

(1) 49 CFR §193.2019(e) Control Systems.

A tracking spreadsheet has been developed to more effectively verify that all relief valves have been inspected and tested on an annual basis. A sample of this spreadsheet has been included in this submittal, reference Appendix A. By presenting consecutive years on a single sheet the inspection summary form is better constructed at assuring that each relief valve receives an annual inspection. Effective 2015, this new format will be implemented for all the facility's relief valve inspections.

(2) 49 CFR §193.2625(a) Corrosion Protection.

To better prepare the facility on identifying points for atmospheric corrosion inspection the following corrosion mitigation project has been developed. This two phase project is expected to take 3-5 years to complete but will provide a resource for future inspections and offers a solution to mitigating future corrosion concerns to visual inspection of coating systems and non-conductive interfaces.

Phase I: Corrosion Audit

An audit will be conducted at the facility to identify points of corrosion, with more detail, that require annual inspection. Areas of highest concern are: 1.) the facility's original pipe support racks where there is no insulating pad between the bottom of the pipe and the supporting steel and 2.) where carbon steel piping has been insulated. To better facilitate this process, a worksheet has been developed to track the audit, see Appendix B. The majority of the information pertaining to each interface can be gathered from visual walkthrough of the facility and by developing a support identification system for the pipe racks. This initial phase of the project is expected to be completed in one year and will serve as a tracking resource for ongoing inspections.

Phase II: Corrosion Inspection/Mitigation

Once each point is clearly defined, the severity of any existing corrosion will need to be evaluated. This evaluation will be based on the procedure outlined in ASME B31G, Manual for Determining the Remaining Strength of Corroded Pipelines. This supplemental guide is considered acceptable since all piping within the facility is constructed of seamless, API 5L or ASTM A106 line piping.

Based on this review, the segment of pipe inspected may receive one of the two following measures:

1.) <u>Pipe Replacement</u> – If the corroded region analyzed exceeds the maximum allowable extent, as defined in Eq. 2 of ASME B31G then this segment will need be replaced with a new segment of pipe. The replaced segment of pipe will receive the facility's required coating system and a non-conductive interface between the pipe and support.

2.) <u>Coating Replacement</u> – If the corroded region analyzed does not exceed the maximum allowable extent then this segment will be properly prepared to receive a new coating system REC contractive interface between the pipe and support.

FFB: 0 2 2015

PA PUBLIC UTILITY COMMISSION SECRETARY'S BUREAU

The use of a non-conductive interface between the pipe and support system will allow for future inspections to be confined to the integrity of the pipe coating system and the adhesion between pipe and insulating shoe. This final phase is expected to take up to five years to complete due to effort required to access the pipe to support interfaces.
