

**BEFORE THE  
PENNSYLVANIA PUBLIC UTILITY COMMISSION**

**Docket No. R-2015-2518438**

**UGI Utilities, Inc. – Gas Division**

**Statement No. 5-R**

**Rebuttal Testimony of  
John F. Wiedmayer C.D.P.**

**Topics Addressed:      Depreciation**

Date: May 10, 2016

REBUTTAL TESTIMONY OF  
JOHN F. WIEDMAYER  
DOCKET NO. R-2015-2518438

1 **I. INTRODUCTION**

2 **Q. Please state your name and address.**

3 A. My name is John F. Wiedmayer. My business address is 1010 Adams  
4 Avenue, Audubon, Pennsylvania 19403.

5

6 **Q. Did you previously submit direct testimony in this proceeding on behalf  
7 of UGI Utilities, Inc. – Gas Division (“UGI Gas” or the “Company”)?**

8 A. Yes. I submitted my direct testimony, UGI Gas Statement No. 5, on January  
9 19, 2016.

10

11 **Q. What is the purpose of your rebuttal testimony?**

12 A. The purpose of my rebuttal testimony is to address the depreciation related  
13 issues discussed in the direct testimony of Office of Consumer Advocate  
14 (“OCA”) witness James S. Garren, OCA Statement No. 5.

15

16 **Q. Please summarize your rebuttal testimony.**

17 A. My rebuttal testimony responds to certain adjustments related to depreciation  
18 expense proposed in the direct testimony of James S. Garren, OCA Statement  
19 No. 5. Specifically, Mr. Garren proposes to reduce the Company’s claimed  
20 amount of depreciation expense of \$41.516 million by \$7.8 million. Mr.  
21 Garren’s recommendation to reduce depreciation expense is based on two

1 primary reasons, as follows: 1) he recommends increasing the service lives for  
2 14 distribution plant accounts even though the company plans to accelerate  
3 replacements of its gas plant assets over the next 14 to 30 years as part of its  
4 Long-Term Infrastructure Improvement Plan ("LTIIIP"); and 2) he recommends  
5 a change in the longstanding, approved depreciation calculation procedure  
6 known as the Equal Life Group ("ELG") procedure to the Average Service Life  
7 ("ASL") procedure. UGI Gas has been using the Equal Life Group procedure  
8 to calculate depreciation rates for vintages 1982 and subsequent for over 30  
9 years. Also, most other Pennsylvania utilities use ELG to calculate  
10 depreciation and have used ELG for many years.

11  
12 **Q. Can you please provide an overview of Mr. Garren's proposals?**

13 **A.** Yes. Mr. Garren is proposing that UGI Gas reduce depreciation expense by  
14 20 percent or by approximately \$7.8 million. Of the \$7.8 million reduction,  
15 approximately \$1.8 million is related to the proposed increase in service lives  
16 and approximately \$6.0 million is due to the change in depreciation calculation  
17 procedures from ELG to ASL. This is a material overall reduction and Mr.  
18 Garren has not presented any credible evidence to support such a large  
19 reduction in depreciation expense. Additionally, even if Mr. Garren's service  
20 lives and shift from ELG to ASL are accepted, which it should not be, his  
21 proposed \$7.8 million reduction should only be \$7.5 million as Mr. Garren  
22 calculates depreciation incorrectly for certain general plant accounts including  
23 Common Plant and Information Services ("IS").

1 **Q. Please explain the error in Mr. Garren's depreciation calculation for**  
2 **General Plant including Common Plant and IS.**

3 A. In OCA Exhibit JSG-1, Mr. Garren compares his proposed curves with the  
4 curves used by UGI Gas. There are no differences listed on OCA Exhibit  
5 JSG-1 for General Plant, Common Plant and IS, yet on page 5 of his  
6 testimony he presents a \$72,183 reduction for General Plant and a \$328,629  
7 reduction for Common Plant and IS. While a small amount of the difference  
8 can be attributed to the difference in depreciation calculation procedures (*i.e.*,  
9 ELG vs. ASL) for accounts not subject to amortization accounting such as  
10 Account 392 and 396, most of the difference is due to Mr. Garren using a  
11 different curve (*i.e.*, O1) for his calculations than the curve (SQ or Square) he  
12 presents in his testimony. The reduction to depreciation expense caused by  
13 Mr. Garren selecting the wrong survivor curve for accounts subject to  
14 amortization accounting (*i.e.*, 391, 394, 397, 398) is approximately \$300,000.

15

16 **Q. Does the Company agree with Mr. Garren's recommendations?**

17 A. No. Mr. Garren's recommendations are largely without merit and should be  
18 rejected in their entirety. Mr. Garren's recommendations to increase service  
19 lives for 14 distribution plant accounts is incongruent with the Company's  
20 outlook and plans. Included in UGI Gas's LTIP is a plan to replace all cast  
21 iron mains within 14 years and all bare steel mains within 29 years as of  
22 March 2013. UGI Gas expects to expend \$51.2 million each year of the LTIP  
23 from 2014 through 2018 for asset replacement. This is nearly double the  
24 amounts previously spent and it includes cast iron and bare steel main

1 replacement and service line replacements. According to the LTIP, UGI Gas  
2 will replace gas service lines on a planned basis in conjunction with the  
3 replacement of the mains to which they are connected. In addition to  
4 replacing certain types of mains and services made of cast iron, wrought iron  
5 and bare steel, UGI Gas plans to replace and relocate approximately 70,000  
6 indoor meters; and replace risers, meter bars, regulator stations and house  
7 regulators in connection with the main replacement program and other items  
8 included in the LTIP. In nearly all of the 14 accounts in which Mr. Garren is  
9 recommending a service life increase, UGI Gas has plans set forth in its LTIP  
10 to accelerate the replacement of its distribution assets. These plans will put  
11 downward pressure on service lives and will likely decrease service lives in  
12 some accounts and increase the mode of the survivor curve in others. It is  
13 unlikely that the service lives for distribution plant will increase given the asset  
14 replacement programs set forth in the Company's LTIP.

15  
16 **II. GENERAL DEPRECIATION ISSUES**

17 **Q. Are there any general issues related to depreciation that you would like**  
18 **to address?**

19 A. Yes. In response to both statements made by Mr. Garren in his testimony and  
20 to his overall approach to his depreciation recommendations, there are two  
21 general issues I would like to address. The first is related to how depreciation  
22 impacts customer rates. Mr. Garren presents a brief discussion of this topic  
23 on pages 2 and 3 of OCA Statement No. 5 and makes suggestions that

1 utilities have an incentive to “overcharge” for depreciation expense.<sup>1</sup> Mr.  
2 Garren’s explanation of depreciation concepts is incomplete, and as a result  
3 his suggestions are incorrect.

4 The second issue is related to the depreciation study process in  
5 general. Depreciation is by its nature a forecast of events that will happen  
6 over many decades. The service life estimates presented in UGI Gas’s  
7 depreciation study represent a projection of the retirements of property  
8 currently in service that will occur over the next fifty years or more. Because  
9 of the nature of forecasting service lives, it is critical that the depreciation  
10 professional not only incorporate statistical analyses of historical data, but also  
11 have detailed knowledge of the property studied and the plans of the  
12 Company. I have performed depreciation studies for UGI Gas for 27 years,  
13 have made field visits to observe their property in 12 Pennsylvania counties on  
14 numerous occasions, have prepared their annual depreciation reports for the  
15 past 27 years (and our firm has prepared these reports for UGI Gas for over  
16 thirty years) and, therefore, I have the requisite experience to provide  
17 reasonable forecasts of service life.

18 In contrast, Mr. Garren’s testimony makes clear that he has little  
19 knowledge of the Company or its plans, and little knowledge of depreciation  
20 practices in the state of Pennsylvania. His service life estimates are based on  
21 little more than mechanically selecting curves from a curve matching  
22 algorithm. As a result, his estimates are in many cases inconsistent with the  
23 Company’s plans (for example, replacement of cast iron and bare steel

---

<sup>1</sup> OCA Statement No. 5, p. 3 lines 5-7.

1 mains) and instead calculates depreciation amounts that are too low and are  
2 based on life estimates that are too high and inconsistent with well-known  
3 Company plans such as its cast iron and bare steel mains replacement plan.  
4

5 **Q. Please address Mr. Garren's comments on pages 2 and 3 of his**  
6 **testimony.**

7 A. On pages 2 and 3 of OCA Statement No. 5, Mr. Garren presents a discussion  
8 on depreciation that inappropriately gives the impression that utilities  
9 intentionally overstate depreciation expense. Mr. Garren first states that  
10 depreciation represents the "[d]irect pass through of cash from the customers  
11 to the utility that the utility retains for non-utility purposes."<sup>2</sup> This cynical and  
12 unsupported statement is not an accurate description of depreciation.

13 Depreciation represents the allocation of the cost of the Company's  
14 assets over the period of time in which the assets will be in service. The costs  
15 of these assets have already been incurred by the Company, *i.e.*, UGI Gas  
16 has already spent money to install assets such as mains, services and  
17 measuring and regulating equipment that are used to provide gas service to  
18 customers. Depreciation represents the return of these costs to the Company,  
19 allocated over the time the assets are in service. It does not represent a  
20 "direct pass through of costs" that the utility can use for whatever it wants.  
21 *Instead, it represents the recovery of costs already incurred.*

22 Further, while it is technically correct that depreciation expense once  
23 recovered can be spent by the utility as needed, it is an inaccurate

---

<sup>2</sup> OCA Statement No. 5, p. 2 line 14 to p. 3 line 1.

1 representation made by Mr. Garren that these funds will generally be used for  
2 "non-utility" purposes. Indeed, UGI Gas typically spends more on capital  
3 additions to plant in service than it records in depreciation expense. For  
4 example, as can be seen in UGI Gas's most recent Annual Depreciation  
5 Report, UGI Gas recorded \$31.3 million in depreciation expense in 2015.  
6 However, the Company added \$105.2 million in plant in the same year, and  
7 incurred an additional \$6.0 million in costs to remove assets that were retired.  
8 UGI Gas therefore spent more than 3.5 times as much as it recovered in  
9 depreciation expense. Mr. Garren's implication that UGI Gas will use  
10 depreciation expense for purposes other than investment in utility service is  
11 therefore misplaced. The Company regularly spends much more than its  
12 depreciation expense, and therefore has to use funds in addition to  
13 depreciation, typically raised in capital markets, in order to operate its  
14 business.

15  
16 **Q. Are there any other statements made by Mr. Garren that you would like**  
17 **to address?**

18 A. Yes. Mr. Garren also states that "[i]n practice, this means that depreciation  
19 expense provides a company with a source of free cash flow. This can  
20 incentivize a company to overcharge for depreciation by understating the  
21 period over which the depreciation is allocated, or overstating a future cost of  
22 removal allowance."<sup>3</sup> I have already explained that a Company such as UGI  
23 Gas typically spends more on capital investments than it recovers in

---

<sup>3</sup> OCA Statement No. 5, p. 3, lines 4-7.

1 depreciation, and so Mr. Garren's implication of "free cash" flow is inaccurate.  
2 Mr. Garren's statement that a Company has an incentive to "overcharge" for  
3 depreciation is also incorrect since accumulated depreciation is a reduction to  
4 rate base.

5  
6 **Q. How does depreciation impact customer rates?**

7 A. Depreciation impacts customer rates in two ways. The first is that depreciation  
8 expense is a direct component of the revenue requirement. Mr. Garren only  
9 discusses this impact. However, Mr. Garren does not mention that  
10 accumulated depreciation<sup>4</sup> is also an offset to rate base. A higher level of  
11 accumulated depreciation results in a lower return on rate base and therefore  
12 lower customer rates when compared to a lower level of accumulated  
13 depreciation.

14 The implication of Mr. Garren's statement is that a utility has an  
15 *incentive for higher depreciation because it results in higher customer rates,*  
16 *and therefore "free cash flow."* However, over the long term this is  
17 fundamentally incorrect. Higher depreciation expense can result in higher  
18 customer rates in the short term, but will over time result in higher  
19 accumulated depreciation. Because average depreciation rates for a utility are  
20 typically in the 2% to 3% range and the return on rate base is higher (typically  
21 7% to 8% or higher), higher depreciation expense tends to produce lower  
22 customer rates over time. Mr. Garren's accusation that a utility has an  
23 incentive to "overcharge" for depreciation expense is therefore incorrect.

---

<sup>4</sup> Accumulated depreciation is the depreciation expense recorded to date, less recorded retirements and cost of removal, plus recorded gross salvage.

1

2 **Q. Can you provide an example of the impact of depreciation on customer**  
3 **rates?**

4 A. Yes. One concept that Mr. Garren challenges is UGI Gas's (and  
5 Pennsylvania's) longstanding use of the Equal Life Group ("ELG") procedure.  
6 I will discuss his proposal in more detail in the Section IV of my testimony.  
7 However, it is true that because ELG produces higher depreciation rates for  
8 younger vintage assets than the Average Service Life ("ASL") procedure, all  
9 else equal, composite ELG depreciation rates are often higher than composite  
10 ASL depreciation rates.

11 UGI Gas has used ELG depreciation rates for new assets since the  
12 early 1980s, and therefore accumulated depreciation is higher than had ASL  
13 been used for this period of time. The use of ELG depreciation rates means  
14 that rate base is lower and the Company earns less of a return than had ASL  
15 been used since the 1980s. As a result, customer rates are lower today than  
16 they would have been had ELG not been adopted. From a revenue  
17 requirement perspective, the use of the ELG procedure has a greater impact  
18 on reducing rate base returns than increasing annual depreciation expense  
19 over a medium to long-term period.

20

21 **Q. Based on Mr. Garren's presentation, what can you conclude regarding**  
22 **OCA's overall presentation on depreciation?**

23 A. As I have explained above, Mr. Garren's overall presentation of depreciation  
24 concepts is *inaccurate and inappropriate*. Additionally, his recommendations

1 and discussions in his testimony demonstrate that he has little knowledge of  
2 the Company or of depreciation practices in Pennsylvania – both of which are  
3 necessary to provide informed estimates of depreciation. I will explain these  
4 deficiencies in Mr. Garren’s recommendations in more detail in subsequent  
5 sections of my rebuttal testimony.

6 In contrast to OCA’s presentation, my recommendations are based on  
7 informed judgment that incorporates the knowledge I have gained from  
8 performing depreciation studies for UGI Gas for nearly thirty years.  
9 Additionally, my firm, Gannett Fleming Valuation and Rate Consultants, LLC,  
10 has been providing depreciation consulting services to UGI Gas for over 50  
11 years. As a result, the recommended depreciation rates in my study provide  
12 far more reasonable and appropriate return of UGI Gas’s investments.

13  
14 **III. SERVICE LIFE ESTIMATES**

15 **A. Introduction**

16 **Q. What will you address in this section of your testimony?**

17 A. In this section I will address the erroneous manner in which service life  
18 estimates were made by Mr. Garren. Not only has Mr. Garren employed an  
19 inappropriate approach to estimating service lives, but his statistical analysis –  
20 which forms the entire basis of his proposals – includes numerous calculation  
21 errors. In this section, I explain the process for life estimation and  
22 demonstrate that service life estimates must be based on more than  
23 mechanical curve matching. Because my survivor curve estimates incorporate  
24 the proper experience and judgment, they set forth the best representation of

1 future service life expectations for UGI Gas related to gas plant in service. In  
 2 contrast, the process employed by Mr. Garren is inappropriate and produces  
 3 results that are unreasonable and unrealistic. I will also discuss the  
 4 calculation errors in Mr. Garren's presentation. Given that he bases his  
 5 recommendations entirely on the results of his statistical analyses, the fact that  
 6 he has made errors in these analyses further compounds the issues with his  
 7 approach.

8  
 9 **Q. Can you summarize the OCA's service life recommendations?**

10 **A.** Yes. I have summarized both my estimates and Mr. Garren's estimates in the  
 11 table below. As the table shows, there are 14 distribution plant accounts  
 12 where Mr. Garren and I have different service life estimates. In all 14  
 13 instances the service lives estimated by Mr. Garren are longer than the service  
 14 lives that I had estimated (resulting in a decrease in depreciation, all else  
 15 equal) for these 14 distribution plant accounts.

16 **Table 1: Comparison of UGI Gas Proposed and OCA Proposed Service Life Estimates**

<u>ACCOUNT</u>	<u>UGI GAS PROPOSED ESTIMATE</u>	<u>OCA PROPOSED ESTIMATE</u>

391	20 - SQ	20 - SQ
391.1	5 - SQ	5 - SQ
391.3	10 - SQ	10 - SQ
391.4	15 - SQ	15 - SQ

1 **Q. Do you have any comments on table 1?**

2 A. Yes. Table 1 demonstrates that for many accounts Mr. Garren's estimates  
3 represent significant changes from my service life estimates, which are the  
4 same estimates approved by the Pennsylvania Public Utility Commission  
5 ("PUC" or "Commission") in the Company's most recent service life study filed  
6 in 2012 with Docket Number M-123100ADR2012. For example, Mr. Garren  
7 has recommended increasing the service life for Accounts 376.2 and 378 by  
8 12 and 11 years, respectively. These are much larger increases than should  
9 be expected in a single depreciation study given that the company performed  
10 a service life study just 4 years ago. Also, his proposed life estimates would  
11 be: 1) above the typical range of service life estimates used by other  
12 Pennsylvania gas utilities; 2) among the longest service lives estimated for gas  
13 plant in Pennsylvania; and 3) are inconsistent with company plans and outlook  
14 of engineering management.

15  
16 **Q. Please explain the process used for life analysis.**

17 A. The estimates I have made for the depreciation study are based in part on the  
18 most commonly used statistical analysis of aged retirements known as the  
19 retirement rate method. This method is applied to assets in the distribution  
20 and general classes of plant and is described in more detail in the  
21 Depreciation Study. The retirement rate method was used for all accounts in  
22 the above classes of plant except for certain accounts in general plant where  
23 amortization accounting was continued.

24 Application of this method requires an extensive compilation of

1 historical aged retirement data as well as related plant accounting data  
2 including additions, acquisitions, sales and transfers. Plant accounting data  
3 for the years 1960 through 2011 were available to study. The life analyses  
4 were performed using Gannett Fleming's depreciation software programs.  
5 The actuarial data may or may not produce a complete life cycle of  
6 experience. A complete life cycle is indicated by the life table reaching zero  
7 percent surviving for the last age interval shown on the life table. The curve-  
8 fitting portion of Gannett Fleming's depreciation software program matches the  
9 stub survivor curves (*i.e.*, from the original life tables) with each member of the  
10 Iowa curve family. The curve-fitting results are based on a least squares  
11 solution of the differences between the stub curve and the Iowa curve.  
12 Survivor data developed by the actuarial analysis and set forth on the original  
13 life table are graphed and compared visually and statistically with the Iowa  
14 curves.

15 There are two distinct steps in the estimation of service lives and  
16 retirement dispersions that must be recognized in the interpretation of the  
17 service life analysis results. The first step, *life analysis*, refers to the  
18 application of statistical procedures to determine life and dispersion indications  
19 based solely on past experience. The second step, *life estimation*, refers to  
20 the exercise of informed judgment in making sound estimates of service lives  
21 and retirement dispersions. Life estimation incorporates known historical  
22 experience, estimated historical trends and estimated future trends or events  
23 in order to define complete patterns of estimated service life characteristics.  
24 The results of the life analyses, performed as the first step, are only one of the

1 relevant factors to be considered during the decision making process of life  
2 estimation.

3  
4 **Q. Please explain the process used for life estimation.**

5 A. The service life estimates were based on informed judgment which considered  
6 a number of factors. Among the factors receiving consideration included the  
7 results of the life analyses using UGI Gas's property accounting data; current  
8 Company policies, plans and outlook as determined during conversations with  
9 engineering management and other technical subject matter experts; and the  
10 survivor curve estimates from previous studies of this company and other gas  
11 companies. I have used my professional judgment based on a consideration  
12 of a number of factors, listed above, to arrive at the most appropriate average  
13 service life and dispersion curve for each of the accounts studied. These  
14 results were provided in pages II-3 through II-4 of UGI Gas Exhibit C (Fully  
15 Projected). The statistical support for the survivor curve estimates is  
16 presented in the section of the UGI Gas Exhibit C (Future) entitled "Service  
17 Life Statistics," and set forth on pages VI-2 through VI-68.

18  
19 **Q. Has Mr. Garren employed the same process as you?**

20 A. No. While Mr. Garren has also used the retirement rate method, there are two  
21 serious issues with his analysis. The first issue is that he bases his estimates  
22 entirely on the statistical analysis, mechanically selecting best fit curves in  
23 almost all cases and ignoring information about the future. As I will explain,  
24 Mr. Garren's approach is explicitly rejected by authoritative depreciation texts,  
25 which are clear that judgment must be incorporated into the estimation of

1 service life. Mr. Garren's approach has also been rejected by the PUC in  
2 previous cases in which his firm has testified. Mr. Garren's approach is further  
3 compromised by the fact that the calculations used in his life analysis are in  
4 many cases incorrect. The result is that Mr. Garren recommends  
5 *inappropriate life estimates that not only are unreasonable, but in many cases*  
6 *defy common sense.*

7  
8 **B. Mr. Garren's Approach to Life Estimation is Inappropriate**

9 **Q. You have described the retirement rate method in the previous section,**  
10 **which is a method of the statistical analysis of historical data. Should**  
11 **the service life estimates be based solely on a mechanical curve-fitting**  
12 **approach related to the performed historical life analysis?**

13 A. No. Authoritative depreciation texts are quite clear that life estimation should  
14 not simply be a mechanical exercise based on statistical analysis of historic  
15 data. Proper judgment must be used to ensure the estimates based on  
16 historic data are the best representation of future life characteristics for the  
17 property being studied. I have incorporated informed judgment based on the  
18 knowledge of UGI Gas's property and Company plans that I have acquired  
19 over the past 27 years of performing depreciation studies for UGI Gas,  
20 including submitting annual depreciation reports and service life study reports  
21 to the PUC.

22  
23 **Q. How does Mr. Garren's analysis differ from yours?**

1 A. Based on Mr. Garren's testimony, his estimates appear to be based almost  
2 entirely on the results of the historic statistical analysis. For the 14 distribution  
3 plant accounts that he is recommending an increase in the service life, he  
4 simply selects the survivor curve that best fits the historical retirement data.  
5 He appears to have incorporated no other information into his life estimation,  
6 and has instead simply accepted the results of the historic statistical analysis,  
7 whether these results are reasonable or not. The result of his approach is that  
8 many of his estimates are very unreasonable for the Company's assets.

9  
10 **Q. So Mr. Garren did not incorporate any information or judgment other**  
11 **than the statistical analysis?**

12 A. No, he did not. Instead, Mr. Garren simply selected the best mathematical fit  
13 survivor curve for each account (or at least for most accounts), without  
14 consideration of any other factors or assessment of the reasonableness of his  
15 results.

16  
17 **Q. Is the acceptance of the mathematical curve fitting results using**  
18 **historical data, as Mr. Garren has done, an acceptable practice for**  
19 **depreciation analysis?**

20 A. No, it is not. As I describe in the Depreciation Study (UGI Gas Exhibit C –  
21 Future) on pages III-2 and III-8, the service life estimates I have made were  
22 based on "judgment that incorporated statistical analysis of retirement data,  
23 discussions with management regarding company plans and outlook and  
24 consideration of estimates made for other gas utilities." It is standard practice

1 in the industry to consider each of these factors. However, Mr. Garren  
2 appears to have only considered one factor – the statistical analysis of  
3 historical (*i.e.*, past) retirement data.  
4

5 **Q. Do any authoritative depreciation texts support your assertion that a**  
6 **depreciation study should incorporate factors other than statistical**  
7 **analysis”?**

8 A. Yes, all depreciation texts are clear that service life estimates are forecasts of  
9 *future* expectations. As a result, sole reliance on the statistical analysis of  
10 *historical* data is inappropriate for life estimation.

11 One such text is the National Association of Regulatory Public Utility  
12 Commissioners’ publication “Public Utility Depreciation Practices” (“NARUC  
13 Manual”). Chapter VIII of the NARUC Manual discusses life analysis.  
14

15 **Q. Does the NARUC manual support Mr. Garren’s dependence solely on**  
16 **mathematical analysis for his life estimates?**

17 A. No. To the contrary, the NARUC Manual is clear that “depreciation analysts  
18 should avoid becoming ensnared in the mechanics of the historical life study  
19 and relying solely on mathematical solutions.”<sup>5</sup> Thus, the NARUC Manual  
20 advises against the exact approach Mr. Garren has used.

21 The NARUC Manual also explains that “several factors should be  
22 considered in estimating property life. Some of these factors are:

- 23 1. Observable trends reflected in historical data,

---

<sup>5</sup> NARUC Manual, p. 126

- 1 2. Potential changes in the type of property installed,
- 2 3. Changes in the physical environment,
- 3 4. Changes in management requirements,
- 4 5. Changes in government requirements, and
- 5 6. Obsolescence due to the introduction of new technologies.”<sup>6</sup>

6

7 **Q. Has Mr. Garren incorporated any of these factors into his life estimation?**

8 A. No, he has not. All of the factors in the NARUC manual cited above require  
9 judgment based on future conditions that are likely to be encountered. Mr.  
10 Garren has recommended 14 changes to the service lives estimated for  
11 distribution plant strictly on the ones that best fit the historical data based on  
12 his determination of which data points from the life table to include. He did not  
13 consider or exercise professional judgment with respect to any additional  
14 factors that would affect service lives in the future.

15

16 **Q. On page III-4 of UGI Gas Exhibit C (Future), you indicate that the service  
17 life estimates were based on “judgment which considered a number of  
18 factors.” Does the NARUC Manual discuss “judgment”?**

19 A. Yes, it does. The NARUC Manual discusses the use of “informed judgment” in  
20 detail on page 128, explaining that “the use of informed judgment can be a  
21 major factor in forecasting.” It goes on to explain that:

22 “Judgment is not necessarily limited to forecasting and is used in  
23 situations where little current data are available. The analysis gathers

---

<sup>6</sup> NARUC Manual, page 129

1            what is known about a particular situation and modifies and refines the  
2            data to reflect the actual circumstances. The analyst's role in  
3            performing the study is to review the results and determine if they  
4            represent the mortality characteristics of the property. Using judgment,  
5            the analyst considers such things as personal experience, maintenance  
6            policies, past company studies, and other company owned equipment  
7            to determine if the stub curve represents this class of property."  
8

9    **Q. Did Mr. Garren incorporate any judgment to “review the results and**  
10    **determine if they represent the mortality characteristics of the**  
11    **property”?**

12    A. No, he did not.  
13

14    **Q. Is judgment also important in the actual curve fitting process?**

15    A. Yes. As discussed above, judgment is critical in the life estimation process.  
16    Indeed, although he does not appear to incorporate any judgment in his  
17    estimates, Mr. Garren appears to acknowledge that judgment may be required  
18    in some cases, stating “[t]here are numerous factors that might lead a utility  
19    depreciation expert, familiar with the particular plant account for a given  
20    company for a given account, to deem that future depreciation expectations  
21    are different than historical experience.”<sup>7</sup> I will explain that Mr. Garren's  
22    recommendations demonstrate that he is not at all familiar with UGI Gas's  
23    property.

---

<sup>7</sup> OCA Statement No. 5, p. 16, lines 14-17.

1           However, judgment is also critical for the actual curve fitting process.  
2           Depending on the selection of data points and the judgment in extrapolating  
3           the survivor curve beyond the available or significant data, the curve fitting  
4           process can produce very different results. For this reason, judgment is also  
5           important to ensure that the data is interpreted and extrapolated properly. Mr.  
6           Garren's approach, which is to mechanically select mathematical, best-fitting  
7           survivor curves based on almost all of the data points – whether significant or  
8           not – does not properly interpret the historical data.

9  
10   **Q.    Are there any examples of cases in Pennsylvania in which Mr. Garren or**  
11   **his firm used a similar approach to service life estimation?**

12   A.    Yes. There are two examples in which Michael Majoros, a colleague of Mr.  
13   Garren at Snavely King, proposed service life recommendations using the  
14   same inappropriate approach of solely relying on mathematical curve  
15   matching. Both cases were litigated before the PUC. In each of those cases,  
16   my firm prepared the utility's depreciation study using the same well-accepted  
17   approach to life estimation and curve fitting that I employed in the Depreciation  
18   Study in this case. In each of those cases, Mr. Majoros testified on behalf of  
19   the OCA and, as with Mr. Garren here, recommended significantly longer  
20   depreciable lives for some accounts based on a formulaic application of  
21   mathematical curve fitting to all historical retirement data without regard to the  
22   statistical relevance of the data.

23           In the first case, *Pa. P.U.C. v. Philadelphia Suburban Water Co.*, 219  
24   PUR 4th 272 (2002), the PUC adopted the life estimates developed in Gannett

1 Fleming's depreciation study and expressly rejected Mr. Majoros's sole  
2 reliance upon mathematical curve fitting, stating as follows:

3 We agree with the ALJ that the OCA's proposal on this issue  
4 should be rejected. (R.D., p. 50). We have previously, in a  
5 number of cases, rejected similar OCA proposals which are  
6 based on insignificant data, even when supported by a  
7 retirement rate analysis. We have never viewed the  
8 calculation of the appropriate survivor curves as a purely  
9 mechanical exercise, based simply on a statistical analysis  
10 of unadjusted data. In this case, PSWC properly exercised  
11 its expert judgment in rejecting insignificant data.<sup>8</sup>  
12

13 The second case was *Pa. P.U.C. v. Pennsylvania-American Water Co.*,  
14 231 PUR 4th 277 (2003). In that case, the PUC again rejected Mr. Majoros's  
15 curve fitting approach.<sup>9</sup>  
16

17 **Q. Are you aware of any other Pa. PUC decision rejecting Mr. Majoros's**  
18 **mathematical curve fitting approach to life estimation?**

19 A. Yes. In *Pa. P.U.C. v. The York Water Co.*, 62 Pa. P.U.C. 459 (1986), Gannett  
20 Fleming prepared the depreciation study submitted by the utility. Mr. Majoros  
21 testified on behalf of the OCA, disagreed with the life estimates developed in  
22 the depreciation study, and proposed significantly longer lives derived from his  
23 purely mathematical approach to fitting smooth survivor curves to all (or  
24 almost all) available historical retirement data regardless of its statistical  
25 significance.

26 Before addressing the specific issue presented, the PUC referenced a  
27 summary of general principles for service life estimation that it had developed  
28 in prior cases:

---

<sup>8</sup> 219 PUR 4th at 300.

<sup>9</sup> 231 PUR 4th at 308-309.

1 Life estimates are essentially based upon engineering  
2 judgment, and, where possible, such judgment should, to an  
3 extent, be predicated upon respondent's actual retirement  
4 experience, together with future plans with respect to the  
5 specific plant in question. In the absence of these data,  
6 average service lives which appear reasonable should be  
7 selected. The experience of comparable utilities, though not  
8 controlling, has certain probative value in developing  
9 estimated average service lives and may be considered.<sup>10</sup>  
10

11 *The PUC rejected Mr. Majoros's recommendations as inconsistent with the*  
12 *fundamental and well-accepted principles of service life estimation, quoted*  
13 *above, stated in 62 Pa P.U.C. at 469.*  
14

15 **Q. Does the lack of informed judgment exercised in Mr. Garren's study lead**  
16 **to any problems with his results?**

17 A. Absolutely. Had he reviewed his results with the proper informed judgment, it  
18 should have been clear that many of his estimates do not represent the future  
19 "mortality characteristics of the property" being studied. Examples of some of  
20 the accounts studied provide clear evidence to demonstrate how  
21 unreasonable some of Mr. Garren's estimates are.  
22

23 **Q. Please provide an example to illustrate the unreasonableness of Mr.**  
24 **Garren's recommendations.**

25 A. Account 376.2, Mains - Cast Iron provides a very good example of Mr. Garren  
26 ignoring information regarding future conditions and strictly adhering to his  
27 curve fitting algorithm when making a life estimate. In 2013, UGI Gas publicly

---

<sup>10</sup> 62 Pa. P.U.C. at 468

1 declared its intention to accelerate its replacement of cast iron mains and  
2 retire all cast iron mains by March 1, 2027. As of December 31, 2012, UGI  
3 Gas had 348 miles of cast iron mains in service. UGI Gas plans to replace  
4 between 24-26 miles per year for the next 14 years starting in 2013. Prior to  
5 2013, UGI Gas was replacing cast iron mains at a pace of approximately 7  
6 miles per year. Based on the Company's plans to accelerate the replacement  
7 of cast iron mains as set forth in the LTIP, all cast iron mains will be replaced  
8 by March 1, 2027, 33 years ahead of the prior timetable. This is important  
9 information related to specific company plans that needs to be factored into  
10 the life estimate for cast iron mains. The survivor curve estimates that I have  
11 made incorporate this information while Mr. Garren's survivor curve estimates  
12 does not. I will demonstrate this later on in the testimony. In the Company's  
13 most recent service life study performed and approved in 2012, the survivor  
14 curve estimate was revised from a 78-R0.5 to a 70-R1 in anticipation of the  
15 company formalizing a plan to accelerate the replacement of their cast iron  
16 mains. Mr. Garren's recommendation is to increase the service life estimate  
17 from 70 years to 82 years solely based on the Company's historical retirement  
18 experience for cast iron mains. This recommendation is astoundingly  
19 inappropriate given the Company's plans to replace all cast irons mains by  
20 March 1, 2027. The calculated composite remaining life for cast iron mains  
21 using the survivor curve estimated by Mr. Garren (*i.e.*, 82-L0.5) as of year-end  
22 2017 is 44.8 years. All cast iron mains will have been replaced by March 1,  
23 2027, which is less than 10 years beyond the end of the fully projected future  
24 test year. Clearly, the survivor curve estimated by Mr. Garren is wholly

1 inadequate for UGI Gas's cast iron mains. Based on UGI Gas's cast iron main  
2 replacement plans it is impossible for Mr. Garren's survivor curve estimate  
3 (82-L0.5) to be correct since we know the remaining life for cast iron mains will  
4 be substantially less than 44.8 years.

5  
6 **Q. Please explain how you used information such as company plans to**  
7 **determine an appropriate survivor curve estimate for cast iron mains.**

8 A. Cast iron mains were the pipe material of choice for UGI Gas and other gas  
9 companies since their formation in the mid-1800's. Cast iron and wrought iron  
10 pipe were used predominantly up through 1925 at UGI Gas at which time steel  
11 mains became prevalent. Cast iron mains along with steel mains continued to  
12 be installed at UGI Gas up through 1959. The most recent service life study  
13 for UGI Gas was submitted to the PUC in March 2012. At the time of the  
14 study, the company had not formalized its LTIIP plans although I was aware  
15 through discussions with company management that there were plans to  
16 accelerate the replacement of cast iron and bare steel mains and services.  
17 During our meeting with UGI Gas's engineering management, we were  
18 informed that the accelerated replacement of cast iron mains would likely  
19 occur over 20 years but they were working at the time to finalize their plans in  
20 conjunction with the PUC. This period later turned out to be a 14 years  
21 instead of 20 years. Using this information and professional judgment  
22 regarding cast iron mains, we estimated that future retirement rates for cast  
23 iron mains would increase particularly for those cast iron mains ages 52.5 and  
24 above. The youngest significant cast iron main installation occurred in 1959.

1 As of year-end 2011, the age of the 1959 installation pipe is approximately  
2 52.5 years. Since there are no newer significant installations of cast iron pipe  
3 on the system than 1959, we knew future retirements were only going to affect  
4 the life tables for age intervals greater than 52.5. Based on this information, I  
5 visually fit the experience band from 1960-2011 trying to select a curve that fit  
6 the first 52 data points reasonably well, while also attempting to select a  
7 survivor curve that indicated higher rates of retirement for cast mains for age  
8 intervals 52.5 years and older. So, using my professional judgment, I  
9 envisioned a survivor curve that reasonably approximated the historical  
10 experience through age 52.5, but indicated greater rates of retirement for  
11 assets age 52.5 and older than what was indicated by the original survivor  
12 curve (a.k.a., "original life table", "OLT", "data points") from experience band  
13 1960-2011. Based on my knowledge of company plans as of March 2012 to  
14 accelerate cast iron main replacements, I adjusted the survivor curve estimate  
15 for cast iron mains from 78-R0.5 to 70-R1. That is, in the most recent service  
16 life study, I reduced the average service life for cast iron mains from 78 years  
17 to 70 years and I increased the mode of the survivor curve to account for  
18 increased rates of retirements in the future occurring at ages older than 52  
19 years regarding cast iron mains.

20  
21 **Q. Can you illustrate how you used professional judgment to incorporate**  
22 **Company plans such as the plans to accelerate the replacement of cast**  
23 **iron mains?**

1 A. Yes. I assumed most of the changes to the original life table in future years  
2 would occur in ages 52.5 and older since 1959 was the last year of cast iron  
3 main installation of any significance. The 1959 installations of cast iron mains  
4 were 52.5 years old at December 31, 2011. In Figure 1 below, I have  
5 prepared a chart of the original life table for Account 376.2, Mains – Cast Iron  
6 depicting the full experience band (*i.e.*, 1960-2011) as of the last service life  
7 study and have also plotted the original life table incorporating future  
8 retirements of cast iron mains covering the period 1960-2027. This period,  
9 1960-2027, is referred to as the experience band. Figure 1 presents a  
10 comparison of the 2 experience bands. The comparison clearly demonstrates  
11 that retirement rates have increased significantly for ages 52.5 and higher for  
12 the future experience band while the first 52 age intervals are relatively the  
13 same for both bands. The difference in the OLT's shown in Figure 1 below will  
14 occur in other distribution plant accounts as well as where future retirements  
15 rates are expected to increase at older ages than has been historically  
16 experienced.

17

1

Figure 1: UGI Original Life Table for Account 376.2

2

3

4 **Q. Please continue with your life estimation process incorporating future**  
5 **plans related to cast iron mains.**

6 A. On Figure 2 below, I have plotted the same two original life tables as Figure 1.  
7 Additionally, on Figure 2, I have graphed Mr. Garren's proposed survivor curve  
8 (82-L0.5) along with the survivor curve that I had proposed in the 2011 service  
9 life study (70-R1). The survivor curve estimates used in the 2011 service life  
10 study are the same as those used by UGI Gas in this proceeding. In addition,  
11 I have presented a third survivor curve (64-R1) which represents the best fit  
12 survivor curve encompassing past and future years, *i.e.*, experience band  
13 1960-2027, based on information we have from the LTIIP filing. As shown on

1 Figure 2 below, Mr. Garren's estimate (82-L0.5) fits the OLT well for  
2 experience band 1960-2011. That is not surprising since he selected the best  
3 fit curve of the historical retirement data and used that as the basis for  
4 forecasting future service lives for cast iron mains. However, what is important  
5 to observe on Figure 2 is that Mr. Garren's proposed survivor curve estimate is  
6 a poor fit when future cast iron main retirement data is included, *i.e.*,  
7 experience band 1960-2027. This circumstance always will occur when the  
8 service life estimate is based solely on the historical retirement data and the  
9 historical data and future data are expected to be materially different.

10 In the 2011 service life study, I revised the prior survivor curve estimate of  
11 78-R0.5 to the 70-R1 to incorporate Company plans for increased cast iron  
12 main replacements. I used informed professional judgment to select a curve  
13 that in my estimation would fit the historical data through age 52.5 well, but  
14 needed to be below the historical OLT (*i.e.*, experience band 1960-2011) for  
15 ages 52.5 and older in order to reflect increased rates of retirements for cast  
16 irons mains older than 52.5 years that would occur in future years. As  
17 indicated in Figure 2, my service life reduction from 78 to 70 years apparently  
18 was not a large enough life reduction as the original life table for experience  
19 band 1960-2027 indicates a 64 year average service life (*i.e.*, 64-R1 survivor  
20 curve). Regardless, Mr. Garren's recommendation to increase the service life  
21 for cast iron mains by 12 years is clearly inappropriate as it ignores pertinent  
22 information regarding the Company's replacement plans.

1

**Figure 2: UGI Original Life Table and Survivor Curves for Account 376.2**

2

3

4 **Q. Did Mr. Garren indicate in his testimony that there are instances where**  
 5 **using the mathematical best fit life and curve for life estimation purposes**  
 6 **are not appropriate?**

7 **A. Yes, he did. On page 16, lines 12-20 of OCA Statement No. 5, Mr. Garren**  
 8 **stated:**

9 The mathematical best fit is appropriate in most cases  
 10 where the future depreciation can reasonably be expected  
 11 to follow historical experience. However, this is not always  
 12 the case. There are numerous factors that might lead a  
 13 utility depreciation expert, familiar with the particular plant  
 14 account for a given company for a given account, to deem  
 15 that future depreciation expectations are different than  
 16 historical experience. These factors, including major  
 17 replacement or maintenance projects, differing life

1 expectations of new technologies, or simply economic or  
2 engineering decisions of utility management might  
3 significantly affect the expectations for future retirement  
4 rates.  
5

6 **Q. Do you agree with Mr. Garren's statements on page 16, line 12-20 listed**  
7 **above?**

8 A. Yes, I do. When making an estimate regarding future survivor characteristics  
9 of utility plant, one needs to consider all relevant factors that can impact future  
10 service lives. These factors include information regarding future conditions,  
11 changes in technology, company plans, etc. A depreciation professional  
12 needs to incorporate information about the future into existing historical  
13 information as much as possible when making a life estimate.  
14

15 **Q. Did Mr. Garren follow his own guidance as set forth on page 16, line 12-**  
16 **20 of his direct testimony?**

17 A. No, he did not. For the 14 distribution plant accounts that he recommends a  
18 change in service life, all of his proposed survivor curve estimates are the  
19 ones that best fits the historical data. He increases the service lives for 14  
20 distribution plant despite the fact that UGI Gas is embarking upon its largest  
21 and most aggressive asset replacement program in its history. Clearly, future  
22 retirements levels will be much different than those experienced by UGI Gas.  
23 Making service life forecasts based solely on past experience as Mr. Garren  
24 has proposed in this proceeding is inappropriate. As I have demonstrated with  
25 cast iron mains, future service lives for most distribution plant accounts will be

1 different and shorter than those service lives historically experienced due to  
2 the level of replacement activity set forth in the LTIP.

3  
4 **C. OCA's Approach to the actual curve fitting process is also**  
5 **inappropriate**

6 **Q. Is judgment also important in the actual curve fitting process?**

7 A. Yes. As discussed above, judgment is critical in the life estimation process.  
8 Judgment is also critical for the life analysis of historical retirement data  
9 including the actual curve fitting process. Depending on the selection of data  
10 points and the judgment in extrapolating the survivor curve beyond the  
11 available or significant data, the curve fitting process can produce very  
12 different results. For this reason, judgment is also important to ensure that  
13 the data is interpreted and extrapolated properly. Mr. Garren's approach,  
14 which is to mechanically select best fitting mathematical curves based on  
15 almost all of the data points – whether significant or not – does not properly  
16 interpret the historical data.

17  
18 **Q. Do authoritative sources support your approach to curve fitting?**

19 A. Yes, in the well-regarded depreciation text titled *Depreciation Systems*, by  
20 Wolf and Fitch, the authors explain that when curve fitting, the depreciation  
21 professional must “decide which points or sections of the curve should be  
22 given the most weight.” Wolf and Fitch go on to explain:

23 Points at the end of the curve are often based on fewer  
24 exposures and may be given less weight than points

1 based on larger samples. The weight placed on those  
2 points will depend on the size of exposures. Often the  
3 middle section of the curve (that section ranging from  
4 approximately 80% to 20% surviving is given more  
5 weight than the first and last sections. This middle  
6 section is relatively straight and is the portion of the curve  
7 that often best characterizes the survivor curve.<sup>11</sup>

8 Wolf and Fitch also explain that mathematical curve matching should not be  
9 the only analysis performed:

10 On the surface, the removal of judgment from the fitting  
11 process may appear to be an advantage, but blind  
12 acceptance of mechanical fitting processes will  
13 occasionally but consistently result in poor results. A  
14 better procedure is to use the least squares method to  
15 select *candidates* for the best fit. Comparison of the sum  
16 of squares will reveal situations where the difference  
17 between the best choices is small. The analyst should  
18 then visually examine the observed data and compare  
19 them to the theoretical curves. This can be done quickly  
20 on a computer with graphic capabilities so that the  
21 analyst need not use time to plot the observed curve by  
22 hand. The analyst can consider single points that  
23 contribute significantly to the sum of squares but that

---

<sup>11</sup> *Depreciation Systems*, Frank K. Wolf and W. Chester Fitch, 1994, pp. 46-47.

1 may deserve less weight than other points. Fits at  
2 various sections on the curve can be evaluated and  
3 weighted using the judgment of the experienced  
4 analyst.<sup>12</sup>  
5

6 **Q. Have you followed this approach to curve fitting?**

7 A. Yes.  
8

9 **Q. Has OCA followed this approach to curve fitting?**

10 A. No. OCA relies solely on the results of mathematical curve matching, and  
11 includes almost all data points in its curve matching results. As Wolf and  
12 Fitch explain, this is not an appropriate approach. OCA gives equal weight to  
13 all data points (or almost all points) whether they are meaningful or not.  
14

15 **Q. Please provide another example to illustrate the unreasonableness of Mr.  
16 Garren's recommendations.**

17 A. Account 378.0, Measuring and Regulating Station Equipment - General  
18 provides a very good example of the unreasonableness of his proposals. I  
19 have selected the 50-R0.5 survivor curve, which represents a good fit of the  
20 data through the most representative data points and is a reasonable  
21 representation of the mortality characteristics for the type of property in this  
22 account.

---

<sup>12</sup> Ibid, pp. 47-48.

1           The original life table for this account has been presented on pages VI-  
 2           25 through VI-27 of the Depreciation Study (UGI Gas Exhibit C – Future), and  
 3           a graph of the survivor curve I have selected as well as the most  
 4           representative data points from the original life table is presented on page VI-  
 5           24 of UGI Gas Exhibit C (Future). I have reproduced this graph below in  
 6           Figure 3 below. In my life analysis for this account, I have selected to study  
 7           the data points from age 0 through age 56.5. Therefore, the T-cut that I have  
 8           selected for this account is 56.5.

9           **Figure 3. UGI Gas Estimate and Original Life Table for Account 378**

10

11

12

13

As demonstrated in Figure 4 below, my estimate fits the data points through age 50 reasonably well and it takes into consideration increasing rates of

1 retirement for assets beyond age 50. Future rates of retirement will increase  
 2 for this account as the Company implements their accelerated cast iron and  
 3 bare steel main replacement program. The Company's low-pressure gas  
 4 system is located primarily in areas where cast iron mains are installed. As  
 5 cast irons mains get replaced in the urban areas, the low pressure gas system  
 6 (0.25 PSI or 7 inches of water column (wc)) will be replaced as the area will  
 7 have been converted to medium or intermediate gas pressure (~55 PSI).  
 8 Once the low pressure system has been replaced, there will no longer be a  
 9 need for the district M&R stations that were built to serve the low pressure  
 10 system.

12 **Figure 4: UGI Original Life Table and Survivor Curves for Account 378**

13

1           Additionally, my estimate is representative of the mortality characteristics of  
2           the assets being studied. One of the primary reasons for the retirement of  
3           M&R station equipment, other than functional obsolescence, is deterioration  
4           and the difficulty in getting spare parts to replace worn or deteriorated  
5           equipment. Thus it would be expected to see retirements increase as M&R  
6           station equipment age. My estimate reflects these phenomena as well as the  
7           expectation for increased rates of retirements beyond age 50 in the future as a  
8           result of the Company's asset replacement plans set forth in the LTIIP. Once  
9           the curve shown in Figure 4 above reaches about 40 years of age, my  
10          proposed survivor curve begins to move downwards at a higher rate (that is  
11          the slope of the curve becomes more negative) than Mr. Garren's. This curve  
12          shape reflects that assets are more likely to retire as they age, which is  
13          reasonable for this type of property. Mr. Garren's estimate, however, does not  
14          incorporate this trend and instead incorporates the expectation that some  
15          assets will last 120 years or more.

16                 On Figure 4 above I show both proposed survivor curves, mine and Mr.  
17          Garren's. Additionally, on Figure 4 above, I show the data points from the  
18          OLT through age 80.5. The additional data points from the OLT from ages  
19          57.5 to 80.5 are data points that Mr. Garren relies on and I do not. In general,  
20          the two proposed survivor curves fit the historical data through age 56.5  
21          reasonably well as they are similarly shaped curves through age 45. The  
22          difference in the two proposed survivor curves becomes pronounced beyond  
23          age 56.5.

1           Relative to the age intervals beyond 56.5, Mr. Garren relies on these  
2 data points between ages 57.5 and 80.5 even though most data points for  
3 these age intervals contain less than \$30,000 worth of plant investment (*i.e.*, a  
4 relatively small sample). The shape of the survivor curve proposed by Mr.  
5 Garren is unduly influenced by data points at the tail end of the original curve  
6 for ages containing few exposures (*i.e.*, minor plant investment). As I have  
7 demonstrated in the cast iron example above in Figures 1 & 2, the OLT will be  
8 different in the future for accounts where increased rates of retirement will  
9 occur at older ages than has been previously experienced. For life estimation  
10 purposes, future circumstances such as company plans need to be  
11 incorporated when extrapolating beyond the known and reliable portion of the  
12 original curve. I have attempted to do this by estimating survivor curves with  
13 higher rates of retirement at older ages than what previously has been  
14 experienced and Mr. Garren has not made this attempt.

15  
16 **Q. Do you have any comments on Mr. Garren's estimate?**

17 **A.** Yes. An evaluation of the survivor curve selected by Mr. Garren confirms the  
18 unreasonableness of his estimate. An Iowa survivor curve, such as the 61-  
19 L0.5 curve he has selected, describes not only the average life of a group of  
20 property, but also the dispersion of lives around the average. Thus, the  
21 survivor curve estimate describes the range of lives expected to be  
22 experienced by the entire group. When one examines the implications of the  
23 survivor curve selected by Mr. Garren, it becomes clear how unreasonable the  
24 61-L0.5 survivor curve is.

1           The graph in Figure 4 above shows the percentage of assets expected  
2 to survive, or remain in service, for each age. The smooth line describing the  
3 61-L0.5 survivor curve in Figure 4 above represents Mr. Garren's estimate.  
4 Thus, because the smooth line reaches age 40 at about 67 percent surviving,  
5 Mr. Garren expects about 67 percent of the asset to have lives of at least 40  
6 years. This is not unreasonable based on the data (shown as black squares in  
7 the graph), and is similar to the expectation based on my proposed curve (*i.e.*,  
8 50-S0.5) shown in Figure 4 above. However, it is at the later ages where Mr.  
9 Garren's estimate becomes very unreasonable. His estimate projects that 15  
10 percent of the assets in this account will last at least 100 years, and that about  
11 8 percent will last at least 120 years. The maximum life for the survivor curve  
12 he has selected occurs at about 247 years for M&R station equipment  
13 compared with 100 years for the survivor curve that I have estimated.

14  
15 **Q. Do you believe that this is unreasonable?**

16 A. Absolutely. Services lives exceeding 120 years for measuring and regulating  
17 station equipment are unreasonable; yet, that is what Mr. Garren  
18 recommends. The equipment included in this account such as regulators,  
19 valves, heaters, piping, gauges, odorizing equipment will be removed well in  
20 advance of the assets reaching 120 years for safety and reliability reasons, in  
21 addition to other common reasons such as deterioration and obsolescence.

22  
23 **Q. Does any of the company's actual experience support that these types of**  
24 **assets can last this long?**

1 A. No. Even the data points Mr. Garren has used, which are shown in Figure 4  
2 above, only extend to 80 years of age. There are no actual data for assets  
3 that have lasted beyond 101 years at UGI Gas.  
4

5 **Q. Mr. Garren discusses a “T-cut” in his testimony.<sup>13</sup> What is a T-cut?**

6 A. A T-Cut designates which points are included in a mathematical curve  
7 matching routine. Certain points can be excluded if they are not  
8 representative of the future experience for an account. The problem with  
9 mathematical matching is that it gives each data point equal weighting in the  
10 curve matching. As I will explain, this is not always a reasonable assumption.  
11 For this reason visual curve matching and judgment should also be used to  
12 determine the most appropriate survivor curve.  
13

14 **Q. Do you agree with the T-cut Mr. Garren has used for this account?**

15 A. No. In my opinion Mr. Garren has incorporated too many data points that are  
16 not statistically robust enough to provide a reasonable indication of service life.  
17 Additionally, because his curve matching routine gives these data points equal  
18 weighting, he has placed far too great an emphasis on later ages.  
19

20 **Q. What is a more appropriate approach?**

21 A. This account contains over 350 measuring and regulating (“M&R”) stations on  
22 the UGI Gas system. The purpose of the M&R stations is primarily to regulate  
23 the pressure of the gas in the system by reducing the pressure generally from

---

<sup>13</sup> OCA Statement No. 5, p. 10-11.

1 intermediate pressure to low pressure. The account includes assets such as  
2 regulators, piping, valves, heaters, gauges, odorizing equipment, etc.  
3 Therefore, in order to have a fairly large sample of assets to study, there  
4 should be a reasonably large level of exposures in the original life table. The  
5 term "exposures" means the total population of asset investment exposed to  
6 retirement for a given age interval (e.g., age interval 0.0 to 0.5 years).

7 The exposures and the original life table for this account are shown on  
8 pages VI-25 through VI-27 of the Depreciation Study. For example, age zero  
9 has \$20,238,567 in exposures. The percent surviving listed in the life table for  
10 the next age interval, age 0.5, is based on this amount of exposures multiplied  
11 by its survivor rate. The percent surviving for subsequent ages is determined  
12 in the same manner. The exposures at age 0 of \$20,238,567 is a large  
13 amount and contains a large number of assets. However, later ages contain  
14 far less exposures. For example, beyond age 60.5 the exposures are less  
15 than \$40,000. This amount (\$40,000) represents a fairly small number of  
16 assets and a relatively small sample size. Thus, the data for these ages in my  
17 judgment cannot be relied on. Yet, not only does Mr. Garren include many of  
18 these data points in his curve fitting, but he gives them equal weight to data  
19 points with much, much larger levels of exposures. The inclusion of these  
20 data points at very old ages near the tail of the original curve influences the  
21 results of the mathematical curve-fitting routine in a manner that, in my  
22 judgment, is inappropriate. The inclusion of these data points tends to  
23 improperly skew the service lives longer than what is reasonable and this is  
24 inappropriate.

1

2 **Q. What is a more appropriate portion of the curve to consider for curve**  
3 **fitting?**

4 A. In my opinion, data points through age 56.5 are more representative of the  
5 future experience for this account. The data for these ages based on relatively  
6 large dollar amounts (over \$178 thousand) and therefore contains a  
7 reasonably large number of assets. Just as important, the data through these  
8 points also represents a reasonable indication of the life expectations for this  
9 account. As can be seen in Figure 4 above, after about age 60.5 the life table  
10 (black squares) begins to have a more erratic pattern and presents less of a  
11 definitive trend. After about age 70 it declines much more slowly. As I have  
12 discussed previously, I would expect the retirements in this account to tend to  
13 increase as they age, not decrease. Therefore, this later portion of the life  
14 table is most likely not representative of the actual life characteristics for this  
15 account. Instead, the erratic movements occur because there are relatively  
16 few exposures and sporadic retirements, and in my judgment these later ages  
17 beyond age 56.5 should not be relied on. Also, the M&R station equipment  
18 built to serve the company's low pressure gas system, primarily serviced by  
19 cast iron mains, will no longer be needed and will result in larger future  
20 retirements for this account.

21

22 **Q. Do Mr. Garren's other estimates have similar problems?**

23 A. Yes. Almost all of his estimates exhibit the problems one would expect when  
24 basing an estimate solely on the adherence to statistics. Mr. Garren selected

1 survivor curves entirely based on the results of statistical analysis, and as a  
2 result ignored other factors, such as company plans and those other factors  
3 noted in the NARUC Manual including "personal experience, maintenance  
4 policies, past company studies, and other company owned equipment."<sup>14</sup> The  
5 fact that his analysis is based on erroneous data only compounds the problem.  
6

7 **D. OCA's Calculation Issues**

8 **Q. Are there issues with Mr. Garren's application of the retirement rate  
9 method?**

10 **A.** Yes. Mr. Garren's estimates are based on original life tables developed from  
11 the Company's historical data using the proprietary software of his firm,  
12 Snavely-King. The original life tables calculated by Mr. Garren have  
13 differences from those I have calculated for the depreciation study. There  
14 should not be any differences. The same historical plant accounting data was  
15 used by both parties. There are a handful of reasons for the differences,  
16 including how Mr. Garren's software processes historical transactions. His  
17 software ignores certain correcting entries and accounting adjustments.  
18 However, there is one issue in particular I would like to focus on, as it is  
19 consistent with the fact that Mr. Garren is not familiar with UGI Gas, its  
20 operations and its accounting practices.  
21

22 **Q. On page 15 of his testimony Mr. Garren explains why his "best fitting"  
23 results differ from yours. Can you address his claim?**

---

<sup>14</sup> NARUC Manual, p. 128

1 A. Yes. Mr. Garren states that the statistical best fitting curves from his analysis  
2 “differ from the best fits resulting from Mr. Wiedmayer’s analysis because I am  
3 using the full band of depreciation data available, rather than only the data  
4 from 1960 forward.”<sup>15</sup> In other words, Mr. Garren produces different  
5 mathematical results because he assumes that the Company has historical  
6 data prior to 1960.

7  
8 **Q. Does the Company have historical data prior to 1960?**

9 A. No. Like many utilities, UGI Gas did not start to maintain aged plant  
10 accounting data (*i.e.*, data for which the vintage year of each transaction is  
11 known) until 1960. This is a piece of information I am aware of from my many  
12 years of conducting studies for UGI Gas. There is no data available for the life  
13 analysis prior to 1960, and therefore when I used “only the data from 1960  
14 forward” I did in fact use the “full band of depreciation data available.”

15 Mr. Garren assumed there was aged plant accounting data starting in  
16 1852. There was not. Most utilities that I am familiar with didn’t start recording  
17 aged plant accounting data until 1938 at the earliest, with other utilities starting  
18 later. Mr. Garren should have realized that there is no utility company in the  
19 country that maintains aged plant accounting data from 1852. He should have  
20 revised his experience band in accordance with the data he was provided  
21 which covered the period 1960-2011. Also, he should have analyzed  
22 additional bands such as the ones that I selected and used in the study.

23

---

<sup>15</sup> Direct Testimony of James Garren, p. 15, lines 10-12.

1 **Q. What is the impact of Mr. Garren's erroneous assumption that data was**  
2 **available prior to 1960?**

3 A. Mr. Garren uses experience bands for many accounts that go as far back as  
4 the 1850s. Because there is no plant accounting data prior to 1960, there are  
5 no recorded retirements prior to 1960. The effect of Mr. Garren's error is that  
6 he therefore assumes when constructing his original life tables that the  
7 Company did not retire a single asset from the 1850s through 1959. This is  
8 clearly an incorrect assumption.

9

10 **Q. Do you have any further comments regarding the life tables calculated**  
11 **by Mr. Garren?**

12 A. Yes, we asked Mr. Garren in UGI Gas to OCA-I-24 parts b-d to verify and  
13 explain the numbers listed in his life tables in his testimony on page 12 of OCA  
14 Exhibit JSG-3, particularly the exposure column for Account 376.1, Mains –  
15 Primarily Steel. He provided a response with an excel spreadsheet  
16 attachment showing the calculation. However, the amounts that he  
17 determined and listed in his response to UGI Gas to OCA-I-24 parts b-d do not  
18 even match the amounts set forth in his testimony on page 12 of OCA Exhibit  
19 JSG-3.

20

21 **Q. Given Mr. Garren's approach to estimating service lives, is his error of**  
22 **particular concern?**

23 A. Yes. The fact that Mr. Garren has not calculated the correct original life tables  
24 is of particular concern since Mr. Garren has mechanically selected best fit

1 survivor curves, and did not incorporate professional judgment or other  
2 information into his life estimates. As I have explained, Mr. Garren's approach  
3 of simply selecting best fitting curves is inappropriate in its own right.  
4 However, the fact that he has mechanically selected the best fitting curves  
5 from the wrong data makes his estimates all the more incorrect.

6  
7 **E. Conclusion**

8 **Q. What can you conclude regarding OCA's service life estimates?**

9 A. OCA's service life estimates are based both on a flawed methodology,  
10 erroneous data and a complete disregard of Company plans regarding asset  
11 replacements. They therefore have no sound basis and produce very  
12 unreasonable results. As a result, OCA's service life estimates should be  
13 rejected in their entirety. The estimates I have made in the depreciation study  
14 incorporate all relevant factors and represent the best estimates of future  
15 survivor characteristics for each account.

16  
17 **IV. EQUAL LIFE GROUP DEPRECIATION**

18 **Q. What is the Equal Life Group procedure?**

19 A. Under the Equal Life Group procedure ("ELG"), a group of property (e.g., a  
20 vintage within a property account) is subdivided into groups having equal  
21 service lives. The size of these "equal life groups" is based on the estimated  
22 survivor characteristics of the account. Depreciation can then be calculated  
23 for each equal life group based on the straight line method; that is, an equal  
24 amount of the group's service value is recorded as depreciation expense in

1 each year of service. The total depreciation for an account is then the  
2 summation of the calculated depreciation for each equal life group. In other  
3 words, based on the survivor curve estimate for an account, the ELG  
4 procedure mathematically estimates the life for each unit in the account, and  
5 then depreciates each unit over its expected life. For this reason, the  
6 procedure is also known as the unit summation procedure. By calculating  
7 depreciation for each equal life group, the ELG procedure contrasts with the  
8 Average Service Life ("ASL", also referred to as "Average Life Group", or  
9 "ALG") procedure, which depreciates every asset within an account over the  
10 average life of the account.

11  
12 **Q. Has the ELG procedure been previously adopted in Pennsylvania?**

13 A. Yes. ELG is the predominant method used in Pennsylvania, and has been  
14 used for many years. As Mr. Garren acknowledges,<sup>16</sup> ELG was adopted for  
15 UGI Gas in 1984 at Docket No. R-832331. UGI Gas has used ELG  
16 depreciation ever since.<sup>17</sup> Most other Pennsylvania utilities have adopted ELG  
17 and used this procedure for many years.

18  
19 **Q. Given that the use of ELG is the predominant and longstanding practice**  
20 **in Pennsylvania, has Mr. Garren provided evidence as to why UGI Gas**  
21 **should be required to deviate from this practice?**

22 A. No. Mr. Garren has provided very little discussion of ELG. Apparently, he

---

<sup>16</sup> OCA Statement No. 5, page 18, lines 6-7.

<sup>17</sup> I should note that ELG was adopted for UGI, and many other PA utilities, on a go forward basis. For this reason, vintages of plant subsequent to the adoption of ELG use ELG and older vintages use ASL. For UGI, vintages 1982 and subsequent use ELG and vintages 1981 and prior use ASL.

1 wants the Commission to overturn its longstanding precedent, but simply fails  
2 to provide a valid reason for the change. As I will explain, his one argument  
3 against ELG – that it is more susceptible to “errors” than ASL - demonstrates  
4 little other than his lack of understanding of Pennsylvania depreciation  
5 practices. He also appears to disagree with ELG because it can produce  
6 higher depreciation rates. This of course is not a reason to overturn  
7 longstanding precedent. Moreover, as I will explain below, Mr. Garren is  
8 incorrect that the longstanding use of ELG costs customers more than ASL. In  
9 fact, the opposite is true.

10  
11 **Q. Before turning to your discussion of Mr. Garren’s arguments, please**  
12 **explain the ELG procedure.**

13 **A.** A simple two unit example will demonstrate how the ELG procedure more  
14 appropriately matches cost recovery through depreciation to consumption than  
15 the ASL procedure. In this example, each unit costs \$1,000. Unit A will be in  
16 service for 5 years and Unit B will be in service for 15 years. There is no net  
17 salvage for these units.

18 Under the ASL procedure, the average service life for the two units is  
19 10 years  $((5+15)/2)$ . The annual depreciation rate is 10%  $(1/10)$ . Thus, for the  
20 first five years the total annual depreciation amount is \$200  $(\$2,000 \times 10\%)$ .  
21 At the end of year 5, the total of annual accruals for the account is \$1,000  
22  $(\$200 \times 5)$ . At this time, Unit A is retired, which results in a deduction of  
23 \$1,000 from accumulated depreciation. At the start of year 6, Unit B remains  
24 in service and the original cost  $(\$1,000)$  is offset by the accumulated

1 depreciation of \$0. However, at this point one third of Unit B's service life has  
2 expired, so its accumulated depreciation should not be zero.

3 For the remaining 10 years, \$100 (10% x \$1,000) of annual  
4 depreciation expense is charged to accumulated depreciation, for a total of  
5 \$1,000 of expense over this period. When Unit B is retired, \$1,000 is  
6 deducted from accumulated depreciation and both the original cost and  
7 accumulated depreciation will equal zero. Thus, at the time of Unit B's  
8 retirement, the Company will have fully recovered the total depreciable cost of  
9 both units. However, at the end of year five only one unit remained in service  
10 with two-thirds of its life expectancy still to be consumed, but with 100% of the  
11 original investment in that unit still to be recovered. As a result, the ALG  
12 procedure was ineffective in matching cost recovery to the actual consumption  
13 of the asset.

14  
15 **Q. How is depreciation determined using the ELG procedure?**

16 **A.** When depreciation is determined using the ELG procedure, the pattern of cost  
17 recovery better matches actual consumption. Using the same two unit  
18 example, the annual depreciation expense under the ELG procedure is  
19 calculated by summing the annual expense for each equal life group. In this  
20 case, there are two equal life groups – one for Unit A, which has a life of 5  
21 years, and one for Unit B, which has a life of 15 years. The annual  
22 depreciation rate for Unit A is 20% (1/5) and for Unit B is 6.67% (1/15). Thus,  
23 the annual accruals for years 1 through 5 will be \$200 (20% x \$1,000) for the  
24 first equal life group (Unit A) summed with \$66.67 (6.67% x \$1,000) for the

1 second (Unit B), or \$266.67. At the end of year 5, when Unit A is retired, the  
2 total accruals would be \$1,333.33. The retirement of Unit A results in a  
3 deduction of \$1,000 to accumulated depreciation and, at the start of year 6,  
4 the \$1,000 original cost of Unit B remains with \$333.33 in accumulated  
5 depreciation. Thus, with one third of Unit B's life consumed, accumulated  
6 depreciation is exactly one third of the original cost for this unit.

7 In the years 6 through 15, the annual depreciation expense is \$66.67  
8 for a total of \$666.67 over the 10 year period. Thus, after the retirement of  
9 Unit B, the accumulated depreciation is \$0 (\$1,000 of accruals less the \$1,000  
10 retirement of Unit B), and the full recovery of both units has been obtained.

11 As this example shows, the ELG procedure better matches the cost  
12 recovery of both units with their actual service lives. Figure 5 below provides a  
13 graph of the accumulated depreciation for both procedures. The end of year 5  
14 provides the best illustration of the difference between the two procedures.  
15 Under the ELG procedure, Unit A is fully recovered when retired at the end of  
16 year 5; Unit B is one third through its service life and has had one third of its  
17 cost recovered. This contrasts with the ALG procedure, in which accumulated  
18 depreciation is \$0 at the end of year 5, despite the fact that the only unit  
19 remaining in service has consumed one third of its service life. Clearly, the  
20 ELG procedure better matches the actual service lives for these units.

21

Figure 5

2

3

4 **Q.** You have provided a simple two unit example demonstrating how ELG  
5 works. Do the same principles apply to larger property groups with  
6 many units?

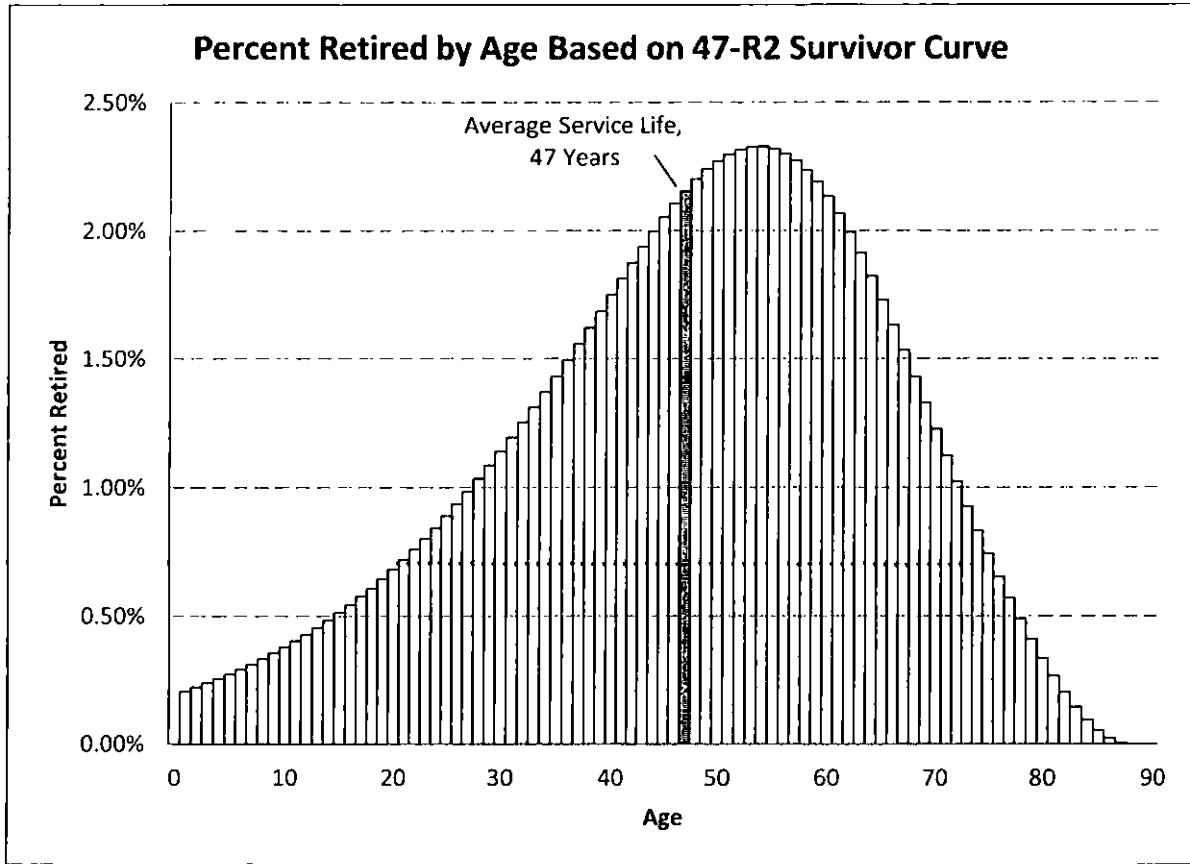

7 **A.** Yes. The same principles apply when the ELG procedure is applied to a large  
8 group of property with many units, as is typical of utility property. The survivor  
9 curve estimated for each property account can be used to divide an account  
10 into equal life groups. The survivor curve allows for the calculation of the  
11 percentage of the property account that is in each equal life group, which  
12 allows for the calculation of ELG annual depreciation accruals for the entire

1 property group. Under the ALG procedure, the depreciation expense for all  
2 property in the account is calculated based on the average service life for the  
3 entire group.

4 The ELG procedure recognizes the reality of dispersion. Specifically, it  
5 recognizes that in actual utility operations only a very small percentage of the  
6 account will actually be retired at the average service life. Figure 6 below, is a  
7 chart of the frequency curve for the 47-R2 survivor curve used for Account  
8 380, Services. The frequency curve shows the percentage of property in this  
9 account that will be retired at each age, based on the estimated survivor  
10 curve. This percentage is also the size of each equal life group.

11 The shaded bar in Figure 6 represents the percentage of property that  
12 will have a life of 47 years. In other words, this shows the percentage of  
13 property that is expected to be in service for the average service life. As the  
14 chart shows, only 2.16% of the assets will be in service for 48 years;  
15 conversely, 97.84% will have a different service life. Some service lines will  
16 be damaged or have to be relocated and therefore will be retired much earlier  
17 than the average, while others will be in service much longer than the average.  
18 Most will fall somewhere in between these extremes.

The ELG procedure recognizes this dispersion, and allocates costs for each equal life group over the expected life for that group. As a result, the ELG procedure allocates cost in a manner that approximates the result of each asset being depreciated over its actual life. Conversely, the ASL procedure depreciates every unit of property within an account over the same life, that is, the average life. As Figure 6 shows, this average life will be incorrect the majority of the time – in this example, the average life will be the wrong life for 97.84% of the assets.

Thus, just as was the case for the two unit example provided above, the

1 ELG procedure better matches capital recovery with the actual lives forecast  
2 by the estimated survivor curve.

3

4 **Q. You have explained above that ELG has been used in Pennsylvania for**  
5 **many years. Is the ELG procedure also supported by other depreciation**  
6 **authorities?**

7 A. Yes. ELG is discussed and supported in authoritative depreciation texts and  
8 academic literature. For example, Robley Winfrey, who developed the Iowa  
9 survivor curves at Iowa State University and is generally regarded as the  
10 father of utility depreciation practices, referred to the ELG procedure as “the  
11 only mathematically correct procedure.”<sup>18</sup>

12

13 **Q. What are Mr. Garren’s arguments against the use of the ELG procedure?**

14 A. While Mr. Garren acknowledges that ELG is “a more precise application of the  
15 same life and retirement pattern assumed in the ASL procedure,”<sup>19</sup> he  
16 provides very little reason as to why he believes the Commission should  
17 reverse its longstanding precedent in order to use a procedure he admits to be  
18 less precise. Mr. Garren only states that:

19 Due to this precision, ELG is much more susceptible to errors  
20 resulting from forecasting inaccuracies. Because of this, ELG  
21 makes it necessary for the Company to file for annual updates to  
22 its average service lives in order to remain accurate. Given that

<sup>18</sup> Robley Winfrey, *Depreciation of Group Properties*, Bulletin 155 (Ames, IA: Iowa State University Press, 1942, reprinted 1969); p. 71

<sup>19</sup> OCA Statement No. 5, p. 18, lines 10-11

1 UGI only performs service life studies every five years, ELG is  
2 not a good fit for UGI. Finally, ELG remaining life calculations  
3 tend to understate the remaining lives of recent vintages when  
4 not updated frequently. As a result, the practical effect of this  
5 disaggregation is higher depreciation rates.<sup>20</sup>

6 Mr. Garren is incorrect that ELG is more subject to “errors.” However, his  
7 statements also demonstrate that he does not understand depreciation  
8 practices for Pennsylvania utilities.

9  
10 **Q. Please explain.**

11 **A.** Mr. Garren argues that ELG requires depreciation rates to be “updated  
12 frequently.” This is the exact practice in Pennsylvania, which has been  
13 followed by UGI Gas for many years. Utilities in Pennsylvania file Annual  
14 Depreciation Reports (“ADR”) each year, in which depreciation rates are  
15 calculated based on current plant balances. These updated depreciation rates  
16 are then used by the utility on its books for that year. Further, when the ADR  
17 is prepared, the plant and accumulated depreciation activity for the previous  
18 year is reviewed in order to determine if any changes in service lives may be  
19 necessary. In most cases, updates to service lives are not necessary because  
20 service life estimates for utility property typically do not change significantly  
21 from year to year. However, although utilities file service life studies every five  
22 years, because the data is reviewed each year when the ADR is prepared,

---

<sup>20</sup> OCA Statement No. 5, p. 18, line 15 to p. 19, line 2.

1 service lives can be modified in the interim period between service life studies  
2 if needed.

3 For these reasons, UGI Gas's current practice already satisfies Mr.  
4 Garren's statement that a utility "file for annual updates to its average service  
5 lives in order to remain accurate." His only argument against ELG is therefore  
6 already refuted by the depreciation practices established in Pennsylvania by  
7 the Public Utility Commission over 30 years ago including the actual  
8 depreciation practices used by UGI Gas.

9

10 **Q. Are there any other statements made by Mr. Garren related to ELG you**  
11 **would like to address?**

12 A. Yes. Mr. Garren posits that the result of ELG is "higher depreciation rates,"  
13 which he appears to believe is not in the "best interest of ratepayers."<sup>21</sup> In  
14 making this claim, not only does Mr. Garren ignore the impact of depreciation  
15 expense on rate base, but he fails to note that any benefit to current  
16 customers of his proposal to use ASL depreciation rates only results from the  
17 change from ELG to ASL – not from the overall use of the ASL procedure  
18 itself.

19

20 **Q. Please explain this concept further.**

21 A. In Section II, I explained that over time higher depreciation expense results in  
22 a lower rate base, because accumulated depreciation is a reduction to rate  
23 base. As a result, the longstanding use of ELG depreciation rates for UGI Gas

---

<sup>21</sup> OCA Statement No. 5, p. 19, lines 1-5.

1 has resulted in a lower rate base than had ASL been used for the past thirty  
2 years. Customers today therefore pay lower customer rates than had ASL  
3 been used for all of these years. As a result, it has in fact been in the  
4 customers' interest to use ELG for this time – at least in terms of the fact that  
5 customer rates are lower than they would be had ASL been used.

6 Again, over time ASL will actually result in higher customer rates than  
7 ELG. However, if the Company were to switch from ELG to ASL there would  
8 be a short term benefit to current customers. However, this is not because  
9 ASL is in the customers' best interest in the long term, but instead only  
10 because current customers would benefit from both lower ASL depreciation  
11 rates and from the lower rate base that exists due to the longstanding use of  
12 ELG.

13 Mr. Garren's proposal is therefore not a recommendation that is in the  
14 long term interest of lower customer rates. It is instead a short term subsidy  
15 only to current customers who benefit from higher ELG depreciation rates paid  
16 by a previous generation of customers. The costs of a higher rate base will be  
17 paid for by future customers who will have to pay higher overall customer  
18 rates.

19 Mr. Garren's proposal is therefore not in "the best interest of  
20 customers." Instead, it is better thought of as an intergenerational subsidy to  
21 current customers at the expense of other generations of customers.

22  
23 **Q. Mr. Garren also states that "ELG remaining life calculations tend to**  
24 **understate the remaining lives of recent vintages when not updated**

1 **frequently.”<sup>22</sup> Can you address this comment?**

2 A. Yes. First, as I have explained the depreciation rates for UGI Gas are updated  
3 annually, and therefore the remaining lives are “updated frequently.” Second,  
4 I should be clear that ELG does not understate remaining lives of recent  
5 vintages. Instead, as I have explained, ELG properly recognizes that a portion  
6 of assets in recent vintages will have service lives much shorter than the  
7 average. ELG therefore results in the correct remaining lives of recent  
8 vintages. ASL, by depreciating all plant over the average life rather than the  
9 unit life (or its proxy known as the equal life group), actually overstates the  
10 remaining lives of recent vintages.

11  
12 **Q. Do you have any further comments regarding the selection of the Equal  
13 Life Group depreciation calculation procedure?**

14 A. Yes. The selection of the depreciation calculation is one of several decisions  
15 that a depreciation professional needs to make when defining a depreciation  
16 system used to calculate depreciation expense. There are options that need  
17 to be selected regarding the methods of depreciation (*i.e.*, straight-line vs.  
18 accelerated or decelerated methods), depreciation techniques (*i.e.*, whole-life  
19 vs. remaining life) and depreciation procedures (*i.e.*, ELG vs. ASL). A  
20 *consistent* approach using the same depreciation methods, techniques and  
21 procedures is best from an accounting and ratemaking perspective. The use  
22 of an alternative procedure should only occur in rare instances when there are  
23 compelling reasons to change. Mr. Garren has not presented any compelling

---

<sup>22</sup> OCA Statement No. 5, p. 18, line 19 to p. 19, line 1.

1 reasons to change depreciation calculation procedures. The American  
2 Institute of Certified Public Accountants' definition of depreciation accounting  
3 reflects the concept of depreciation as a cost of operation as such:

4 Depreciation accounting is a system of accounting that aims  
5 to distribute cost or other basic value of tangible capital  
6 assets, less salvage (if any), over the estimated useful life of  
7 the unit (which may be a group of assets) in a *systematic*  
8 and *rational* manner.

9 The key phrase regarding the definition of depreciation accounting is that the  
10 depreciation calculations should be determined "in a systematic and rational  
11 manner." Changing the depreciation calculation procedures to suit a  
12 particular current circumstance is inconsistent with the approach  
13 encompassed by the AICPA's definition of depreciation accounting.

14  
15 **Q. What do you conclude regarding the ELG issue?**

16 A. ELG is the longstanding and predominant practice in Pennsylvania, and has  
17 been used by most utilities in the state for many years. Mr. Garren has  
18 provided minimal evidence in support of his proposal to reverse this  
19 longstanding precedent. Further, what little evidence he provides is incorrect  
20 and demonstrates a lack of understanding of the actual practices used by  
21 Pennsylvania utilities. ELG should therefore continue to be used by UGI Gas,  
22 as has been the case for over thirty years.

23

1 Q. Does this conclude your rebuttal testimony?

2 A. Yes, it does.
