenarios examined in this study (base achievable and maximum achievable) are intended to align with the aggressiveness of program delivery, generally aligned with program spending

levels and the associated average incentive rates. The SWE Team used the EDCs' historical incentive rates coupled with other regional trends to inform the aggressiveness of the market adoption for the base achievable scenario in this study. Findings from the willingness-to-pay research collected during the baseline studies were used to inform the achievable scenarios.

- This study includes a comprehensive list of energy efficiency measures for the residential, commercial, and industrial sectors. For example, consumer electronics are treated as a comprehensive end use in the residential sector in this analysis. The SWE Team included all of the energy efficiency measures in the 2015 Pennsylvania Technical Reference manual in this study.
- The SWE Team closely examined and included the anticipated impacts of the federal lighting standards (EISA and EPCAct) in its measure research (among other code impacts). While these higher baselines eroded a large share of eligible energy savings claimed by EDCs during Phase I and Phase II of Act 129, the SWE Team still found a reasonable share of remaining potential in the lighting end use for Phase III.
- All equipment measures were assumed to be eligible to revert back to the code baseline when they reached the end of their useful life. This assumption allows for savings to be collected regardless of the prior equipment's efficiency. The 2012 potential study omitted already efficient equipment from future potential which resulted in fewer eligible measures and lower potential for savings.
- Administrative costs were not included when screening measures for cost-effectiveness, but were included in program acquisition costs and the calculation of the TRC cost effectiveness test.
- While measure costs are assumed to hold constant for cost-effective screening, the SWE Team did apply an inflation rate to both incremental measure costs and administrative costs when estimating program delivery and TRC costs over the five-year period.
- The SWE team found that the vast majority of space cooling equipment measures (e.g., unitary air conditioners) are no longer cost-effective in Pennsylvania under the TRC cost effectiveness test. While the SWE Team did not conduct a full investigation into this finding, we believe the reduction in the effective full load hours (EFLH) in the 2015 TRM played a significant role. This finding reduced savings in the space cooling end use and resulted in an overall lower acquisition cost than what might have otherwise occurred had space cooling equipment been cost-effective (as was the case in the 2012 study).
- This study considered the latest available forecasts of electric avoided costs provided by the seven EDCs. Future updates to EDC avoided costs could result in a different cost-effective measure mix and alternate estimates of electric energy efficiency potential.

It is clear that electric energy efficiency programs could save residents and business owners of Pennsylvania a substantial amount of electricity by 2020, despite the savings achieved to-date by the EDCs and increasing equipment efficiency standards. The SWE Team estimates that the attainable statewide program potential electricity savings, based on the sum of first-year savings for the five-year period (2016-2020), amounts to 6,629,460 MWh (a 4.5% reduction in the projected 2010 baseline MWh sales). The SWE Team further finds that DSM programs offered by the EDCs will continue to be cost-effective in a possible Phase III with an estimated TRC ratio of 1.9. The electric energy efficiency potential estimates and the TRC savings provided in this report are based on the latest load forecasts and avoided cost forecasts provided by the EDCs. Over time, additional technologies are likely to become available in the market that may serve to increase the potential for energy and demand savings and warrant additional attention. Finally, actual energy and demand savings will depend upon the level and degree of Pennsylvania residences and business participation in the energy efficiency programs offered by the EDCs.

APPENDIX A

GLOSSARY

GLOSSARY

The following list defines many of the key energy efficiency terms used throughout this energy efficiency potential study.

Achievable Potential: The amount of energy use that energy efficiency can realistically be expected to displace. Achievable potential takes into account real-world barriers to convincing end-users to adopt efficiency measures, the non-measure costs of delivering programs (for administration, marketing, tracking systems, monitoring and evaluation, etc.), and the capability of programs and administrators to ramp up program activity over time. (*See also Base Achievable Potential and Maximum Achievable Potential*).

Acquisition Costs are defined within this report as program expense dollars spent to acquire first-year energy savings. Program expense dollars include all program costs such as rebates, incentives, administrative costs, as well as marketing, outreach, and evaluation expenditures. Discussion of acquisition cost is useful because of its simplicity (costs divided by first year savings). However, this metric does have important limitations, because it does not reflect the value of the energy savings as a resource. Additional savings parameters would need to be included, specifically measure lifetime, to determine the value of the savings resource.

Adoption Rate is the rate at which new technologies, processes and innovations spreads through a society, and why they are adopted over old methods.

Applicability Factor: The fraction of the applicable dwelling units or businesses that is technically feasible for conversion to the efficient technology from an engineering perspective (e.g., it may not be possible to install CFLs in all light sockets in a home because the CFLs may not fit in every socket in a home).

Avoided Costs: The cost of producing or delivering power that the utility can avoid by lowering capacity and energy requirements.

Base Achievable Potential: An achievable potential scenario that is based on historical incentive levels and the corresponding program adoption rates observed from the Pennsylvania EDCs, other regional utility demand-side management (DSM) programs, and willingness-to-participate surveys conducted for the 2014 PA PUC baseline studies

Base Case Equipment End-Use Intensity: The electricity used per customer per year by each base-case technology in each market segment. This is the consumption of the electric energy using equipment that the efficient technology replaces or affects. For example, if the efficient measure is a high efficiency light bulb (CFL), the base end-use intensity would be the annual kWh use per bulb per household associated with an incandescent light bulb that provides equivalent lumens to the CFL.

Compound Annual Growth Rate (CAGR) is the year-over-year growth rate of an investment over a specified period of time.

Cost-Effectiveness: A measure of the relevant economic effects resulting from the implementation of an energy efficiency measure. If the benefits are greater than the costs, the measure is said to be cost-effective.

Cumulative Annual: Refers to the overall annual savings occurring in a given year from both new participants and annual savings continuing to result from past participation with energy efficiency measures that are still in place. Cumulative annual does not always equal the sum of all prior year incremental values as some energy efficiency measures have relatively short lives and, as a result, their savings drop off over time.

Commercial Sector: Comprised of non-manufacturing premises typically used to sell a product or provide a service, where electricity is consumed primarily for lighting, space cooling and heating, office equipment and other appliances.

Conservation Voltage Reduction (CVR): A change in the voltage made by a physical adjustment in transformer settings governing voltage at the substation. By adjusting substation voltage, the program impacts hourly energy flows and capacity, including demand coincident with the system peak period(s).

Demand Response: Refers to demand resources involving dynamic hourly load response to market conditions, such as curtailment or load control programs.

Energy Use Intensity (EUI): A unit of measurement that describes a building's energy use. EUI represents the energy consumed by a building relative to its size.

Early Replacement: Refers to an efficiency measure or efficiency program that seeks to encourage the replacement of functional equipment before the end of its operating life with higher-efficiency units.

Economic Potential: The subset of the technical potential that is economically cost-effective as compared to conventional supply-side energy resources. Economic ignores market barriers to ensuring actual implementation of efficiency. Finally, economic potential only considers the costs of efficiency measures themselves, ignoring any programmatic costs (e.g., marketing, analysis, administration) that would be necessary to capture them.

End-Use: A category of equipment or service that consumes energy (e.g., lighting, refrigeration, heating, process heat, cooling).

Energy Efficiency: Using less energy to provide the same or an improved level of service to the energy consumer in an economically efficient way. Sometimes "conservation" is used as a synonym, but that term is usually taken to mean using less of a resource even if this results in a lower service level (e.g., setting a thermostat lower or reducing lighting levels).

First Year Savings: Savings accrued in the first year of the measure's installation. Future benefits are not considered.

Gross Savings: Gross energy (or demand) savings are the change in energy consumption or demand that results directly from program-promoted actions (e.g., installing energy-efficient lighting) taken by program participants regardless of the extent or nature of program influence on their actions.

Incentive Costs: A rebate or some form of payment used to encourage people to implement a given demand-side management (DSM) technology. The incentive is calculated as the amount of the

technology costs that must be paid by the utility for the participant test to equal one and achieve the desired benefit/cost ratio to drive the market.

Incremental Annual: Savings or costs in a given year associated only with new installations happening in that specific year.

Industrial Sector: Comprised of manufacturing premises typically used for producing and processing goods, where electricity is consumed primarily for operating motors, process cooling and heating, and space heating, ventilation, and air conditioning (HVAC). Business types are included in section 5 – methodology.

Maximum Achievable Potential: An achievable potential scenario that assumes the most aggressive program scenario possible (e.g. providing end users with payments for the entire incremental cost of more efficient equipment).

Measure: Any action taken to increase energy efficiency, whether through changes in equipment, changes to a building shell, implementation of control strategies, or changes in consumer behavior. Examples are higher-efficiency central air conditioners, occupancy sensor control of lighting, and retro-commissioning. In some cases, bundles of technologies or practices may be modeled as single measures. For example, an ENERGY STAR[®]™ home package may be treated as a single measure.

MW: A unit of electrical output, equal to one million watts or one thousand kilowatts. It is typically used to refer to the output of a power plant.

MWh: One thousand kilowatt-hours, or one million watt-hours. One MWh is equal to the use of 1,000,000 watts of power in one hour.

Net Savings: Net energy or demand savings refer to the portion of gross savings that is attributable to the program. This involves separating out the impacts that are a result of other influences, such as consumer self-motivation. Given the range of influences on consumers' energy consumption, attributing changes to one cause (i.e., a particular program) or another can be quite complex.

Participant Cost: The cost to the participant to participate in an energy efficiency program.

Portfolio: Either a collection of similar programs addressing the same market, technology, or mechanisms; or the set of all programs conducted by one energy efficiency organization or utility.

Program: A mechanism for encouraging energy efficiency that may be funded by a variety of sources and pursued by a wide range of approaches (typically includes multiple energy efficiency measures).

Program Potential: the efficiency potential possible given specific program funding levels and designs. Program potential studies can consider scenarios ranging from a single program to a full portfolio of programs. A typical potential study may report a range of results based on different program funding levels. For this study, the SWE Team has opted to utilize a simple-scaling approach to estimate program potential given the available DSM budgets stipulated under Act 129 (2% of 2006 revenues).

Remaining Factor: The fraction of applicable units that have not yet been converted to the electric energy efficiency measure; that is, one minus the fraction of units that already have the energy efficiency measure installed.

Replace-on-burnout: A DSM measure is not implemented until the existing technology it is replacing fails or burns out. An example would be an energy efficient water heater being purchased after the failure of the existing water heater at the end of its useful life.

Retrofit: Refers to an efficiency measure or efficiency program that seeks to encourage the replacement of functional equipment before the end of its operating life with higher-efficiency units (also called “early retirement”) or the installation of additional controls, equipment, or materials in existing facilities for purposes of reducing energy consumption (e.g., increased insulation, low flow devices, lighting occupancy controls, economizer ventilation systems).

Savings Factor: The percentage reduction in electricity consumption resulting from application of the efficient technology. The savings factor is used in the formulas to calculate energy efficiency potential.

Technical Potential: The theoretical maximum amount of energy use that could be displaced by efficiency, disregarding all non-engineering constraints such as cost-effectiveness and the willingness of end users to adopt the efficiency measures. Technical potential is constrained only by factors such as technical feasibility and applicability of measures.

Total Resource Cost Test: The TRC measures the net benefits of the energy efficiency program for a region or service area as a whole. Costs included in the TRC are costs to purchase and install the energy efficiency measure and overhead costs of running the energy efficiency program. The benefits included are the avoided costs of energy and capacity. For purposes of this study, non-electric benefits were not included in the calculation of TRC benefits.

Other General Modeling Assumptions

| | |
|--|--------|
| Avoided Cost Inflation Rate <i>(BLS Statistic)</i> | 1.87% |
| Residential Line Loss Multiplier | 1.0910 |
| Commercial Line Loss Multiplier | 1.0790 |
| Industrial Line Loss Multiplier | 1.0790 |

APPENDIX C

EXAMPLES OF PROGRAM WITH HIGH MARKET ADOPTION

EXAMPLES OF PROGRAMS WITH HIGH MARKET ADOPTION

GDS collected information on electric and gas energy efficiency programs conducted during the past three decades where high penetration has been achieved. Ten examples of such programs are listed below.

1. The US EPA Energy Star website reports that the following appliances and electronics have an Energy Star market penetration in 2013 above 70 percent:
 - Commercial ovens (73%)
 - Commercial refrigerators and freezers (72%)
 - Dehumidifiers (99%)
 - Dishwashers (90%)
 - Imaging Equipment (81%)
 - LCD Monitors (82%)
 - Multifunction Devices & Printers (90%)
 - Notebook Computers (74%)
 - Refrigerators (74%)
 - Room Air Conditioners (72%)
 - Set Top Boxes (89%)
 - Televisions (84%)
 - Water Coolers (86%)
2. The Residential Multifamily/Low-Income Program in Vermont achieved a market share of over 90% for new construction and nearly 30% for existing housing.¹
3. A 2014 residential baseline study of 490 randomly selected homes conducted for the State of Pennsylvania found that 89% of homes in the state have at least one CFL.
4. A 2010 residential baseline study for the State of Maryland found that 81% of homes have at least one CFL installed.
5. The residential water heater bundle-up program conducted by Central Maine Power Company achieved a market penetration of over 80% of residential electric water heaters in the Company's service area. This program has been operated by CMP since the 1980s.
6. In the State of Wisconsin, a natural gas energy efficiency program to promote high efficiency gas furnaces attained a penetration rate of over 90%.²
7. KeySpan Energy Delivery's high efficiency residential furnace program achieved a market share of approximately 70% over nine years (1997-2005).³
8. Many states in the US and provinces in Canada have replaced 100% of incandescent traffic signals with LED traffic signals.⁴
9. In 1985 the Hood River project performed a community-wide direct install, primarily weatherization effort. There was no cost to customers. The project sought to achieve 100% participation at a time when typical participation rates in utility-sponsored conservation

¹ York, Dan; Kushler, Martin; America's Best: Profiles of America's Leading Energy Efficiency Programs," published by the American Council for an Energy Efficient Economy, March 2003. Report Number U032.

² Hewitt, David. C., "The Elements of Sustainability", paper presented at the 2000 ACEEE Summer Study on Energy Efficiency in Buildings. Washington: American Council for an Energy Efficient Economy. Pages 6.179-6.190. The Wisconsin furnaces case study data can be found in the 2000 ACEEE Summer Study Proceedings on pages 6.185-6.186.

³ American Council for an Energy Efficient Economy, "America's Best Gas Energy Efficiency Programs", 2003.

⁴ Increasing Market Penetration of LED Traffic Signals in New York State: Review of Articles and Information on LED Traffic Signals, published by the *Lighting Research Center, Rensselaer Polytechnic Institute American Council for an Energy Efficient Economy*, Prepared for the New York State Energy Research and Development Authority, Final July 20, 2000.

programs were on the order of 3% to 6%. Overall 91% of homes agreed to the energy audit and 85% of homes chose to implement some combination of efficiency measures. This project is still commonly referenced as the basis for maximum achievable potential in the Pacific Northwest.
