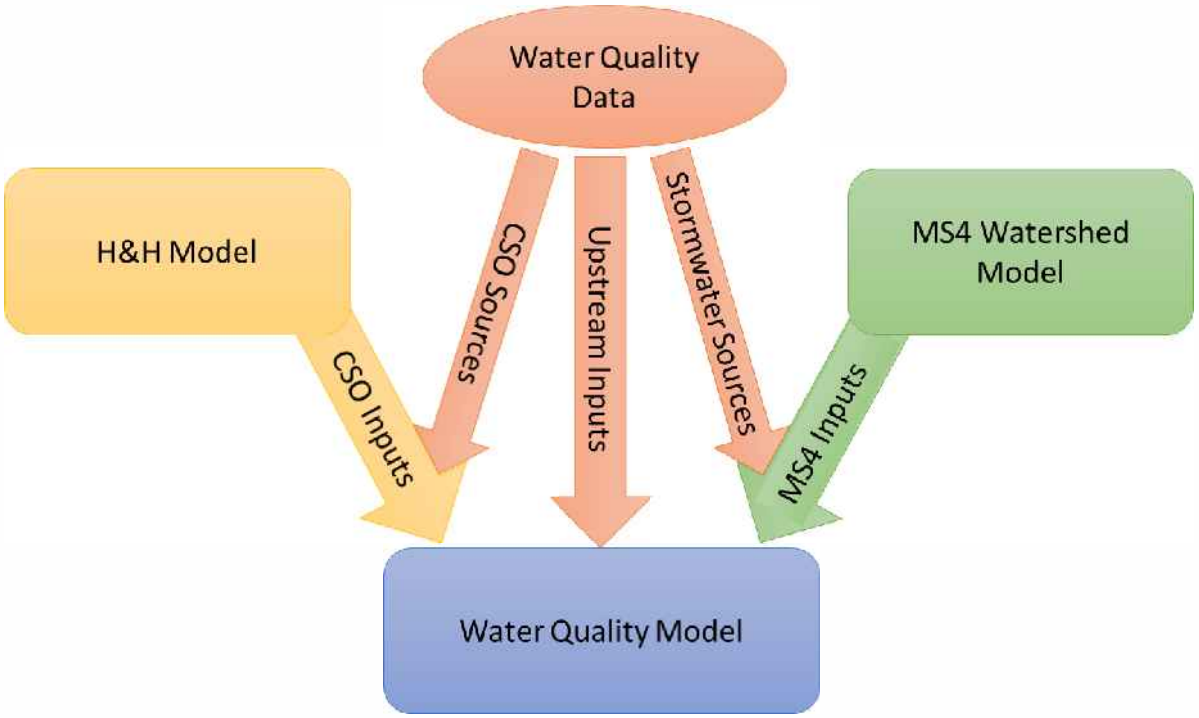
The water quality modeling objectives are to develop a calibrated and validated Water Quality Model that can be used to assess impacts of the DELCORA combined sewer system overflows on current POC concentrations in the receiving waters as well as the relative water quality benefits from CSO control alternatives considered for DELCORA's LTCP update consistent with the Consent Decree requirements in Paragraph V.A.15.a described in Section 1.3 of this report. The water quality impacts in the receiving waters will rely primarily on comparisons to applicable water quality standards or guidelines.

In order to achieve these objectives, a CSO, a watershed, and a receiving water quality model will be created and connected (Figure 2-2). The CSO model, also called the "H&H" model, is currently being developed for the Long Term Control Plan, with calibration and validation to be completed in April 2017. The H&H model is designed to simulate CSO discharges from the DELCORA service area within the City of Chester. The watershed model is a new model that will be created to model the non-CSO areas that are adjacent to the spatial domain of the receiving water model. The watershed model will simulate discharges from these non-CSO or background sources. The receiving water model is also a new model that will be used to simulate the bacteria POC concentrations in the receiving waters, including the Delaware River, Chester Creek and Ridley Creek.

Figure 2-2: DELCORA Water Quality Modeling Framework



This project requires development and calibration of a receiving water quality model that can accurately simulate water quality in the Delaware River, Chester Creek and Ridley Creek. The project also requires a watershed model that can accurately simulate water quality in the portion of the watershed in the vicinity of Chester, PA outside the combined sewer system service area. Both models need to be capable of simulating the system under a range of environmental conditions so that they can be used to evaluate the benefits of CSO reduction scenarios. There are several objectives to consider when selecting appropriate modeling software for the watershed and receiving water model, including:

- Technical objectives: can the model software adequately represent the physical, chemical, and temporal characteristics of the project site? Can it address the complexities of the project site without being overly complex or overly simplistic?
- Regulatory objectives: Can the model software produce results that can be used to evaluate water quality against applicable water quality standards. Does it have a proven track record with similar regulatory projects? Will it help fulfill regulatory requirements as described in the Consent Decree?
- User objectives: does the end user have the necessary hardware and expertise to properly apply the model software to its fullest potential? Are there financial constraints to be considered with the model?

Careful selection of the most suitable modeling platform was conducted prior to model development as discussed in the Water Quality Model Work Plan. A number of factors were considered in selecting the watershed and water quality models, including understanding of the project, knowledge of the available data gained through review of existing data, the project modeling objectives defined in the Consent Decree, and knowledge of available modeling platforms The modeling objectives, the model attributes to support model objectives, and the recommended modeling platform are described in the following sections of this QAPP.

2.3 Project/Task Description (A.6) and Schedule

The Water Quality Monitoring Program (WQMP) is designed to collect data that will be used to develop and calibrate watershed and receiving water quality models which will be used to assess water quality concerns for the POCs identified in the Identification of Sensitive Areas and Pollutants of Concern Report (Greeley and Hansen, 2016). Existing water quality data provide insight into the conditions in rivers and streams in the project area but are of insufficient frequency and spatial density to fully support the modeling process. In addition, *E. coli*, one of the identified POCs, was not monitored in the available data.

The monitoring program will start in early spring 2017. The sampling events are planned to be distributed across the sampling season, which is assumed to be March through June 2017. Monitoring and sampling locations have been selected to characterize the watershed at a sub-watershed level, recognizing various political and hydrologic features, land uses and potential pollutant sources. Site selection and analytical parameters are designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. The sampling locations are shown in Figure 2-3 and listed in Table 2-2, Table 2-3, and Table 2-4. Sampling locations may be moved slightly if the accessibility and safety of the selected locations of the stations are below expectations.

The WQMP is designed to collect data that will be used to assess water quality concerns identified in the Delaware River watershed and its tributaries, Chester Creek and Ridley Creek, in the vicinity of Chester, PA. In completing the initial step of characterizing the watershed, historical data was compiled, reviewed and assessed to determine the need to augment existing data to address the watershed issues identified. This review indicated that several of the POCs have not been sampled in the receiving waters and the data that have been collected are of insufficient frequency and spatial density to be useful in the modeling process.

As a result of the data review, the need for additional water quality information was identified. The need to further characterize the Delaware River, Chester Creek and Ridley Creek under dry and wet weather conditions is required to support water quality modeling, pollutant source identification, the subsequent development of a preferred alternative for controlling DELCORA's combined sewer overflows (CSO), and to allow DELCORA to complete its LTCP consistent with the Consent Decree. The need to characterize the watershed adjacent to

Chester's combined sewer system under wet weather conditions is also required to support water quality modeling and to allow DELCORA to complete its LTCP consistent with the Consent Decree.

Monitoring stations have been selected to characterize the watershed at a subwatershed level recognizing various political and hydrologic features, land use and potential pollutant sources. Site selection and analytical parameters are designed to characterize stream segments and pollutant sources primarily along the main stem and select tributaries. The sampling locations are shown in Figure 2-3 and listed in Table 2-2, Table 2-3, and Table 2-4. The tables include summaries of the rationales for each sampling location selected. The Chester Creek and Ridley Creek locations were selected to distinguish, to the extent possible, between upstream, stormwater and Chester CSO pollutant loads. The Delaware River sampling locations will provide a characterization of water quality entering the Chester CSO area from either tidal direction as well as water quality within the CSO discharge area. During wet weather, three samples will be collected across the transect corresponding to the DR-04 sampling location during each sampling round, when sampling across the river is feasible, to characterize lateral variability in the Delaware River during storm events. Delaware River conditions may be too hazardous for safe collection of one or more samples and/or sampling rounds (e.g. during periods of heavy barge traffic, small craft advisories, lightning, etc.). When these conditions occur, sampling will not be conducted in the river for safety reasons.

The CSO sampling locations were selected based on their outfall discharge location, relatively high frequency of overflow, their overflow volume, and their accessibility. The stormwater sampling locations were selected to characterize the water quality associated with the predominant land uses (residential and commercial/industrial) in the study area. Each stormwater sampling location is in an area that is representative of the land use elsewhere in the City's stormwater area.

Note that it may be necessary to adjust the one or more sampling locations in response to hazards, construction or other factors that affect the safety of field sampling personnel. The CSO and stormwater sampling locations will be finalized prior to the initiation of the sampling program based on accessibility of sampling, safety of sampling personnel, equipment risk, and available resources.

Figure 2-3: Proposed Receiving Water (RW), Combined Sewer (CSO) and Stormwater (SW) Monitoring Locations

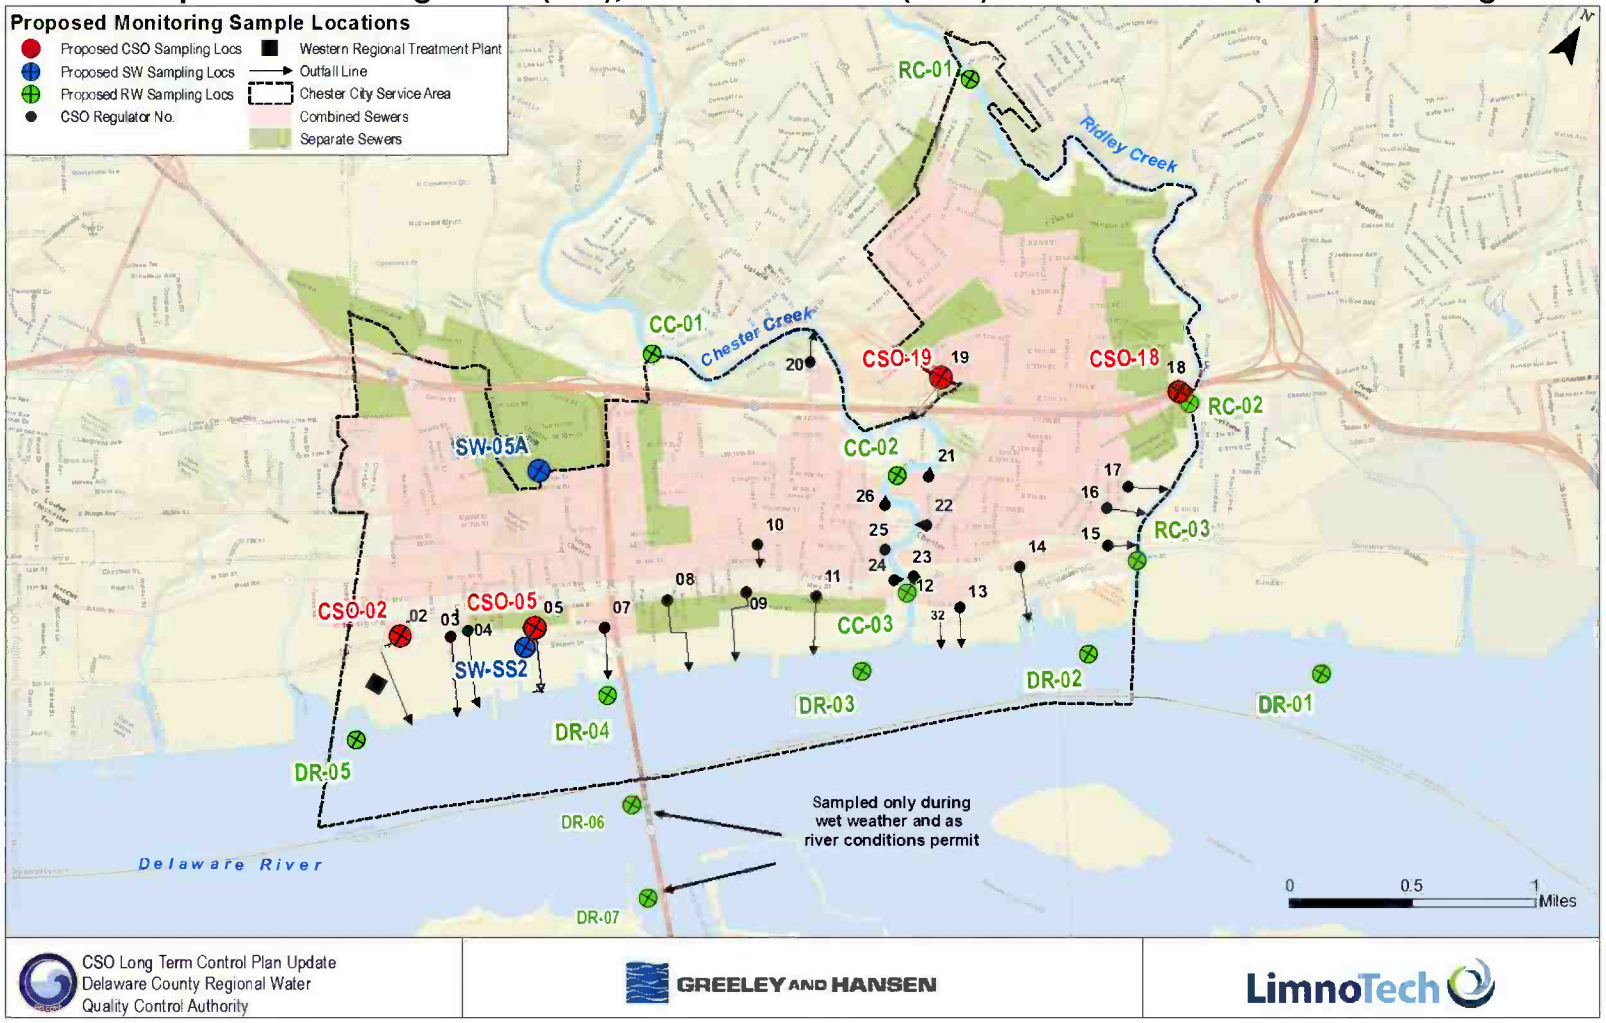


Table 2-2. Tributary Receiving Water Sampling Locations

Station ID	Latitude[1]	Longitude[1]	Receiving Water	Type	Description	Rationale
CC-01	39.850122	-75.386348	Chester Creek	Tributary	Chester Creek at Upland-Incinerator Rd.	Upstream of all City sources and upstream of tidal influence
CC-02	39.850709	-75.365530	Chester Creek	Tributary	Chester Creek at the 9th St Bridge; 54 W 9th St	Characterize impacts from non-CSO urban runoff sources
CC-03	39.845227	-75.360284	Chester Creek	Tributary	Chester Creek at E 2nd St., William Penn's Landing Park	Characterize impacts from all CSOs discharging to Chester Creek
RC-01	39.873264	-75.375183	Ridley Creek	Tributary	Ridley Creek at Chester Park Drive Bridge; 298 East Elkington Blvd	Upstream of all City sources and upstream of tidal influence
RC-02	39.863016	-75.348686	Ridley Creek	Tributary	Ridley Creek at Morton Ave. Bridge; 1300 Sun Drive	Characterize impacts from non-CSO urban runoff sources
RC-03	39.853435	-75.346350	Ridley Creek	Tributary	Ridley Creek at East 4th St. (Harrah's) Bridge	Characterize impacts from all CSOs discharging to Ridley Creek

Notes:

Table 2-3. Main Stem Receiving Water Sampling Locations

Station ID	Latitude[1]	Longitude[1]	Receiving Water	Type	Description	Rationale
DR-01	39.85282	-75.3299	Delaware River	Main stem	Delaware River between Ridley Creek and Crum Creek	"Upstream" of DELCORA's CSO discharges[2]
DR-02	39.84715	-75.3462	Delaware River	Main stem	Delaware River between CSO-14 and Ridley Creek	Characterize Ridley Creek impacts on Delaware River, in the upper Delaware River (Secondary contact area)
DR-03	39.8398	-75.3606	Delaware River	Main stem	Delaware River between CSO-11 and Chester Creek	Characterize Chester Creek impacts on Delaware River, in the upper Delaware River (Secondary contact area)
DR-04	39.83132	-75.3766	Delaware River	Main stem	Delaware River at the boat launch off Highway 322	Priority area, in the lower Delaware River (Primary contact area)
DR-05	39.82182	-75.3917	Delaware River	Main stem	Delaware River between CSO-002 and Stony Creek	"Downstream" of DELCORA's CSO discharges[2], in the Atlantic sturgeon sensitive area
DR-06[3]	39.82636	-75.371	Delaware River	Main stem	Delaware River mid-stream along the transect of DR-04	Characterize lateral variability in the Delaware River during storm events
DR-07[3]	39.82203	-75.3665	Delaware River	Main stem	Delaware River far shore (left descending bank) along the transect of DR-04	Characterize lateral variability in the Delaware River during storm events

Notes:

[1] GPS Coordinates, WGS 1984

[2] "Upstream" and "downstream" subject to tidal conditions at time of sampling

[3] These locations will be sampled during the wet weather events only, when river conditions permit. POC concentrations are assumed to be laterally well-mixed during dry weather due to the absence of significant pollutant sources.

Table 2-4. CSO and Stormwater Sampling Locations

Station ID	Latitude[1]	Longitude[1]	Receiving Water	Type	Description	Rationale
CSO-19	39.857132	-75.366105	Chester Creek	CSO	14th and Crozer Hospital; 1 Medical Center Blvd	Discharges to Chester Creek, one of the largest volume CSOs in DELCORA system
CSO-05	39.832598	-75.383958	Delaware River	CSO	Front and Townsend; 101 Townsend St	Discharges to Delaware River, one of the largest volume CSOs in DELCORA system
CSO-02	39.828334	-75.392570	Delaware River	CSO	Front and Booth; 100 Booth St	Aggregates cumulative effect of CS conditions, one of the volume CSOs in DELCORA system
CSO-18	39.863501	-75.349203	Ridley Creek	CSO	Sun Drive and Hancock St.; 1310 Sun Dr	Discharges to Ridley Creek
SW-05A	39.838501	-75.387708	Chester Creek	SW	7th and Engle Street; by tennis courts	Characterize runoff quality from predominantly residential area representative of the residential portion of the study area
SW-SS2	39.832853	-75.384193	Delaware River	SW	Front and Townsend; 105 Townsend St	Characterize runoff quality from predominantly commercial/industrial area representative of the commercial/industrial portion of the study area

Notes:
[1] **GPS Coordinates, WGS 1984**

2.3.1 Scope of Sampling

This section describes the scope of water quality sampling to be completed for this project.

Dry Weather Sampling

Collection of water quality samples will be performed for three (3) dry weather events; with one dry weather sampling event planned to be collected during a low-flow period (less than 25th percentile flow) in Chester Creek and Ridley Creek (if possible). Two rounds of sampling will be conducted for each dry weather survey: one round to be completed during ebb (outgoing) tide and the second round to be completed during flood (incoming) tide.

Dry weather event samples will be taken at up to eleven (11) locations:

- **Three (3) locations on Chester Creek** that will characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations will also reflect these tidal influences on water quality.
- **Three (3) locations on Ridley Creek** that will characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations will also reflect these tidal influences on water quality.
- **Five (5) locations on the Delaware River** that will characterize water quality in the vicinity of DELCORA's CSO discharges. Sampling locations have been selected to separate, to the extent possible, the effect of DELCORA's CSOs on water quality from other sources contributing pollutants to the waterways. Sampling will be conducted near the shoreline adjacent to the City of Chester.

The locations of these stations are shown in Figure 2-3. Details for these stations are provided in Table 2-2 and Table 2-3. The set of parameters for which the samples will be analyzed is provided in Table 2-4.

In-situ measurements of physical parameters, such as salinity, temperature, and conductivity will be collected at each sampling location with a sonde. In the Delaware River, in situ measurements will be made at three depths at each sampling location during each round of sampling. Grab samples will be collected near the surface in each waterway.

Wet Weather Event Sampling

Collection of water quality samples will be performed for three (3) wet weather events. The purpose of the wet weather sampling is to characterize the impact of CSO discharges and non-CSO source runoff on in-stream water quality. The wet weather events will span a range of precipitation, flow and seasonal conditions.

Wet weather event samples will be taken at all 13 in-stream locations as well as at up to six source locations in the intervals described below:

- **Six (6) In-Stream Tributary Sampling Locations:** Three (3) locations will be on Chester Creek and three (3) locations on Ridley Creek. The locations will be the same locations used for the dry weather surveys. Tributary locations will be sampled up to five times per event at the following approximate intervals: Hour 0.5-2.5, Hour 4.5-6.5, Hour 8.5-10.5, Hour 14.5-16.5, and Hour 22-24. Sampling intervals will be defined by the start of rainfall rather than CSO or SSO activation. A total of 30 samples will be collected during each wet weather sampling event from in-stream locations. One field blank and one field duplicate will be collected during each event to be used as field quality control (QC).
- **Up to Seven (7) In-Stream Delaware River Locations:** Up to seven locations will be on the Delaware River and will be sampled up to ten times per event at the following approximate intervals: Hour 0, Hour 2, Hour 4, Hour 6, Hour 9, Hour 12, Hour 15, Hour 18, Hour 21, and Hour 24. Sampling intervals will be defined by the start of rainfall rather than CSO or SSO activation. The frequency of sampling is intended to capture in-stream impacts in the vicinity of DELCORA's service area from both DELCORA's CSOs as well as upstream sources. Two additional locations on the Delaware River, one at mid-stream and one near the far shore, have been added to characterize lateral variability in water quality during storm event conditions, when sampling across the river is feasible. The sampling regimen is also designed to allow a semi-quantitative mass balance to be computed over a complete tidal cycle. A total of 70 samples may be collected during each wet weather sampling event. If river conditions are unsafe for sampling (e.g. small craft advisories, heavy barge traffic, etc.), sampling may be suspended for one or more locations and/or sampling rounds. One field blank and one field duplicate will be collected during each event to be used as field QC. Final selection of sampling locations and sampling intervals will be determined prior to the start of the sampling program and will be based on logistic considerations (e.g. can seven locations be sampled and dropped off to a courier within the 3 hour sampling window), safety and accessibility to the Delaware River, and available resources.
- **Up to Six (6) Outfall Locations:** Sampling will be conducted at up to two (2) stormwater outfalls and up to four (4) combined sewer overflow outfalls. The CSO and stormwater sampling locations will be finalized prior to the initiation of the sampling

program based on accessibility of sampling, safety of sampling personnel, equipment risk, and available resources.

It is assumed that each of the outfall locations will have up to eight sets of samples collected for each event at the following intervals: 1st flush, 30 minutes, and 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, 24 hours. If a location is not flowing, no sample will be collected. As many as 48 samples may be collected during each wet weather sampling event, depending on the number of monitored outfalls and if all monitored outfalls discharge for 24 hours. However, the actual number of samples is likely to be less than the amount indicated since it is unlikely that all of the monitored outfalls will discharge for the full 24 hour monitoring period. One field blank and one field duplicate will be collected during each event to be used as field QC.

The location of these stations are shown in Figure 2-3. Details for these stations are provided in Table 2-2, Table 2-3, and Table 2-4. The set of parameters for which the samples will be analyzed are summarized in Table 2-5. In situ measurements will not be collected at the outfall locations.

Sampling crews will conduct all wet weather event sampling using the protocols described in the Quality Assurance Project Plan. Samples will be delivered to the laboratory where the samples will be analyzed for the laboratory parameters identified in Table 2-5.

Determination to mobilize for a Wet Weather Event will be a collaborative effort between Greeley and Hansen, LimnoTech, the field sampling contractor and the laboratory contractor personnel. The intent is to identify a 4 to 6 hour window in which a wet weather event may commence 24 hours in advance to assist in mobilization of the sampling crews.

Table 2-5: Analytical and Field Parameters

Parameter	Description	Sampling Program	Type of Measurement
E. coli	Escherichia coliform	Dry, Wet	Grab
Enterococcus	Enterococcus sp.	Dry, Wet	Grab
Fecal coliform	Fecal coliform	Dry, Wet	Grab
wTemp	Water temperature	Dry, Wet Receiving Water Only	In-situ
Cond	Conductivity	Dry, Wet Receiving Water Only	In-situ
Salinity	Salinity	Dry, Wet Receiving Water Only	In-situ

Tributary Bathymetry

The project team has requested HEC models of the receiving waters from the U.S. Army Corps of Engineers. However, in the absence of these models, additional bathymetry data is needed for the tributaries to inform the development of the water quality model. If required, bathymetry surveys will be conducted in approximately the lower three miles of both Chester Creek and Ridley Creek, corresponding to the approximate extent of the water quality model

domain. Because these reaches are in the tidal zone, they are unlikely to be wadeable so each transect will be characterized using a boat and a combination of sonar and ADCP profiler equipment. Transects will be spaced approximately every 0.25 miles or at significant morphometric features (e.g. dams, islands, etc.).

2.3.2 Water Quality Model Attributes and Platform

The Water Quality Model is a tool that computes the movement and concentrations of pollutants in water bodies of interest. Many water quality model codes are available and these models vary in their recognition by USEPA and their applicability to the Delaware River and its tributaries. LimnoTech reviewed a range of potentially applicable hydrodynamic and water quality models and has identified USEPA's Environmental Fluid Dynamics Code (EFDC) as the model framework most appropriate for the DELCORA receiving waters. This modeling framework computes water depths and velocities to inform predictions of bacteria water quality conditions. EFDC is selected over other candidate modeling frameworks due to its flexible and scalable design, computational efficiency and wide application base at similar sites around the United States. This model is supported by USEPA and has been successfully applied by the project team at similar sites and to meet similar project objectives (Ohio River, James River, Berry's Creek).

It may be beneficial to couple EFDC with another model to reduce simulation run times. EFDC could be used to compute hydrodynamics and those results could be linked to the RCA (Row-column AESOP) water quality model for water quality calculations. This potential approach would reduce model run times by allowing for a longer time step and for a smaller water quality model extent. RCA, like EFDC, is a highly regarded water quality model that has been applied at numerous sites by the project team (Lake Erie, Mississippi River, Great Miami River).

LimnoTech also reviewed a range of potentially applicable watershed runoff models and has identified USEPA's Storm Water Management Model (SWMM) as the model framework most appropriate for the DELCORA watershed model. This modeling framework simulates hydrologic and water quality conditions in the watershed to estimate runoff and pollutant concentrations from areas outside the combined sewer system area in the vicinity of Chester, PA. This area is primarily within the City of Chester's municipal separate storm sewer system (MS4).

EFDC Background and General Capabilities

The EFDC model is a state-of-the-art finite difference model that can be used to simulate hydrodynamic and sediment transport behavior in one, two, or three dimensions in riverine, lacustrine, and estuarine environments. EFDC was developed at the Virginia Institute of Marine Science in the 1980s and 1990s, and the model is currently maintained under support from the U.S. EPA. Recently, LimnoTech has successfully applied EFDC to a number of sites, including the James River (near Lynchburg and Richmond), Berry's Creek (NJ), San Diego Bay (CA), the lower Great Miami River, the Ohio River (near Cincinnati (OH), Evansville

(IN) and Wheeling (WV), the lower Licking River (Northern Kentucky), Missisquoi Bay (Lake Champlain), Saginaw Bay (Lake Huron), Maumee Bay (Lake Erie), Saginaw River (Michigan), and the Tittabawassee River (Michigan). The EFDC model is both public domain and open source, meaning that the model can be used free of charge, and the original source code can be modified if necessary to tailor the model to the specific needs of a particular application.

The model input parameters include variable hydrologic inflows and outflows from tributaries and landside sources, their associated bacteria concentrations for the POCs, and water level boundary conditions. EFDC can represent the model grid using either a generalized vertical coordinate (GVC) system or a sigma system. Both options are capable of accurately describing vertical gradients in systems with rapidly changing bathymetry, if necessary. The model outputs will include the movement of water in the river (i.e., flows and velocities), water level, and bacteria densities throughout the model domain.

SWMM Background and General Capabilities

The proposed watershed model framework for this project is SWMM (Storm Water Management Model), which is supported by the USEPA and has been successfully applied by the project team at similar sites and for related purposes, including in East Rutherford, NJ, Washington, DC, and Richmond, VA. SWMM is a dynamic rainfall-runoff simulation model used for single event or continuous simulation of runoff quantity and quality from primarily urban areas (USEPA, 2015). A review of the Chester Creek and Ridley Creek watersheds using the USGS StreamStats[1] tool show that these two watersheds are 42% and 37% urban respectively. Additionally, the current H&H model for the DELCORA service area is also built using the SWMM software, so choosing SWMM for the watershed model provides consistency in the suite of models used by DELCORA.

SWMM can account for different subcatchment physical characteristics such as slope, imperviousness, length and width, and soils through the parameterization of spatial resolution. Additionally, it will be able to predict variations in timing, peak flows, and flow volumes.

A variety of enhanced SWMM platforms are available that integrate the EPA SWMM software with user friendly interfaces and GIS capabilities. For this project, PCSWMM, developed by CHI, will be used. Once the watershed model is built, the model files can be provided as PCSWMM or EPA SWMM files.

2.4 Quality Objectives and Criteria (A.7)

The monitoring information that will be collected to support the development of the updated LTCP will meet the quality assurance objectives outlined in this section. Data quality will be

[1] http://water.usgs.gov/osw/streamstats/

measured in terms of the data's accuracy and precision, completeness, representativeness, comparability, and the required detection limits for the analytical methods.

Model quality will be based on the successful calibration and validation to hydrodynamic and water quality data from the Sampling Program as well as the model's ability to be meet the project objectives.

2.4.1 Water Quality Monitoring

2.4.1.1 Accuracy

Accuracy is the measure of agreement between an observed value and an accepted reference value or true value. Table 2-6 provides a summary of the laboratory and field measurement accuracy objectives.

Table 2-6: Data Quality Objectives

Parameter	Data Accuracy Objectives (% R)		Data Precision Objectives				Required Detection Limits	
			Field Precision (RPD)		Analytical Precision (RPD)			
	Estimated By	Objective	Estimated By	Objective	Estimated By	Objective	Reference Method	RL*
Fecal coliform	Presence/ Absence Control	P/A	Field Duplicates	50%	Lab Replicates	40%	SM 9222D	10 No./ 100 ml
Escherichia coliform (E. coli)	Presence/ Absence Control	P/A	Field Duplicates	50%	Lab Replicates	40%	EPA 1603	10 No./ 100 ml
Enterococcus	Presence/ Absence Control	P/A	Field Duplicates	50%	Lab Replicates	40%	EPA 1600	10 No./ 100 ml
Water Temperature	Factory calibration	NA	Readings	10%	NA	NA	Field Instrument/ EPA 170.1	0.1 °C*
Conductivity	Calibration check standard	Instrument reading within 10% of standard	Readings	10%	NA	NA	Field Instrument/ EPA 120.1	1 uS/cm*
Salinity	Calibration check standard	Successful daily calibration	Readings	10%	NA	NA	Field instrument/ SM 2520 B	0.1 part per thousand

* - Sensitivity value listed for field parameters (Temp., Cond., Salinity) - instrument must be capable of reporting to nearest incremental sensitivity value listed
P/A - method detects presence when bacteria is present in control (P) and method does not detect bacteria when absent in control (A).
NA - not applicable
RL - Reporting Limit
SM - Standard Methods of the Examination of Water and Wastewater, 22nd Edition

Laboratory Accuracy Objectives

Accuracy cannot be directly measured for bacterial samples. Accuracy will be assessed by the laboratory through the analysis of positive and negative controls and laboratory blanks and with field blanks in the field.

Dilution blank samples and method blank samples will be generated by the contract laboratory and used to assess contamination resulting from laboratory procedures. Duplicate analyses will be performed to check for sampling and analytical reproducibility.

Field Accuracy Objectives

Accuracy cannot be directly measured for bacterial samples. Accuracy will be assessed by the laboratory through the analysis of positive and negative controls in the laboratory and with field blanks in the field. In order for the accuracy assessment to be relevant, all appropriate protocols concerning sample collection, handling, preservation, and hold times must be maintained. Field blanks will be collected by each crew during each sampling event. A detailed discussion of these protocols is provided in the Water Quality Monitoring Plan.

Field blanks will be used to determine if samples collected have been contaminated. Equipment that is used to collect samples for analysis may become contaminated through the normal course of monitoring. If not properly cleaned and rinsed, samples may be contaminated during sampling from previous locations or in the laboratory between sample analyses. Field blanks consisting of reagent grade distilled water will be submitted to the analytical laboratory to assess the quality of the data resulting from the field monitoring program. Field blanks will be used to assess cross-contamination of samples by the equipment or sampling techniques. Field blanks will also be analyzed to check for procedural contamination at the laboratory that may cause sample contamination.

Field measurement accuracy will be assessed through pre- and post-monitoring checks to calibration standards. Probe performance within the specifications of the parameter will be used as confirmation of accuracy. Probe performance outside the specifications of the parameter will be qualified using the data validation protocols described in Section 5.

2.4.1.2 Precision

Precision is a measure of agreement between two or more measurements. Duplicates and replicates samples will be taken for a portion of the samples. Table 2-6 provides a summary of the data precision objectives for field and laboratory measurements. Table 2-6 applies if the average result of the duplicate/replicate samples is greater than five times the analysis detection limit. If the average result of the duplicate/replicate samples is less than five times the analysis detection limit, the precision test will not be utilized.

Laboratory Precision Objectives

The precision of the laboratory analysis is assessed by the comparison of laboratory replicate analyses. The RPD is calculated as follows:

$$RPD = \frac{|C_1 - C_2|}{0.5(C_1 + C_2)} \times 100$$

Where: C_1 = measured concentration of the first sample replicate
C_2 = measured concentration of the second sample replicate

Note that the average concentration of C_1 and C_2 must be at least five times greater than the reporting limit (Table 2-6) for the analyte to be in sufficient quantity to provide a reasonable measure of precision.

Field Precision Objectives

Field precision tests are conducted for grab samples and physical parameter readings. The precision of grab samples is assessed by the comparison of field duplicates. The relative percent difference (RPD) between the analyte levels measured in the field duplicates will be calculated as follows:

$$RPD = \frac{|C_A - C_B|}{0.5(C_A + C_B)} \times 100$$

Where: C_A = measured concentration of sample
C_B = measured concentration of duplicate sample

The precision of physical parameter readings is assessed by the comparison of each instrument's calibration readings versus the post check readings. The RPD between the readings will be calculated as follows:

$$RPD = \frac{|R_X - R_Y|}{0.5(R_X + R_Y)} \times 100$$

Where: R_X = calibration reading
R_Y = post check reading

2.4.1.3 Completeness

Completeness is a measure of the amount of valid data obtained from the monitoring program compared to the amount of data that were expected. Events that may contribute to reduction in

measurement completeness include sample container breakage, inaccessibility to proposed sampling locations, automatic sampler failure, and laboratory equipment failures.

The percent completeness (%C) is determined as follows:

$$\%C = \frac{(M_V)}{(M_P)} \times 100$$

Where: M_V = number of valid measurements
M_P = number of planned measurements

If the completeness objectives are not achieved for any particular category of data, the Field Manager will provide documentation why the objective was not met and how the lower percentage impacts the overall study objectives. If the objectives of the study are compromised, re-sampling or re-measurement may be necessary.

Field Completeness Objective

Field completeness is determined by the number of measurements collected versus the number of measurements planned for collection. The details concerning the actual number of field measurements and samples to be collected are discussed in the Water Quality Monitoring Work Plan. The number of measurements collected is validated by the Field Manager. The completeness criterion for all measurements and sample collection is 90 percent, but will be influenced by environmental situations that may alter monitoring schedules.

Laboratory Completeness Objective

Laboratory completeness is a measure of the amount of valid measurements obtained from all samples submitted for each sampling activity. The Laboratory Manager validates the numbers of valid measurements. The completeness criterion for all measurements is 95 percent.

2.4.1.4 Representativeness

Representativeness is the degree to which data accurately and precisely represents a characteristic of a population, parameter variations at a sampling point, a process condition, or an environmental condition. Representative data of dry weather and wet weather conditions are required to support the evaluation and modeling efforts.

For sample collection, representativeness will be assured by following the Water Quality Monitoring Work Plan and applying proper collection techniques including the proper sample sizes and volumes, sampling times, and sampling locations. The volumes of the samples depend on the analytical methods and should allow for QC sample analysis and reanalysis, if required. In the laboratory, representativeness will be ensured by using the appropriate sample preparation

techniques, by following appropriate analytical procedures, and by meeting the recommended sample holding times.

2.4.1.5 Comparability

The objective for data comparability is to generate data for each parameter that related water quality conditions between sampling locations and over time. Data comparability will be promoted by:

1. Using standard U.S. EPA approved methods, where possible.
2. Consistently following the sampling methods detailed in the SAP.
3. Consistently following the analytical methods detailed in the QAPP.
4. Achieving the required detection limits detailed in the QAPP.

All sample collection and analytical methods will be specified, and any deviations from the methods will be documented. All results will be reported in the standard units shown in Table 2-6. All field and laboratory calibrations will be performed using standards traceable to National Institute of Science and Technology (NIST) or other U.S. EPA approved sources.

2.4.1.6 Required Detection Limits

The required detection limits (RL) and methodology for the study is provided in Table 2-6. For the analytes specified for this study, all the RLs are at levels required for calibration of the water quality models to be developed.

Refer to Table 2-7 for the specification limits of the field measurement instruments.

Table 2-7: Specification Limits of Field Measurement Instruments

Parameter	Instrument	Range	Accuracy	Resolution
Temperature	YSI	-5 to 45°C	±0.15°C	0.01°C
Conductivity	YSI	0 to 100 mS/cm	±1% of range	4 digits
Salinity	YSI	0 – 70 ppt	±0.1 ppt	0.01 ppt

2.4.2 Water Quality Modeling

Model development for the DELCORA LTCP consists of four tasks leading to a calibrated and validated EFDC model for use in evaluating CSO control applications in the local waterways of the DELCORA service area. These tasks are addressed in this QAPP and are listed below.

- Model Input Development
- Model Calibration and Validation

- Model Scenario Application
- Documentation and Reporting of Results

Each of these model development tasks is described below.

2.4.2.1 Criteria for Model Inputs/Output

This task includes the processing of the necessary background, input, and calibration datasets for model development. Model development of the hydrodynamic (EFDC) and water quality (RCA) components of the EFDC-RCA model for the DELCORA waterways will occur sequentially, with EFDC development occurring first, followed by development of the RCA model. Model development for each component is discussed below.

EFDC-RCA Water Quality Model

Initial EFDC model development efforts will focus on development of a model grid, followed by processing of data to specify external hydraulic and water quality forcing functions (i.e., flows, loads) into a format that can be input to the model.

The major components of the model development process include the following items:

Grid development – Available bathymetric data will be assembled and used as the basis for development of a model grid with adequate resolution to capture the significant characteristics of the system for purposes of this project. At present, a one-dimensional grid is planned for the tributaries and three dimensional grid for the Delaware River portion of the model domain. The model grid will be an orthogonal grid within a curved perimeter suitable for numerical modeling. Where bathymetric data are not available, previously developed flood models will be obtained and the model bathymetry will be used to fill bathymetric gaps. Additionally, bathymetry surveys as described in Section 2.3.1 will be conducted in the tributaries. If reaches exist where no bathymetric data or hydraulic models exist, bathymetry will be extrapolated from upstream and downstream information.

Input development – Model upstream and tributary flows will be derived from available flow data at USGS gaging stations. CSO flows will be derived from the calibrated and validated hydrologic and hydraulic (H&H) model. Stormwater flows will be derived from a SWMM watershed model. Model upstream and tributary water quality will be based on the data collected during the WQMP. CSO and stormwater quality will be input using event mean concentrations (EMCs) derived from the CSO sampling program data collected during the WQMP.

Available water quality data to support model development and calibration have been compiled and reviewed to develop the WQMP. Available data have been incorporated into a project-specific database that will be used to generate model inputs and included in the pre- and post-processor for the model to facilitate comparisons of model results to observed data during calibration, as appropriate.

SWMM Stormwater Watershed Model

The main attributes of the proposed watershed model are that it will be able to predict dry and wet weather flows and associated bacteria loads. The watershed model will provide necessary spatial resolution to account for different subcatchment physical characteristics such as slope, imperviousness, length and width, and soils. Additional, it will be able to predict variations in timing, peak flows, and flow volumes.

Catchment Development – SWMM simulates surface runoff from catchments that represent physical areas in the watershed. For the DELCORA modeling framework, catchment areas will be developed for the areas outside of the combined sewer system collection system adjacent to the spatial domain of the Water Quality Model. Catchment areas will be defined similarly to the areas shown in Figure 1-3 and will be informed by the physical characteristics of the area, including slope, soils, imperviousness, and topographical or other defined watershed boundaries (e.g. roads).

Input Development – SWMM model inputs include catchment characteristics, such as area, width, imperviousness, and slope. Other characteristics affecting the hydrologic simulation include roughness, depression storage, and soil infiltration rates. Rainfall and temperature are temporal inputs. Runoff water quality will be input using EMCs derived from the stormwater sampling program data collected during the WQMP.

Available water quality data to support model development and calibration have been compiled and reviewed to develop the WQMP. Available data have been incorporated into a project-specific database that will be used to generate model inputs and included in the pre- and post-processor for the model to facilitate comparisons of model results to observed data during calibration, as appropriate.

2.4.2.2 Calibration and Validation

Once each EFDC model component is configured to the DELCORA watershed, the next step in the model development process is model calibration. During the calibration process, model inputs will be adjusted to allow the model to best fit the described observed data. The focus of calibration is the adjustment of model coefficients within an acceptable range (dictated by the field data and laboratory literature values) to achieve the best agreement between model and data within the constraints of both model and data. The model calibration approach will be consistent with the well-accepted methods presented in the EPA guidance manual for development, evaluation, and application of regulatory environmental models (EPA, 2009). Model coefficients will be calibrated independently to the extent possible, with calibrated coefficients left fixed while other coefficients are adjusted. For example, all hydraulic parameters will be calibrated prior to conducting any water quality calibration. Calibration of each model component is discussed further below.

EFDC Model Hydraulic Calibration and Corroboration

The hydraulic calibration will be informed by data from NOAA gages in the Delaware River, as

listed below:

- Water level gages: #8540433 (Philadelphia, PA), #8546252 (Bridesburg, PA), #8539094 (Burlington, NJ), and #8548989 (Newbold, PA)
- Current velocity meter: Station dB0301 (Philadelphia, PA)

Hydraulic calibration will primarily focus on reproducing observed water levels and current velocities in the Delaware River. This approach provides a robust calibration by focusing on the hydraulic attributes that are the primary dependent variables of the hydrodynamic model. Calibration goodness will be determined by qualitative visual comparison of model and data time series, one-to-one plots, and cumulative frequency distributions (CFDs). Calibration will involve adjustment of the roughness height to values that best replicate water level and velocities at NOAA stations.

After satisfactory calibration is achieved, the EFDC hydrodynamic model will be validated by applying the model for a different time period than the calibration. The roughness height used in the calibration will be used for the validation run.

EFDC Model Water Quality Calibration and Validation

Water quality calibration will rely primarily on the dry and wet weather data to be collected in the WQMP in Chester Creek, Ridley Creek and the Delaware River. The model coefficients determined in the calibration process will be independently corroborated (a process that has historically been called validation) via application of the model to a data set independent of that used for model calibration. The LimnoTech standard approach for selecting periods for calibration and validation is to divide the available data into periods of relatively equal duration and to use the most robust (or otherwise most representative) period as the calibration data set. Using this approach, the dry weather data and two of the sampled wet weather events will serve as the calibration dataset and the remaining third sampled wet weather event will serve as the validation data set.

Calibration will involve adjustment of model coefficients within an acceptable range (dictated by the field data and laboratory literature values) until the difference between model computations and measured state variables is within acceptable tolerance. The key calibration parameter for indicator bacteria in EFDC is the loss rate. The loss rate represents the net effect of bacteria settling, die-off and other physical and chemical processes as a first order loss rate.

Calibration will include the use of qualitative (graphical) comparisons of model results to data, such as:

- Time series
- 1:1 plots
- Cumulative frequency distributions

Quantitative comparisons of model to data will also be used to judge the calibration, with the objective of minimizing differences between model and data. For comparisons of simulated vs. observed parameters, these may include:

- Mean absolute error and/or mean relative % difference
- PBIAS (percent bias)

Diagnostic analyses (e.g., sensitivity analyses, mass balance checks, and comparison of results to simple models) will be conducted during the water quality calibration process. LimnoTech experience has shown that conducting these diagnostic analyses helps to:

- Confirm that inputs are being provided to the model in the required format,
- Troubleshoot unstable and unexpected behavior exhibited by model simulations,
- Assess the relative importance of different input parameters and systems simulated within the modeling framework, and
- Provide insights into system behavior based on predictions of the calibrated model.

Model validation will involve running the EFDC water quality model for the validation time period and calculating the same model-data comparison statistics as were used for model calibration.

Quality Objectives and Criteria for Model Inputs/Outputs

LimnoTech will develop and apply the calibrated and corroborated EFDC water quality model to evaluate management option scenarios as described Section 2.2.2 of this QAPP. The two overall modeling objectives for this QAPP follow and are described further below.

- to ensure the performance of the model; and
- to ensure the quality of the model inputs, model outputs, and conclusions made in support of CSO control alternatives evaluation.

Model Performance

During the application of the model, performance will be evaluated after each model run. The output will be compared against previous model runs to ensure that the outcome was expected, and within reasonable ranges. A reasonable range is defined as being within known ranges of possible outcomes. The range of possible outcomes is determined from previous model runs and user experience with the parameters being modified for the current run. For example, if the model is run to steady state with 50% of the annual load, then the steady-state water column concentration is expected to be 50% of the original value. In this example, model results that are not 50% of the original value (for this model run) would be subject to further review.

Model Input Data

Model inputs will be comprised of existing secondary data (i.e., previously collected, reported,

modeled or synthesized data) and will be used for the purposes of receiving water characterization and modeling efforts. Work under this QAPP will not generate any direct environmental data measurements. The data quality objectives (DQO) and associated criteria for the secondary data used for this project are listed below.

- Data are from a known and reliable source. The data sources will be documented. Data will be compiled primarily from reliable local, state, federal and peer-reviewed sources.
- Data are of known quality. The quality of secondary data will be reviewed prior to use for this project.
- Data are appropriate for the intended use as indicated by the following criteria:
    - data satisfy project objectives;
    - data satisfy evaluation and modeling requirements;
    - data exhibit appropriate characteristics (e.g., quality, quantity, temporal, spatial); and,
    - data were generated using appropriate methods.

Data sets to be used in the project will be reviewed for completeness, quality and conformance with the DQOs and associated criteria listed above. Data will be accepted for use if they conform to the DQO and criteria, and all accepted data will be cited appropriately including:

- Type of data and collection dates;
- Originating organization;
- Report title, author and date; and,
- Data format (electronic, hardcopy) and database names.

Identified data limitations will be documented, where applicable, and these datasets will be accepted for use on a case-by-case basis. Data of unknown/non-verifiable quality will be considered suspect and documented accordingly. To ensure transparency and defensibility in the decision making process, related project reports and/or existing data that were not used for this project will be clearly documented.

Model inputs will be carefully reviewed by the technical staff prior to each model run to ensure that the inputs are consistent with the modeling approach and scenario objectives. Any model inputs that are questionable or not fully documented will not be used to generate final results. All modifications to the model inputs will be documented in a separate file that lists the date, run ID, and inputs that were modified. All model inputs will be stored in the same folder as the corresponding model output to keep a complete record of each simulation used for each management scenario.

Model Outputs and Conclusions

Processing of model results will be accomplished through an automated post-processor that ensures the consistent treatment of model output for each model run. Model results will be reviewed by the technical staff as a final quality check to ensure that the model results are within reasonable ranges. Processed model outputs will always be stored in a folder with the run ID and the unprocessed model output.

2.4.2.3 Application

The calibrated EFDC water quality model is intended to be used to evaluate CSO control alternatives wherein indicator bacteria POC loads are reduced by specified amounts to evaluate impact on water quality in the Delaware River and the tributaries adjacent to the DELCORA service area. The list of model scenarios representing the CSO control alternatives to be evaluated will be developed in collaboration with DELCORA and Greeley and Hansen.

A baseline scenario will be developed, against which all load reduction scenarios will be compared. This baseline scenario will be developed in collaboration with DELCORA and Greeley and Hansen and will include:

- A representative time period to capture the range of river conditions including dry, wet and average conditions.
- A representation of current CSO discharge flows and quality.

Once scenarios have been defined, inputs to the calibrated model will be adjusted for each scenario to fit the specific change that the management option is considering. Model results for each scenario will be compared to the baseline scenario for a specific set of water quality response variables, including, but not necessarily limited to:

- Compliance with applicable water quality standards
- Reductions in levels of POCs

Compliance with applicable water quality standards will be evaluated assuming contributions from CSO and non-CSO sources and from CSO sources alone. If non-CSO (e.g. background) sources prevent compliance of water quality standards, the scenarios simulated will be configured assuming that background pollutant levels are reduced such that in-stream concentrations upstream of the CSO outfalls are no more than 75% of the applicable water quality standard.

2.5 Special Training/Certification (A.8)

Special training/certification needed for project, field, laboratory, and modeling staff to successfully complete project work is discussed in this section.

2.5.1 Project Staff

Greeley and Hansen, LimnoTech, Weston Solutions, and Eurofins QC professional staff will be involved in this monitoring program and water quality model development. Project staff will be assigned duties based on their qualifications to accomplish the task. The Field Manager will determine the appropriateness of individuals on their staff to undertake a task.

2.5.2 Field Staff

Training sessions will be carried out for all field staff on proper sampling, sample handling and submission and general field procedures prior to conducting the first sampling event. Specific emphasis will be placed on QA/QC issues as well as on health and safety. Field Safety Instructions will be prepared to outline the safety issues of concern.

Field crews will also receive training involving the operation, maintenance and calibration of field equipment including multi-parameter probes, velocity meters, and all other on-site equipment used throughout the field program.

Standard Operating Procedures (SOPs) for program elements will be distributed to staff and available at all times. The field Standard Operating Procedures (SOPs) and the Sampling Analysis Plan (SAP) referenced in the following sections of this report are provided in Appendix C.

2.5.3 Laboratory Staff

The Laboratory Manager or delegate will be the main point of contact for coordinating all sample drop-offs, pick-ups, etc. The Laboratory Manager or delegate will be assisted by the laboratory QA/QC Manager in performing review and validation of all data generated to assure all data quality objectives have been met. The Laboratory Manager or QA/QC Manager will contact the Field Manager immediately with any problems with samples noted during log in or with analysis. Prior to conducting the first sampling event, the Monitoring Task Manager and Field Manager will meet with the laboratory manager to review details of the planned progression of sampling events.

The laboratory staff will include chemists and technicians with specific experience in receiving water and source sampling analysis. The laboratory staff will be on call 24 hours a day and 7 days a week for wet weather events, including weekends.

All laboratory personnel receive training and have proven proficiency in their designated analytical procedures. Laboratory personnel have been provided copies of the appropriate Standard Analytical Procedures (SAPs), which will be available at all times and are provided in Appendix B.

2.5.4 Model Staff

Staff engineers and scientists comprising the modeling team are trained professionals with advanced technical degrees and skills necessary to successfully develop and apply water quality models for the system. All modeling activities will be overseen by the project's Water Quality

Model Task Manager who has extensive experience in applying water quality models to support CSO LTCP development.

2.6 Documentation and Records (A.9)

The Project Manager is responsible for ensuring that the most current approved version of the QAPP is distributed. The approved QAPP and any approved updates will be distributed to the list of project personnel identified in the Distribution List at the beginning of this document. These personnel are responsible for distributing copies of the QAPP to relevant personnel within their organization.

2.6.1 Monitoring Data

The Project Manager is responsible for initiating project files and for overseeing maintenance of the files during the course of the project. All project files will be properly identified by client, project name, project number, file description, and file number for all appropriate correspondence, memoranda, calculations, technical work products, and other project-related data. In addition, a quality assurance file will be maintained by LimnoTech containing all QA/QC related information. A back up of all computer files containing important project information will also be maintained.

Documents to be generated by field activities include staff notes, field logs, equipment logs, field on-site measurement data sheets, field audit reports, chain of custody forms. Documents to be generated by laboratory activities include QA/QC reports, laboratory bench sheets, laboratory results, and laboratory audit reports. These documents will be included in project reports.

At the conclusion of the project, relevant information from the project files and electronic files will be turned over to DELCORA to be archived.

2.6.2 Model Files

The development, calibration and corroboration of the Water Quality Model will be documented in a Water Quality Model Report. This report will be submitted to EPA and PADEP within 60 days after this Water Quality Model Work Plan is approved and fully implemented. The project report will include discussions of the data collected during the WQMP, additional data analyzed and used to support the modeling, model development and calibration processes and the calibration and corroboration. An initial draft of the report will be prepared for internal review. After this internal review is complete, the draft report will be edited accordingly and then delivered to the EPA and PADEP for their review. The final report will then be prepared.

A daily back up of all computer files containing important project information will also be maintained on LimnoTech's computer network. No files will be maintained on individual personal computers unless they are temporary working files. All data and work products will be saved to their respective network files daily.

Documents to be generated by this project include this modeling QAPP, technical memoranda, and the draft and final project reports.

Records that will be generated during this project include model inputs and output files, model post-processing files (e.g., those produced using Microsoft Excel, databases or other data analysis software programs), and the draft and final Water Quality Model reports. These records will be complete and detailed enough to allow the model to be re-loaded and re-run independently with the same data sets and producing the same results.

At the conclusion of the project, all relevant information from the project files and computer disks will be archived by LimnoTech, with data, deliverables and technical records retained for at least 10 years.

Section 3 Data Generation and Acquisition (Group B)

This section of the Quality Assurance Project Plan (QAPP) addresses quality assurance/quality control (QA/QC) elements related to the monitoring activities. The monitoring program QAPP was developed based on U.S. EPA requirements (EPA, 2001) following U.S. EPA guidance (EPA, 1998).

3.1 Sampling Process Design (B.1)

As described in the previous section, dry weather and wet weather monitoring will be conducted at six tributary in-stream locations, five Delaware River locations, and up to ten CSO and stormwater outfall locations. The sampling process design is discussed in the Water Quality Monitoring Work Plan portion of this Work Plan.

3.2 Sampling Methods (B.2)

SOPs will be employed to provide consistency and reproducibility to the sampling methods used by field personnel. The following sections present or reference the detailed methods for performing sampling activities, including related support procedures for equipment cleaning, field measurements, and calibration and maintenance of field instruments. Sample custody procedures are presented in the Sample Handling and Custody Section of this QAPP. For all sampling related procedures, personnel will use personal protective equipment as required by the Field Safety Instructions for the WQMP.

3.2.1 Surface Water Sample Collection

Surface water and outfall grab samples will be collected as specified in the WQMP Work Plan and/or according to the SOP.

3.2.2 Field Water Quality Measurements and Monitoring

Instantaneous water quality measurements (such as temperature, conductivity, and salinity) and depth data using field instruments will be collected as specified in the WQMP Work Plan and according to the standard operation procedures. All data generated is recorded for transfer to the project files.

3.3 Sample Handling and Custody (B.3)

Sample handling will be performed to collect, store, submit to the laboratory and obtain representative samples using methods as specified in the work plans and according to the SOPs. Sample containers, volumes, preservatives and holding times are summarized in Table 2-6. Proper sample handling and custody procedures will be employed as discussed in the following subsections of this QAPP.

3.3.1 Field Sample Custody

The objective of field sample custody is to ensure that samples are traceable and are not tampered with between sample collection and receipt by the analytical laboratory. A person will have custody of a sample when:

- The person is one of the authorized personnel;
- The sample is in their physical possession;
- The sample is in their view after being in their possession;
- The sample is in their personal possession and secured to prevent tampering; and
- The sample is in a restricted area accessible only to authorized personnel.

Field custody documentation will consist of both field log books and chain of custody forms.

Chain-of-Custody Forms

Completed chain-of-custody forms will be required for all samples to be analyzed. Chain-of-custody forms will be filled-out by the field sampling crew during the sample collection events. The chain-of-custody form will contain the following information for each sample:

- Unique identification number;
- Sample date and time;
- Sample description;
- Sample type;
- Sample preservation (if any);
- Analyses required.

The original chain-of-custody form will accompany the samples to the laboratory. Copies of the chain-of-custody form will be made prior to shipment for separate field documentation. The chain-of-custody forms will remain with the samples at all times. The samples and signed chain-of-custody form will remain in the possession of the sampling crew until the samples are delivered to the courier or to the laboratory.

Sample Packing and Shipping Requirements

Sample packaging and shipping procedures are designed to ensure that the samples and the chain-of-custody forms will arrive at the laboratory intact and together. Samples will be properly packaged for shipment according to the SOPs and submitted to the appropriate laboratory for analysis. Shipping containers will be secured with strapping tape and custody seals, if required, for shipment to the laboratory. The cooler is strapped shut with strapping tape in at least two locations.

All shipments will be accompanied by the chain-of-custody form identifying the contents. It is preferred that a separate chain-of-custody form be completed for and placed in each shipping container. The original form will accompany the shipment and copies will be retained by the sampler for the sampling office records.

3.3.2 Laboratory Sample Custody

Laboratory sample custody will be performed in accordance with the laboratory's Quality Assurance Manual (QAM), consistent with the guidelines set forth in this section of the QAPP, and/or compliance with laboratory accreditation requirements specified in 25 Pa. Code Chapter 252 .

The laboratory must have written SOPs for sample custody to protect the integrity of the samples, including, but not limited to:

- Sample receipt and maintenance of custody;
- Sample storage; and
- Sample tracking.

Sample Receipt and Maintenance of Custody

The laboratory shall have written procedures that document receipt of all sample containers and maintain chain of custody. Although a designated sample custodian responsible for receipt of samples is preferable, it is not required provided the laboratory has procedures for handling environmental samples, including

- Procedures for checking and recording the thermal and/or chemical preservative and sample container(s);
- Use of a record-keeping system that documents receipt of all sample containers that includes pertinent sample and laboratory information describing each sample; and,
- A sample acceptance policy that clearly outlines the circumstances that samples can be accepted or rejected. Departures from acceptable circumstances will be noted to be discussed with the Field Manager.

Sample Storage

After samples are received, they are placed in secure storage in accordance with the individual method requirements referenced by U.S. EPA or Standard Methods (e.g., maintained at less-than-or-equal-to six (6) degrees Celsius).

Consistent with 25 Pa. Code Chapter 252 and/or the National Environmental Laboratory Accreditation Program (NELAP), the laboratory will have documented procedures describing storage areas for samples in the laboratory, and steps taken to prevent sample contamination.

3.4 Analytical Methods (B.4)

The following section details the aspects of the analytical requirements, ensuring that appropriate analytical methods are employed. Appendix A includes the laboratory Quality Assurance Program and Appendix B includes the Standard Operating Procedures (SOPs) of the laboratory subcontractor. Table 2-6 summarizes the analytical methods to be used by the laboratory.

3.4.1 Parameter Specific Information

Table 3-1 displays the required container type, sample volume, preservation, and hold time for each parameter according to the previously referenced methods. The contract laboratory will provide sample containers from a commercial supplier. Sample containers will be new and pre-cleaned by the supplier. In addition, the contract laboratory will provide sample labels for each bottle and add the required preservative for each parameter, if necessary.

Table 3-1: Guidelines for Sample Container Preparation and Preservation.

Parameter	Container	Volume	Preservative	Holding Time
E. coli	Plastic	100 ml	$Na_2S_2O_3$	8 hours[1]
Fecal coliform	Plastic	100 ml	$Na_2S_2O_3$	8 hours[1]
Enterococcus	Plastic	100 ml	$Na_2S_2O_3$	8 hours[1]

Notes:
[1] The desired hold time, 8 hours, is shown in Table 3-1. Laboratory Chain of Custody Procedures

3.4.2 Laboratory Chain of Custody Procedures

Use of the chain-of-custody form will terminate when laboratory personnel receive the samples and sign the form. The laboratory custodian will open the sample coolers and carefully check the contents for evidence of leakage and to verify that samples were kept on ice. The laboratory will then verify that all information on the sample container label is correct and consistent with the chain-of-custody form. Any discrepancy between the sample bottle and the chain-of-custody form, any leaking sample containers, or any other abnormal situation will be reported to the Laboratory Manager or his/her designee. The Laboratory Manager will inform the Field Manager of any such problem, and corrective actions will be discussed and implemented.

3.4.3 Analytical Records

The analytical data results and a case narrative will be submitted by the contract laboratory to the Water Quality Monitoring and Modeling Project Manager in an electronic format within a specified time frame from the completion of each sampling event (dry and wet weather). A summary of the laboratory QC results (see Table 2-6 for QC measures and Table 4-1 for QC frequency) generated during the analysis of the samples will be submitted to the Water Quality

Monitoring and Modeling Project Manager in an electronic format. This file will include the accuracy (method blank, presence/absence control results) and precision (replicate RPDs) quality control results (e.g. +/-,and RPDs). Also, the laboratory will maintain copies of all bench sheets generated during the processing of these samples and data sheets that include sample identification information that can be provided as requested by LimnoTech for every sample analyzed.

3.5 Quality Control (B.5)

Analytical quality control will be performed in accordance with the specified analytical methods and as discussed under the Quality Objectives and Criteria Section of this QAPP.

3.6 Instrument/Equipment Testing, Inspection, and Maintenance (B.6)

Field analytical equipment that may be used in this project includes instruments for measuring depth, salinity, conductivity, and temperature, and instruments for collecting water samples. These may be handheld instruments or autosamplers. Testing, inspection and maintenance will be conducted in accordance with manufacturer instructions. Preventative maintenance will be conducted as needed according to the SOPs.

Laboratory instrumentation and equipment testing, inspection and maintenance will follow manufacturer instructions and/or accepted procedures associated with the selected analytical methods, the laboratory's QAM and SAPs.

3.7 Instrument/Equipment Calibration and Frequency (B.7)

Calibration procedures for field equipment will follow manufacturer instructions. To maintain field precision and accuracy, the water quality instruments will be calibrated to known standards.

Laboratory instrument calibration will follow manufacturer instructions and accepted procedures associated with the selected analytical methods, the laboratory's QAM and SAPs.

3.8 Inspection Acceptance of Supplies and Consumables (B.8)

All supplies and consumables for field and laboratory activities will be inspected for compliance with the acceptance criteria by the identified responsible party prior to use. Supplies or consumables not meeting the acceptance criteria upon inspection will not be used. Supplies and consumables will be stored in accordance with individual method requirements referenced by U.S. EPA or Standard Methods.

3.9 Data Acquisition Requirements (Non-direct Measurements) (B.9)

Non-direct measurements will not be used in implementation of the monitoring program.

As described in Section 2.4.2.3, LimnoTech will evaluate multiple CSO control alternatives using the EFDC Water Quality Model. These activities will involve the use of secondary data from

multiple sources, including federal and state databases, peer-reviewed papers, and modeling results. Many of the state and federal datasets have undergone rigorous QA/QC prior to being released for public use. Other data comes from peer-reviewed sources that have also undergone internal QA/QC checks. LimnoTech has extensive experience in dealing with these types of data sources and will review and document the data sources, quality, completeness and appropriateness for use of all data to be considered for this project prior to their use in developing the Water Quality Model.

As described in Section 2.4, the data to be used for this project will be judged acceptable for their intended use if they conform to the DQOs and criteria. Data will be:

- accepted if they pass the screening criteria;
- qualified if the data do not pass the initial screening but the discrepancy is within the range of uncertainty for a given analytical method; or
- rejected.

Limitations in non-direct measurements identified through application of the acceptance criteria will be addressed by either using the data while identifying the implications of its limitations on the study results or, for non-critical non-direct measurements that do not pass acceptance criteria, conducting the tasks or analyses without the use of those non-direct measurements. Any limitation to the use of data and subsequent interpretation of study results will be reported in the final project report.

3.10 Data Management (B.10)

Data generated through field and laboratory activities will be used for developing models and reports. Reporting formats will vary depending on the purpose for which the data has been assembled. The Water Quality Monitoring and Modeling Project Manager has the responsibility of maintaining documents and data associated with field programs. The Laboratory Manager has the same responsibility for laboratory data and information.

3.10.1 Field Data and Information Management

Field data reporting shall be conducted principally through the transmission of data sheets containing tabulated results of all measurements taken in the field, and documentation of all field calibration activities. Copies of the field logs will be turned over to the Field Manager following each monitored event. Following review by the Field Manager, the field logs will be transmitted to the Quality Assurance Officer (QAO) for review and inclusion in the project's data management system. The QAO will transmit the field sheets to the appropriate Project Manager for his/her keeping after their review. Specific QA/QC procedures, including data and records management and QA audits, will be conducted according to the SOPs.

3.10.1.1 Field Logs

The field logs will serve as a daily record of events, observations, and measurements during field activities. All information pertinent to sampling activities will be recorded in field logs. Personal computers may also be used to record field data. Field logs will be maintained by field staff at all times documenting activities and conditions. A copy of the field logs will be turned in by field staff following each monitored event. Copies of all field logs will be made following each monitored event and maintained in the QA/QC project file. Field logs will include the following:

- Names of field crew and specifically the author of the field log
- Date and time of the sample round beginning and ending
- Location of sampling activity
- Date and time of sample collection
- Sample identification numbers
- Field measurements
- Field observations and details related to analysis or integrity of samples (e.g., weather conditions, noticeable odors, colors, stream flow description, etc.)

3.10.1.2 Equipment Logs

As installation, calibration and maintenance functions are completed on equipment, equipment logs will be maintained and included in the QA/QC project file.

3.10.1.3 Field On-Site Measurements – Data Sheets

Field measurement information recorded in the field log book will be compiled and the information transferred into electronic format by office staff. The Field Manager will review the source document and the electronic version to verify the accurate transfer of information. Following this review, electronic field data will be transferred to the QAO for review, then to the appropriate Project Manager for his/her keeping. The original data sheets will be maintained in the QA/QC project file.

3.10.2 Laboratory Data and Information Management

The reporting of laboratory data will begin after the Laboratory Manager or designee has concluded the verification review. The contract laboratory will prepare and submit full analytical and QC reports to the Project Manager that will include the following, as appropriate.

- Case narrative, including a statement of the conditions that samples were received, description of any deviation from standard procedures, explanation of any data qualifiers used, and identification of any problems encountered during analysis.

- Computer-generated report form containing all sample results in the forms of
  - a hard copy version of the report, and
  - an electronic version of the report.
- Hard copy and electronic QC summary report for each parameter by batch including the results of replicates, matrix spikes, matrix spike duplicates, controls, dilution blanks, method blanks, verification tests, etc.
- Copies of all laboratory bench sheets (upon request).
- Copies of all chain-of-custody forms.

Following receipt of laboratory data by the Project Manager, the data will be reviewed and validated by the Quality Assurance Officer following the procedures outlined in Section 4.

3.10.3 Electronic Data Management

All data collected during the course of the study will be entered into a database by LimnoTech for use in the modeling tasks. LimnoTech will manage and maintain the database. All electronic files will be backed up on a regular basis. At the conclusion of the project, relevant information, project files and electronic data will be turned over to Greeley and Hansen. The files will be archived for a minimum of ten years.

3.10.4 Model File Management

Data used during the project will be maintained in electronic format in a centralized project database. Manipulation of the downloaded data is identified as one of the major preventable error sources in the project effort. User-induced error can be identified and corrected under an appropriate level of QA/QC. Multiple steps will be taken to ensure errors are minimized. Data formatting will be reviewed, including the data element type, format, allowable values and ranges, and other parameters. Any manually entered parameter values from paper sources will be evaluated by reviewing hard copy printouts. The review will include a comparison of the original data sources and paper documentation. Any record identified as having issues will be reviewed to determine whether corrected data can be acquired or the record omitted. The project database will be used as a central repository for the data that will be used in model development and calibration.

The management of model code, input files, and output will be handled electronically. All input files are either contained within a specified format in a text file, or contained in an Excel file that is used to keep track of key time series forcing functions. Each set of model runs (input/output files) will be contained within a unique folder identified by a run ID. A log of every model run will be documented and maintained by LimnoTech, and will be a part of the project records. The run log will identify the run and include a brief description of the specifics of the model run.

3.10.4.1 Hardware/Software Configuration

The EFDC Water Quality Model is available as a Windows platform compatible executable. The minimum requirements of the model are easily met by any modern desktop PC. The input files required to run the model are contained in simple text files that can be viewed or edited with any simple word processing software (e.g. Notepad or Wordpad). Pre- and post-processing capabilities are available through several Microsoft Excel files. Any recent Microsoft Excel software (Excel 2007 or later) is capable of viewing and editing the additional processing files. The pre- and post-processors facilitate the writing and reading of the input and output files. In this configuration two copies of the model inputs and results always exist (in the text file and in the Excel file).

LimnoTech use a Microsoft Outlook-based email server for secure electronic communications, and secure access to networked file storage devices is provided for remote employees through the use of Virtual Private Network (VPN) protocols. These means of electronic communications and connectivity (for file transfers and backup) are expected to be secure for the needs of this project. No additional security measures are planned at this time.

Page intentionally left blank for double-sided printing

Section 4 Assessment and Oversight (Group C)

The Group C Assessment and Oversight elements are addressed in this section.

4.1 Assessment and Response Actions (C.1)

Internal quality control checks are performed to ensure that the field and laboratory generated measurements meet the project quality assurance objectives. In addition, the quality control checks are intended to identify any need for corrective action.

The EFDC Water Quality Model will be specifically developed to investigate CSO control alternative scenarios for the waterways tributary to the DELCORA service area. The development, calibration, and validation of the EFDC Water Quality Model will be performed as part of this project, as described in the preceding sections of this QAPP.

If potential quality assurance issues are identified following model calibration and/or scenario application, corrective actions required to address these issues will be performed by the modeling team. The LimnoTech Water Quality Model Task Leader and Project Manager will be responsible for ensuring that identified corrective actions are implemented. The modeling team will document these activities as they occur, and the information will be maintained by the project team. This documentation will be included in the project records.

The LimnoTech Water Quality Model Task Leader and Project Manager will review the modeling work conducted for this project, including model results and documentation of the modeling effort to ensure that a scientifically credible product is produced. The modeling team will address technical issues identified from these reviews.

If the review results in detection of unacceptable conditions or data, the LimnoTech Water Quality Model Task Leader will be responsible for developing and initiating corrective action. Staff will be notified if the nonconformance relates to their work. Corrective response actions may include review or validation of data, performing additional model runs, or editing and modifying report deliverables. Determination of the appropriate corrective response will be coordinated by the LimnoTech Project Manager and Water Quality Model Task Leader. Decisions will be documented in the Water Quality Report. LimnoTech will meet all QA requirements prior to approval of the final deliverables.

4.1.1 Field Measurements

Field quality control checks will consist of QA/QC samples that will be collected or prepared by the field crews to be submitted for laboratory analysis. These samples will consist of duplicates/replicates, and field blanks. Each sampling crew will collect a field duplicate per sampling crew, and blanks will be collected at a frequency of one blank per sampling crew during each sampling event. The acceptable control limits are discussed in Section 2.4. Upon receipt of

the data from the monitored event, the Field Managers will assess the adequacy of the quality control checks and identify any problems.

Quality control checks will be conducted in advance of using multi-parameter meters. The checks will involve the review of the previous calibration sheets. Any problems with sensors will be addressed immediately. The result of each review will be recorded on the instrument's calibration sheet. At the conclusion of each monitored event, all calibration sheets will be reviewed by the Field Crew Manager and the Field Manager to assess the adequacy of the quality control checks and to review the instrument's performance to identify any problems.

The Field Manager will inform the Monitoring Task Manager and the Project Manager in writing of any quality control check issues and to discuss corrective actions. All quality control documents will be contained in a file for each monitored event.

4.1.2 Laboratory Measurements

The contract laboratory will perform quality control checks as described in this QAPP. These will include replicates, control samples, and method blanks as appropriate. Quality control procedures for analytical services will be conducted by the contract laboratory in accordance to their standard operation procedures and the individual method requirements referenced by U.S. EPA or Standard Methods. The acceptable control limits for this project are discussed in Section 2.4. The Laboratory Manager or designee will inform the QA/QC Manager immediately of any quality control check issues and to discuss corrective actions.

At the conclusion of each monitored event, the contract laboratory will provide a summary of all QA/QC results. The QA/QC summary will be reviewed by the Laboratory Manager or designee and the QA/QC Manager to assess the adequacy of the quality control checks and to identify any potential problems. Table 4-1 summarizes the laboratory quality control check frequencies.

Table 4-1: Laboratory Quality Control Check Frequencies.

Parameter	QC Check	Frequency
E. coli	Positive/Negative Controls[1]	See footnote 1
	Replicate[3]	20 samples[3]
	Method Blank[2]	See footnote 2
Fecal coliform	Positive/Negative Controls[1]	See footnote 1
	Replicate[3]	20 samples[3]
	Method Blank[2]	See footnote 2
Enterococcus	Positive/Negative Controls[1]	See footnote 1
	Replicate[3]	20 samples[3]
	Method Blank[2]	See footnote 2

Notes:

[1] The frequency for analysis of the bacteria controls can be done at the option that occurs most often: 1) new media lot; 2) one set per event; 3) one set per month.

[2] Method blank frequency depends on the analytical method but the recommendations include, to the extent applicable: 1) check of dilution water; 2) when a low concentration sample (e.g. Delaware River) is analyzed using the same filter apparatus after a high concentration sample (e.g. CSO or SW sample); 3) at the start of a new batch of samples.

[3] When sample volume allows, the replicate should be a DELCORA sample.

4.1.3 System Audits and Technical Reviews

All project team members are committed to providing quality services. The primary responsibility for the quality of work products rests with the individuals doing the work and with their immediate supervisors.

For certain project components an independent technical reviewer will audit or review the work products. This reviewer may be the Monitoring Task Manager or a consultant team member not directly involved with the work being audited. The independent technical reviewer will perform a critical, written evaluation of the work product, and the independent technical audit or review will be incorporated in the project record.

The Monitoring Task Manager is responsible for identifying the work products to be audited/reviewed and the scope of the audit/review, for scheduling independent technical audits/reviews, for assigning competent, qualified independent technical auditors/reviewers, and for making sure that appropriate follow-up actions are taken to correct reported deficiencies.

4.1.3.1 Field System Audits

Field system audits will be completed to ensure that the actual field procedures conform to those documented in the SAP and associated SOPs. The Project Manager or designee will perform the

field system audits. The audit will include a check of all field records and a review of all activities to document if procedures were conducted in compliance with the specified documentation.

4.1.4 Corrective Action

Corrective actions will be implemented as required to rectify problems identified during the course of normal field and laboratory operations. Possible problems requiring corrective action include:

- Equipment malfunctions;
- Analytical methodology errors; or
- Non-compliance with quality control systems.

Equipment and analytical problems that require corrective action may occur during sampling and sample handling, sample preparation, and laboratory analysis.

For non-compliance problems, steps for corrective action will be developed and implemented at the time the problem is identified. The individual who identifies the problem is responsible for immediately notifying the Field Manager.

Any non-conformance with the established quality control procedures outlined in the QAPP will be identified and corrected. The Field Manager will issue a Corrective Action Memorandum for each non-conformance condition. All non-conformance memoranda will be discussed in the final report submitted to the Project Manager.

4.1.4.1 Field Measurements and Sample Collection

Project staff will be responsible for reporting any suspected QA non-conformance or deficiencies to the Field Manager. The Field Manager will be responsible for assessing the suspected problems in consultation with the Monitoring Task Manager to review the sampling protocols and provide additional training if necessary. If it is determined that the situation warrants a corrective action, then a Corrective Action Memorandum will be issued by the Field Manager.

The Field Manager will be responsible for ensuring that the corrective action for non-conformance takes place by:

- Evaluating all reported incidences of non-conformance;
- Controlling additional work on nonconforming items;
- Determining what corrective action is needed;
- Maintaining a log of non-conformance issues;
- Reviewing responses to corrective action memoranda;
- Ensuring that copies of corrective action memoranda and responses are included in the project files

No additional work will be performed until appropriate corrective action has been implemented and documented in response to the corrective action memoranda.

4.1.4.2 Laboratory Analyses

Corrective actions are required whenever laboratory conditions, instrument malfunction or personnel situations have led or could potentially lead to errors in the analytical data. The corrective action taken will be dependent on the analysis and the event.

Laboratory personnel are alerted that corrective actions may be necessary if:

- QC data are outside the acceptable range for precision and accuracy as identified in Section 2 ;
- Blanks contain target analyses above acceptable levels;
- Undesirable trends are detected in spike recoveries or RPD between duplicates;
- Excessive interference is noted; or
- Deficiencies are detected by the QA staff during laboratory system audits as described in Section 4.1.3.

Corrective action procedures are often handled at the bench level by the analyst, who reviews the preparation or extraction procedure for possible errors, checks the instrument calibration, spike and calibration mixes, and instrument sensitivity, etc.

Corrective action taken within the laboratory is the responsibility of the Laboratory Manager who informs the Monitoring Task Manager when a problem occurs and of the steps taken to resolve the problem. All non-conformance memoranda initiated by the contract laboratory will be discussed in the case narrative or included in the laboratory reports.

4.2 Reports to Management (C.2)

The Monitoring Task Manager and Laboratory Manager provide independent reporting to the Project Manager on an as needed basis. This communication is facilitated through the use of electronic mail, which provides ready access. In addition, the team leaders will provide written reports to the Project Manager on quality assurance issues as described in the QAPP.

Field and laboratory system audits will be performed as described in Section 3.1.3 and the results will be provided to the Project Manager. The results of all audits will be summarized in written reports, with copies retained in the Project Files. The audit reports will be completed for field and laboratory system audits according to the general outline described below.

All audit reports will include the following sections:

- Introduction – provides background of the project, laboratory, or program element, description of personnel and affiliation of all staff involved, the name of the auditor, the time and date of the audit, and a description of the activities audited.

- Audit Findings – describes the results of the audit including a deficiency report identifying all instances where the procedures in the SAP, QAPP, or laboratory QAM were not followed.
- Conclusions – summarizes the results of the audit and includes recommended actions to address any noted deficiencies.

The delivered documents and associated data will be accurate, complete, and traceable. The LimnoTech Water Quality Model Technical Leader and Project Manager will also provide independent reporting via emails on quality assurance issues to Greeley and Hansen and DELCORA on an as needed basis. Communication will be initiated concerning any of the following:

- Adherence to project schedule and budget;
- Any deviations from the QAPP;
- Potential uncertainties in decisions based on model predictions and data; or
- Data quality assessment findings regarding input data and model outputs.

Monthly project status reports will be prepared and delivered with monthly invoices. The status reports will describe (by task) activities during the previous month, and upcoming anticipated activities. The Water Quality Model report will document all aspects of the project.

Section 5 Data Validation and Usability (Group D)

The Group D Data Validation and Usability elements are addressed in this section. The purpose of these elements is to determine if the data meet the project's Data Quality Objectives (DQOs) (validation) and to evaluate the data against the method, procedural and/or contractual requirements (verification). Data validation, verification, and usability assessment will be conducted as outlined in this QAPP.

The data generated from the sampling program will be subjected to a multi-tiered review process described below. This process includes:

- A review of the data at the bench and field levels;
- A secondary review of field records by the Field Managers and analytical results within the laboratory by the QA/QC Manager to verify the data against method and SOP requirements;
- A screening level review of the verified data by the Monitoring Task Manager for reasonableness and to identify obvious data anomalies;
- A validation by an objective third party; and finally,
- An assessment of the data by project team members for its usability in the project as described in Section 5.1 of this QAPP.

5.1 Data Review, Verification and Validation (D.1)

All environmental measurement data collected by project staff will be subjected to quality control checks before being utilized in the interpretive reporting. A data generation system that incorporates reviews at several steps in the process is designed to protect the integrity of the data and reduce the number of data that do not meet the DQOs or the project goals. This section describes the requirements of each review step that will be used in this project.

5.1.1 Data Verification Requirements

The definition of data verification, as described in the EPA's "Guidance on Environmental Data Verification and Data Validation" (EPA QA/G-8) is:

> "…the process of evaluating the completeness, correctness, and conformance/compliance of a specific dataset against the method, procedural or contractual requirements."

Data verification will occur at the field and laboratory level as described in Section 2.4. This section describes the requirements of the data verification.

5.1.1.1 Field Activities Data Verification

The Field Manager will be responsible for ensuring that the samples are collected and handled according to the procedures specified in the Water Quality Monitoring Work Plan. Sample collection verification will include confirming that the samples were collected with the proper equipment at the appropriate locations with the appropriate frequency. Sample handling verification will include confirming that the samples were stored in the appropriate containers (see Table 3-1) with the correct preservative, that the samples were stored at the proper temperature during transport from the field to the laboratory, and that all of the appropriate information is logged on the chain-of-custody records.

5.1.1.2 Lab Activities Data Verification

The laboratory QA/QC Manager will be responsible for verification of laboratory-generated data, although the laboratory SAPs for each method require some components of the verification to also be conducted at the bench level. Laboratory verification will include assessing that the procedures used to generate the data are consistent with the method requirements as specified in the laboratory's SOPs and that the QA/QC requirements for each method are met. Examples of method requirements include verifying the calibration and data reduction procedures. However, these requirements vary by analyte and are presented in more detail in the laboratory's QAM and SOPs (Appendices A and B, respectively). Once the data have been verified and approved by the laboratory, they will be released to the Monitoring Task Manager.

5.1.2 Data Review Requirements

The Field Manager will perform data reviews consisting of screening the field and laboratory data sheets according to established criteria listed in this section. If the established screening criteria are violated, an additional review of the quality control checks and any relevant laboratory bench sheets will be conducted. The investigation of the issue will be documented and the data will be discarded or flagged appropriately, identifying the limitations of the data. This is an additional step of review that is designed to provide an early assessment of the data's use in meeting the project goals by evaluating it within the context of well-understood constituent relationships.

5.1.2.1 Field Data Sheet Reviews

The following criteria will be used to screen the recorded physical parameter measurements:

1. Salinity readings – do values seem reasonable?
2. Temperature readings – do values seem reasonable?
3. Conductivity readings – do concentrations seem reasonable?

5.1.2.2 Laboratory Data Sheet Reviews

The following criteria will be used to screen the analytical measurements performed by the contract laboratory:

1. Equipment blanks – are values less than detection limits?
2. Method blanks – are values less than detection limits?
3. Field blanks – are values less than detection limits?
4. Review of all values – do concentrations/densities seem reasonable?

5.1.3 Data Validation Requirements

The purpose of data validation, as described in the EPA's "Guidance on Environmental Data Verification and Data Validation" (EPA QA/G-8) is:

> "…an analyte- and sample-specific process that extends the evaluation of data beyond method, procedural, or contractual compliance to determine the analytical quality of a specific data set."

According to U.S. EPA guidance, the data validation is typically performed by someone independent of the project activity and not associated with the organization responsible for producing the dataset. However, the data validator needs to be familiar with both the data validation requirements and the project objectives. The identified QAO from LimnoTech will conduct the data validation.

The first requirement in this project's data validation is to inspect the data verification and review records to ensure that no oversights were made during that process. The second requirement of the data validation is to evaluate the data against the project's DQOs, which are presented in Section 2.4. If data do not meet one or more of the DQOs, the data validation process will include an investigation into causes and an assessment of the impact of the noncompliant data on project objectives. The third requirement of the data validation is to evaluate the data in the context of the project's overall objectives, which are described in Section 2.1. The fourth requirement of the data validation is to communicate the data validation results to the rest of the project team.

5.2 Verification and Validation Methods (D.2)

All environmental measurement data and samples collected by project staff will be subjected to quality control prior to being entered into the project database. This is a multi-step process where the laboratory QA/QC Manager will have primary responsibility for verifying the data and a third party, who is not involved in the data collection or analysis, conducts the data validation. These steps are described in more detail in the following sections.

5.2.1 Data Verification

This section describes the procedures that will be utilized in this project for verifying the data against method, procedural and/or contractual requirements.

5.2.1.1 Field Activities Data Verification

Individual crew leaders will verify the completion of their field data sheets and chain-of-custody forms. In addition, crew leaders will also verify the proper calibration and operation of their multi-parameter instruments. At the completion of each monitored event, the Field Manager will review all field data sheets, calibration sheets, and chain-of-custody forms for accuracy and completeness. The Field Manager will also verify that monitoring QA objectives for all accuracy, precision, completeness, and adherence to the required collection techniques are being met.

5.2.1.2 Laboratory Analytical Results Verification

Individual analysts will verify the completion of the appropriate analytical test and required bench sheets. The Laboratory Manager or designee will review calculations and inspect laboratory bench sheets and log books daily to verify their accuracy, completeness, and adherence to the specified analytical method protocols. Calibration and QC data will be examined daily by the individual analyst. The Laboratory Manager or designee will verify that all instrument systems are under control and that QA objectives for accuracy, precision, completeness, and adherence to the required detection limits are being met.

A summary of all QA/QC results and any non-conformance issues will be included in the laboratory deliverable to the Field Manager.

5.2.2 Data Validation

This section describes the process that will be used to validate the data generated for this project. The first requirement in this project's data validation is to inspect the data, verification and review records to ensure that no oversights were made during that process. A complete set of field and laboratory information will be provided to the data validator for this task. The data management components described in Section 3.10 will be sufficient for this purpose.

The primary objective of the data validation in this project is to evaluate the data against the DQOs presented in Section 2.4. These DQOs include criteria for accuracy, precision, completeness, representativeness, comparability and compliance with required detection limits. The data management components described in Section 3.10 will provide the necessary information to make this evaluation. The following must be checked as part of the measurement data and analytical data validation activities.

1. field measurements data collection
2. field sample collection

3. sample custody
4. laboratory analytical results and case narrative
5. data reviews
6. quality control data

The QAO will conduct a systematic review of the data for compliance with the established quality control criteria based on duplicate, replicate, spiked, control, and blank data results provided by the laboratory. In addition, quality assurance evaluations of data accuracy, precision, and completeness will be performed on the field measurement data and the laboratory analytical results for each monitored event. The data validation qualifiers listed in Table 5-1 will be used when validating the data:

Table 5-1: Data Validation Qualifiers

Qualifier	Definition
U	The material was analyzed for, but was not detected above the level of the associated value. The associated value is either the sample quantitation limit or the sample detection limit.
J	The associated value is an estimated quantity.
R	The data are unusable (note: analyte may or may not be present)
UJ	The material was analyzed for, but was not detected. The associated value is an estimate and may be inaccurate or imprecise.

If quality control checks or objectives were not met, an investigation of the non-conformance will be initiated by the QAO with the project team personnel, including the Field Manager, the laboratory QA/QC Manager, and the Project Manager. The non-conformance will be documented and the affected data set will be flagged appropriately, identifying any limitations.

Another objective of the data validation is to evaluate the data within the context of the project goals. As described in Section 2, these goals include providing datasets that can be used to develop model inputs, to calibrate and validate the models, and to ensure consistency among different sources of data. Suitable datasets for the modeling portion of this project will be based on the data quality assessment described above as well as an assessment of the spatial and temporal extent of the sample collection. Comparability with other sources of data will be evaluated by comparing and, if necessary, plotting the data with previously collected data to identify outliers or anomalous values.

The data validation results will be communicated to the project team in the form of a summary table that lists the validation tasks performed and the associated results and conclusions. If the validated dataset includes non-compliant data, this data will be addressed in a memo that accompanies the summary table. Data qualifiers assigned to the data during validation will be maintained in the project database to ensure communication of validation results with current and future data users.

5.3 Departures from Validation Criteria

This section describes the process to assess the usability of model results. All interim and final model results will be evaluated by the LimnoTech Principal Investigator.

Criteria will be established to decide whether to accept, reject, or qualify the data collected for the project and generated by the model. This work is done by adopting validation and verification criteria. Validation criteria specifies whether data satisfy user requirements, and verification criteria determine if data are sufficient for drawing data quality conclusions and project objectives. For all data, sufficient metadata must be available to allow persons unfamiliar with the data to make intelligent use of them. All data will be reviewed for usability, general quality, and consistency with other available data sources, prior to use in the modeling activities. Limitations in the data sets will be acknowledged and included in discussions of their use. All data entered manually or electronically will be confirmed by checking the source data.

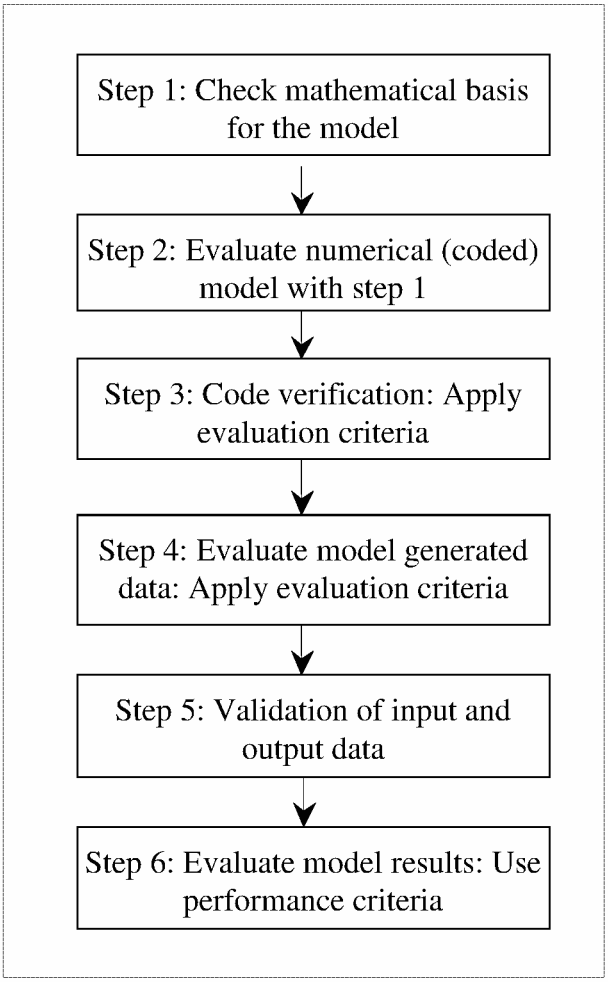
Qualified data will be examined on a case by case basis relative to including it in calculations. The decision to include qualified data will depend on a sensitivity analysis of the effect of uncertainty in the data on the calculation outcome. The data review and compilation task will be performed by experienced personnel.

With regard to the use of data in the modeling, each data set will be categorized according to validation criteria into different groups by its usability, as described in Section 3.2. The categories will include:

- Accepted (results can be used without any restrictions);
- Qualified (acceptable under certain conditions) – the team will specify conditions and provide the validation and usability of the results to satisfy the project objectives; and
- Rejected (cannot be used; will identify the problems and reasons for unsuitability).

The acceptance criteria for the modeling process includes evaluation of the model at various stages of the process as described in Figure 5-1. Model simulations will be compared with an independent data set that was not used for model development and model calibration purposes. Evaluations will be done by comparing plots of data and model predictions. These plots will not only provide the quantitative estimates, but will also provide qualitative assessments. As information is passed from one step of the modeling process to another, different assessments will be planned to determine if they are acceptable to pass on to the next phase. The individual assessments of the steps identified in Figure 5-1 will provide the basis of the overall assessment. The modeling team will discuss all issues identified pertaining to these criteria, alert the LimnoTech Project Manager and Water Quality Model Technical Leader about any identified issues, and will document any procedures used to resolve them. In general, judgments on the accuracy of the model results will be made by comparing the simulated results with previous results that have been peer reviewed, and with observed trends in the data. If the model results do not compare well, the inputs will be reexamined and the model will be run with adjusted inputs if needed.

Figure 5-1: Criteria for Various Stages of Modeling Process



All project deliverables will undergo in-house review and validation by project staff, review by the Field Manager Task Leader, Water Quality Model Task Leader and the Project Manager, and review by Greeley and Hansen.

5.3.1 Validation Methods

The model input data and model results will undergo extensive review for quality control by the project staff, Principal Investigator and Project Manager. As described in Section 4.1, model runs that are used to generate final results will be compared against model results from previous scenario runs to ensure consistent results. Any deviations from previous model runs will be noted and investigated to ensure that the model predictions are accurate and reasonable.

Data used for inputs will be evaluated for adequacy in terms of the common data quality indicators, such as precision, accuracy, comparability, representativeness, and completeness. Judgments on the accuracy of the data will be checked by comparing the data trends and by comparing data with any historical data available. Each data set will be categorized in different groups by its usability, as described in Section 2.4.

The project team is responsible for establishing and maintaining the QA/QC processes outlined in this QAPP to ensure the quality of the project data. The modeling team will discuss all the issues identified pertaining to available data, alert the LimnoTech Project Manager, Water Quality Monitoring and Modeling Task Leaders and Quality Assurance Manager about any identified issues, and will document in the final report the procedures used to resolve them.

5.3.2 Reconciliation with User Requirements (D.3)

Once all field measurements and analytical data have been reviewed, quality control measures assessed, and any problems addressed, the measurement and analytical data will be assessed.

The assessment of the information generated from the monitoring program will be initiated by entering all analytical data and field measurement data into the project database. In addition, precipitation, flow data, velocity data, stage data, field notes, and information on any sampling anomalies will be appended. All of these data will be evaluated and any relationships or correlations will be noted. The compilation of all information surrounding a sampling and/or monitoring event will be available to facilitate reconciliation with user requirements. Ultimately, these data will be used in the development of the watershed and water quality models.

The modeling staff, which includes the LimnoTech Project Manager, Water Quality Model Task Leader and Quality Assurance Manager, will review the model results, incorporating the uncertainty in model predictions, and will check model predictions for reasonableness and relevance based on observed data. The model development and testing are intended to ensure that if the step to develop the cause-effect relationship meets its own internal quality standards, the output of this step (i.e., the output of modeling framework) will meet the requirement for the entire project. Therefore, if the model outputs meet the internal criteria for establishing the cause-effect relationships, as described in this plan, requirements for the overall modeling framework will be met.

1.0 APPROVAL OF IMPLEMENTATION

1.1 The personnel listed on Page 1 of this document authorize the implementation of the management of this Quality Systems Manual (QSM).

2.0 TABLE OF CONTENTS

2.1 Refer to Page 2.

3.0 INTRODUCTION AND SCOPE

3.1 Introduction

3.1.1 On May 1, 2015, QC Inc. was acquired by Eurofins Scientific, a global laboratory company based in Europe, and the Company became Eurofins QC, Inc. (EQC), a solely-owned subsidiary of EQC Holdings, Inc., incorporated in the State of Delaware.

3.1.2 EQC was originally founded in 1943 as a dairy testing lab, and since that time, the Company has evolved into a full-service environmental laboratory. The Company has also expanded its product offerings to include food and pharmaceutical testing. Food, dairy, and pharmaceutical operations (collectively referred to as Life Sciences) are now located at the laboratory facility in Horsham, PA. Operations at the Southampton facility consist primarily of environmental laboratory testing and associated support functions. EQC provides analytical services to support testing under the Clean Water Act (CWA) through the National Pollution Discharge Elimination System (NPDES) and the Safe Drinking Water Act (SDWA). EQC supports homeowners and public water suppliers through the analysis of potable water governed by the National Primary and Secondary Drinking Water Regulations (SDWA), the Private Well Testing Act (PWTA) of New Jersey, and other state regulations. Laboratory testing also supports site assessments, hazardous waste determinations, remedial investigations, and other characterizations regulated by Resource Conservation and Recovery Act (RCRA), Toxic Substance Control Act (TSCA), and other state, Federal, or private programs. Accreditations held by EQC are listed in Table 1. The foremost goal of the laboratory is to provide analytical data of the highest quality that are complete, accurate, legally-defensible, and produced in an ethical and timely manner.

3.1.3 EQC also operates satellite facilities in Horsham, PA; East Rutherford, NJ; Vineland, NJ; Wind Gap, PA; Reading, PA; and New Castle, DE.

3.2 Scope

3.2.1 The QSM, previously titled Quality Assurance Program Plan (QAPP), describes measures taken to ensure that laboratory data of known and acceptable quality are provided in compliance with all regulatory requirements. More detailed procedures are contained in the laboratory's Standard Operating Procedures (SOPs), which include operation, maintenance, and quality control procedures practiced routinely in the laboratory. The QSM and SOPs function together to assure laboratory analysis of the highest quality.

3.2.2 Satellite facilities are maintained in strategically-located areas (see Section 3.1.2) and serve primarily as intermediate transfer points for samples en route to the Southampton laboratory. Samples are transferred from satellite facilities to the testing laboratories according to procedures described in SOP QC0432 (Sample Transfers between EQC's Satellite Offices and the Southampton Laboratory) and SOP QC0889 (Sample Handling Details: Addressing Sample Movement from the Field or Deliveries to the Satellite). Satellite facilities also maintain accreditation for a limited number of microbiological and field testing parameters. The EQC-Delaware satellite location is accredited for microbiological and general chemistry parameters.

3.2.3 The QSM, SOPs and other documents referenced in this manual apply to the Environmental Division laboratory operations at EQC-Southampton and its satellite facilities. A separate QSM covers Life Sciences operations at EQC-Horsham.

4.0 ORGANIZATION

4.1 Laboratory Organizational Structure

4.1.1 EQC's organization chart structure is shown in Figure 1. Floor plans of EQC's major laboratory facilities are shown as follows: Figures 2A and 2B (EQC-Southampton, PA facility), Figure 2C (EQC-Horsham, PA facility), and Figure 2D (EQC-Delaware, New Castle facility).

4.2 Responsibility and Authority

4.2.1 Support for the overall system is provided by management through the allocation of material and human resources as needed. Implementation of the quality systems described in this manual is an operational responsibility for all employees. Laboratory managers and analytical personnel are trained in the

applicable procedures and decision-making processes for which they are responsible. General oversight of the program rests with the Quality Assurance Director who reports directly to the President. Responsibilities of key personnel are described in Section 20.0 (Personnel).

5.0 MANAGEMENT

5.1 Introduction

5.1.1 The laboratory's quality management system includes documentation of policies and procedures necessary to assure the quality of the test results.

5.2 Quality Policy

5.2.1 EQC is committed and dedicated to providing analytical data of the highest quality to its clients. Data produced and reported must meet the requirements of its clients and also comply with the letter and spirit of regulations and guidelines promulgated by various municipal, state, and federal agencies. Protocols and procedures are based on approved documents developed primarily from methods and regulations issued by various federal or state agencies, e.g. the United States Environmental Protection Agency (USEPA), Pennsylvania Department of Environmental Protection (PADEP), and the New Jersey Department of Environmental Protection (NJDEP), for the analysis of multimedia samples for a broad range of inorganic, organic, microbiological, and biological constituents. EQC's quality program encompasses the requirements for producing and reporting data of known and documented quality to its clients. It is understood that data are to be used by clients to make rational, confident, cost-effective decisions regarding assessment and resolution of their environmental compliance requirements.

5.2.2 It is the policy of EQC to incorporate the highest standard of quality into all analytical programs by adhering to the following practices:

5.2.2.1 EQC will only offer environmental analyses for which it can consistently demonstrate compliance with high-quality, traceable, and legally-defensible performance standards.

5.2.2.2 All EQC personnel are committed to good professional practice and honesty in the production and reporting of data.

5.2.2.3 EQC personnel are employed by or under contract to EQC. All personnel are qualified, supervised, and trained as required by the company's quality system.

5.2.2.4 Staff who become aware of misrepresentation of facts or manipulation of data are required to immediately inform the Quality Assurance Director, Laboratory Director, or Laboratory President.

5.2.3 EQC is operated under an *Open Door Policy* that enables every employee to have free access to senior management. This *Open Door Policy* is intended to foster two-way communication, encourage ethical behavior, and identify inappropriate data production and reporting practices. It is clearly understood that such information is treated confidentially. Any undue pressures to report

non-compliant data, either financial or commercial, from corporate owners, supervisors, employees, or clients, are to be immediately reported to management.

5.2.3.1 The Quality Assurance Department provides oversight that is independent of laboratory operations to ensure that unbiased judgment and integrity are maintained at all times.

5.2.4 Objectives of the Quality Systems Manual

5.2.4.1 The QSM describes the procedures used in the laboratory to ensure that data generated meet the requirements of the relevant standards including: TNI Standards, PA Chapter 252, EPA's *Manual for the Certification of Laboratories Analyzing Drinking Water*, other applicable federal, state and municipal regulations, and the quality objectives of all clients and regulatory programs.

5.2.4.2 The QSM describes procedures for routine data review that facilitate early recognition and remediation of problems which might affect the reliability and reproducibility of the analytical results.

5.2.4.3 The QSM establishes and maintains procedures to ensure the traceability of activities associated with sample analysis beginning with sample collection and continuing through reporting and storage of all associated records, including the following: sample chain of custody; sample preparation and analytical records; methods used and documentation of any deviations from the method; pertinent calibration and continuing calibration verification data, including preparation and traceability of standards; associated quality control data including, but not limited to, matrix spikes, duplicates, laboratory control samples, method blanks, surrogates, and internal standards; records of routine and non-routine equipment maintenance; and analyst training records demonstrating competence in tests performed.

5.2.4.4 The QSM establishes a program to minimize the possibility of loss or damage through administrative SOPs which address data retention, including, but not limited to, archival and storage of data files, computer media, and hard-copy laboratory data.

5.2.4.5 The QSM establishes a program to minimize data integrity issues or tampering with data by administering an ethics training program which describes unethical, fraudulent, and improper laboratory practices. This includes proper manual integration techniques to identify inappropriate instrument manipulation practices.

5.3 Quality Systems Manual Implementation

5.3.1 The Quality Assurance Director is responsible for updating, revising, and distributing the QSM for EQC. The QSM is a numbered, controlled document which enables each copy to be tracked and revisions to be distributed. The QSM is reviewed at least every twelve months and revised as necessary. All

previous versions are archived in compliance with relevant state and federal regulations. A copy of the QSM is maintained in each laboratory department and is available for review by the analysts and supervisors. The QSM is required reading for all laboratory staff during initial training.

5.3.2 The Quality Assurance Director, in cooperation with the Laboratory Director and Department Manager(s), is responsible for training laboratory personnel and implementation of the QSM.

5.3.3 Staff listed on the title page of this document represent the approved laboratory personnel and signatories responsible for the implementation and application of this QSM.

5.4 Ethics and Data Integrity Policies

5.4.1 EQC maintains a data integrity program which includes the following: data integrity and ethics training; an employee-signed ***Eurofins' Ethics Policy Statement*** (Figure 2); monitoring of data integrity using internal audits of laboratory methods and standard operating procedures; and signed documentation of these data integrity procedures by laboratory management.

5.4.2 The ***Ethics Policy Statement*** is signed at the time of hire or within two weeks of receipt of this policy. The agreement, signed by both the employee and a representative of the corporation, is a pledge by the employee that he/she understands the EQC ethics program. By signing the document, the employee commits to the ethical analysis and reporting of data. Any employee violating the agreement is subject to disciplinary action which could include termination of employment or legal action.

5.4.3 Data integrity and ethics training is provided within three months of employment for new employees and annually thereafter within 14 months of the anniversary of the previous training date for all employees. Training documents are issued, which includes the organizational mission, key integrity issues, procedures for reporting data integrity issues, examples of improper practices, and consequences of such practices. Training is mandatory and attendance is documented.

5.4.4 Data integrity procedures are reviewed annually and updated by management as required. Monitoring of data integrity is accomplished primarily through the quality assurance audits conducted by the Quality Assurance Department as described in Section 17.0 (Audits). Adherence to standard operating procedures and laboratory protocols is maintained to ensure data integrity.

5.4.5 Management is responsible for upholding the spirit and intent of the data integrity procedures by effectively implementing the specific requirements of the program. Management support for this program is acknowledged through their approval of implementation of this QSM as well as acceptance of the corrective actions proposed in the laboratory audits.

6.0 DOCUMENT CONTROL

6.1 Controlled Documents

6.1.1 All documents used as part of the quality system and issued to laboratory personnel are considered controlled documents.

6.1.2 Controlled documents are authorized by the Quality Assurance Director, or his/her designee, and Laboratory Director and may include SOPs, policy statements, and other documents required to support the quality system.

6.1.3 Additional information regarding controlled documents is contained in Section 16.0 (Control of Records).

6.2 Obsolete Documents

6.2.1 Invalid or out-of-date documents are removed from use by retrieving documents from the recorded recipients and/or issuing a revised document. The Quality Assurance Department provides the recorded recipient with a notice of expiration for the retired document when the document cannot be retrieved.

6.3 Standard Operating Procedures

6.3.1 Analytical SOPs are prepared to encompass the requirements of the regulatory methods and to document actual laboratory procedures, especially in cases where established methods specifically allow for method flexibility. EQC's analytical SOPs follow a standard format which includes the following:

6.3.1.1 Scope, application, and discussion of the method including applicable matrices, detection limits, and limitations of the method.

6.3.1.2 Definitions of acronyms and terminology.

6.3.1.3 Discussion of potential interferences.

6.3.1.4 Required safety measures.

6.3.1.5 Sample collection preservation, handling, and storage requirements.

6.3.1.6 Apparatus, instrumentation, reagents, and standards.

6.3.1.7 Quality control requirements including criteria and corrective action to be taken in the event of a quality control failure.

6.3.1.8 Step-by-step procedures including calculation and reporting.

6.3.1.9 Requirements of initial demonstration of capability to perform the procedure.

6.3.1.10 Method performance data, either derived from internal laboratory data or taken from the original reference method.

6.3.1.11 Contingencies for handling out-of-control or unacceptable data.

6.3.1.12 Pollution prevention measures and instructions on waste management and techniques to be employed for waste reduction.

6.3.1.13 Reference to the regulatory or reference method from which the laboratory procedure is derived.

6.3.1.14 Tables, diagrams, and flow-charts, when applicable.

6.3.1.15 Signatures of Quality Assurance Director (or designee) and Laboratory Director (or designee)

6.3.1.16 Effective date and records of dates of all previous revisions.

6.3.2 In addition to the laboratory analytical SOPs, EQC's administrative SOPs provide instructions on performing other routine company procedures, including preparation of SOPs and issuance of policy statements.

6.3.2.1 Policy statements are interim documents that are issued to immediately address or define an issue which may not be addressed in an SOP or the QSM.

6.3.2.2 Policy statements are reviewed annually and integrated into an SOP or the QSM as required.

6.3.2.3 Only approved SOPs may be used for laboratory analyses.

6.3.3 SOPs and the QSM are approved and signed by both the Quality Assurance Director and the Laboratory Director, or their designees. All SOPs and the QSM are handled according to EQC's controlled document policies. The Quality Assurance Department maintains and distributes all original copies of SOPs and the QSM.

6.3.3.1 Authorized copies are assigned unique copy numbers, and distribution is controlled and documented allowing the retrieval and replacement of outdated SOPs. When new SOPs are issued, the old version is collected and archived. Analysts performing analyses under the SOP are required to document their understanding as part of their training.

6.3.3.2 Copies of EQC's controlled documents are available for review by outside vendors at the laboratory. Authorization from the Quality Assurance Director must be obtained by any individual wishing to obtain copies of any controlled document(s).

6.3.3.3 Electronic copies (.PDF format) of current SOPs are maintained in a shared directory by the Quality Assurance Director or designee. SOPs may be reviewed but are protected from unauthorized modification. Analysts may not make uncontrolled copies of SOPs.

6.3.3.4 Paper copies or scanned copies (.PDF format) of SOPs are maintained for a period not less than five years following the last date of use.

6.3.4 A listing of EQC SOPs is provided in Table 3.

6.3.5 SOPs may be supplemented by reference documents which are considered part of the controlled SOP. Documents may include all or part of the reference method and manufacturer's operating manuals.

6.3.6 Copies of current SOPs are kept in each department and are easily accessible to all analysts.

6.3.7 Laboratory SOPs are reviewed at least every 12 months by a manager or other authorized staff member. Revisions are made as necessary.

6.4 Control of Quality Assurance Documents

6.4.1 Controlled documents generated by the Quality Assurance Department are uniquely identified and contain a date of issuance, a revision number, and departmental approval signatures.

6.4.2 Controlled documents may be paper copy or electronic media.

6.4.3 Current revisions of controlled documents are available in the general location of usage.

6.4.4 Documents are periodically reviewed and revised by the Quality Assurance Department to ensure suitability and compliance with the intended purpose.

6.4.5 Making copies of controlled documents is strictly prohibited. Confidential, uncontrolled documents may be issued to outside entities, e.g. regulatory authorities and clients, with approval and documentation of the Quality Assurance Department.

6.4.6 Uncontrolled documents are labeled with an expiration date to prevent extended use.

6.4.7 The laboratory uses reference documents from several external sources for a wide range of tests from a variety of method sources that have been nationally and internationally recognized for use in environmental analysis including the following:

- Methods for Chemical Analysis of Water and Wastes (USEPA)
- Methods for Organic Chemical Analysis of Municipal and Industrial Wastewater (USEPA)
- Methods for the Determination of Metals in Environmental Samples (USEPA)
- Methods for the Determination of Inorganic Substances in Environmental Samples (USEPA)
- Methods for the Determination of Organic Compounds in Drinking Water (USEPA)
- Standard Methods for the Examination of Water and Wastewater (APHA, AWWA.WEF)
- Test Methods for Evaluating Solid Waste, SW-846 (USEPA); and
- Technical Standards - American Society for Testing and Materials (ASTM)

7.0 REVIEW OF WORK REQUESTS, TENDERS, AND CONTRACTS

7.1 Procedure for the Review of Work Requests

7.1.1 All new work requests are reviewed to assure that requirements are clearly defined, the laboratory has adequate resources and capability, and the test method is applicable to the needs of the customer. This process ensures that analytical data reported to the customer meet all applicable standards and project objectives.

7.1.2 Contracts for new work may consist of formal bids with signed documents, written or electronic quotes with or without client acknowledgement, or verbal quotes based on published price schedules.

7.1.3 The Laboratory Director or his/her designee shall review tenders, contracts and requests for analytical work in consultation with laboratory or client service staff and/or the Quality Assurance Director, as needed. The review includes, but is not limited to, laboratory accreditation status, analytical capability, laboratory workload, staff requirements, project-specific quality control requirements and/or reporting limits, turn-around time, and cost. EQC only accepts work for which it can meet project-specific objectives, regulatory requirements, and EQC's performance standards.

7.1.4 The Laboratory Director or his/her designee notifies the client of any potential conflict, deficiency, lack of accreditation, or inability of the lab to complete the work satisfactorily.

7.1.5 Test method, target analyte list, project-specific reporting limits, project-specific quality control requirements, turnaround time, and requirements for data deliverables are specified in the contract documentation.

7.1.6 The client is informed of any deviation from the contract including the test method or sample handling processes. All differences between the request and the final contract are resolved and recorded before any work begins. It is necessary that the contract be acceptable to both the laboratory and the client.

7.1.7 The review process is repeated when there are amendments to the original contract by the client. Participating personnel are given copies of the amendments.

7.1.8 The laboratory notifies the customer when the method proposed by the customer is inappropriate or out of date.

7.1.9 Following contract acceptance, the laboratory notifies the customer when there is a change in laboratory accreditation, staffing, instrumentation, or any other area that affects its ability to meet the client's requirements.

7.2 Documentation of Review

7.2.1 Records are maintained for every contract or work request. This includes pertinent discussions relating to the client's requirements or the results of the work during the period of execution of the contract.

7.2.2 Records of all project-related communication with the client (including e-mails, fax or written correspondence, and telephone conversations) are kept on file.

8.0 SUBCONTRACTING

8.1 Samples may be received for analyses for which EQC does not hold accreditation or which exceed the laboratory's current capacity to complete the analysis in a timely manner. In such instances, EQC subcontracts these samples to another NELAP-accredited laboratory or to a laboratory that meets the applicable statutory and regulatory requirements, i.e. a state-certified laboratory for which the samples are

appropriate. EQC notifies the client, as required, of its intention to subcontract any portion of the testing. The Laboratory Director and the Manager of Environmental Laboratory Administration maintain a documented list of approved subcontract laboratories. Subcontractors also may be employed to perform other functions, e.g. sample collection.

8.2 EQC maintains responsibility to the client for the subcontractor's work, except in the case where the client or a regulatory authority specifies which subcontractor is to be used.

8.3 It is the responsibility of the sample custodian or designee to assure that all subcontracted samples are appropriately preserved and that sufficient volume is available to perform the analysis. If sufficient volume has not been provided by the client, the client will be immediately notified and options will be discussed, including but not limited to re-sampling, reporting increased detection limits, or using an alternative method of analysis.

8.4 Samples to be subcontracted are entered into the LIMS according to routine procedures, the containers are assigned unique identification numbers, and the samples are tracked based on their LIMS identification numbers.

8.5 Each subcontracted sample is accompanied by a completed chain of custody form (COC), which includes all information specified in SOP QC0302 (Chain of Custody Procedure). Samples are relinquished by the Sample Custody Department to a laboratory courier or other transportation service for delivery to the subcontract facility. All requirements for maintenance of sample chain of custody apply to subcontracted samples.

8.6 Any analysis performed by the subcontractor is clearly identified in the associated laboratory report.

9.0 PURCHASING SERVICES AND SUPPLIES

9.1 All purchases of supplies and services are made through reputable service providers. The laboratory evaluates the suppliers of critical consumables, supplies and services that will affect the quality of the analyses performed.

9.2 Purchased supplies, reagents, and consumable materials are not used until they have been inspected or otherwise verified as complying with SOP requirements.

9.3 Detailed information about purchasing of services and supplies that affect analytical procedures is available in SOP QC0478 (Purchasing of Services and Supplies).

10.0 SERVICE TO THE CLIENT

10.1 Client Confidentiality

10.1.1 All test reports, analytical data, and information produced by EQC are confidential and will be released by EQC to another party only upon receipt of a written statement of release from the client and acknowledged by laboratory management. Outside parties may not review proprietary client data without first obtaining written permission from both EQC management and the original data end user. A client is that person(s) or entity requesting EQC services who is the responsible party for remuneration of such services. All EQC employees

are required to sign a Confidentiality Agreement (Figure 3) upon employment with the company.

Exceptions to this procedure follow in Sections 10.1.1.1 and 10.1.1.2.

10.1.1.1 EQC will release data if information is requested by a regulating agency with statutory authority, e.g. Pennsylvania Department of Environmental Protection (PADEP), the United States Environmental Protection Agency (USEPA), or other regulatory entity. Information is released only upon the display of acceptable identification.

10.1.1.2 EQC will release data if information is subpoenaed by any entity for enforcement or litigation. In these cases, the client is notified that this information has been supplied, and all information, e.g. requesting entities or individuals, is provided to the client by EQC.

10.1.2 EQC considers all documents governed under the controlled document policy to be proprietary. Therefore, EQC's policy is to distribute them to vendors and clients only with authorization and if required by contract. All documents and data records are available for review at the laboratory by clients, regulatory auditors, or other authorized personnel.

10.1.3 The distribution of any information without authorization is strictly prohibited. This includes verbal communications, electronic communication by FAX, email, text, or other means, written correspondence, or distribution of information in any other manner pertaining to a EQC client. Information subject to confidentiality includes, but is not limited to, specific report results and/or data associated with those results, client projects or programs, and regulatory requirements. EQC's confidentiality policy also protects material such as customer name, address, phone numbers, as well as any information regarding data, sample containers, and disposal methods.

10.1.4 Access to the LIMS is restricted, and employees are allowed access only to programs or authorization levels applicable to their job description. Access is approved by the Laboratory Director.

10.1.5 All data entries in LIMS are traceable to the employee and to the time of entry to ensure data integrity.

10.1.6 Access to archived information at the Southampton facility is controlled and documented with an access log. Laboratory data generated at EQC-Delaware are scanned and archived electronically as password-protected .PDF files to the EQC server. All archived records are protected against fire, theft, loss and environmental deterioration as described in Section 16.0 (Control of Records).

10.2 Customer Feedback

10.2.1 EQC seeks customer feedback from its clients, and positive and negative feedback are evaluated to improve the analytical processes, management system, and customer service.

11.0 COMPLAINTS

11.1 Client inquiries and/or complaints are directed to the Client Services Department. The customer service representative documents all issues and their resolutions in the LIMS Account History File. These include, but are not limited to, client inquiries regarding previously-reported analytical results or possible modifications to test methods, preservation issues, temperature violations, and all other sample issues. Client requests for confirmation of results are documented in LIMS and tracked through the Data Review Request (DRR) Maintenance file. A LIMS procedure is used to track unresolved issues, and a daily report (the "Issues List") is assigned to specific employees for resolution. The "Issues List" report acts as a reminder to staff to address unresolved issues within a reasonable time period. If any reviews indicate that the data quality is suspect, the customer is notified immediately and all relevant information is documented. Additional information is provided in SOP QC0510 (Customer Complaints). The report is reviewed periodically by the Laboratory Director or his/her designee, and repeated issues are investigated by the QA Department and targeted for corrective or preventive actions where necessary.

11.2 Following review of the original data, as discussed in Section 11.1, samples may be reanalyzed for confirmation of questionable results at the laboratory's discretion.

11.3 All resolutions and any changes made to final laboratory reports are recorded in LIMS.

11.4 In the event that the laboratory transfers ownership or goes out of business, all active customers will be notified in writing of the event. Customers will be given ten (10) working days to request custody of their analytical records. Additional information is provided in SOP QC0460 (Archiving and Storage of Data Files and Computer Media).

11.5 As part of EQC's on-going efforts to improve customer satisfaction, a survey is sent periodically to clients. The feedback obtained from these surveys is evaluated to improve performance and customer satisfaction.

12.0 CONTROL OF NON-CONFORMING WORK

12.1 Analytical data that deviate from required standards are reviewed by the Laboratory Director and Quality Assurance Director before reporting to any client or regulatory agency. This process is initiated through the use of a formal Data Variance Request (DVR) which is documented in LIMS. Procedures for initiating, submitting, and approving DVRs are described in SOP QC0515 (Data Variance Requests).

12.2 The Data Variance Request (DVR) is used to document deviations from policies, procedures, or quality control criteria or when it is not possible to comply with required corrective action procedures described in the SOP. Depending on the nature of the deviation, sample analysis may be suspended.

12.3 A DVR may be initiated by the analyst or department supervisor following initial review of the laboratory data. The DVR is initiated before results are entered into LIMS and within 72 hours of the identification of the issue, and the time of analysis.

12.4 A DVR is prepared and tracked in LIMS using a unique tracking number assigned by the system.

12.5 The DVR includes a description of the issue, reasons why it is not possible to meet the required quality control criteria, and any supporting documentation (e.g. raw data or summarized quality control results).

12.6 The DVR also includes the resolution proposed by the laboratory and any corrective or preventive actions taken to prevent a recurrence of the problem.

12.7 The DVR and associated data documentation are initially reviewed by the Department Manager. At this time, the required action for the DVR is logged into LIMS, i.e. it is accepted for further review or rejected as unnecessary. Following entry into LIMS, the Laboratory Director, Quality Assurance Director, and analysts are notified of the status of the DVR.

12.8 The DVR and associated documentation are reviewed by the Department Manager or, if necessary, the Quality Assurance Director and the Laboratory Director, to determine whether results are reportable. Comments or data qualifiers are included in the final report to document deviations from accepted methods that could impact the final results.

12.9 Before releasing analytical results to clients, the Manager of Environmental Administration or designee is responsible to assure that all relevant comments and data qualifiers have been entered into the LIMS.

12.10 Suspended analyses can resume upon the approval by the Quality Assurance Director and Laboratory Director.

13.0 CORRECTIVE ACTIONS

13.1 Selection and Implementation of Corrective Actions

13.1.1 Corrective and preventive actions (CAPA) reports are initiated upon identification of non-conforming work or deviations from policies and procedures in the management system or technical operations. CAPA reports are initiated, reviewed, and approved in LIMS in a manner similar to that for DVRs as described in SOP QC0515.

13.1.2 Deviations may be identified by routine quality control data review, internal or external assessments, client complaints, client queries, management review or feedback from clients.

13.1.3 Corrective action starts with an investigation to determine the root cause(s) of the problem. Once a root cause is determined, correction actions are taken which typically include instrument repair or maintenance, revision of laboratory processes and SOPs, purchase of new reagents or standards, and/or analyst retraining.

13.1.4 Depending on the nature of the deviation, analytical work may be suspended during the investigation. In cases where analytical work has been suspended, analyses may resume after it is verified that the corrective actions have been effective and the CAPA report has been approved.

13.1.5 CAPA reports are reviewed by the Laboratory Director, Department Manager (s), and Quality Assurance Director. Other management staff may be consulted and copied on CAPA reports. Upon approval of the CAPA report, suspended analytical work may resume.

13.1.6 Clients are notified by comments or data qualifiers on the final report that document deviations from accepted methods that could impact the final results.

13.2 Monitoring of Corrective Actions

13.2.1 Corrective and preventive actions are tracked in LIMS using Corrective and Preventive Action (CAPA) reports or Data Variance Requests (DVRs).

13.2.2 DVR and CAPA procedures are described in SOP QC0515.

13.2.3 The effectiveness of corrective actions is monitored by review of procedures and/or follow-up audits.

13.3 Policy of Permitting Departures from Documented Policies and Procedures

13.3.1 See Section 12.0 of this QSM.

14.0 IMPROVEMENT

14.1 EQC continually strives to improve the effectiveness of its management system through the use of the quality policy, quality objectives, audit results, data analysis, corrective and preventive actions, and management review.

14.2 A variety of audit, review, and survey reports are used to evaluate laboratory performance and implement changes for improvement. These include, but are not limited to, review of Proficiency Test (PT) study results, internal blind study results, internal and external audit reports, management review reports, and customer feedback surveys. For any unacceptable PT results, a root cause analysis is performed and documented, and required corrective and preventive actions are taken.

15.0 PREVENTIVE ACTIONS

15.1 Preventive action is a proactive process to identify opportunities for improvement, rather than a reaction to specific problems or complaints. Preventive actions may be taken as a result of trend analysis based on evaluation of quality control samples (e.g. LCS, surrogate, and MS/MSD recoveries), evaluation of proficiency testing results, internal blind study results, internal and external audit reports, management review reports, process changes based on recommendations from staff or clients, and customer feedback surveys.

15.2 Preventive actions typically include instrument repair or maintenance, revision of laboratory processes and SOPs, purchase of new reagents or standards, development of new methods, and/or analyst retraining.

16.0 CONTROL OF RECORDS

16.1 Procedures for archiving and storage of data are described in SOP QC0460. In general, EQC retains all original project records for a minimum of five years, unless otherwise agreed to with the client or required by regulation (e.g. lead/copper testing documentation is maintained for 12 years).

16.2 Laboratory records associated with the quality system include, but are not limited to, client communication records (e.g. letters, email communications, and phone logs), contracts, equipment maintenance and calibration records, employee training documentation, temperature tracking logs, standards and media records, and the applicable QSM and SOPs. Laboratory records are maintained for a period of five years unless otherwise agreed to with the client.

Project and laboratory records are maintained on site for an interim period depending on available storage space and frequency of use. Records are then transferred to a secured, offsite facility for the remainder of the five-year period.

16.3 Paper copies of project and laboratory records are indexed for later retrieval. Electronic files associated with LIMS and instrument workstations are backed up daily on QC Inc. servers.

16.4 Electronic data generated at EQC-Delaware are backed up to the EQC Server. Hard copy records (e.g. logbooks, spreadsheets, instrument printouts, and chain of custody records) are scanned in .PDF format and archived on the EQC server. Backup procedures are described in Section 16.1.

16.5 General records are considered to be company documents that are not related to data generation or data quality, e.g. health and safety records, general personnel files, accounting and financial documents. General records are archived according to guidelines applicable to the specific functional area as summarized below.

16.5.1 Safety-related documents, e.g. Laboratory Safety Procedure Manual, Material Data Safety Sheets (MSDS), Safety Data Sheets (SDS), are maintained indefinitely in hard copy at each facility and are also accessible online. A list of chemicals used by the laboratory is maintained for 30 years after last use.

16.5.2 Accounting, contract, and financial records are maintained for ten years.

16.5.3 Records related to general personnel files, payroll, and benefits plans are maintained in accordance with requirements of the EEOC (Equal Employment Opportunity Commission), ADEA (Age Discrimination in Employment Act), and FLSA (Fair Labor Standards Act). Personnel records are maintained for at least one year following the last date of employment. Payroll records are maintained for at least three years. Benefit plan information is maintained for at least one year following termination of the plan.

17.0 AUDITS

17.1 Internal Audits

17.1.1 The correct and complete implementation of the programs described in this QSM is confirmed periodically by federal and state auditors as well as outside clients. In addition, internal audits are conducted periodically of all analytical systems by the Quality Assurance Department. Findings and recommendations of each internal audit are documented and reported to the appropriate Department Manager(s), the Laboratory Director, and President. Internal audit procedures are documented in SOP QC0488 (Annual Review of Operations and Internal QA Assessments).

17.1.2 Laboratory management is responsible to respond to all audit findings and deficiencies. Corrective actions are monitored by the Quality Assurance Director as part of the audit follow-up process. Responses to audit findings are reviewed by the Quality Assurance Director. Clients are notified no later than the close of the following business day if audit findings affect data quality or will prevent reporting within the required time frame.

17.1.3 Internal audit procedures focus on the following areas:

17.1.3.1 Adherence to standard operating procedures and conformance to reference methods.

17.1.3.2 Evidence of required data reviews and approvals by technical and supervisory personnel.

17.1.3.3 Adequacy of document filing, storage, and retrieval systems.

17.1.3.4 Documentation of required quality summary reports (e.g., control charts, calibration curves) and CAR reports or DVRs documenting corrective actions for deviations and out-of-control analytical events.

17.1.3.5 Evidence of proper training of analysts (e.g. understanding of laboratory SOPs and troubleshooting procedures).

17.1.3.6 Documentation of proper maintenance of laboratory facilities and equipment.

17.1.4 Internal audits are conducted at least monthly to evaluate conformance to applicable regulatory standards. For each audit, one area of the laboratory operation is selected so that each area is audited twice by the end of a biennial cycle.

17.1.5 The Quality Assurance Department also conducts periodic reviews of randomly-selected projects.

17.2 External Audits

17.2.1 EQC cooperates with clients for vendor qualification inspections or any client-required, third-party audits.

17.3 Performance Audits

17.3.1 Review of Proficiency Test (PT) study data is a key element of performance audits. Corrective actions are implemented for non-conforming data and CAR reports are tracked in LIMS.

17.4 System Audits

17.4.1 The quality system is audited at least every year for conformance to applicable standards promulgated by TNI, EPA, or other regulatory authorities.

18.0 MANAGEMENT REVIEWS

18.1 An internal review of the overall quality systems is conducted annually by the Quality Assurance Director and Laboratory Director based on results of quality documentation for the previous 12 months. Documentation that is reviewed includes, PT performance results, customer complaint documentation, internal operational documentation, internal audit reports, reports from certification audits, field service records, DVR and CAR documentation, LIMS documentation, and data package error logs. Internal audit procedures are documented in SOP QC0488 (Annual Review of Operations and Internal QA Assessments). Issues resulting from the annual management review are identified and assigned to staff for action.

19.0 DATA INTEGRITY INVESTIGATIONS

19.1 Investigations resulting from data integrity issues are conducted in a confidential manner. These investigations are tracked and documented using tools including Data Review Request (DRR) forms, CAR reports, or DVR forms in LIMS as well as other internal documentation and memoranda. Clients are notified no later than the close of the following business day if investigation findings affect data quality or will prevent reporting within the required time frame.

20.0 PERSONNEL/JOB DESCRIPTIONS AND TRAINING

20.1 Job Descriptions

Job descriptions are issued to all employees. Each document outlines the employee's duties, responsibilities, education requirements, and minimum level of qualifications. Specific jobs may require additional training or education (e.g. supervisor positions or other specialized technical positions requiring knowledge of specific, complex methods). These requirements are identified in the individual SOPs. Training courses or workshops on specific equipment, analytical techniques, or laboratory procedures are documented in the employee training records.

Job descriptions for key positions are provided below.

20.1.1 Quality Assurance Director

20.1.1.1 Report directly to the President and has direct access to the Laboratory Director(s).

20.1.1.2 Serves as the focal point for implementation of the QSM and is responsible for oversight and review of quality control data.

20.1.1.3 Functions independently from laboratory operations.

20.1.1.4 Determines the effectiveness of the overall quality system within the laboratory and recommends appropriate corrective actions or modifications of laboratory procedures.

20.1.1.5 Monitors laboratory-training records, including but not limited to Initial Demonstrations of Capability, Annual Demonstrations of Proficiency, and documentation of Method Detection Limit (MDL) studies.

20.1.1.6 Serves as a quality resource and advisor for the Laboratory Director and Department Managers.

20.1.1.7 Coordinates laboratory participation in inter-laboratory accreditation and proficiency programs and analysis of internal "blind" quality control samples.

20.1.1.8 Arranges for periodic laboratory audits and the annual management review of technical operations.

20.1.1.9 Supervises all personnel in the Quality Assurance Department.

20.1.1.10 Reviews analytical deviations in cooperation with the Laboratory Director to determine potential effects on validity and reportability

of sample results. Recommends and monitors corrective actions when needed.

20.1.1.11 Has documented training and/or experience-with laboratory quality assurance and quality control procedures and is knowledgeable of the quality systems as defined under applicable EPA, TNI and independent state regulatory programs.

20.1.1.12 Has a general knowledge of the analytical tests for which data review is performed.

20.1.1.13 Is able to evaluate data objectively and perform independent assessments free from outside influence.

20.1.1.14 Has the education and training as outlined in the current EPA, TNI documents with the following minimum requirements: BA/BS/AA degree or greater from an accredited institution in a chemical, physical, biological, or environmental; at least 1-year experience in the chemical analysis of drinking water, water pollution, or solid/hazardous waste samples; and completion of a formal training course in quality assurance practices and NELAP requirements.

20.1.1.15 Is empowered with the authority from company management to execute the duties of the position as described in the EQC QSM.

20.1.1.16 Has the authority to release analytical results to clients.

20.1.2 Laboratory Director

20.1.2.1 Has responsibility of the day-to-day laboratory procedures and reporting of results.

20.1.2.2 Monitors standards of performance in quality control and quality assurance.

20.1.2.3 Monitors the validity of data generated in the laboratory. Interfaces with the Quality Assurance Department to maintain and improve the overall quality system.

20.1.2.4 Ensures that adequate qualified personnel are employed to supervise and perform the work of the laboratory.

20.1.2.5 Is responsible to oversee implementation of corrective actions outlined in the QSM.

20.1.2.6 Ensures availability of sufficient instrumentation, equipment, reagents, gases, and chemicals to perform procedures for which the laboratory is accredited.

20.1.2.7 Provides educational direction to laboratory staff.

20.1.2.8 Reviews analytical deviations in cooperation with Quality Assurance Director to determine the validity and reportability of sample results. Implements corrective action when needed.

20.1.2.9 Designates appropriate deputies to assume responsibilities in the event of a scheduled short-term absence.

20.1.2.10 Reviews quotes for new work as required to evaluate whether the laboratory has the required certifications, facilities and resources to complete the scope of work.

20.1.2.11 Issues periodic ~~a~~ memoranda as required outlining specific contract requirements for MDLs, matrix, frequency of testing, parameters to be tested, turnaround time, data package requirement, start date and any additional customer-specific information.

20.1.2.12 Has the education and training requirements as outlined in the current NELAP or other applicable regulatory documents.

20.1.1.13 Is empowered with the authority from company management to execute the duties of the position as described in the EQC QSM.

20.1.3 Department Manager (also referred to as Supervisor or Technical Director)

20.1.3.1 Reports directly to the Laboratory Director.

20.1.3.2 Take measures to assure that all results issued by ~~their~~ department meet data quality requirements of SOPs and conform to applicable regulatory and internal quality control standards. Approves final analytical results.

20.1.3.3 Provides oversight of daily activities of laboratory technical staff and all analytical operations within department.

20.1.3.4 Supervises quality control for routine analytical operations as required by SOPs and the QSM.

20.1.3.5 Identifies and resolves technical problems in cooperation with the Laboratory Director and Quality Assurance Director following requirements of the QSM.

20.1.3.6 Reviews all quality control to verify that the department is meeting established criteria.

20.1.3.7 Evaluates new analytical techniques, procedures, instrumentation, and quality control methods, and provides recommendations to the Laboratory Director and Quality Assurance Director as applicable.

20.1.3.8 Has the education and training requirements as outlined in the current NELAP or other applicable regulatory documents.

20.1.3.9 Is required to have an operational understanding of all aspects of departmental SOPs including methodology, instrumentation, and quality control requirements.

20.1.3.10 Is empowered with the authority from company management to execute the duties of the position as described in the EQC QSM.

20.1.4 Analyst/Technician

20.1.4.1 Reports directly to Department Manager.

20.1.4.2 Performs analytical procedures and data processing in accordance with company SOPs. Reviews data for acceptability according to quality control requirements of the SOP.

20.1.4.3 Is responsible for preparation and maintenance of standard curves and the analysis of duplicates, spikes, blanks, and other quality control samples as directed.

20.1.4.4 Is responsible for documentation of routine and non-routine instrument maintenance.

20.1.4.5 Demonstrates acceptable performance on Initial Demonstration of Capability (IDOC) and Method Detection Limit (MDL) studies, quality control samples required by SOPs (e.g. blanks, laboratory control samples, and matrix spikes), PT samples, or internal, blind quality control samples.

20.1.4.6 Immediately reports non-conformances to the Department Manager to ensure that corrective action is taken.

20.1.4.7 Meets the education and training requirements outlined in job description and/or specific SOP.

20.1.5 Sample Custodian

20.1.5.1 Reports directly to the Laboratory Director.

20.1.5.2 Signs chain of custody forms to document sample receipt.

20.1.5.3 Arranges for proper and secure sample storage and distribution to individual departments. Defers distribution of non-compliant samples (i.e. do not meet sample handling and preservation requirements) until receipt of confirmation from client to proceed or resample.

20.1.5.4 Maintains internal custody records of sample transfer to respective laboratory departments.

20.1.5.5 Inspects samples for tampering and proper preservation, including temperature, in accordance with EQC SOPs on sample handling, receipt, and rejection.

20.1.5.6 Is responsible for entry of each sample into the LIMS for tracking throughout analysis.

20.1.5.7 Is responsible to ensure that permanent labels with correct, unique sample identification numbers (assigned by the LIMS) are attached to each sample.

20.1.5.8 Has completed the education and training requirements as outlined in his/her job description.

20.1.5.9 Is empowered with the authority from company management to execute the duties of the position as described in the EQC's QSM.

20.1.6 Deputies

20.1.6.1 In the event of an absence of either the Laboratory Director or the Quality Assurance Director for a period exceeding 16 consecutive calendar days, official notification of the appointment of the deputy director is made through inter-laboratory memo. During the period of absence, the deputy assumes the day-to-day responsibilities of the absent director. Additionally, all primary state accrediting authorities are notified in the event that an absence of either director exceeds 30 consecutive calendar days.

20.1.7 Support Personnel (data reviewers, customer service, forms specialists, computer specialists, scheduling specialists, field staff, and all others)

20.1.7.1 Reports directly to the Department Manager.

20.1.7.2 Has completed the education and training requirements as outlined in the job description.

20.1.7.3 Performs duties in accordance with Company SOPs and QSM.

20.1.7.4 Reports any deviations from the Company's standard operating procedures to the Department Manager.

20.1.8 Manager of Environmental Laboratory Administration

20.1.8.1 Reports to the Laboratory Director.

20.1.8.2 Reviews laboratory data in the final format and approves data for client reports.

20.1.8.3 Manage sub contract data and state forms.

20.1.8.4 Reviews progress of re-analyses and client data challenges.

20.2 Training

20.2.1 Each Department Manager is responsible for training new employees including personnel transferring from other departments. Specific requirements for the initial demonstration of capability to perform the procedure are listed in each method SOP, SOP QC0499 (General Preparation and Evaluation of Demonstration of Capability), and SOP QC0495 (Method Detection Limits). Training documentation is maintained on standardized laboratory training forms along with supporting data as described in SOP QC0499. Summary training records for each analyst are centrally managed by the Quality Assurance Department. Training records are maintained for a minimum of five years following termination of employment.

20.2.2 All new employees are trained in general Company procedures and policies including the Company's quality policy, the QSM and procedures for laboratory data retention, sample collection and handling laboratory documentation, facility access, instrumentation, safety, and good laboratory practices. The Company provides specific training on policies and procedures for data integrity and ethics which is described in Section 5.4. This preliminary training is provided upon hiring and is completed within two weeks from date

of hire. Training for specific method SOPs is performed concurrently with general training.

21.0 ACCOMMODATIONS AND ENVIRONMENTAL CONDITIONS

21.1 EQC facilities meet or exceed requirements for acceptable performance of analytical procedures performed by the Company.

21.2 The laboratory monitors, controls, and records environmental conditions as required by the relevant test methods and procedures. These conditions may include temperature, noise, biological stability, dust, radiation, humidity, or lighting.

21.3 Testing procedures are suspended when environmental conditions jeopardize data quality.

21.4 Adequate separation is maintained between neighboring areas in which incompatible activities are performed.

21.5 Access to EQC facility in Southampton is controlled through the use of key cards issued to each individual employee. Unescorted visitors are not allowed. Visitors, including contractors and janitorial staff, are made aware of safety and security guidelines. Unauthorized personnel are not permitted in laboratory areas. Other EQC satellite locations are locked unless the front door access is monitored by the EQC staff.

21.6 Laboratory facilities at all locations are kept free from mice, rodents, and other infestations by using authorized service providers to apply insecticides and/or pesticides that have been approved for use by laboratory management and will not negatively affect sample analyses.

22.0 ANALYTICAL METHODS AND VALIDATION

22.1 Analytical Method Implementation

Analytical methods used by EQC generally are dictated by the regulatory application of the sample data. Typically, analyses are based on client requests and the approved parameter list from the laboratory certification documents. Special requests for non-routine methods are handled on a case-by-case basis.

To implement a new analytical method, a method SOP is developed and approved by the Laboratory Director and Quality Assurance Director. The Laboratory Director then creates a product in LIMS incorporating the necessary information for sample analysis and reporting. Subsequently, addition, revision, and/or deletion of methods, SOPs, or analytes is centrally-managed by the Quality Assurance Department. The request contains a brief explanation for the revision and is approved by the Department Manager, Laboratory Director, and Quality Assurance Director. LIMS is updated accordingly.

22.2 Initial Method Performance Evaluation

The laboratory conducts initial method performance evaluations of each analytical method to demonstrate the ability to achieve acceptable results. These evaluations are conducted before the analysis of samples and following significant changes in hardware or analytical systems. Required elements of the initial method performance evaluation are described in the following sections.

22.2.1 Method Detection Limit (MDL) and Limit of Detection (LOD)

22.2.1.1 The Method Detection Limit (MDL) is determined as described in SOP QC0495. An MDL is determined by matrix for each test method and target analyte. MDLs are determined during the initial method validation and annually thereafter where required. When the same parameter is analyzed on multiple instruments, the highest MDL value is used for reporting purposes.

22.2.1.2 Procedures for determination of the appropriate concentration for the LOD quality control sample are described in SOP QC0684 (Determination of LOD and LOQ).

22. 2.1.3 An MDL study is not performed for any analysis for which spiking solutions or quality control samples are not available, e.g. temperature, or when MDLs are not applicable to the procedure (e.g. flash point).

22.2.2 Limit of Quantitation (LOQ)

22.2.2.1 When an MDL study has not been performed, a result may not be reported at a value below the LOQ (Limit of Quantitation) which is generally the lowest calibration standard. The LOQ is also referred to as the Reporting Limit (RL). The LOQ is determined according to procedures in SOP QC0684 (Determination of LOD and LOQ). The validity of the LOQ is confirmed by analysis of a quality control sample containing the analyte(s) of concern at a level of 1-2X the reported LOQ.

22.2.2.2 The analysis of the LOQ quality control samples is considered to be acceptable when the recovery of each analyte is within the established test method acceptance criteria or client data quality objectives for accuracy.

22.2.2.3 Analysis of the LOQ quality control sample is not required if the accuracy of the measurement system is evaluated at the LOQ.

22.2.2.4 For tests that do not utilize a calibration curve, e.g. settleable solids and residue tests, the RL is established at a value that is able to be measured with a defined level of accuracy during routine analysis. For settleable solids, the RL is set at 0.5 mL/L, and for residue tests, the RL is calculated using a minimum weight value, typically 1 mg, on an analytical balance.

22.2.3 Evaluation of Precision and Accuracy

22.2.3.1 Precision is defined as the closeness of a set of duplicate observations or measurements of the same property which are obtained under similar conditions. Accuracy is defined as the degree of closeness of a measurement to the actual true value. A typical example of measuring precision is to analyze a sample in duplicate and compare the results. Analysis of a laboratory control standard (LCS) with known concentration may be performed in duplicate for

this purpose. Precision results are reported as a percent difference of measurements, standard deviation, variance, or range. Analysis of a matrix spike (MS) and matrix spike duplicate (MSD) may also be used as a measure of precision of a given method in a specific sample matrix. Trip and Field Blanks are not used as MS/MSD samples. Analysis of an LCS or other sample with a known or certified value may be used to evaluate accuracy.

22.2.3.2 Specific criteria for assessment of precision and accuracy measurements are described in laboratory SOPs or project-specific documents. These procedures conform to the requirements of applicable regulatory programs, including but not limited to the Safe Drinking Water Act (SDWA), the Clean Water Act (CWA), and the Resource Recovery and Conservation Act (RCRA). Where not dictated by regulation, criteria for accuracy and precision of each test method are based on actual laboratory performance in the specific sample matrix. Criteria conform to the standards of TNI. Laboratory samples used as matrix spikes and spike duplicates are selected randomly and rotated between clients based on availability of required tests and sample volume.

22.2.3.3 Precision and accuracy criteria are specified in the various approved methods required by the SDWA (500-series methods), CWA (600-series methods), RCRA (SW-846 methods), or other reference documents, e.g. Standard Methods for the Examination of Water and Wastewater. Additional criteria may be specified in state and federal regulatory programs. Data quality objectives established by EQC meet or exceed the applicable criteria specified by the method or regulatory program. In cases where criteria are not established, quality control limits are calculated internally using historical data tabulated by test method and sample matrix.

Procedures for preparation of control charts and determination of quality control limits are described in SOP QC0916 (Laboratory Quality Control Limits). Upper and lower warning limits are calculated as the mean $\pm 2\sigma$, while upper and lower control limits as the mean $\pm 3\sigma$. Precision warning and control limits are calculated similarly at $+2\sigma$ and $+3\sigma$. Limits are updated periodically with the actual interval dependent upon the total number of samples tested by each method. General data trends and overall analytical system control are tracked through control charts as described in Section 13.0 of SOP QC0499 (General Preparation and Evaluation of Demonstrations of Capability) and SOP QC0916).

22.2.3.4 While overall trends and method performance are tracked through control charts, daily method performance is tracked based on data from individual run sequences. Required corrective actions to be taken in individual instances of data non-conformances are described in the analytical SOPs.

22.2.4 Estimation of Uncertainty

22.2.4.1 The total uncertainty of a measurement is based on many factors including but not limited to, contributions from human factors, environmental conditions, sampling, equipment, test method application, and calibration. Estimations of uncertainty are based on published method performance, previous experience, and specific data validation procedures. Procedures for determination of uncertainty are described in SOP QC0831 (Measurement of Uncertainty).

22.3 Initial Demonstration of Capability (IDOC)

22.3.1 All analysts complete an Initial Demonstration of Capability (IDOC) before independently performing a procedure. Procedures for performing the IDOC are described in SOP QC0499 (General Preparation and Evaluation of Demonstrations of Capability).

22.3.2 A new IDOC is performed whenever there is a change in instrumentation, method, or personnel.

22.4 Continuing or On-going Demonstration of Capability

22.4.1 Continuing or on-going demonstration of capability (DOC) is satisfied and documented as follows:

22.4.1.1 When the analyst successfully analyzes at least four consecutive laboratory control samples from a secondary source and precision and accuracy meet criteria.

22.4.1.2 When the analyst performs another Initial Demonstration of Capability (IDOC).

22.4.1.3 When the analyst performs an acceptable analysis of an internal, single blind sample.

22.4.1.4 When the analyst performs an acceptable analysis of an external, blind Proficiency Test (PT) sample using a similar test method with the same technology.

22.4.1.5 When the analyst completes required activities described in the SOP and a quantitative test is not available, e.g. settleable matter and TCLP extractions.

22.5 Manual Integrations

22.5.1 Eurofins QC, Inc. (EQC) uses software developed by instrument manufacturers or third party suppliers to reduce chromatography data from an analog signal to an accurate concentration present in the sample. Efforts are made during method development to include the best instrument parameters that allow for automatic integration of chromatographic peaks by the data system in most cases. However, instances occur when the automated software does not integrate a peak correctly. Manual integration is employed to correct an improper integration performed by the data system.

22.5.2 All peaks must be integrated consistently in standards, samples, and QC samples. Integration parameters, both automated and manual must adhere to valid scientific chromatographic principles. The reason for manual integration must always be documented. Under no circumstances should manual integration be performed solely for the purpose of meeting quality control criteria. In other words, peak shaving, peak enhancing, or manipulations of the baseline to achieve these ends must never occur as this results in an improper integration rather than correcting a data system

22.5.3 Policies and procedures for manual integrations are described in QC0559 (Proper Manual Integration Techniques for GC and GC/MS).

22.6 Validation of Laboratory-Developed, Non-Standard Methods

22.6.1 Policies and procedures for validation of non-standard methods are described in SOP QC0485 (Acceptance/Rejection Criteria for Unspecified Methods).

23.0 CALIBRATION REQUIREMENTS

23.1 General Equipment Requirements

23.1.1 Analytical Instrumentation and Laboratory Facilities

EQC's laboratory instrumentation and facilities meet or exceed the technical, quality, and capacity requirements of clients, applicable methods, and regulatory agencies. Floor plans of EQC's major laboratory facilities are shown as follows: Figures 2A and 2B (EQC-Southampton, PA facility), Figure 2C (EQC-Horsham, PA facility), and Figure 2D (EQC-Delaware, New Castle facility). A listing of the laboratory's environmental testing equipment is provided in Table 2.

23.1.2 The laboratory's current and anticipated analytical work-load is tracked through the scheduling features of the LIMS and periodically reviewed by laboratory management to assure that incoming projects will not exceed the laboratory's capacity.

23.1.3 The potential need to update and/or purchase new laboratory equipment is reviewed during the preparation of the annual budget.

23.2 Support Equipment

Support equipment includes all devices that are not directly used for laboratory measurements, but are needed to indirectly support laboratory operations. These include, but are not limited to, balances, ovens, refrigerators, incubators, hot blocks, digestion equipment, extraction devices, and volumetric dispensing devices. Procedures for support equipment maintenance and calibration, if applicable, are described in the analytical SOPs, equipment specific SOPs, or manufacturer's operating manuals. Procedures are summarized in the following sections.

23.2.1 Support Equipment Maintenance

23.2.1.1 All support equipment is maintained in proper working order according to the recommendations of the manufacturer or specific

SOP. Records of maintenance are kept in the department where the equipment is located.

23.2.1.2 When support equipment is relocated, the equipment is shut down following recommended procedures. Following shutdown, the equipment is required to meet recommended operating conditions prior to being put back into service.

23.2.2 Support Equipment Calibration

23.2.2.1 Performance of all support equipment is periodically verified and documented according to procedures in the analytical SOPs, equipment-specific SOPs, or manufacturer's operating manuals. In cases where equipment requires calibration, the equipment is calibrated at least annually using standards or calibration materials (e.g. thermometers or weight sets) that are traceable to a recognized entity, such as NIST. Calibration materials are selected to bracket the applicable range of use as required by methods, operating manuals, or regulatory criteria. Applicable acceptance criteria for the calibration of support equipment are described in individual SOPs. Calibration records for thermometers and balances generally are maintained centrally by the Quality Assurance Department, while other operating documentation (e.g. oven or refrigerator logs) are kept in the department where the equipment is located.

Key elements of support equipment calibration are described in the following sections.

23.2.2.2 Analytical balances and weights are serviced and calibrated annually by a certified technician. Class 1 or better weights are used.

23.2.2.3 Except for Class A glassware, the delivery volumes of mechanical volumetric dispensing devices are checked at least quarterly. The accuracy is required to be within 2.5% of the expected value. Volumetric devices that do not meet this criterion are refurbished or taken out of service.

23.2.2.4 Temperature measuring devices such, as liquid-in-glass thermometers, are calibrated at least annually using a NIST-traceable thermometer, which is graduated in at least 0.2 °C increments.

23.2.2.5 A working thermometer is not used if it has a Correction Factor (CF) of 1.0 °C or greater from the reference thermometer. If the calculated CF is less than the graduation increment of the working thermometer, the CF is not applied.

23.2.2.6 Thermometers are graduated in increments of 0.5 °C or less for all analyses except fecal coliform analysis. Thermometers used for fecal coliform analysis have graduations of 0.2 °C or less.

23.2.2.7 Electronic data loggers are calibrated at least annually against NIST thermometers. In addition to the electronic records, calibration records and summary data are maintained in logbooks.

23.2.2.8 Operating conditions of autoclaves are documented in logbooks according to schedules described in laboratory SOPs. Documentation includes demonstration of sterilization through use of biological indicators and verification of cycle temperature.

23.2.2.9 The temperature of each laboratory refrigerator and freezer is documented at least daily. Refrigerators for storing environmental microbiology samples are required to maintain a temperature of 1 to 5 °C. Other samples are stored in refrigerators with a temperature range from 0-6 °C. Freezer temperatures are less than 0 °C to -20 °C.

23.2.2.10 Temperatures of water baths and ovens are verified each day, before use. Temperatures of microbiological incubators and water baths are verified twice daily, and the measurements are taken at least 4 hours apart.

23.2.2.11 Calibration of electronic, dial-type, and other non-glass thermometers, including thermocouples and metal thermometers, is verified on a quarterly basis with a NIST-certified thermometer. Note: Dial-type thermometers for ice cream sampling is calibrated every 6 months as specified by PA Department of Agriculture dairy sampling forms.

23.2.2.12 Certified NIST thermometers are recalibrated at least once every two years by an authorized independent firm. The certificates documenting the traceability to NIST standards are kept on file by the Quality Assurance Department in Southampton. In cases where regulatory authorities require local access to the certification documents, a copy is provided to the individual remote facility.

23.2.2.13 Equipment that does not meet calibration criteria is taken out of service and clearly marked to prevent usage.

23.2.2.14 When equipment is taken out of service, calibration and test data from the analytical run immediately preceding the out-of-service date/time are evaluated. This evaluation ensures that the tests were satisfactory and data were not affected by the equipment malfunction.

23.3 Analytical Instruments

23.3.1 Maintenance for Analytical Instruments

23.3.1.1 When an instrument does not meet the specifications of the approved methods or manufacturer, operation is suspended and maintenance or repair is performed as necessary. Maintenance or repairs are performed by qualified personnel, either experienced EQC operators or outside service personnel. Outside service

personnel generally are representatives of the manufacturer or independent contractors who perform non-routine instrument maintenance and repairs, as well as any periodic maintenance required by manufacturer's service contracts. Potential analytical down-time is minimized through the availability of backup instruments and/or alternate methods. Following maintenance or repair and prior to initiation of sample analysis, instrument performance is verified for conformance to regulatory requirements.

23.3.1.2 Preventative maintenance schedules and procedures are detailed in the individual instrument operations manuals, analytical SOPs, or in specific preventative maintenance SOPs.

23.3.1.3 Records of all routine and non-routine maintenance are maintained in instrument maintenance logs kept in each department.

23.3.1.4 When instruments are taken out of service by moving or placing in storage, EQC follows the applicable manufacturer's instructions and/or applicable SOP to ensure proper functioning and to prevent contamination or deterioration. Following moving or storage, instrument performance is verified for conformance to regulatory requirements prior to initiation of sample analysis and return to service.

23.3.2 Initial Instrument Calibration

23.3.2.1 Intervals for calibration are, at a minimum, those recommended by the manufacturer or those required by the analytical method, whichever is shorter. Calibration standards are prepared and analyzed in concentrations bracketing the range of the samples to be analyzed. Results within the calibration range, but not bracketed by the initial calibration standards, may be reported with a qualifying flag or comment as described in the specific analytical SOP. In cases where calibration is performed with a single standard and calibration blank (e.g. ICP-OES and ICP-MS), a linear dynamic range (LDR) is determined according to the specified method, and results above the single point standard used for calibration, but within the LDR, may be reported.

23.3.2.2 Standards used for initial calibration are verified using a standard (however named) prepared from an independent, second-source material. The second-source standard is obtained from a different manufacturer or from a different lot from the same manufacturer.

23.3.2.3 All sample results are quantitated from the initial instrument calibration and not from any continuing instrument calibration verification.

23.3.2.4 Calibration response may be determined using linear regressions, quadratic fit, or an average calibration response factor (e.g. area response or peak height versus amount injected as is the case with

chromatographic analyses). The required number of calibration standards is described in each analytical SOP. Linear and quadratic calibration acceptability are defined by SOP-defined statistics that establish the minimum value that is acceptable relating to the goodness of fit of the calibration curve. Acceptability of calibrations utilizing calibration response factors is based on calculation of the relative standard deviation (RSD). Acceptance limits for RSDs are listed in each analytical method.

23.3.2.5 When initial calibration criteria are not met, one or more of the following actions are taken until acceptable calibration data are obtained. Corrective actions include, but are not limited to: a) mechanical or electronic adjustment of the instrument followed by reanalysis of the initial calibration standards; b) instrument maintenance followed by reanalysis of the initial calibration standards; c) preparation of new standards and a new initial calibration curve; d) evaluation of one or more components of the standard for abnormally high response, indicating contamination, followed by corrective action to eliminate the contamination and reanalysis of the initial calibration standards; or e) removal of the instrument from service for subsequent repair. Additional corrective actions may be described in each analytical method.

23.3.3 Continuing Instrument Calibration

23.3.3.1 Continuing calibration verification standards (CCV) are analyzed at the frequency specified by the analytical methods or regulatory program and when calibration is not performed on the day of analysis.

23.3.3.2 Continuing calibration verification standards have defined acceptance criteria and are listed in each specific standard operating procedure.

23.3.3.3 If the continuing instrument calibration verification results obtained are outside the established acceptance criteria and analysis of an immediate second consecutive calibration verification fails to produce results within acceptance criteria, corrective actions are performed. Corrective actions include, but are not limited to, instrument maintenance and evaluation of chromatographic performance, software integration and mathematical calculations, and standard stability. Following corrective action, calibration verification is demonstrated by analyzing two consecutive passing calibration verifications. Alternatively, a new initial instrument calibration can be performed. Sample analyses are not initiated until the analytical system is calibrated and the calibration is verified.

23.3.3.4 When samples are analyzed using a system on which calibration has not been verified, the following rules apply:

a. When the acceptance criteria for the CCV are exceeded high (i.e., high bias) and there are associated samples that are non-detects, then those non-detects may be reported with a qualifying comment.

b. When the acceptance criteria for the CCV are exceeded low (i.e., low bias) and there are associated samples that have values exceeding a regulatory limit, those results may be reported with a qualifying comment.

c. In all other cases, the samples affected by the unacceptable calibration verification are re-analyzed after a new calibration curve has been established, evaluated, and accepted.

d. PA-regulated drinking water samples with qualified results must receive pre-approval from the state prior to reporting.

23.3.4 Other Method- or Instrument-Specific Calibration Requirements

Additional method- or instrument-specific procedures may be required and are specified in individual method SOPs. These include, but are not limited to, tuning of mass spectrometers and minimum RRF criteria (GC/MS and ICP/MS), PEM breakdown and retention time verification (pesticides), wavelength calibration of spectrophotometers (colorimetric determinations), and inter-element correction factor and linear dynamic range verification (ICP-OES and ICP/MS).

24.0 MEASUREMENT TRACEABILITY

24.1 Reference Standards and Reagents

24.1.1 EQC purchases analytical standards and reagents from established vendors. Suppliers are approved according to procedures described in EQC SOP QC0478 (Purchasing of Services and Supplies). Standards are prepared and analyzed according to the requirements of the analytical methods. Initial calibration standards are verified by analysis of second source standard prepared independently of the initial calibration standard.

24.1.2 Handling and documentation of standard materials and reagents is described in SOP QC0486 (Reagent/Reference Material Receipt, Labeling, Expiration, Storage and Disposal). Records document the traceability of working standards or reagents to the stock materials. Documentation also includes certificates of analysis or purity, receipt date, and information specific to the standard or reagent preparation (e.g. date of preparation, method of preparation, expiration date and preparer's initials). All prepared standards and reagents bear a unique identifier with expiration date and are traceable back to stock standards or reagents.

24.1.3 The sources of deionized water within the laboratory are tested periodically for the parameters listed in Table 24.1.3 (Deionized Water Monitoring Criteria). Additional parameters may be added as required by individual regulatory authorities or specific clients. Samples that are routinely monitored are

scheduled in the company LIMS for the following locations: EQC-Southampton, 2nd floor; EQC-Southampton, 1st Floor; and EQC-Delaware.

Samples of deionized water are collected from the discharge port of each DI water system after allowing water to run for at least one minute. Samples are collected according to procedures described in Section 10.11 of SOP QC0548 (General Field Sampling Procedures).

Samples are analyzed for the scheduled tests according to the appropriate SOP. Deionized water must meet all test requirements indicated in Table 24.1.3 to be suitable for use. Deionized water that does not meet these requirements must be re-sampled and re-tested. Management is notified if repeat analyses do not give acceptable results.

Table 24.1.3
Deionized Water Monitoring Criteria

Parameter	Requirements	Frequency
TOC NH3	<1 mg/L <0.1 mg/L	Monthly
Organic Nitrogen	<0.1 mg/L	Monthly
Conductivity	< 2.0 micromhos/cm or >0.5 MΩ resistance at 25 °C	Monthly
Residual Chlorine	<0.1 mg/L	Monthly
Heterotrophic Plate count	< 500 CFU/mL	Monthly
Suitability/Bacteriological Water Quality	Ratio: 0.8 - 3.0	Annually
Heavy and Trace Metals	≤ 0.05 mg/L per metal, ≤ 0.1 mg/L collectively	Annually
SiO_2	<0.1 mg/L	Annually

24.2 Reference Materials

24.2.1 Materials used for method validation or instrument calibration are, wherever possible, traceable to certified reference materials. See additional information in SOP QC0478 (Purchasing of Services and Supplies).

24. 3 Transport and Storage of Reference Standards and Materials

24.3.1 Handling and documentation of reference materials is described in SOP QC0486 (Reagent/Reference Material Receipt, Labeling, Expiration, Storage and Disposal).

24.3.2 Reference standards and materials are handled in a safe manner to protect their integrity and to prevent contamination or deterioration.

25.0 SAMPLE COLLECTION AND MANAGEMENT

25.1 Sample Collection

25.1.1 Sample collection by EQC personnel is performed in accordance with EQC SOPs or client-specified procedures. Sample collection procedures comply with applicable EPA and state regulations. Applicable field sampling SOPs are listed in Table 3.

25.2 Sample Containers

25.2.1 Selection of sample containers is based on the requirements specific to the analyte, matrix and analytical method. Acceptable sampling containers are described in SOP QC0346 (Policy for the Acceptance and Rejection of Environmental Samples).

25.3 Preservation and Holding Time

25.3.1 Samples preservation is verified and documented upon receipt in the laboratory. Each sample is evaluated to ensure that the holding time is met for all analytes. Preservation and holding time requirements are described in SOP QC0346.

25.4 Sample Receipt and Acceptance

25.4.1 Samples are checked in according to SOP QC0303 (Sample Log-in Procedure)

25.4.2 Policies and procedures for accepting samples at the laboratory are described in SOP QC0346 (Policy for the Acceptance and Rejection of Environmental Samples).The samples are checked for tampering, closure integrity, proper collection procedures, and proper preservation, including use of approved containers, temperature, pH, chlorine residual, or presence of other required chemical preservatives as described in SOP QC0346.

25.4.3 The COC form is reviewed for all relevant information. When required, EQC personnel follow established procedures to contact the client and obtain complete and accurate information for the sample submittal (see SOP QC0346). All COC issues are documented in the LIMS and the client is notified.

25.5 Chain of Custody

25.5.1 All samples received by the laboratory must be accompanied by a completed COC form available from the client services at EQC. The COC provides a record of sample handling history beginning with the date and time of sample collection and continuing through laboratory receipt and distribution to individual departments for analysis. EQC has the ability to provide a complete internal chain of custody record including handling by individual analysts through final analysis and disposition of the samples upon request. These procedures are described in SOP QC0302 and SOP QC0468 (Electronic Chain of Custody and Sample Transfer). Key elements of these procedures are summarized in the following sections.

25.5.2 Documentation of a sample chain of custody begins with proper completion of a COC which is initiated by the sampler at the time of sample collection. The field identification of each sample is recorded on the COC, and a durable label including the unique field identification is affixed to each sample container providing traceability of each sample to the COC record.

25.5.3 In addition to sample identification information and other project information associated with the terms of each individual contract, the COC also includes

specifics regarding required analyses, numbers of containers for each sample, field measurements, sample preservation and other client notes.

25.5.4 Each sample container is labeled in accordance with relevant health and safety requirements when preservation chemicals are added. This label also provides additional traceability to ensure the container and preservation are those specified for the analytical requirements indicated on the COC.

25.5.5 The sampler, project coordinator, or courier maintains custody prior to, during, and after sampling until the samples are relinquished to EQC laboratory personnel.

25.5.6 In the event that the laboratory receives an incomplete or incorrect chain of custody form, EQC personnel follow established procedures to contact the client and obtain accurate information for the samples. These procedures are described in SOP QC0346 (Policy for the Acceptance and Rejection of Environmental Samples).

25.6 Sample Identification and Login

25.6.1 All samples are assigned a unique identification number and are logged into the LIMS according to procedures described in SOP QC0303. When there are more than one bottle per sample, each sample container will be uniquely identified.

25.6.2 The sample number is printed on a permanent label which is attached to each sample container. Each label includes a sample/project number traceable to the LIMS as well as a second container identifier code unique to that individual container, also tracked in the LIMS. Sample identification information, the unique container identification, and preservatives added to the container are all encoded onto the sample container using bar code labels.

25.6.3 EQC prepares pre-printed forms ("pick sheets") for field service staff to use in order to identify samples requiring pickup. Pick sheets contain the unique sample identification that is used during sample login. Pick sheets use the letter "P" as a prefix to the sample identification. Upon sample login, the "P" is changed to an "L" which indicates the sample is available for analysis, and this designation, along with the unique sample identification, is maintained thereafter.

25.7 Sample Storage, Handling, and Transfer

25.7.1 Sample storage and handling procedures are described in SOP QC0308 (Sample Storage Procedure) and SOP QC0468. All samples are tracked and transferred using the unique identification number assigned by LIMS. All analysts responsible for department sample custody and sample custodians at EQC's main laboratory in Southampton are assigned a unique identification number and badge. Information including analyst's name and department is encoded onto the bar code included on the identification badge. The LIMS uses this information to maintain a record of all sample transfers. Additional safeguards have been encoded into the electronic system to prevent unauthorized personnel from receiving or relinquishing laboratory samples.

For EQC-Delaware, other satellite locations, or where electronic documentation is not possible, sample transfers are documented manually.

25.7.2 In cases where holding time or other constraints require sample transfer prior to bar coding, the transfer is tracked manually using a rush sample custody log. With the rush sample custody log, all signatures are obtained manually. Then, following analysis, the samples are returned to the sample custodian for entry into the LIMS and attachment of bar code labels.

25.7.3 Individual sample containers are relinquished to the appropriate departments for storage. During analysis, the samples are stored, tracked, and transferred thereafter by each department as required by applicable methods.

25.7.4 It is the responsibility of the Sample Custodian or designee to assure that all samples are logged into LIMS. Laboratory personnel are responsible for receiving and processing samples as described in Section 25.7.1.

25.7.5 Custody of samples and sample extracts/digestates transferred between various laboratory departments is maintained either electronically or manually through a transfer logbook.

25.7.6 Each sample digestate or extract is assigned a unique identifier that is traceable to the original sample container. Whenever possible, a bar code label is printed and affixed to the extract or digestate container and custody is tracked electronically as above. When it is not possible to affix a bar code label (i.e., due to the small size of an injection vial), custody of these samples is tracked using manual signatures in a department-specific sample transfer logbook. The sample digests or extract vial labels (e.g. for GC and GC/MS analyses) contain sample batch identification, unique sample identification, client name, and the analysis required or a cross-reference to this information.

25.8 Sample Disposal

25.8.1 Samples and sample preparation products, e.g. extracts, leachates, and digestates, are stored in the laboratory under required storage conditions. Procedures for disposal of these materials are described in SOP QC0479 (Laboratory Waste Disposal).

25.8.2 Original samples and sample preparation products are retained for a minimum 10 days following report generation, but not fewer than 15 days from sample receipt. The samples may be retained for a longer time if previously agreed with the clients.

26.0 QUALITY ASSURANCE FOR ANALYTICAL TESTING

26.1 Essential Quality Control Elements and Internal Procedures

The following quality control procedures or indicators are incorporated into applicable laboratory SOPs and the QSM. Specific procedures for data evaluation, corrective actions and data qualification are described in individual method SOPs and SOP QC0913 (Laboratory Data Review and Reporting).

26.1.1 **Demonstrations of Capability.** Each analyst is required to complete an Initial Demonstration of Capability (IDOC) and also perform an annual On-Going Demonstration of Capability (DOC). Additional details regarding the IDOC and the on-going DOC are contained in Sections 22.3 and 22.4 respectively.

26.1.2 **Method Detection Limit (MDL) Determinations**. MDL studies are performed at annually according to procedures in SOP QC0495.

26.1.3 **Blank Analysis**

26.1.3.1 **Laboratory Reagent Blanks**. The purpose is to evaluate contamination resulting from laboratory processes, reagents, or glassware. Laboratory reagent blanks are performed at a frequency of one per analytical batch of 20 or less.

26.1.3.2 **Method blanks.** EQC systematically prepares and analyzes method blanks with each batch of samples, to continuously evaluate analytical system interferences and background contamination. An aliquot of deionized (DI) water or other appropriate analyte-free matrix is submitted to the entire testing procedure. The presence of the analyte (s) of interest in the method blank render associated data suspect and requires corrective action. Method blanks are performed at a frequency of one per analytical batch of 20 or less.

26.1.3.3 **Field Blanks.** Field blanks are equipment rinsate blanks prepared in the field or samples of clean water sent to the sample site for transfer by the client into clean sample containers with subsequent shipment back to the laboratory with the field samples. Field blanks are analyzed according to client requests for all required analytes. Results provide valuable information regarding contamination introduced by the field sampling procedures which could affect sample data.

26.1.3.4 **Trip Blanks.** Trip blanks accompany associated samples requiring volatile organic analyses from the time of sample container preparation, shipment to and from the sampling site, and analysis by the laboratory. Trip blanks are analyzed to detect accidental or incidental contamination. Organic-free water is provided to the client by the laboratory in closed 40-mL vials or other appropriate containers. These containers are taken onsite, but not opened, and are subsequently shipped to the laboratory with associated field samples. The holding time for trip blanks begins at the time actual field samples are collected.

26.1.4 **Laboratory Fortified Blank (LFB) or Laboratory Control Sample (LCS)**

LFBs or LCSs are analyzed routinely to confirm proper method performance and to evaluate method accuracy. The LCS serves as the primary batch quality control check, and sample results may not be reported unless the LCS or LFB meet method-specified criteria. Laboratory control samples may be purchased as pre-prepared, whole-volume samples or in concentrate or dry reagent form

to be prepared by the laboratory for analysis. Laboratory control samples are obtained from a source different from that used to prepare the calibration standards. Analysis of laboratory control samples, in conjunction with matrix spikes and duplicates, allow delineation between matrix effects that may affect analysis of individual samples and overall method performance affecting analysis of all samples. Unless otherwise specified within the SOP, a LCS or LFB is analyzed with each batch of up to 20 samples per matrix per day.

26.1.5 Laboratory Spikes, Spike Duplicates, and Serial Dilutions

26.1.5.1 Matrix Spikes/Matrix Spike Duplicates (MS/MSD). These are also described as Laboratory Fortified Matrix (LFM) and LFM Duplicate. These samples are analyzed to assess matrix interference problems and method precision. At a minimum, an MS and MSD (or LFM and LFM Duplicate) are analyzed with each batch of 20 samples. The frequency of analysis of the MS/MSD could be greater if required by the analytical method or request for a specific project. The MS/MSD data are used to document the effect of matrix on analyte recovery and method precision. MS/MSD recoveries are evaluated based on quality control limits established by the method, or, if recovery criteria are not specified, using control limits established by the laboratory.

26.1.5.2 Post-Digestion Spikes

When MS/MSD recoveries for metals analyses (e.g. hexavalent chromium in solids, ICP-OES, and ICP-MS) do not meet acceptance criteria, post-digestion spikes may be required to evaluate whether recovery deviations are caused by instrumental interferences or problems with sample preparation. The sample digest is spiked at the level specified by the individual method SOP, and post-digestion spike recoveries are evaluated according to method acceptance criteria. Possible matrix interferences that are identified from evaluation of MS/MSD and post-digestion recovery data are documented.

26.1.5.3 Serial Dilution

Serial dilution is performed for ICP-OES and ICP-MS analyses to determine if significant chemical or physical interferences are caused by the sample matrix. Matrix interferences may be present if the diluted sample does not agree with the undiluted sample within the range specified by the method. Data not meeting the serial dilution criterion are reported with appropriate qualifiers.

26.1.6 Duplicates

26.1.6.1 Field Duplicates

Duplicates of field samples are collected at the time of sample collection. Field duplicate analyses are used to assess precision of

sampling processes. Field duplicates are collected as required by field sampling plans.

26.1.6.2 Laboratory Duplicates

The laboratory, or matrix, duplicate is a second aliquot of sample that is processed through the entire analytical procedure. Results of duplicate analyses are used to evaluate the precision of the analysis for that specific sample. However, usable precision data are produced only when the target analytes are present in the samples. Matrix spike duplicates (Section 26.1.5.1) are used in these cases to provide detectable levels of analytes to aid in evaluation of precision. Duplicates are analyzed at a minimum of one per analytical batch of 20 samples, or as required by method SOPs. The precision is evaluated by calculation of Relative Percent Difference (RPD) and comparison with acceptance criteria in the individual method SOP.

26.1.7 Internal Standards and Surrogate Spikes

Internal standards are used for GC and GC/MS analysis, when required by the methods, to compensate for chromatographic drift, establish relative retention time windows, and determine quantitation response factors for target analytes. Surrogate spikes, consisting of non-targeted compounds exhibiting responses similar to the targeted compounds, are added to each GC and GC/MS sample, extract, and standard. Surrogate spikes provide continuous evaluation of method performance and measurement of matrix effects on the recoveries of target analytes. Poor recoveries of surrogate spikes render associated sample data suspect. Corrective action is required and it may be necessary to reanalyze samples or qualify associated analytical results if it is not possible to obtain acceptable surrogate spike recoveries. Corrective actions are specified in individual method SOPs.

26.1.8 Initial and Continuing Calibration

Initial and continuing calibration of analytical instruments is performed as required by the applicable methods. Requirements for initial and continuing calibration are described in Section 23.3.2 and 23.3.3.

26.1.9 Control Charts

Control charts are used as described in Section 26.2.

26.1.10 Corrective and preventive action and root cause analysis

Policies and procedures for corrective and preventive action are described in Sections 13.0, 14.0, and 15.0.

26.1.11 Quality control acceptance criteria

EQC analytical SOPs contain acceptance criteria required by the approved analytical methods.

26.1.12 Definition of preparation and analytical batches

The frequency of analysis of quality control samples generally is dictated by the size of the analytical batch. Unless otherwise specified by the method or specific project, an analytical batch is a batch of 20 samples or less prepared within 48 hours from the beginning of the sample preparation process. Other requirements may be specified in the individual method SOPs.

26.1.13 Minimum frequency for conducting all quality control elements

Quality control elements are performed at defined frequencies according to procedures described in the individual analytical method SOPs.

26.1.14 Inhibitory Residue Test

Microbiological laboratories must perform the inhibitory residue test upon the first use of a dishwashing detergent or when the brand or type of detergent is changed. This test ensures that the glassware is free of toxic material. This test is not required if the certificate of analysis includes results of the inhibitory residue test.

26.2 Quality Control Limits

26.2.1 Quality control measures are assessed and evaluated on an on-going basis, and quality control acceptance criteria are established as specified in the approved methods. In the absence of method-specified limits, internally-generated or lab-defined control limits are used.

26.2.2 Control charts are prepared to create internally-generated control limits for both accuracy and precision as required by each analytical method or company standard operating procedure. Procedures for preparation of control charts are described in SOP QC0916.

26.2.3 Trend analysis: EQC uses control charts for monitoring data quality for specific contaminants of concern, based on data obtained from multiple instruments.

26.3 Marginal Exceedances

26.3.1 If a large number of analytes are in the LCS, it becomes statistically likely that a few will be outside control limits. This does not necessarily mean that the system is out of control, and therefore corrective action may not be required. Upper and lower marginal exceedance (ME) limits can be established to determine when corrective action is necessary.

26.3.2 A marginal exceedance (ME) is defined as being beyond the LCS control limit (three standard deviations), but within the ME limits. ME limits are between three and four standard deviations around the mean. The number of allowable marginal exceedances is based on the number of analytes in the LCS. If more analytes exceed the LCS control limits than are permitted by the method, or if any one analyte exceeds the ME limits, the LCS fails and corrective action is necessary.

26.3.3 This marginal exceedance approach is relevant for methods with numerous analytes. It does not apply to target analyte lists with fewer than eleven

analytes. The number of allowable marginal exceedances is determined using Table 26.3.3.

Table 26.3.3
Determination of Allowable Marginal Exceedances

Number of analytes in LCS	Number allowed as marginal exceedance
> 90	5
71-90	4
51-70	3
31-50	2
11-30	1
<11	0

26.3.4 If the same analyte exceeds the LCS control limit on consecutive analyses, it is an indication of a systemic problem requiring corrective action and the ME allowance does not apply.

26.4 Proficiency Test (PT) Samples or Inter-laboratory Comparisons

26.4.1 Analytes and methods for which EQC is certified are evaluated through the analysis of certified Performance Evaluation (PE) samples obtained from NELAC- accredited Proficiency Test (PT) sample providers.

26.4.2 EQC participates annually in two single-blind, single-concentration PT studies for each analyte on the NELAP designated Field of Proficiency Testing. A minimum of one PT is analyzed per year for non-NELAP parameters. Additional PT samples are analyzed as required by specific projects or other programs for which EQC holds accreditation.

26.4.3 Additionally, EQC conducts three internal blind PT Studies each year. These studies are conducted by the Quality Assurance Department to evaluate on-going proficiency in the analysis of potable water (Water Supply-WS) and non-potable water (Water Pollution-WP).

26.4.4 Each PT sample is integrated into the normal workload and tracked through LIMS. PT samples are diluted according to instructions provided by PT provider, and the diluted PT sample is then considered to be the actual sample. All PT samples are managed, analyzed, and reported in the same manner as normal environmental samples utilizing the same staff, methods, and quality control practices dictated by EQC SOPs.

26.4.5 All associated quality assurance data is reviewed for compliance with applicable criteria as specified in EQC SOPs.

26.4.6 EQC has established the following practices regarding analysis and reporting of PT samples:

26.4.6.1 EQC does not send any PT sample, or a portion of a PT sample, to another laboratory for analysis, nor will EQC knowingly receive any PT sample, or a portion of a PT sample, from another laboratory for analysis.

26.4.6.2 All EQC personnel, including laboratory management, are prohibited from communicating with any individual at another laboratory concerning the PT sample. All EQC personnel, including laboratory management, are prohibited from attempting to obtain the assigned value of any PT sample from a PT provider.

26.4.6.3 Final reporting of PT results is coordinated by the Quality Assurance Director who assures that all results are reported to the proper accrediting authorities and PT sample providers.

26.4.6.4 The laboratory maintains copies of all written, printed, and electronic records resulting from the analysis of PT samples according to policies described in Section 16.0 of the QSM. The laboratory records are available to auditors during on site audits of the laboratory.

26.4.7 PT samples for the State of Delaware shall be completed during the first quarter of the calendar year.

26.5 Data Reduction and Review

26.5.1 Data reduction and review procedures are described in SOP QC0913 (Laboratory Data Review and Reporting of Analytical Results). Permanent records of essential information pertinent to the analysis are maintained as described in Section 16.0 (Control of Records).

26.6 Expanded Data Packages

26.6.1 EQC provides expanded data packages required by various state and federal regulatory programs or site-specific project plans. Several routine options are available to clients ranging from a basic quality control summary to a complete data package with raw data that is suitable for validation. Procedures for preparation of expanded data packages are described in SOP QC0913 (Laboratory Data Review and Reporting of Analytical Results).

27.0 REPORTING OF RESULTS

27.1 Result Entry to LIMS

27.1.1 Data from most laboratory instruments are automatically entered into LIMS by interfacing the instrument workstations directly to LIMS. The automated data entry system is used at Southampton for most organic, metals, and wet chemistry instruments. Analysts review all results for conformance with applicable quality control criteria prior to initiation of data transfer. Department managers or peer review analysts then verify the accuracy of the data transfer. Data entry procedures are described in SOP QC0913 (Laboratory Data Review and Reporting of Analytical Results).

27.1.2 Manual data entry to LIMS is required for non-instrumental methods or procedures for which automated data transfer is not available. In these cases, a dual data entry system is used in LIMS whereby results (e.g. numerical value, date of analysis, analyst, dilution factor) are entered twice by the same person. LIMS monitors agreement between the two entries and provides a hardcopy report of the verification. Any discrepancies are evaluated and resolved before

a result is accepted by LIMS. Analysts review all results for conformance with applicable quality control criteria prior to initiation of data entry. Data entry procedures are described in SOP QC0913 (Laboratory Data Review and Reporting of Analytical Results).

27.2 Release and Reporting of Results

27.2.1 Following entry of results into LIMS, all chemistry results are reviewed prior to release to clients by the Laboratory Director, Manager of Environmental Laboratory Administration, Quality Assurance Director, or their designee. Microbiology results are reviewed by the Department Manager, Technical Director, or their designee. Results are reviewed for compliance with applicable regulatory limits, relationship to historical data if available, permit exceedances, MCL exceedances for compliance samples which are reported as required to the applicable regulatory authority, and other general criteria. Procedures for review, approval, and release of results are described in SOP QC0913 (Laboratory Data Review and Reporting of Analytical Results). Reports are issued with serial numbers in the format specified by the client.

27.3 Environmental Testing Obtained from Subcontractors

27.3.1 Subcontracted analyses are reported either by entry into LIMS or by attaching a copy of report from the subcontract laboratory to the EQC final report. The report clearly indicates the name and the laboratory identification number of the laboratory performing the analysis.

27.4 Electronic Transmission of Results

27.4.1 Clients have the option to access analytical results online using a secure access code.

27.4.2 Online analytical reports cannot be modified by the client.

27.5 Amendments to Test Reports

27.5.1 Amended test reports are identified with a new serial number as described in Section 27.2.1. Amended reports indicate the serialized report that it replaces and the reason for issuance of the revised report.

28.0 HEALTH AND SAFETY

EQC has established a formal health and safety program, which is detailed in its Safety Procedure Manual. The program includes policies and procedures that are essential for the safe operation of the laboratory. Training is provided to all employees on the key elements of this program.

28.1 Policy: EQC provides a safe and healthy working environment for all its staff. The Company's safety program complies with the requirements of Occupational Health and Safety Administration (OSHA) and other applicable regulatory agencies. EQC's objective of the health and safety program is to promote safe work practices that prevents or minimizes injuries and accidents, by raising awareness, and through safety training.

28.2 **Elements of Health and Safety Program:**

28.2.1 New Employee Safety Orientation: Training is provided to all new employees upon hiring. This training includes hazard communication, safe handling of laboratory equipment, chemicals and reagents, and Right Know Training. Policies adhere to OSHA's Hazard Communication Standard, Title 29, Code of Federal Regulations 1910.1200. Safety Data Sheets (SDS), previously, Material Safety Data Sheets (MSDS) are available for employees to access at each laboratory location, or via EQC's Intranet site for SDS.

28.2.2 Chemical Hygiene Plan: This plan includes identification and operating procedures of safety equipment and personal protective equipment (PPE). Potential health hazards of hazardous chemicals and reagents, and safe handling procedures are covered in this plan. EQC maintains a hazardous Chemicals Inventory at every laboratory location, and this list is updated annually.

28.2.3 Chemical Spill Response Plan: This plan includes steps to prevent spills, and minimize exposure risks from chemical spill or accidental release of chemicals or gases in the laboratory.

28.2.4 Blood borne Pathogen Plan: Blood borne pathogens are infectious microorganisms present in blood that can cause disease in humans. These pathogens include, but are not limited to, hepatitis B virus (HBV), hepatitis C virus (HCV), and human immunodeficiency virus (HIV), the virus that causes AIDS. EQC has implemented a plan to prevent workers' exposure to blood borne pathogens that are at risk for serious or life-threatening illnesses.

28.2.5 Respiratory Protection Plan: This plan includes steps for protection from exposure to respiratory hazards, when engineering controls and safe practices are inadequate to control the hazards.

28.2.6 Permit-Required Confined Space Program: Identifies confines spaces in the building. It instructs who can, and how to enter the confined spaces.

28.2.7 Radiation Protection Program: Identifies radiation devices, storage, handling and leak-checking requirements and responsibilities.

28.2.8 Fire Prevention Program: Identifies storage location of flammables, potential ignition sources and handling.

28.2.9 Emergency Response and Evacuation Plan: Procedures to protect staff and visitors during emergencies are detailed in this plan. These emergencies could include accidental fire, explosion, gas leaks, hazardous material spills, natural disasters etc. The plan identifies emergency response team that should coordinate the response in times of emergencies.

28.2.10 Lockout/Tagout Plan: When repair or maintenance is required on laboratory equipment, it is critical to ensure that the equipment is safe/inoperable before any work is done by EQC staff or outside contractors. The Lockout/Tagout plan

details procedures to do maintenance on equipment that has the potential to start, energize, or release energy, and cause injury to personnel.

28.3 All employees must wear appropriate personal protective equipment and adhere to the safety guidelines specified in the Safety Procedure Manual of EQC.

28.4 Food, drinks and plants are prohibited in the laboratory work areas.

28.5 Employees should not report to work when their health conditions might negatively affect other personnel or laboratory analysis.

28.6 Safety Committee: The Safety Committee comprises representatives from different laboratories, administrative personnel and Management, and conforms to guidelines of the State of Pennsylvania. The Committee coordinates periodic safety inspections, addresses safety concerns, makes improvements, and tracks facility accidents. The Committee meets monthly to discuss safety issues.

29.0 SUPERSESSION

29.1 This QSM supersedes the previous versions of the EQC QSM. Name references and logos were revised to reflect Eurofins QC, Inc. (EQC). Minor editorial changes were made throughout the document.

The following changes were made to Figures and Tables:

Figure 1	Updated for a new EQC Organization Chart
Figure 2	Updated to reflect the Eurofins' Ethics Policy Statement
Figure 3	Updated to reflect the Eurofins' Confidentiality Agreement
Figure 4	Added to reflect the Eurofins' Quality Policy Statement

Removed floor plans (Figure 2)

Other revisions were as follows:

Section 6.4.7	Added reference to additional reference Methods.
Section 9.0	Updated section with purchasing guidelines
Section 20.1.8	Added Manager of Environmental Laboratory Administration
Section 22.2.2.4	Defined LOQ for tests with no calibration curve
Section 22.5	Deleted to avoid redundancy.
Section 22.5.1	Manual integration policy summary added.
Section 23.3.2.4	Removed term "correlation coefficient" to indicate more general statistical criteria for calibration curves
Section 23.3.3.4.d	Section added to describe reporting of drinking water compliance samples to the state of Pennsylvania
Section 25.6.3	Section added to describe use of "pick sheets"
Section 25.8.2	Updated policy for sample disposal
Section 26.4.7	Added DE state requirement for PTs.
Section 26.1.5.2	Added hexavalent chromium in solids to for post-digest spikes
Section 26.2.3	Trend analysis added.
Section 27.2.1	Added Microbiology Department Manager and Technical Director for approval of microbiology data
Section 28.0	Updated Section 28.0 with detailed information on Health and Safety.

APPENDICES

Figure 1. Eurofins QC, Inc. Organization Chart

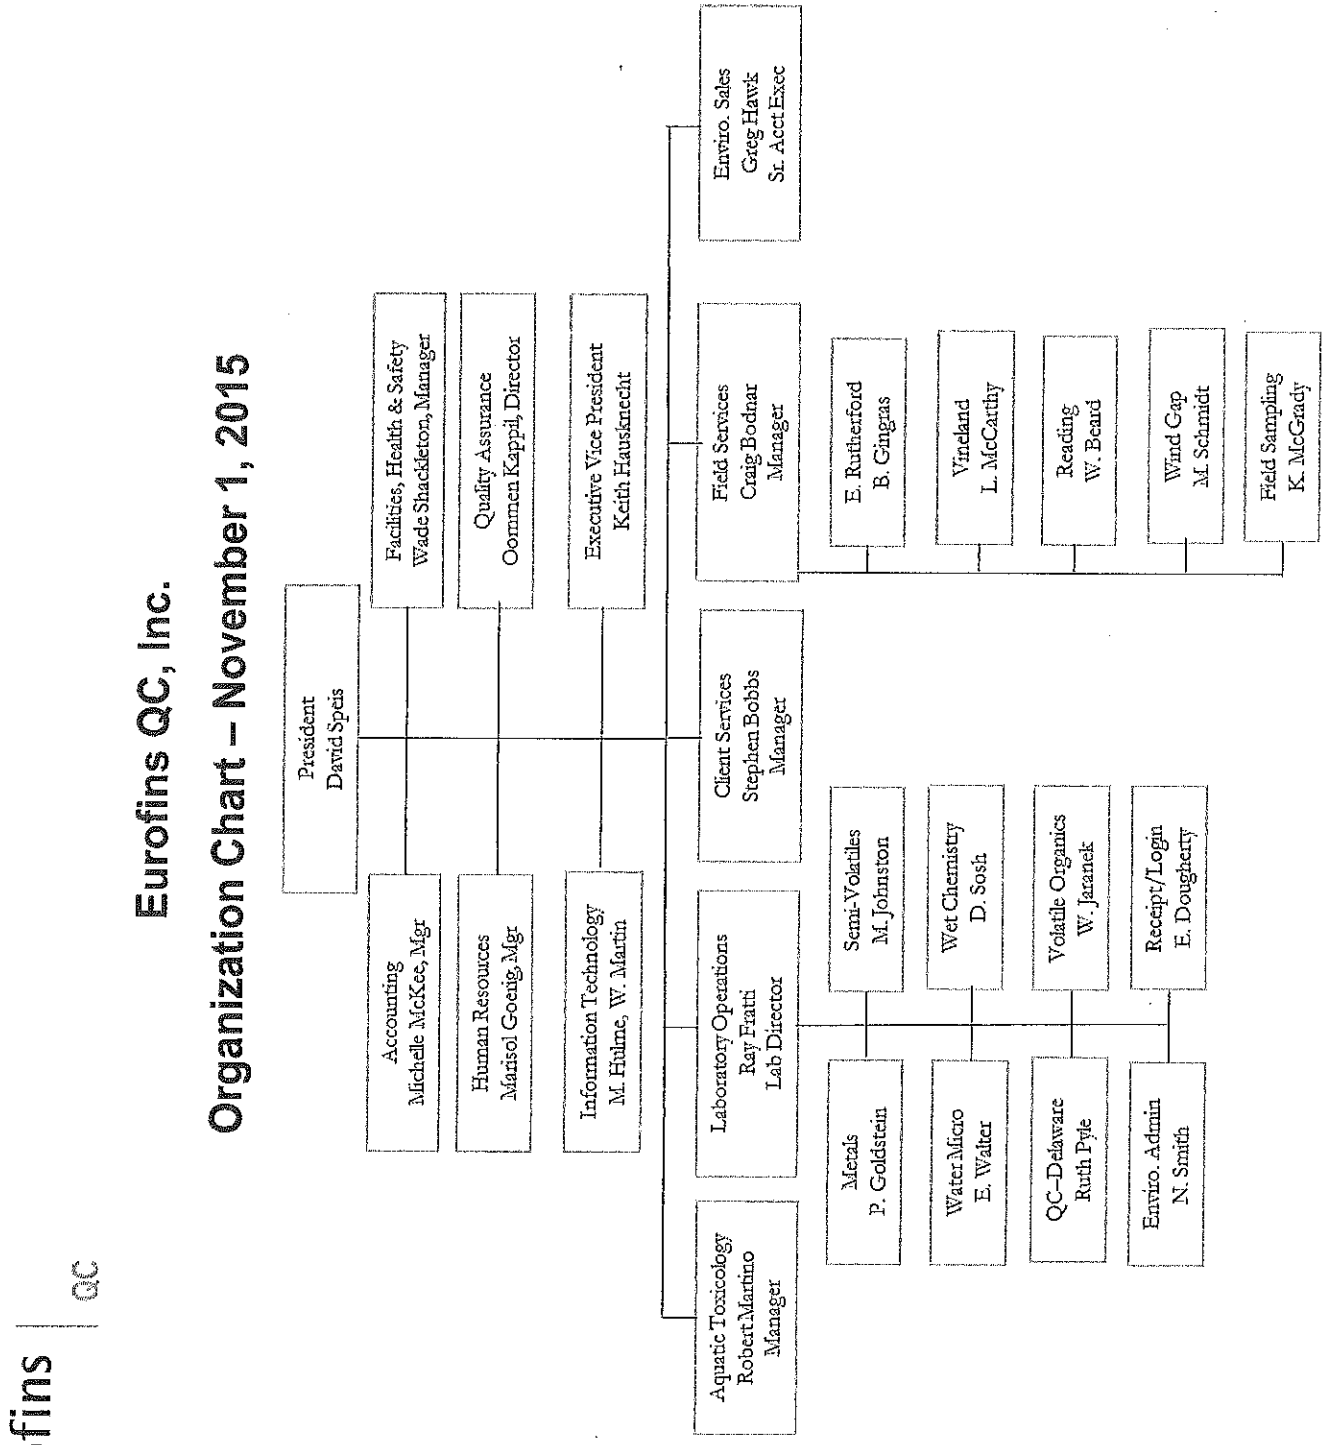

Figure 2

eurofins	Document Title: Eurofins Ethics Policy Statement		
	Eurofins Document Reference: N/A	Revision : 2	Historical Reference: N/A
	Effective date : 05/01/2015	Status: Effective	

Our Company was built on the foundation of high integrity and ethical laboratory practices. To preserve this standard we have a clear expectation that each of us take personal responsibility to do the right thing and uphold the highest level of ethics and quality in all of our dealings.

Here are the ethical responsibilities required of us:

Each and every one of us is expected to adhere to the highest professional and ethical standards. Each employee commits to honest and ethical practices in all daily actions.

- No one will intentionally improperly manipulate or falsify activities in any way.
- Ethical performance and data integrity MUST supersede any other objective of laboratory operations.
- Each employee bears ultimate responsibility for the validation and accuracy of his or her documentation. The analyst's signature signifies that the action taken to generate the data and the documentation are accurate and authentic, and confirm that all proper procedures were followed in the generation of the data in real time.
- Eurofins takes a zero tolerance stance for illegal, unethical, and improper practices affecting the testing process. Each employee is responsible for safeguarding the Lab's ethical practices. For this reason, each employee is responsible to report any situation that may be adversely affecting the quality and integrity of the data produced.
- It is vital that all employees take responsibility to preserve our ethical business practices. Employees who know of, or witness any violation of business, quality, or data integrity policy are required to report the activity to an Ethics Officer, Quality Director, or member of Senior Management. A timely and thorough investigation will occur to remedy any situation regarding these allegations.
- Any employee who knows of or witnesses any violation of business, quality, or data integrity policy, but fails to report it will be subject to disciplinary action.
- During a thorough investigation, the Ethics Officer, and/or Senior Management, will assess the situation and resolve the matter. Since data integrity is so vital to our business practices, any employee found willfully falsifying or manipulating data will be released from employment.
- The Ethics Officer, or Senior Management, in collaboration with appropriate staff, will complete a corrective action plan addressing the root causes. The action plan will be put in place and may include additional training or changes in policies and procedures. All those involved will receive confidential communication regarding corrective action steps taken to remedy the situation.

I understand and commit to these responsibilities. I understand the critical importance of data and business integrity compliance. I realize that any infractions of laboratory integrity procedures could lead to serious consequences including employment separation, debarment, or civil/criminal prosecution. I take personal responsibility to uphold the highest ethical business practices and report any concerns to help preserve Eurofins' integrity.

Eurofins QC, Inc.
CONFIDENTIALITY AGREEMENT

THIS AGREEMENT, made this _____ day of _____, 20__, between Eurofins QC, Inc.., a Pennsylvania corporation, hereinafter called "EQC" and _____, hereinafter called "Employee".

WHEREAS, EQC is engaged in the business of a professional testing laboratory, and

WHEREAS, EQC employs the Employee and the Employee desires to enter or continue in the employ of EQC on the terms, provisions and conditions specified herein as to confidentiality; and

WHEREAS, the employee in the course of his/her employment and as a necessary consequence thereof will receive information and acquire knowledge of the business and affairs of EQC and more particularly technical information which in character is private, peculiar and confidential in nature to EQC, and/or EQC's customers in their business; and,

WHEREAS, the business, success and profits of EQC depend in large part upon the maintenance of confidentiality as to such information and knowledge;

NOW, THEREFORE, in consideration of the mutual undertakings of the parties and the employment or continued employment of the Employee by EQC, incorporating the premises, intending to be legally bound, the parties agree as follows:

1. All technical information of a confidential nature encompassed within this agreement shall be made available to Employee on the basis that such technical information is necessary to Employee's proper performance of the work for which the Employee is responsible.
2. Employee agrees that he/she will not, while in the employ of EQC , or at any time thereafter, communicate or divulge either orally or in writing or otherwise, to anyone any knowledge or information that he/she may acquire or which may be imparted to him/her in the course of his/her employment, regarding the business or affairs of EQC or its customers and particularly, but not in limitation of the generality of the forgoing, knowledge or information regarding technical information of EQC or EQC's customers.
3. Other than as set forth herein, all terms and conditions of the employment of the Employee are as set forth from time to time in the Employee Handbook and any other document relevant to Employee or employees of EQC in general and this agreement shall not be constructed as granting to Employee any special rights or privileges not specifically granted in the said Handbook or other documents.

QUALITY POLICY STATEMENT

eurofins	Document Title: Eurofins US Quality Policy Statement		
	Eurofins Document Reference: 1-P-QM-FOR-9007879	Revision: 6	Historical Reference: Form 2787
	Effective date: July 7, 2014	Status: Effective	

As an organization, all personnel are committed to high quality professional practice, testing and data, and service to our clients.

We strive to provide the highest quality data achievable by:

- Following all documentation requirements; describing clearly and accurately all activities performed; documenting "real time" as the task is carried out; understanding that it is never acceptable to "back date" entries and should additional information be required at a later date, the actual date and by whom the notation is made must be documented.
- Providing accountability and traceability for each sample analyzed through proper sample handling, labeling, preparation, instrument calibration/qualification/validation, analysis, and reporting; establishing an audit trail that identifies date, time, analyst, instrument used, instrument conditions, quality control samples (where appropriate and/or required by the method), and associated standard material.
- Emphasizing a total quality management process which provides accuracy, and strict compliance with agency regulations and client requirements, giving the highest degree of confidence; understanding that meeting the requirements of the next employee in the work flow process is just as important as meeting the needs of the external client.
- Providing thorough documentation and explanation to qualify reported data that may not meet all requirements and specifications, but is still of use to the client; understanding this occurs only after discussion with the client on the data limitations and acceptability of this approach.
- Responding immediately to indications of questionable data, out-of-specification occurrences, equipment malfunctions, and other types of laboratory problems, with investigation and applicable corrective action; documenting these activities completely, including the reasons for the decisions made.
- Providing a work environment that ensures accessibility to all levels of management and encourages questions and expression of concerns on quality issues to management.

We each take personal responsibility to provide this quality product while meeting the company's high standards of integrity and ethics, understanding that improprieties, such as failure to conduct the required test, manipulation of test procedures or data, or inaccurate documentation will not be tolerated. Intentional misrepresentation of the activities performed is considered fraud and is grounds for termination.

I understand the expectations and commit to implementation of all applicable policies and procedures and to providing quality data.

Water Microbiology	1	Incubator	VWR Precision Model 1550 (#ACL-2D)
Water Microbiology	1	Incubator	VWR Precision Model 6M (#DEINC001)
Water Microbiology	1	Incubator	Quincy Labs Model 10-1450 (#L03602)
Water Microbiology		Membrane Filtration Equipment	Gelman , Millipore 3-place
Water Microbiology	1	Microscope	Fisher
Water Microbiology	1	Refrigerator	Danby DCR34W
Water Microbiology	1	UV Lamp 366nm, 6 W	Spectroline EA-160 (#1557885)
Water Microbiology	1	Water Bath (Coliform)	Precision (#66850)
Water Microbiology	1	Water Batch (Colilert)	Precision (#9308-426)
Water Microbiology	2	Quanti-Tray Sealer	IDEXX Model 2X
Wet Chemistry	1	Walk-in Cold Storage Box	Kysor/Needham
Wet Chemistry	2	Oxygen Meters	YSI Model 58/5906 BOD probe
Wet Chemistry	1	pH Meter	Cole-Parmer Mode 6209
Wet Chemistry	1	Analytical Balance	Denver Instruments TL-204
Wet Chemistry	1	Drying Oven #1	VWR Model 1320
Wet Chemistry	1	Drying Oven #2	Thelco Model 17
Wet Chemistry	1	Drying Oven #3	Fisher IsoTemp Model 6916
Wet Chemistry	1	Drying Oven #4	Thermo Precision Model 6958

Table 2. Equipment List (continued)

Department	Quantity	Equipment Description	Manufacturer/Model
EQC-Delaware			
Wet Chemistry	5	BOD Incubators	Fisher Model 507C
Wet Chemistry	1	Muffle Furnace	Lindberg Blue BF51766A
Wet Chemistry	1	Hot Water Bath	Fisher Scientific IsoTemp 120
Wet Chemistry	1	Heating Block	Fisher Scientific IsoTemp 145D
Wet Chemistry	1	Stir Plate	Cimarec 2 Thermolyne Model S46725
Wet Chemistry	1	Stir Plate	Fisher Vuemix Model 116
Wet Chemistry	1	Stir Plate	Fisher Scientific 11-06000-7S
Wet Chemistry	1	Stir Plate	Fisher Thermix Model 120S
Wet Chemistry	1	Stir Plate	Cimarec 3 Thermolyne Model S47035
Wet Chemistry	8	Dessicators	Boekel
Wet Chemistry	1	Dishwasher	Labconco Flask Scrubber
Wet Chemistry	1	Vacuum Pump	Marathon 5KH36KNA510X
Wet Chemistry	1	Turbidimeter	Hach Model 2100N
Wet Chemistry	1	Lachat Flow Injection Analyzer	QuikChem 8000, Lachate Omnion 2.0 Software Block Digestor Lachat Model BD-46
Wet Chemistry	1	Ion Chromatograph	Dionex ICS-1000, Autosampler Dionex AS-40 Software Dionex Chromeleon
Wet Chemistry	1	Ion Chromatograph	Dionex ICS-1600, Autosampler Dionex AS-40 Software Dionex Chromeleon
Wet Chemistry	2	COD Digestion Blocks	Hach 45600-00
Wet Chemistry	1	COD Temperature Probe	Hach 15-077-14
Wet Chemistry	1	Conductivity Meter	Orion (#9098)
Wet Chemistry	3	Stir Plates	VWR Mini-Stirrer Model 200
Wet Chemistry	1	UV-Vis Spectrophotometer	Hach DR-2500
Wet Chemistry	1	UV-Vis Spectrophotometer	Spectronic 20 Genesys
Wet Chemistry	1	Balance	Mettler Model PM-4600
Wet Chemistry	1	Hot Block	Environmental Express Model SC10
Wet Chemistry	1	Hot Block	Environmental Express Model SC100
Wet Chemistry	1	Refrigerator	Kenmore
Wet Chemistry	1	Refrigerator	Magic Chef
Wet Chemistry	1	TOC Analyzer	Teledyne Tekmar Phoenix 8000 Teledyne Tekmar Autosampler and Software
Wet Chemistry	1	Automatic Titrator	Metrohm Model 719S Titrino Autosampler Metrohm Model 730 Software Beckman Titrino Workcell V4.0

Table 3. List of Standard Operating Procedures

Department	Standard Operating Procedure Title	SOP Number
Bioassay	Quality Systems Manual for the Aquatic Toxicology Laboratory	QC0452
Bioassay	Dissolved Oxygen Measurement by Probe-Membrane Method (EPA 360.1)	QC0489
Bioassay	Test Methods and Protocols for Acute Testing Under the NPDES Program	QC0491
Bioassay	In Vitro Determination of Chlorophylls, a, b, $C_1 + C_2$ and Pheopigments in Marine and Freshwater Phytoplankton by Visible Spectrophotometry	QC0492
Bioassay	Sampling, Preparation and Handling of Dilution Waters and Effluent for Use in NPDES Testing	QC0493
Bioassay	Procedure for Cleaning Labware used in Aquatic Toxicity Testing	QC0496
Bioassay	Fathead Minnow, Pimehales Promelas, Larval Survival and Growth Test, EPA Method 1000.0	QC0503
Bioassay	Daphnid, Ceriodaphnia Dubia, Three Brood Survival and Reproduction Test, EPA Method 1002.0	QC0504
Bioassay	Mysid, Mysidopsis Bahia, Survival, Growth and Fecundity Test, EPA Test Method 1007.0	QC0507
Bioassay	Sheepshead Minnow, Cyprinodon Variegatus, Larval Survival and Growth Test, EPA Test Method 1004.0	QC0632
Bioassay	Atlantic Silverside, Menida Beryllina, Larval Survival, and Growth Test EPA Method 1006.0	QC0634
Bioassay	Standard Operating Procedure for Culturing the Green Algae Selenastrum for Testing and Use as Cladoceran Food	QC0635
Bioassay	Green Alga, Selenastrum Capricornutum, Growth Test Method 1003.0	QC0636
Bottle Preparation	Preparing a Bottle Order	QC0429
Bottle Preparation	Preparation and Storage of Pre-preserved Sample Bottles	QC0458
Bottle Preparation	Preparation of Containers for Soil Samples with Methanol	QC0842
Environmental Administration	Review of Routine Laboratory Results	QC0436
Environmental Administration	Review of Permitted Results	QC0436
Environmental Administration	Preparation of PADEP SDWA-Pb,Cu Forms	QC0451
Environmental Administration	Preparation of PADEP SDWA-1, TTHM, HAA, TOC, Alkalinity, PBCU, Bromide, Bromate, Coliform Check Samples, Chlorine Residual and HPC Forms	QC0453
Environmental Administration	Preparation of PADEP SDWA-4, Inorganic/Organic Chemical and Radiological Analysis Forms	QC0462
Environmental Administration	XMIT Program for Exxon	QC0517
Environmental Administration	Laboratory Information Management System (LIMS) Result Rollback Procedure	QC0571
Field Services	Groundwater Monitoring Well Sampling Procedures	QC0305
Field Services	Trip and Field Blank Preparation	QC0309
Field Services	DPD Chlorine and DPD Bromine Using a Taylor Slide Comparator	QC0317
Field Services	Field Measurement of Conductivity, Standard methods 2510B	QC0331

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
Field Services	Field Temperature Measurement	QC0332
Field Services	Field pH Measurement	QC0333
Field Services	Procedure for Collection & Submittal of VOC Field Reagent Blanks for Drinking Water Samples	QC0374
Field Services	Field Sampling Procedure for Swimming Pools, Wading Pools, Hot Tubs, Spas and Bathing Beaches	QC0538
Field Services	Field pH using a Taylor Slide Comparator	QC0547
Field Services	General Field Sampling Procedures	QC0548
Field Services	NJ Private Well Testing Act (PWTA) Sampling Procedures – General Requirements	QC0591
Field Services	NJ Private Well Testing Act (PWTA)– Microbiological Sampling	QC0591A
Field Services	NJ Private Well Testing Act (PWTA) Sampling Procedures – Volatile Organics	QC0591B
Field Services	NJ Private Well Testing Act (PWTA) Sampling Procedures – Nutrients	QC0591C
Field Services	NJ Private Well Testing Act (PWTA) Sampling Procedures – Metals	QC0591D
Field Services	NJ Private Well Testing Act (PWTA) Sampling Procedures – Field pH Measurement	QC0591E
Field Services	NJ Private Well Testing Act (PWTA) Sampling Procedures – GPS Readings	QC0591F
Field Services	NJ PWTA Sampling Procedures – 24 Hour Gross Alpha	QC0591G
Field Services	Sampling of Ice Cream and Frozen Desserts	QC0620
Field Services	Documentation of Field Measurements	QC0637
Field Services	Measurement of Free & Total Chlorine using the Hach® Pocket Colorimeter II	QC0661
Field Services	Low Flow Groundwater Monitoring Well Sampling Procedure	QC0663
Field Services	Grab and Composite Sampling Procedure	QC0664
Field Services	Sampling Procedure for the DRBC PCB Project	QC0711
General	Thermometer Calibration, Maintenance, and Record keeping	QC0339
General	Documentation of Laboratory Data	QC0343
General	Routine and Non-routine Instrument Maintenance	QC0417
General	Laboratory Balance Calibration	QC0470
General	Calibration Verification of Air Displacement Pipetters and non-Class A Disposable or Reusable Pipets	QC0472
General	Calibration of Reagent Delivery Pumps	QC0473
General	Purchasing of Services and Supplies	QC0478
General	Waste Disposal in the Laboratory	QC0479
General	Reagent/Reference Material Receipt, Labeling, Expiration, Storage and Disposal	QC0486
General	Proper Manual Integration Techniques for GC and GC/MS Chromatography	QC0559
General	Review Guidance for Data Deliverables Generated by EISC Software	QC0640

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
General	Culture Transfers between EQC Satellite Offices and the Southampton Laboratory	QC0760
General	Media Transfers between Southampton Laboratory and the EQC Satellite Offices	QC0761
General	Pest Management	QC0797
General	Change Control	QC0838
Metals	Mercury-Manual Cold Vapor Technique, EPA 245.1	QC0263
Metals	Determination of Trace Metals by Graphite Furnace Atomic Absorption, SM 3113B-2011	QC0265
Metals	Glassware Cleaning Procedure for Metals Analyses	QC0272
Metals	Metals and Trace Metals by Inductively Coupled Plasma (ICP) in Aqueous samples by EPA 200.7	QC0280
Metals	Mercury-Manual Cold Vapor Technique Method 7470A	QC0354
Metals	Mercury-Manual Cold Vapor Technique, SW846 Method 7471A & 7471B	QC0355
Metals	Acid Digestion of Aqueous Samples and Extracts for Analysis by SW846 Method 6010 (ICP)	QC0356
Metals	Acid Digestion of Sediments, Sludges, and Soils by Method EPA 3050B for ICP-AES Metals Analysis by Method 6010	QC0371
Metals	Acid Digestion of Waters for Total Recoverable or Dissolved Metals for Analysis by SW846 Method 6010 (ICP)	QC0373
Metals	Turbidity Testing for Metals Digestion (Nephelometric) EPA Method 180.1	QC0430
Metals	Nitric Acid Digestion of Aqueous Samples by SM3030 E- 2004	QC0589
Metals	Calibration Validation of Digestion Vials	QC0592
Metals	Metals and Trace Elements by Inductively Coupled-Plasma Mass Spectroscopy (ICP-MS) by EPA 200.8	QC0599
Metals	Sample Preparation Procedure for the Digestion of Aqueous Samples for Total Recoverable Elements by EPA Method 200.2 for Analysis by EPA Methods 200.7, 200.8 and 200.9	QC0618
Metals	Metals and Trace Elements in Environmental Samples By Inductively Coupled Plasma (ICP) SW-846 Method 6010C	QC0757
Metals	Microwave Assisted Acid Digestion of Sediments, Sludges and Oils Method 3051A	QC0810
Metals	Metals and Trace Elements in Environmental Samples by Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS) by SW-846 Method 6020A	QC0829
Metals	Metals and Trace Elements in Food and Nutritional Samples by Inductively Coupled Plasma (ICP) AOAC Method 990.08	QC0910
Organic Extractions	Pressurized Fluid Extraction (PFE) EPA method 3545A	QC0415
Organic Extractions	Labware Washing Procedure for the Organic Extraction Laboratory	QC0469
Organic Extractions	Solid Phase Extraction-Herbicides by Method EPA 3535A	QC0674
Organic Extractions	Florisil Cleanup EPA 3620C	QC0677

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
Organic Chemistry	Diesel and Gasoline Range Organics by Gas Chromatography Based on USEPA SW-846 Method 8015B	QC0358
Organic Chemistry	Chlorinated Herbicides by Gas Chromatography based on EPA Method 8151A	QC0360
Organic Chemistry	1,2-Dibromomethane (EDB), 1,2-Dibromo-3-Chloropropane (DBCP), 1,2,3-Trichloropropane (1,2,3TCP) by Gas Chromatography based on EPA Methods 504.1 and 8011	QC0368
Organic Chemistry	Chlorinated Phenoxy Acid Herbicides by Gas Chromatography Based on Standard Methods 6640B	QC0412
Organic Chemistry	Organochlorine Pesticides and Polychlorinated Biphenyls by Gas Chromatography based on USEPA Method 608	QC0425
Organic Chemistry	Determination of Haloacetic acids in Drinking Water based on EPA Method 552.2	QC0555
Organic Chemistry	Organochlorine Pesticides and Polychlorinated Biphenyls (PCBs) by Gas Chromatography based on SW846 Methods 8081 and 8082	QC0641
Organic Chemistry	Total Semivolatile Petroleum Hydrocarbons by Gas Chromatography Based on Method NJDEP OQA-QAM-025	QC0680
Organic Chemistry	The Determination of Extractable Petroleum Hydrocarbon Compounds by Flame Ionization Gas Chromatography Method NJ EPH 10/08	QC0756
Organic Chemistry	Determination of Chlorinated Pesticides in Drinking Water By Gas Chromatography with Electron Capture Detector (Method EPA 508 Revision 3.1)	QC0823
Organic Chemistry	Determination of Chlorinated Acids in Drinking Water by Liquid-Liquid Extraction, Derivatization and Gas Chromatography with Electron Capture Detection (EPA Method 515.3 Revision 1.0)	QC0824
Organic Chemistry	Determination of Ethylene Glycol, Propylene Glycol and Diethylene Glycol by Direct Aqueous Injection Using Gas Chromatography-Flame Ionization Detector	QC0825
Organic Chemistry	Analysis of Dissolved Gases in Water Using Headspace Autosampler and Flame Ionization Based on Method PA-DEOP 3686	QC0834
Quality Assurance	Content, Format, Preparation, Review, Approval, Distribution, Revision and Control of Standard Operating Procedures	QC0310
Quality Assurance	Content, Format, Preparation, Review, Approval, Distribution, Revision and Control of Administrative Standard Operating Procedures	QC0418
Quality Assurance	Archiving and Storage of Data Files and Computer Media	QC0460
Quality Assurance	Acceptance Criteria for Unspecified Methods	QC0485
Quality Assurance	Annual Review of Operations and Internal Quality Assurance Assessments	QC0488
Quality Assurance	Method Detection Limit Determination	QC0495
Quality Assurance	General Preparation and Evaluation of Demonstrations of Capability	QC0499
Quality Assurance	Customer Complaints	QC0510
Quality Assurance	Data Variance Requests	QC0515
Quality Assurance	Good Laboratory Practice	QC0673
Quality Assurance	Determination of LOD and LOQ	QC0684
Quality Assurance	Measurement of Uncertainty	QC0831
Sample Custody	Completing a Chain of Custody Form	QC0302
Sample Custody	Sample Log-in Procedure	QC0303
Sample Custody	Sample Storage Procedure	QC0308

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
Sample Custody	Sample Compositing and Sub-sampling	QC0338
Sample Custody	Policy for the Acceptance and Rejection of Environmental Samples	QC0346
Sample Custody	Sample Transfers Between EQC, Satellite Offices and the Southampton Laboratory	QC0432
Sample Custody	Electronic Chain of Custody and Sample Transfer	QC0468
Sample Custody	Preparation of ID Cards for Electronic Sample Custody Transfer	QC0511
Sample Custody	Sample Handling: Details Addressing Sample Movement from the Field or Deliveries to the Satellite and Testing Labs	QC0889
Semivolatile Organics	Semivolatile Organic Compounds Analyzed by GC/MS: SW846-8270C	QC0321
Semivolatile Organics	Semivolatiles Analyzed by EPA Method 625	QC0322
Semivolatile Organics	Reporting of Tentatively Identified Compounds Determined from Mass Spectral Analysis	QC0583
Semivolatile Organics	Semivolatile Organic Compounds Analyzed by GC/MS: EPA 525.2	QC0676
Semivolatile Organics	Semivolatile Organic Compounds Analyzed by GC/MS: SW846-8270D	QC0682
Volatile Organics	Determination of Volatile Organic Compounds by GC/MS: EPA Method 8260B	QC0320
Volatile Organics	Determination of Volatile Organic Compounds by GC/MS: EPA Method 624	QC0329
Volatile Organics	Determination of Volatile Organic Compounds in Drinking Water by GC/MS-EPA Method 524.2	QC0340
Volatile Organics	Determination of Volatile Organic Compounds by EPA 8260C	QC0681
Water Microbiology	Heterotrophic Plate Count by Standard Methods, 9215B (2000)	QC0439
Water Microbiology	Membrane Filter Technique for Members of the Coliform Group (SM9222B-1997, SM21st Ed.)	QC0440
Water Microbiology	Membrane Filter (MF) Technique for Members of the Fecal Coliform Group (SM21st Ed. 9222D)	QC0441
Water Microbiology	Multiple Tube Fermentation (MPN) Technique for Members of the Coliform Group SM9221B,C,E,F-2006)	QC0442
Water Microbiology	Membrane Filter (MF) Technique for Members of the Fecal Streptococcus and Enterococcus Groups SM9230C-2007	QC0444
Water Microbiology	Chromogenic Substrate Technique for Total Coliform and E. Coli (Colilert®) SM9223B 21st Ed.	QC0446
Water Microbiology	Media and Broth Preparation (SM20th Ed., 9050)	QC0448
Water Microbiology	Environmental Monitoring of the Laboratory (Standard Methods 9020B-2005)	QC0477
Water Microbiology	Preparation of Bottles Used for Environmental Microbiological Testing (SM 20th Ed., 9030B, 9040)	QC0480
Water Microbiology	Entering and Verifying Environmental Microbiology Results	QC0481
Water Microbiology	Operation and Maintenance of the Consolidated SR-24C Autoclaves	QC0482
Water Microbiology	Preparation of Phosphate-Buffered Dilution and Rinse Water (Standard Methods, 21st Ed., 9050C)	QC0500
Water Microbiology	Salmonella (SM 9260D)-1997	QC0512

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
Water Microbiology	Water, Waste water, Sludge and Compost Sampling for Microbiological Testing (SM 20th Ed., Methods 9060, 9213)	QC0519
Water Microbiology	Repeat Monitoring for Samples that are in Violation of the National Primary Drinking Water Regulations	QC0586
Water Microbiology	Membrane Filter (MF) Technique for Enterococci (EPA 1600)	QC0613
Water Microbiology	Membrane Filter (MF) Technique for E. Coli in Natural Bathing Beach Waters (SM 20th Ed., 9213D)	QC0617
Water Microbiology	Membrane Filter (MF) Technique for Pseudomonas aeruginosa (SM 20th Ed., 9213E)	QC0624
Water Microbiology	E. Coli in Water by Membrane Filtration using membrane-Thermotolerant Escherichia Coli, (mTEC) EPA1103.1	QC0642
Water Microbiology	*E. coli* in Water by Membrane Filtration using modified Membrane-Thermotolerant *Escherichia coli* Agar (Modified mTEC) (EPA 1603)	QC0665
Water Microbiology	Multiple Tube Fermentation (MPN) Technique for Members Fecal Coliform Group for Sewage Sludge (Biosolids)	QC0759
Water Microbiology	Water Microbiology Sample Receipt and Prioritization	QC0800
Water Microbiology	Documentation of Water Micro data in Logbooks	QC0811
Water Microbiology	Cleaning and Sanitizing Environmental Microbiology Laboratory	QC0818
Water Microbiology	Detection of Pseudomonas Aeruginosa in Recreation Waters (IDEXX Pseudalert Test Method)	QC0839
Water Microbiology	Chromogenic Substrate Technique for Total Coliform and Escherichia Coli by SM9223B (Colilert-18) 2004	QC0888
Water Microbiology	LIMS Report Comments: Water Microbiology Department	QC0901
Wet Chemistry	Specific Conductance Standard Methods 2510B and EPA SW-846 Method 9050	QC0094
Wet Chemistry	Determination of Dissolved Solids by Gravimetric Oven Drying Standard Methods 2540C-2011	QC0123
Wet Chemistry	EPA Method 1664B, n-Hexane Extractable Material and Silica Gel Treated n-Hexane Extractable Material by Solid Phase Extraction	QC0319
Wet Chemistry	Nitrite-Nitrogen: Colorimetric Standard Methods 4500NO_2-B	QC0347
Wet Chemistry	Paint Filter Liquids Test (SW846 9095B)	QC0379
Wet Chemistry	Soil and waste pH EPA 9045	QC0380
Wet Chemistry	pH, Electrometric Measurement (Method 9040)	QC0381
Wet Chemistry	Toxicity Characteristic Leaching Procedure (TCLP): SW846 Method 1311	QC0382
Wet Chemistry	Determination of Inorganic Ion by Ion Chromatography, SW846 Method 9056	QC0385
Wet Chemistry	Total Organic Halides by EPA 9020B and Standard Methods 5320B	QC0386
Wet Chemistry	Ignitability of Solids, SW-846 Method 1030	QC0387
Wet Chemistry	Pensky-Martens Closed-Cup Method for Flashpoint SW846 1010A and ASTM D93-80	QC0389
Wet Chemistry	Synthetic Procedure Leaching Procedure, Method 1312	QC0391

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
Wet Chemistry	Chromium Hexavalent by EPA Method 7196A	QC0392
Wet Chemistry	Total and Amenable Cyanide Distillation, SW846 Method 9010C	QC0393
Wet Chemistry	Manual Spectrophotometric and Titrimetric Determinative Method for Cyanide Using SW846 Method 9014	QC0394
Wet Chemistry	Determination of Reactive Cyanide and Reactive Sulfide, SW846 Chapter 7	QC0396
Wet Chemistry	Titrimetric Procedure for Sulfide, SW-846 Method 9034	QC0397
Wet Chemistry	Alkalinity: All forms. Titration to a pre-determined pH Standard Methods 20th 2320B	QC0408
Wet Chemistry	Labware Washing Procedure For the General Chemistry and Water Microbiology Departments	QC0409
Wet Chemistry	Turbidity, (Nephelometric)	QC0410
Wet Chemistry	Determination of Inorganic Ions by Ion Chromatography, EPA Method 300.0	QC0411
Wet Chemistry	Total Recoverable Phenols: Method 420.1 and Method 9065 (Spectrophotometric, Manual 4-AAP with Distillation)	QC0422
Wet Chemistry	Chromium Hexavalent Standard Methods: Colorimetric Method 3500Cr-B, 2011	QC0424
Wet Chemistry	Nitrogen, Ammonia-Potentiometric, Ion Selective Electrode by Method SM4500NH3-D	QC0456
Wet Chemistry	n-Hexane Extractable Material (HEM) for Sludge, Sediment and Solid Samples, SW846 Method 9071B	QC0457
Wet Chemistry	Chemical Oxygen Demand, Reactor Digestion Method-Hach Procedure 8000	QC0464
Wet Chemistry	Nitrate plus Nitrite and Nitrite alone, Automated Cadmium Reduction, SM4500 NO3-F	QC0466
Wet Chemistry	pH, Electrometric Measurement	QC0467
Wet Chemistry	Alkaline Digestion for Hexavalent Chromium, SW846 Method 3060A	QC0471
Wet Chemistry	Total Cyanide and Cyanide Amenable to Chlorination Manual Distillation, Colorimetric, SM4500 CN-C, E and G	QC0475
Wet Chemistry	Total Carbon and Total Organic Carbon by Combustion SW846-9060	QC0487
Wet Chemistry	Color by Visual Comparison Method, Platinum-Cobalt, SM2120B Rev. 2011	QC0494
Wet Chemistry	Salinity-Electrical Conductivity Method Standard Methods 20th 2520B	QC0514
Wet Chemistry	Phosphorous, Colorimetric, Single Reagent, All forms of Phosphorous Standard Methods 4500-P,B.5, E	QC0535
Wet Chemistry	Total Solids, Dried at 103-105 °C Standard Method 2540B 2011	QC0536
Wet Chemistry	Total Suspended Solids (TSS), (Non-Filterable Residue), and Total Suspended Volatile Solids (TSSVS) Method SM2540D and 2540E APPROVED 1997, Editorial Revisions 2011	QC0537
Wet Chemistry	Total Solids in Solids and Semi-Solid Samples, Dried at 103-105 °C, Standard Methods 2540G	QC0542
Wet Chemistry	Volatile and Fixed Solids and Semi-Solid Samples, Ignited at 550 degree C, SM2540G	QC0543
Wet Chemistry	Volatile Residue (Solids) Following ignition at 550 °C Method: EPA 600, 160.4	QC0544
Wet Chemistry	Acidity, Titration to pH 8.3-Standard Methods 2310B	QC0545
Wet Chemistry	Nitrogen Ammonia-Preliminary Distillation Step SM 4500 NH3-B	QC0546

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
Wet Chemistry	Nitrogen-Total Kjeldahl, Semi-Automated Colorimetry, EPA 351.2	QC0549
Wet Chemistry	Biochemical Oxygen Demand (BOD) and Carbonaceous BOD (cBOD) Standard Methods 5210B 2011	QC0550
Wet Chemistry	Dissolved Oxygen-Azide Modification Standard Methods, 22nd Ed 4500 O-C	QC0551
Wet Chemistry	Oxidation -Reduction Potential of Water, Method 2580B	QC0554
Wet Chemistry	Free and Total Chlorine Measurement in the Laboratory DPD Colorimetric Method SM4500 Cl-G	QC0556
Wet Chemistry	Ammonia as N, Distillation/Titration, Standard Methods 4500 NH3-B, C	QC0558
Wet Chemistry	Dissolved Oxygen-Modified Winkler Azide Method, HACH-Dissolved Oxygen Test Kit for Field Measurements	QC0567
Wet Chemistry	Sulfide: Colorimetric Methylene Blue Method:SM4500 S^2-D-2011	QC0569
Wet Chemistry	Chlorine: Free or Combined Forms DPD-FAS Titrimetric, Standard Methods: 4500-Cl2-F	QC0578
Wet Chemistry	Sulfite-Iodometric Titration	QC0580
Wet Chemistry	Settleable Solids-Imhoff Cone	QC0584
Wet Chemistry	Methylene Blue Active Substances-Anionic Surfactants as MBAS, Standard Methods 5540C	QC0585
Wet Chemistry	Total Organic Carbon Heated Persulfate Oxidation Method Standard Methods 5310C	QC0590
Wet Chemistry	Total Organic Carbon Method: USP 643 for Purified Water	QC0594
Wet Chemistry	UV Absorbing Organic Constituents, UV254	QC0595
Wet Chemistry	Chlorine Demand/Requirement Standard Methods 2350B	QC0598
Wet Chemistry	Threshold Odor Test Standard Methods: 2150B	QC0615
Wet Chemistry	Extractable Organic Halides (EOX) in Solids EPA Method: SW846- 9023	QC0616
Wet Chemistry	Multiple Extraction Procedure: Method 1320 (modified)	QC0621
Wet Chemistry	Organic and Volatile Acids, Distillation Method, Standard Methods 20th 5560C	QC0622
Wet Chemistry	Carbon Dioxide-Titrimetric Method, Standard Methods 4500CO2-C	QC0625
Wet Chemistry	Reserve Alkalinity for Solid Wastes	QC0626
Wet Chemistry	Total Organic Content by ASTM D2974	QC0628
Wet Chemistry	Total Chlorine (TX) in New and Used Petroleum Products EPA Method SW846 9076	QC0629
Wet Chemistry	Dissolved Oxygen-Membrane Electrode Method Standard Methods, 22nd Edition, 4500 O-G	QC0644
Wet Chemistry	Elutriate Preparation: Modified Elutriate Test	QC0649
Wet Chemistry	Shake Extraction of Solid Waste with Water by Method ASTM D3987-85	QC0686
Wet Chemistry	Perchlorate in Water via Ion Chromatography	QC0700
Wet Chemistry	Saturation Index (SI) Using SM2330B	QC0701
Wet Chemistry	Nitrite: Colorimetric Analysis Discrete Colorimetric Analyzer, Standard Methods 4500NO2 B Equivalent	QC0702

Table 3. List of Standard Operating Procedures (continued)

Department	Standard Operating Procedure Title	SOP Number
Wet Chemistry	Acid Producing Soil: pH and Qualitative Sulfate Test	QC0713
Wet Chemistry	Specific Gravity and Density Standard Methods SM2710F	QC0772
Wet Chemistry	Bulk Density	QC0773
Wet Chemistry	Determination of Moisture Content in Cocoa Beans by Method ISO-2291	QC0774
Wet Chemistry	Moisture Content in Food AOAC Official Method 950.46, Modified	QC0781
Wet Chemistry	Ortho Phosphorous Automated Ascorbic Acid Reduction Standard Methods 4500 P-F Discrete Auto Analyzer	QC0783
Wet Chemistry	Sieve Analysis with Hydrometer ASTM D 422-85 and ASTM D 422-43	QC0784
EQC-Delaware*		
General	Determination of Temperature by Standard Methods-SM2550B (For use EQC-Delaware)	QC0862
General	Calibration of Eppendorf and Mechanical Volumetric Pipets (For use at EQC-Delaware)	QC0866
Water Microbiology	Total Coliform and Fecal Coliform by Membrane Filtration by SM9222B-1997 (For Use at EQC-Delaware)	QC0843
Water Microbiology	Heterotrophic Plate Count by SM9215B-2004 (For use at EQC-Delaware)	QC0844
Water Microbiology	E. Coli by Most Probable Number (MPN), 9221F (For EQC-Delaware)	QC0853
Water Microbiology	Glassware Washing and Testing in Microbiological Laboratory (For use at EQC-Delaware)	QC0856
Water Microbiology	Operation of Autoclaves in the Microbiology Laboratory (For use at EQC-Delaware)	QC0857
Water Microbiology	Testing of Sample Containers used for Collection of Microbiological Samples (For use at EQC-Delaware)	QC0858
Water Microbiology	Total Coliform by Most Probable Number (MPN) Standard Methods SM 9221B-2006 (For use at EQC-Delaware)	QC0859

Eurofins QC, Inc.
Quality Systems Manual – Interim Amendment 1

During the period of Q1 through Q3 2016, transitions are underway affecting the Eurofins QC, Inc. (EQC) operations of the Southampton PA laboratory location at 1205 Industrial Blvd and the Horsham PA location at 702 Electronic Drive. The laboratory operations currently performed at the Southampton lab are being moved and the location will ultimately be closed. Chemistry testing is being moved to Eurofins Lancaster Laboratories Environmental (ELLE) in Lancaster PA at 2425 New Holland Pike. Aquatic Toxicology and Microbiology testing currently performed in Southampton is being moved to Horsham. In addition, in February 2016, Oommen Kappil (QA Director of record in the manual) left Eurofins. QA responsibilities are being addressed through Eurofins Environment Testing US by ELLE QA Director, Dorothy Love, effective February 13, 2016.

As a result of the above listed transitions, the current EQC Quality Systems Manual (revision 26, effective 11/30/2015) contains some obsolete information. The manual will not be updated until after all transitions are complete and the Southampton operations cease. In the interim, this amendment serves to identify the sections of the manual that will need to be revised and what the changes will cover.

Section	Change
Cover	Change address to Horsham location
Approvers	List David Speis, Raphael Fratti, Erich Walter, Dorothy Love
Throughout	Change scope of service to be Aquatic Toxicology, Microbiology, and Pharmaceutical Product Testing
3.1.3	Remove Horsham as a satellite location as it will be the main laboratory location
Throughout	Remove all references to Southampton and simply make reference to the laboratory
4.1.1; 23.1.1; 24.1.3	Floor plans – note that these are available for review onsite but, due to security reasons, are not published in the quality manual or provided externally.
Throughout	Remove any sections detailing chemistry specific QC and calibration practices.
10.1.6; 16.3; 16.4	Refers to archives and server at Southampton – update location for these
Multiple	Discussions for client account history files and data review requests will need to be evaluated with the use of eLIMS-EP
12.1-9; 13.1.5; 17.1.2	Specifies CAPA and DVR reviews by the QA director. These may be handled by other QA staff. Add "or designee".
21.5	Describes building security access for Southampton. Revise to address Horsham.
24.1.3	DI water test plan, evaluate any changes that may be in place for Horsham.
25.7.1	Describe electronic sample tracking used at Southampton. Address with what will be used at Horsham.
Figure 1	Replace Oommen Kappil with Dorothy Love as the QA Director; update other positions when the transitions are complete.
Table 1 through 3	All will be revised for reduced scope of work at Horsham.

1.0 Scope and Application

1.1 This Standard Operating Procedure (SOP) is used to determine the density of fecal coliform bacteria by the membrane filtration (MF) technique. The MF technique is highly reproducible, can be used to test relatively large sample volumes and yields results more rapidly than the multiple-tube procedure. The MF technique is extremely useful in monitoring the quality of a variety of natural and recreational waters (lakes, streams, pools, etc.) as well as wastewaters (chlorinated effluents) and may be used in the examination of saline waters.

1.2 This SOP is for use at all Eurofins QC, Inc. (EQC) microbiology departments. Note: the Delaware laboratory in New Castle DE, maintains a separate SOP for fecal coliform by membrane filtration.

2.0 Summary and Discussion of Procedure

2.1 The MF procedure uses an enriched lactose medium and incubation temperature of 44.5 ± 0.2 °C for selectivity and gives 93% accuracy in differentiating between coliforms found in the feces of warm-blooded animals and those from other environmental sources. The sample volume will be dependent on the site from which the sample was taken. Small sample volumes may be necessary for waters in which high turbidity and/or historically elevated levels of fecal coliforms have been

observed. Samples are filtered through a sterile 47 mm, 0.45 micron membrane filter and incubated on M-FC agar for 24 ± 2 hours in a water bath at 44.5 ± 0.2 °C. Colonies produced by fecal coliform on M-FC medium are various shades of blue. Non-fecal coliform colonies are gray to cream-colored.

3.0 Definitions

3.1 *Fecal coliform*: A subgroup of the total coliform group found in the intestinal tract of warm blooded animals distinguished by its ability to grow at elevated temperatures. The occurrence of these bacteria is considered a specific indicator of fecal contamination.

3.2 *Holding Time*. The maximum time a sample may be held prior to analysis. For Microbiology testing the holding time for a sample is determined from the time a sample is collected to the time the sample incubation begins.

4.0 Health and Safety Warnings

4.1 Personnel engaged in laboratory analyses at EQC must be familiar with and adhere to the policies set forth in the current version of the EQC Safety Procedure Manual.

5.0 Cautions

5.1 Start microbiological examination of a water sample promptly after collection to avoid unpredictable changes.

5.1.1 Any deviances in transport or analyzing holding times, missing sampling information, sample volume, or test performed must be communicated to the client representative and notes made in the sample login and history log.

6.0 Interferences

6.1 High levels of background (non-coliform) bacteria, (i.e. 10^4 or greater), may lead to false negative results.

6.2 The MF procedure has limitations, particularly when testing waters with high turbidity or non-coliform (background) bacteria. It cannot be used to assess the quality of wastewaters that have received only primary treatment followed by chlorination because of turbidity in high volume samples or wastewaters containing toxic metals or toxic organic compounds such as phenols.

7.0 Personnel Qualifications

7.1 Before performing this test independent of secondary supervision and review, each analyst must have an approved Demonstration of Capability Certification Statement (DOC) form (see SOP QC0499) on file in the Quality Assurance office.

8.0 Equipment, Apparatus and Materials

8.1 Erlenmeyer flask-clean borosilicate, pre-sterilized for mixing media.

8.2 Petri dishes-60x15 mm pre-sterilized, plastic petri dishes.

8.3 95% ethanol.

8.4 Water bath capable of maintaining a temperature of 44.5 ± 0.2 °C.

8.5 Incubator capable of maintaining a temperature of 35 ± 0.5 °C.

8.6 Dissecting microscope 10-15x with fluorescent light source.

8.7 Filter funnels-47 mm magnetic (Gelman or equivalent).

8.8 Membrane filters-47 mm/0.45 micron sterile membrane filters (Millipore or equivalent).

8.9 Forceps.

8.10 Water-proof plastic bags.

8.11 Rosolic acid. Mix 0.5g of Rosolic Acid with 50 mL of sterile water and 10 mL of 1 N NaOH. Store Rosolic solution in refrigerator until use. Expiration date is two weeks. Record all media preparation data in the Electronic Media Prep Validation logbook as directed in SOP QC0448.

8.12 Vacuum manifold and pump.

8.13 M-FC agar (Acumedia or equivalent): Used for the enumeration of fecal coliform by the MF method. Rehydrate 52 gm of product per 1 L of purified water. Mix with agitation and heat to near boiling to dissolve medium and then remove from hotplate. Do not boil. Add 10 mL of 1% of Rosolic acid dissolved in 0.2 N NaOH. Allow for cooling to below 50 °C. Do not sterilize in autoclave. Dispense 5-7 mL in each 15 x 60 mm petri dishes and let solidify. Final pH should be 7.4 ± 0.2. The amount of media prepared can be adjusted accordingly to the work load. Label each batch and container with the date prepared, batch ID, date EXP, Lot #, temperature for storage and method name. Refrigerate finished media in tightly sealed containers and give a two-week expiration date. Store all prepared plates at 2-8 °C. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for M-FC is *E. coli* and the negative is *E. aeruginosa*. Each new lot of medium must be tested against an acceptable previous lot. Let the water micro manager know when a new lot of media is being made.

8.14 EC broth (Acumedia or equivalent): Used for confirmation of fecal coliform at 44.5 °C. Add 37 grams of medium to 1 liter of purified water. Mix thoroughly. Dispense 10 mL portions into autoclavable, borosilicate glass tubes (with fermentation vials in them) of sufficient size to contain both the culture media and the sample without being three quarters full. Autoclave prepared media at 121 °C for 15 minutes. Final pH must be 6.9 ± 0.2. The amount of media prepared can be adjusted accordingly to the work load. Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Give media a two-week expiration date from prepared date for tubes with "pop" tops and three months for tubes with "screw" tops. Store in a cool, dry, location out of the way of direct light. Test for sterility and growth promotion properties as directed in SOP QC0448.

8.15 Lauryl Tryptose Broth (LTB) (Acumedia or equivalent): Used for the detection of coliform bacteria. Add 35.6 g of powder to 1 L of purified water. Mix thoroughly. Warm slightly to completely dissolve the powder. Dispense 10 mL portions into autoclavable, borosilicate glass tubes (with fermentation vials in them) of sufficient size to contain both the culture media and the sample without being three quarters full. Autoclave prepared media at 121 °C for 15 minutes. Cool the broth as quickly as

possible. Final pH after autoclaving must be 6.8 ± 0.2. The amount of media prepared can be adjusted accordingly to the work load. Label each batch with the date prepared, batch ID, date of expiration, media lot number, storage temp, method number and media name. Store in a cool, dry location out of the way of direct light. Give media a two-week expiration date from prepared date for tubes with "pop" tops and three months for tubes with "screw" tops. Test for sterility and growth promotion properties as directed in SOP QC0448.

8.16 Phosphate Buffered Dilution water: Prepare as directed in SOP QC0500. The amount of media prepared can be adjusted accordingly to the work load. Record prepared dilution water in the Electronic Media Prep Validation logbook as directed in SOP QC0448.

8.17 Sodium Thiosulfate – 100 mg/10 mg active tablets (Cargille Corp. or equivalent) or 10% solution.

8.18 Bottles-125 mL, polypropylene, autoclavable (Single use, sterilized coliform containers from a reputable manufacturer may be used).

8.19 Autoclave indicator tape.

8.20 Weights to keep samples submerged during incubation.

8.21 Computer capable of running live analysis time via the WM electronic logbook.

8.22 Positive control culture, *E. coli* ATTC 11775 or equivalent (BioBalls).

8.23 Negative control culture, *E. aeruginosa* ATTC 13048 or equivalent (BioBalls).

8.24 Autoclave bags for funnel sterilization.

8.25 Syringes- plastic, sterile (10 mL)

9.0 Calibration

9.1 Calibrate thermometers used to monitor the temperature of incubators and water baths against a NIST thermometer annually according to SOP QC0339.

9.2 Schedule annual calibration and maintenance of balances through the manufacturer or other qualified, contracted personnel.

9.3 Calibrate pH meters according to manufacturer's recommendations and SOP QC0467. Record daily calibrations in the Media Prep pH logbook.

9.4 Check incubator temperatures twice daily to ensure temperature requirements are being met. Record readings in the temperature logbooks.

10.0 Sample Preparation and Analysis

10.1 Collect samples as directed in SOP QC0519 Water, Wastewater, Sludge and Compost Sampling for Microbiological Testing. Maintain sample temperatures following collection and transport to the laboratory, on ice between 0 and 10 °C (do not freeze). When samples are stored at the testing laboratory, prior to analysis, store refrigerated between 0.5 °C and 6 °C.

10.2 The maximum holding time for fecal coliform testing is eight (8) hours from sample collection.

10.3 Sample size

10.3.1 Size of sample will be governed by the expected bacterial density and/or the degree of sample turbidity. An ideal sample volume will yield 20 to 60 fecal coliform colonies on a membrane filter surface. Where the bacterial density is expected to be high and/or turbidity situations exist, filter appropriate dilutions (i.e. 1:10, 1:100, etc.) prepared in phosphate buffered dilution water through a membrane. When analyzing a new site or the density of fecal coliform is unknown test using three dilutions (example: 100 mL, 10 mL, 1.0 mL) to obtain the best-expected density and reportable count.

10.4 Sterile filtration units

10.4.1 Begin each filtration series with a sterilized filter funnel. If more than 30 minutes elapses between sample filtrations during a filtration series, open and use a second sterilized filter funnel.

10.5 Filtration of sample

10.5.1 Using sterile forceps, place a sterile membrane filter (grid side up) over the porous plate of the filtration unit. Pour sample into filtration unit and filter under partial vacuum. With the membrane still in place, rinse the interior surface of the funnel 3 times with a 20-30 mL portion of sterile dilution water from a squeeze bottle to prevent carryover contamination. Upon completion of final rinse, and the filtration process, disengage vacuum, unlock and remove funnel, and immediately remove the membrane filter with sterile forceps, and place it on a M-FC agar dish which has been allowed to warm to room temperature with a rolling motion to avoid entrapment of air.

10.5.2 The first sample filtered on any sterile funnel is a "Sterility Blank". This serves as the 'Initial Sterility Blank'. Refer to section 11.3.

10.5.3 When more than one sample is processed on an individual funnel, the last sample filtered on a funnel is a "Final Sterility Blank". Refer to Section 11.3.

10.5.4 Analyze a Rinse Water check as a sample, one time, for each new bottle of sterile rinse water bottle opened. Rinse water counts as a sample in the filtration series. Refer to Section 11.3.

10.6 Filtration series

10.6.1 A filtration series is considered to be interrupted when an interval of 30 minutes or longer elapses between sample filtrations. After such interruption, treat any further sample filtration as a new filtration series and replace the filter funnels with new sterile filter funnels.

10.6.2 Do not process more than ten (10) filtrations on any funnel. That is, after ten filtrations, including samples, rinse water or sample dilutions, change-out the filter funnel to a second, sterile funnel.

10.6.3 During testing in the laboratory, multiple funnels may be used for less than 10 field sample filtrations in order to meet holding times or when, in the judgment of the analyst, a new funnel should be used following a sample with

a suspected high level of bacteria. Always complete any funnel use with a filter blank.

10.7 Place prepared samples in waterproof plastic bags, seal, invert and submerge in a water bath at 44.5 ± 0.2 °C for 24 ± 2 hours. Anchor dishes below water surface to maintain critical temperature requirements. Place all samples in the water bath within 30 minutes after filtration.

10.8 Counting fecal coliform colonies

10.8.1 Use a low power (10-15x) binocular wide-field dissecting microscope with a cool white fluorescent light source directed to provide optimal viewing.

10.8.2 Colonies produced by fecal coliform on M-FC medium are various shades of blue. Count colonies of any size including pinpoint blue colonies. Non-fecal coliform colonies are gray to cream-colored. Normally, few non-fecal coliform colonies will be observed on M-FC medium because of the selective action of the elevated temperature and addition of rosolic acid salt reagent.

10.8.3 Count and record in the Water Microbiology (WM) electronic logbook the number of fecal coliform colonies found on the membrane. Note: the ideal colony count for this test is a count or 20 to 60 CFU. Refer to section 12.0 for details.

10.9 Confirming fecal coliform colonies

10.9.1 Inoculate a tube of Lauryl Tryptose Broth (LTB) and EC Broth with a suspect fecal coliform colony directly from the membrane with an inoculating loop.

10.9.2 Incubate the LTB for 24 ± 2 hours in an incubator set at 35 ± 0.5 °C and examine for gas production with growth (turbidity). Incubate the EC Broth for 24 ± 2 hours in a circulating water bath at 44.5 ± 0.2 °C and examine for gas production with growth. If the confirmation does not verify the initial response, notify your supervisor. Test results will be qualified.

10.9.3 Gas production with growth in an EC broth culture within 24 ± 2 hours or less is considered a positive fecal coliform reaction. Failure to produce gas (with little or no growth) constitutes a negative reaction. If heavy growth occurs with no gas production, subject the culture to a fecal coliform or *E. coli* test using a different medium. Check with your supervisor if a different medium may be required.

11.0 Quality Control

11.1 Test all microbiological broth after preparation as directed in SOP QC0448 and record in the Water Microbiology Validation logbook.

11.2 Check each lot # of membrane filters for sterility by incubating in tryptic soy broth for 24 hours at 35 ± 0.5 °C and looking for growth. Reject any lot that is found to be non-sterile. Record results in the Water Microbiology Quality Control Logbook.

11.3 Perform the following checks when using autoclavable (multi-use) funnels.

11.3.1 Analyze an initial sterility blank, as the first sample for each sterile funnel used. Rinse each funnel with 20-30 mL of sterile water as performed in the

rinse step for a sample. Do not use additional rinses. Complete the analysis of the sterility blank as a regular sample.

11.3.2 Analyze a final sterility blank following all samples analyzed with any funnel, WHEN more than one sample is analyzed on a funnel. If only one sample is processed per funnel, a final sterility blank is not required.

11.3.3 For each autoclavable funnel, up to a maximum of ten (10) filtrations may be performed. A filtration include any: sample, sample dilution or rinse water check.

11.3.4 Results from the sterility blank or the rinse water check are reviewed for contamination. The data represent colonies per funnel or colonies per rinse. The criteria for these check is <1 cfu / funnel or < 1 cfu / rinse.

11.4 Disposable sterile funnels.

11.4.1 When using disposable sterile funnels, an initial sterility check or end procedural check is not required.

11.4.2 Disposable sterile funnels are lot checked for sterility when received at the laboratory.

11.5 Check each **batch** of rinse water for sterility by adding 50-mL water to 50- mL double strength tryptic soy broth, incubating at 35 ± 0.5 °C for 24 ± 2 hours and checking for growth. Reject any batch of rinse water that is found to be non-sterile. Record results in the electronic Media Prep logbook.

11.6 Check each newly opened rinse water bottle for sterility. Use 50 mL from the newly opened rinse water bottle and process by filtration as a sample.

11.7 Each lot of sample containers must be tested for sterility before use by adding approximately 100 mL of a non-selective broth (i.e. Tryptic Soy Broth), incubating for 24 ± 2 hours at 35 ± 0.5 °C and checking for growth (turbidity).

11.8 On a monthly basis, verify a minimum of 10 fecal coliform colonies (10 typical and 10 atypical) as directed in Section 10.9. Record results in the Water Microbiology Fecal Coliform Verification Logbook. The adjusted count may be REDUCED if the confirmation for any typical colony is negative. The adjusted count may be increased if the confirmation for any atypical colony is positive.

Example:

45 TOTAL Colonies

30 Typical Colonies, and 15 atypical colonies.

Reported Result = 30 colonies / 100 mL presumptive

Confirmation Phase: use percentage of colonies confirmed as below:

8 out of 10 typical show positive: adjust count DOWN to [(8/10) x 30] = 24

2 out of 10 atypical colonies show positive: adjust count UP by [(2/10) x 15] = 3

Actual count = 24 + 3 = 27 colonies / 100 mL

Edit and send the client a revised test report.

11.9 Compare old and new lots of MFC using dilution blanks inoculated with the appropriate ATC culture (Bio-Balls) to produce colony counts ranging from 20 - 60 CFU. Record results in the Electronic Water Microbiology log book.

11.10 Corrective actions are taken when nonconforming work or departures from policies and procedures in the management system or technical operations have been identified. Preventive action is a proactive process to identify opportunities for rather than a reaction to the identification of problems or complaints.

11.10.1 Analytical work may be stopped if necessary during the investigation, and analyses may resume after it is verified that the corrective actions taken have been effective.

11.10.2 Corrective actions may include, but not limited to instrument repair or maintenance, re-prep of media, resampling, reanalysis of samples, etc.

11.10.3 Preventive actions may include, but not limited to preventive maintenance, retraining of analysts, change in procedures etc.

11.10.4 Refer to EQC's Quality Systems Manual for more information.

12.0 Calculations and Record Keeping

12.1 Compute the count, using membrane filters with 20 to 60 fecal coliform colonies per membrane, by the following equation:

$$\text{Fecal coliform colonies/100 mL} = \frac{\text{Fecal coliform colonies counted} \times 100}{\text{mL sample filtered}}$$

(The 20 to 60 colony restriction is due to the larger colony size on M-FC medium.)

12.2 With water of good quality, the occurrence of fecal coliforms will be low. Therefore, count all fecal coliform colonies (disregarding the lower limit of 20 colonies cited in Section 12.1) and use the above formula given above to obtain fecal coliform density.

12.3 If the total number of fecal coliform colonies exceeds 60 per membrane, with one (1) dilution or if the colonies are not distinct enough for accurate counting, record the results as **>60** and compute and report the actual result by using the equation in the above equation.

12.4 For water other than drinking water quality

12.4.1 As with potable water samples, if no filter has a fecal count falling in the ideal range (20 to 60 CFU), total the fecal counts on all filters and report as the total number per 100 mL.

12.4.1.1 For example, if **duplicate 50-mL portions** were examined and the two membranes had 5 and 3 fecal coliforms, respectively, report the count as 8 fecal coliform colonies per 100 mL.

$$[(5 + 3) \times 100] / (50 + 50) = 8 \text{ CFU/100 mL}$$

12.4.2 Similarly, if 50-, 25-, and 10-mL **portions** were examined and the counts were 15, 6, and <1 fecal coliform colonies, respectively, then calculate **on the basis of the most nearly acceptable value** and report the fecal coliform count with a qualifying comment as "**estimated** 30 CFU/100mL":

[(15) X 100] / (50) = estimated 30 CFU/100 mL

12.4.3 On the other hand, if 10, 1.0, and 0.1-mL portions were examined with counts of **40**, 9, and <1 fecal coliform colonies, respectively, then select the 10-mL portion only for calculating the fecal coliform density because the filter had a fecal coliform count falling **in the acceptable range**, and report result as 400 CFU/100 mL:

(40 X 100) / 10 = 400 CFU/100 mL

12.4.4 If colony counts are **greater than the upper limit** then calculate on the basis of the most nearly acceptable value and report, with a qualifying comment.

An example: If 10, 1.0, and 0.1-mL portions were examined with counts of TNTC, 110, and 62 fecal coliform colonies, respectively, then calculate on the basis of the most nearly acceptable value and report, with a qualifying comment, as **estimated** 62,000 CFU/100 mL:

(62 X 100) / 0.1 = estimated 62,000 CFU/100 mL

12.4.5 If there is **more than one dilution having an acceptable range** of counts then sum the total coliform counts on the two filters and divide by the sum of their volume to obtain the final reported value:

An example: If 1.0, 0.3, 0.1, and 0.03 mL portions were examined with counts of TNTC, TNTC, 58, and 21 coliform colonies, respectively, then sum the total coliform counts on the two filters and divide by the sum of their volume to obtain the final reported value of 61 000 CFU/100 mL:

[(78 + 21) X 100] / (0.1 + 0.03) = 61 000 CFU/100 mL

12.4.6 If counts from all membranes are zero, calculate final result using the largest volume filtered.

12.4.7 If colony counts are both **above and below the upper and lower limits**, select the most nearly acceptable count.

12.4.8 For the sample in question (12.4.1.4) an error at the bench may have occurred investigate the issue, and report results with a qualifying comment or re-sample when possible.

12.5 Report confluent growth with or without discrete fecal coliform colonies as confluent growth per 100 mL with (or without) fecal coliforms and request a new sample via the field services department.

12.6 All results are required to be adjusted as per 11.8 if the sample was selected for colony confirmation.

12.7 If any sterility control sample, such as initial sterility blank, final sterility blank, or rinse water check, contains fecal coliform colonies, inform the supervisor

immediately. Qualify sample results on the test report and if possible, obtain a re-sample.

12.8 If a Laboratory accident, or cross-contamination is suspected, inform the supervisor immediately. For the sample(s) in question, investigate the issue and report with a qualifying comment and if possible, obtain a re-sample when possible.

12.9 Documentation of Laboratory work

12.9.1 Enter and initial the date and time sample was taken, received, run, and completed in designated areas on the EQC Chain of Custody form.

12.9.2 Document all laboratory data as outlined in SOP QC0343 Documentation of Laboratory Data.

12.9.3 Record all media preparation data in the Electronic Media Prep Validation logbook as directed in SOP QC0448.

13.0 Method Performance

13.1 Method performance is evaluated by the analysis of method blanks, positive and negative controls.

14.0 Pollution Prevention/Waste Management

14.1 Keep storage of chemicals in individual departments to a minimum, in order to minimize the potential for large spills and exposure to hazardous substances. Each laboratory manager or designee is required to inspect their department on a semi-annual basis for expired reagents and chemicals. Notify the Safety Director for disposal of expired reagents and chemicals.

14.2 Minimize the amount of waste generated by preparing only the minimum required amount of a reagent.

14.3 Expired hazardous chemicals, reagents, and samples requiring lab packing or other outside disposal/treatment are stored in a designated waste storage facility (such as the chemical shed) until final disposal. This is under the direction and supervision of the Safety Director. Individual analysts may not transfer chemicals or other substances to a waste storage facility without obtaining authorization from the Safety Director. All microbiological waste generated during the performance of this procedure (including used petri dishes) must be disposed of in accordance to the Laboratory Waste Disposal SOP, QC0479 and SOP QC0482 Operation and Maintenance of SR-24C Autoclaves. Additional details regarding specific disposal of chemical waste at EQC are given in the EQC Safety Procedure Manual, which is incorporated herein by reference.

==========

1.0 Scope and Application

1.1 The EPA has been increasingly concerned with the public health risks of infectious diseases caused by microbial organisms in a variety of waters including recreational fresh and marine waters. One such group of organisms under scrutiny is the Enterococci. Studies have indicated a direct relationship between the density of enterococci in recreational fresh and marine waters and the risk of gastrointestinal illness associated with swimming in the water.

1.2 This Standard Operating Procedure (SOP) applies to determination of microbial organisms in a variety of non-potable waters including recreational fresh and marine waters. The method outlined in this SOP describes a membrane filter (MF) procedure for the detection and enumeration of enterococci in water. Unlike the ME methods of 9213D and 1106.1 the enterococci 1600 method is a single step method which does not require a transfer of the filter to another medium. The modified medium of MEI has a reduced amount of triphenyltetrazolium chloride (TTC) and also includes indoxyl β-D-glucoside, a chromogenic cellbiose analog that is used in the place of esculin. The β-glucosidase, where positive enterococcus produces an indigo blue complex, diffuses into the MEI forming a blue halo around the colony. Enterococci are commonly found in the feces of humans and other warm-blooded animals. Although some strains are ubiquitous and not related to fecal pollution, the presence of enterococci in water is an indication of fecal pollution and the possible presence of enteric pathogens.

1.3 This SOP is to be performed by trained laboratory personnel anytime the enumeration of enterococci by membrane filtration in a water sample is required.

2.0 Summary and Discussion of Procedure

2.1 The MF method provides a direct count of bacteria in water based on the development of colonies on the surface of the membrane filter. A water sample is filtered through the membrane, which retains the bacteria. Following filtration, the membrane containing the bacterial cells is placed on mEI agar and incubated at 41 ± 0.5 °C for 24 ± 2 hours. All colonies greater than or equal to (≥) 0.5 mm in diameter (regardless of color) with a blue halo are recorded as enterococci colonies.

3.0 Definitions

3.1 Enterococcus – a subgroup of the fecal streptococci that includes *S. faecalis, S. faecium, S. gallinarum,* and *S. avium* differentiated from the fecal streptococci by their ability to grow in 6.5% sodium chloride, at pH 9.6 and at 10 and 45 °C. They are a valuable bacterial indicator for determining the extent of fecal contamination of recreational surface waters.

In Method 1600, enterococci are those bacteria, which produce colonies greater than or equal to (≥) 0.5 mm in diameter with a blue halo after incubation on mEI agar. The blue halo should not be included in the colony diameter measurement.

3.2 Serial dilutions: This procedure is used to identify the number of viable micro-organisms in a fixed amount of a liquid. Serial dilution involves repeatedly mixing known amounts of sample with sterilized liquid. 1 mL added to 9 mL gives a 10-fold dilution; 1 mL added to 99 mL gives a 100-fold dilution. The first 10-fold dilution is termed the 10^{-1} dilution. The first 100-fold dilution is termed the 10^{-2} dilution. An undiluted sample is termed the 10^{0} dilution. The buffer used for dilution depends on the substance being diluted. When fixed amounts of this dilution series are plated and incubated, then different numbers of colonies will be obtained. By working back from an easily counted plate and using the appropriate dilution factor, the number of micro-organisms in the original source can be calculated.

3.3 Holding Time: The maximum time a sample may be held after collection until analysis. Results reporting for regulatory purposes must be from an analysis within the established holding time. For microbiology samples holding time is determined from the sample collection time to the time the sample is placed into incubation.

4.0 Health and Safety Warnings

4.1 Personnel engaged in laboratory analyses at Eurofins QC, Inc. (EQC) must be familiar with and adhere to the policies set forth in the current version of the EQC Safety Procedure Manual.

5.0 Cautions

5.1 Start microbiological examination of a water sample promptly after collection to avoid unpredictable changes.

5.2 Notify a client service representative when any chain of custody record is not clear such as missing sample time or sample ID information or requested test. Document the notification and reason in the company LIMS History Log.

6.0 Interferences

6.1 Water samples containing colloidal or suspended particulate materials can clog the membrane filter and prevent filtration, or cause spreading of bacterial colonies, which could interfere with the enumeration and identification of target colonies.

7.0 Personnel Qualifications

7.1 Before performing this test independent of secondary supervision and review, each analyst in a NELAC facility must have an approved Demonstration of Capability Certification Statement (DOC) form (see SOP QC0499) on file in the Quality Assurance Department.

8.0 Equipment, Apparatus and Materials

Equipment:

8.1 Autoclave capable to maintain a high pressure saturated steam at 121 C (249 F) for around 15-30 minutes depending on the size of the load and the contents.

8.2 Flame Burner, for flame-sterilizing forceps.

8.3 Carboy capable of holding 20 L.

8.4 Erlenmeyer flask, clean borosilicate, for mixing media.

8.5 Filtration funnel units: filter funnels 47-mm magnetic (Gelman or equivalent), graduated at 50 and 100 mL, in assembly with base, sterile, re-usable.

Note: As an alternative, disposable, sterile filtration funnel units can be used (Fisher, Catalog # 09-740-30D or equivalent).

8.6 A filter manifold to hold a filter bases. A vacuum filter manifold.

8.7 Forceps.

8.8 Hand tally.

8.9 Incubators, capable of maintaining temperatures of 41 ± 0.5 °C, 35 ± 0.5 °C and 45 ± 0.5 °C.

8.10 Refrigerators capable of maintaining a temperature of 0 - 6 °C and 2 - 8 °C.

8.11 Stereo microscope with fluorescent light source.

8.12 Test tubes, screw-cap, 20 x 125 mm, borosilicate glass or plastic.

8.13 UV light (6 watt, 365 nm).

8.14 Water bath capable of maintaining a temperature of 44.5 ± 0.2 °C.

Supplies:

8.15 Autoclave funnel wrap: aluminum foil or kraft paper.

8.16 Autoclave Indicator tape.

8.17 Alcohol: Reagent alcohol, purchased reagent grade chemical for forceps sterilization. Store in a flammable cabinet at room temperature.

8.18 Inoculating loops, plastic, sterile.

8.19 Membrane filters 47-mm/0.45 micron pore-size, sterile (Millipore or equivalent).

8.20 Petri dishes, 60 x 15 mm plastic, presterilized.

8.21 Sample containers, 125 mL, polypropylene, containing Sodium Thiosulfate tablet for chlorine neutralization.

Media and Reagents:

8.22 mEI agar (Difco or equivalent)

8.22.1 Suspend 72 g of the powder into 1 L of purified water. Mix thoroughly. Heat with frequent agitation and boil for 1 minute to completely dissolve the powder. Autoclave prepared media at 121 °C for 15 minutes and then cool media in a 50 °C water bath. Add nalidixic acid and TTC solutions to the medium as outlined in the Sections 8.22.2.1 and 8.22.2.2 below, and mix. Read pH. Final pH must be 7.1 ± 0.2.

8.22.1.1 Mix 0.24 g nalidixic acid in 5-mL reagent grade water. Add a few drops of 0.1N NaOH to dissolve. Add this solution to 1 L of the mEI medium.

8.22.1.2 Add 2 mL (0.02 g) of 1% solution triphenyl tetrazolium chloride (TTC) separately to 1 L the mEI medium and mix.

Note: If larger volume of mEI prepared, the amount of nalidixic acid and TTC solutions must be adjusted accordingly to the work load.

8.22.2 Dispense mEI agar in 4 to 6 mL quantities into 60 x 15 mm disposable petri dishes and allow to solidify. The amount of media prepared can be adjusted accordingly to the work load. Label each batch and container of media with date prepared, batch ID, date expired, lot #, temperature for storage and method name. The positive control for mEI is *E. faecalis* and the negative control is *E coli*. Test for sterility and growth promotion properties using positive and negative controls as directed in SOP QC0448. Store all prepared plates at 2 - 8 °C for up to 2 weeks. Record all media preparation data in the Media Electronic Logbook (Media Logbook) as directed in SOP QC0448.

8.23 Brain-heart infusion agar (BHIA) (BD BBL or equivalent).

Used in the verification of fecal streptococcus and enterococcus colonies.

8.23.1 Suspend 52 g of the powder in 1 L of purified water. Mix thoroughly. Heat with frequent agitation and boil for 1 to completely dissolve the powder. Autoclave at 121 °C for 15 minutes. Before use agitate gently to distribute the precipitate uniformly throughout the medium. Final pH must be 7.4 ± 0.2 after autoclaving.

8.23.2 Dispense 10 mL of agar into tubes for slants, or 15 – 20 mL into petri dishes, and allow to solidify. Prepared media will be slightly hazy and amber color. The amount of media prepared can be adjusted accordingly to the work load. Label each batch and container of media with date prepared, batch ID, date expired, lot #, temperature for storage and method name. The positive control for brain heart infusion agar is *E. faecalis* and the negative control is not needed. Test for sterility and growth promotion properties as directed in SOP QC0448. Store all prepared plates at 2 - 8 °C for up to 2 weeks and

tubes for up to 3 month. Store unprepared medium in a cool, dry, location out of the way of direct light. Record all media preparation data in the Media Logbook as directed in SOP QC0448.

8.24 Brain-heart infusion broth (BHIB) (Acumedia or equivalent)

8.24.1 Dissolve 37 g of medium into 1 L of purified water. Heat with frequent agitation to completely dissolve the medium. Autoclave for 15 minutes at 121 °C. Final pH must be 7.4 ± 0.2 after autoclaving.

8.24.2 Dispense 10 mL into autoclavable, borosilicate glass tubes of sufficient size to contain both the culture media and the sample without being three-quarters full. No inserts are needed in the culture tubes. Prepared media may have precipitate, will be a clear light to medium amber color. The amount of media prepared can be adjusted accordingly to the work load. Label each batch and container of media with date prepared, batch ID, date expired, lot #, temperature for storage and method name. The positive control for brain heart infusion broth is *E. faecalis* and the negative control is not needed. Test for sterility and growth promotion properties as directed in SOP QC0448. Store all prepared tubes at 2 - 8 °C for up to 3 month. Store unprepared medium in a cool, dry, location out of the way of direct light. Record all media preparation data in the Water Media Logbook as directed in SOP QC0448.

8.25 Brain-heart infusion broth with 6.5% NaCl (BHIB with 6.5% NaCl) (Acumedia or equivalent)

8.25.1 Dissolve 37 g of medium into 1 L of purified water. Heat with frequent agitation to completely dissolve the medium. Add 60 g of NaCl for every liter of broth made.

Note: BHIB with 6.5% NaCl is the same as BHIB above (Section 8.24), but with additional NaCl.

Add 60 g of NaCl to formula provided in Section 8.24 above and follow all preparation steps in Section 8.24.

8.25.2 The positive control for brain heart infusion broth with NaCl is *E. faecalis* and the negative control is not needed.

8.26 Bile esculin agar (Remel or equivalent)

8.26.1 Suspend 64 g of medium into 1 L of purified water. Heat to boiling with agitation to completely dissolve. Autoclave for 15 minutes at 121 °C. Final pH must be 6.8 ± 0.2 after autoclaving.

8.26.2 Dispense 10 mL into autoclavable, borosilicate glass tubes of sufficient size to contain both the culture media and the sample without being three-quarters full. The amount of media prepared can be adjusted accordingly to the work load. Label each batch and container of media with date prepared, batch ID, date expired, lot #, temperature for storage and method name. The positive control for esculin agar is *E. faecalis* and the negative control is *E. coli*. Test for sterility and growth promotion properties as directed in SOP QC0448. Store unprepared medium in a cool, dry location out of the way of

direct light. Store prepared medium at 2 - 8 °C. Record all media preparation data in the Media Logbook as directed in SOP QC0448.

8.27 Tryptic soy agar (BD BBL or equivalent)

8.27.1 Suspend 45.7 g of the powder into 1 L of purified water. Mix thoroughly. Heat with frequent agitation. Boil for 1 minute to completely dissolve the powder. Autoclave at 121 °C for 15 minutes. Final pH must be 7.3 ± 0.2 after autoclaving.

8.27.2 Dispense 15 to 20 mL into 15 x 100 mm sterile petri dishes and allow to solidify. The amount of media prepared can be adjusted accordingly to the work load. Label each batch and container of media with date prepared, batch ID, date expired, lot #, temperature for storage and method name. The positive control for TSA is *E. coli* and a negative control is not needed. Test for sterility and growth promotion properties as directed in SOP QC0448. Store in a cool, dry, location out of the way of direct light. Record all media preparation data in the Media Logbook as directed in SOP QC0448.

8.28 Nalidixic acid.

8.29 0.1N NaOH.

8.30 Phosphate Buffered Dilution water

8.30.1 Prepare as directed in SOP QC0500. The amount of media prepared can be adjusted accordingly to the work load. Record all media preparation data in the Media Logbook as directed in SOP QC0448.

8.31 Phosphate Buffered Saline (PBS)

8.31.1 Composition:

Sodium dihydrogen phosphate (NaH_2PO_4)	0.58 g
Disodium hydrogen phosphate (Na_2HPO_4)	2.5 g
Sodium Chloride (NaCl)	8.5 g
Reagent-grade water	1.0 L

8.31.2 Dissolve the reagents in 1 L of reagent-grade water and dispense in appropriate amounts for dilutions in screw cap bottles and/or into containers for use as rinse water. Autoclave at 121 °C for 15 minutes. Final pH must be 7.4 ± 0.2. Record all media preparation data in the Water Microbiology Validation book as directed in SOP QC0448.

8.32 Sodium chloride.

8.33 Triphenyl Tetrazolium Chloride dye (TTC), 1% solution.

Cultures:

8.34 Positive control culture *Enterococcus faecalis*, ATCC 19433 or equivalent (BioBalls, *Enterococcus faecalis,* NCTC 775).

8.35 Negative control culture *E. coli*, ATCC 11775 or equivalent (BioBalls, *E. coli,* NCTC 9001).

9.0 Calibration

9.1 Calibrate glass thermometers used to monitor the temperature of incubators and water baths against a NIST thermometer annually according to SOP QC0339. Calibrate all others (digital, infrared, etc.) quarterly.

9.2 Schedule annual calibration and maintenance of balances through the manufacturer or other contracted personnel. See SOP QC0470, Laboratory Balance Calibration.

9.3 Calibrate pH meters according to manufacturer's recommendations and SOP QC0467, pH Electrometric Measurement.

9.4 Check incubator temperatures twice daily, four hours apart to ensure temperature requirements are being met. Record readings in the temperature logbooks.

10.0 Sample Preparation and Analysis

10.1 Collect samples as directed in SOP QC0519 Water, Wastewater, Sludge and Compost Sampling for Microbiological Testing. Store collected samples from the field to the laboratory on ice at a temperature between 0 and 10 °C (do not freeze). When samples are stored at the testing laboratory, prior to analysis, store refrigerated between 0.5 and 5 °C (do not freeze). At no time shall the sample be frozen.

10.2 The maximum holding time for samples analyzed by this procedure is eight (8) hours.

10.3 Sample size

10.3.1 The size of the sample will be governed by the expected bacterial density based on the previous historical enterococci levels of the source. An ideal sample volume will yield 20 to 60 enterococcus colonies on a membrane filter surface. **A minimum of 3 dilutions must be used for any new sample source.** In instances where the bacterial density is expected to be high, turbidity situations exist, no known history of bacterial density or for legal cases, filter at least three appropriate dilutions from 1 to 100 mL using log interval (e.g. 100, 10, 1, 0.1, etc.) or half log intervals (e.g. 100, 30, 10, 3, 1 mL) prepared in phosphate buffered dilution water through a membrane.

10.3.2 For special projects, such as river project samples, where the bacterial density is expected to be high, use 10-fold or 100-fold dilution technique. Certain samples may require a 10^{-6} dilution.

10.4 Sterile filtration units

10.4.1 Use for filtration series

10.4.1.1 A filtration series is considered to be interrupted when an interval of 30 minutes or longer elapses between sample filtrations. After such interruption, treat any further sample filtration as a new filtration series and replace the filter funnels with new sterile filter funnels.

10.4.1.2 Do not process more than ten (10) filtrations on any funnel. That is, after ten filtrations, including samples, rinse water or sample dilutions, change-out the filter funnel to a second, sterile funnel.

10.4.1.3 During testing in the laboratory, multiple funnels may be used for less than 10 field sample filtrations in order to meet holding times or

when, in the judgment of the analyst, a new funnel should be used following a sample with a suspected high level of bacteria. Always complete any funnel use with a filter blank.

10.4.2 Use for serial diluted single sample (i.e., river samples, etc.)

10.4.2.1 Use separate sterile filtration unit for each sample to be tested. Start filtration from the highest dilution to lowest. Rinse the interior surface of the funnel 3 times with a 20-30 mL of the sterile dilution water after each filtration. Place filtration unit into the autoclave container when sample filtration is done, and place a new sterile funnel onto manifold for new sample use.

10.5 Enterococci procedure

10.5.1 Using sterile forceps, place a sterile membrane filter (grid side up) over the porous plate on the filter base and attach the funnel to the base so that the membrane filter is now held between the funnel and the base.

10.5.2 Shake the sample in an up and down motion for a minimum of 25 times. Measure the desired volume of sample or dilution into the funnel. Select sample volumes based on previous knowledge of the enterococci level, to produce 20 - 60 enterococci colonies on filter.

10.5.3 Smaller sample size or sample dilutions can be used to minimize the interference of turbidity or for high bacterial densities. Multiple volumes of the same sample or sample dilutions may be filtered.

Note: When analyzing smaller sample volumes (e.g., <20 mL), 20 – 30 mL of PBS or phosphate-buffered dilution water should be added to the funnel or an aliquot of sample should be dispensed into a dilution blank prior to filtration. This will allow even distribution of the sample on the membrane.

10.5.4 Filter the sample under partial vacuum. With the membrane still in place, rinse the interior surface of the funnel 3 times with a 20 - 30 mL portion of sterile dilution water from a squeeze bottle to prevent carryover contamination. Upon completion of final rinse, and the filtration process, disengage vacuum, unlock and remove funnel, and immediately remove the membrane filter with sterile forceps, and place it on a mEI agar dish which has been allowed to warm to room temperature with a rolling motion to avoid entrapment of air.

10.5.5 Invert culture plates and incubate at 41 ± 0.5 °C for 24 ± 2 hours.

10.5.6 After incubation, count and record colonies on those membrane filters containing, if practical, 20 - 60 colonies with any blue halo that are 0.5 mm or larger (not including blue halo) regardless of colony color as an enterococci colony (see Figure 1). Count enterococcus colonies using a measuring magnifier and a low power binocular wide-field, stereo microscope with a cool white fluorescent light source to give maximum visibility of colonies.

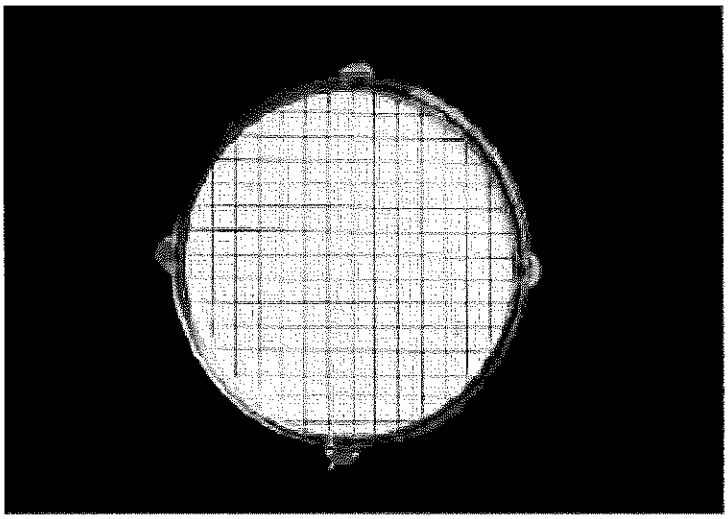

Figure 1. Enterococci colonies on mEI produce blue halos.

10.6 Verification Procedures

10.6.1 Frequency Tracking

The main lab and satellites offices must track the number of samples that contain typical and atypical colonies. Verification tests are performed at the main lab.

10.6.1.1 Following plate counting, use the Sample Tracking file for this method (EPA 1600) and bar-code each sample that has either typical or atypical colonies into the file for tracking frequency.

10.6.1.2 For satellites offices, take a picture of the plate. Send the plate and photo to the main lab for verification. Notify the main lab staff when plates are being sent.

Note: The main lab will use the picture as a reference for confirmation of original count of typical and atypical colonies.

10.6.1.3 After receiving plates from a Satellite office, initiate the verification the same day or at a minimum by the following day to ensure the quality of data.

10.6.1.4 Verification must be performed each month based on the following frequency: Verify a minimum of 10 typical (positive) and 10 atypical (negative) enterococci colonies or 1 typical and 1 atypical colony from 10% of all plates showing growth, whichever is more frequent.

10.6.1.5 When routine samples do not provide at least 10 typical and at least 10 atypical colonies, a source known to satisfy this requirement must be analyzed and verified. Such sources can include samples from local pounds or streams.

10.6.1.5.1 Collect a sample from local pound or stream and analyzed as a regular sample.

10.6.2 Verification tests performing

10.6.2.1 Using a sterile inoculating loop, transfer cells from the centers of at least 10 typical and 10 atypical colonies into BHI broth (BHIB) tubes and onto BHI agar (BHIA) plate. Incubate the broth tubes for 24 ± 2 hours at 35 ± 0.5 °C and the agar plates for 48 ± 3 hours at 35 ± 0.5 °C.

10.6.2.2 After 24 hours of incubation (10.6.2.1), transfer a loopful of growth from the BHIB tubes to the following:

10.6.2.2.1 Bile Esculin agar (BEA) and incubate at 35 ± 0.5 °C for 48 ± 3 hours.

10.6.2.2.2 BHI broth with 6.5% NaCl and incubate at 35 ± 0.5 °C for 48 ± 3 hours.

10.6.2.2.3 BHI broth and incubate at 45 ± 0.5 °C for 48 ± 3 hours.

10.6.2.3 After 48 hours of incubation, observe for turbidity (growth) and record any growth in each of the above tubes/plates.

10.6.2.4 After 48 hours of incubation, perform a gram stain on any growth found on each BHI agar plate/slant (10.6.2.1).

10.6.2.5 Gram positive cocci which grow and hydrolyze esculin on BEA (i.e. produce a black or brown precipitate) and grow in BHI broth at 45°C, and BHI broth with 6.5% NaCl at 35 °C, are verified as enterococci.

10.6.2.6 Alternately, commercially available multi-test identification systems (e.g. Vitek®) may be used to verify colonies. Such multi-test identification systems should include Esculin hydrolysis and growth in 6.5% NaCl.

10.6.2.7 Record all information (Typical or Atypical colonies, media batch number, incubation times, etc.) into Enterococci Verification logbook Form #3031. The laboratory manager or his designee must review the Logbook for accuracy.

10.6.3 Adjust results based upon percentage of Enterococcus colonies confirmed. The adjusted count may be REDUCED if the confirmation for any typical colony is negative. The adjusted count may be increased if the confirmation for any atypical colony is positive.

Example:

45 TOTAL Colonies
30 Typical Colonies, and 15 atypical colonies.
Reported Result = 30 colonies / 100 mL presumptive

Confirmation Phase: use percentage of colonies confirmed as below:

8 out of 10 typical show positive: adjust count DOWN to [(8/10) x 30] = 24
2 out of 10 atypical colonies show positive: adjust count UP by [(2/10) x 15] = 3
Actual count = 24 + 3 = 27 colonies / 100 mL

Edit the original data entered in to the company LIMS and send the client a revised report with comment.

11.0 Quality Control

11.1 Test all microbiological media after preparation as directed in SOP QC0448.

11.2 Check each lot # of membrane filters for sterility by placing a membrane on a tryptic soy agar plate for 24 ± 2 hours at 35 ± 0.5 °C. Absence of growth indicates sterility of the filter. Reject any lot that is found to be non-sterile. Record results in the Water Microbiology quality control book.

11.3 Duplicate analyses. Perform duplicate analyses at a minimum of a 5% (1 out of every 20 samples) frequency or 1 per week, whichever is more frequent. Refer to SOP QC0952 for further information.

11.4 Check each batch of PBS and phosphate-buffered rinse water for sterility by adding 50 mL water to 50 mL double strength trypticase soy broth, incubating at 35 ± 0.5°C for 24 ± 2 hours and checking for growth. Record results in the Water Microbiology quality control book.

11.5 On a monthly basis, verify a minimum of 10 typical and 10 atypical enterococci colonies (can be from a single membrane) or 1 typical and 1 atypical colony from 10% of all samples with growth, whichever is more frequent as directed in Section 10.6. Record results in the Method Verification Logbook.

11.6 Initial precision and recovery (IPR)

The IPR analysis is used to demonstrate acceptable method performance (recovery and precision) by each laboratory before the method is used for monitoring field samples. IPR samples must be accompanied by an acceptable method blank (sterile Phosphate-buffered saline (PBS)) and appropriate media sterility checks. The IPR procedure is as follows:

11.6.1 Prepare four, 100-mL samples of **PBS** (Section 8.31) and spike each sample with *Enterococcus faecalis* ATCC 19433 by aseptically adding one BioBall to each container and mixing by vigorously shaking the sample bottle a minimum of 25 times.

11.6.2 Filter and process each IPR sample according to the procedure outlined in Section 10.0 and calculate the number of Enterococci per 100 mL according to Section 12.0.

11.6.3 Calculate the percent recovery (R) for each IPR sample using the following equation:

$$R = 100 \times \frac{(Ns - Nu)}{(T)}$$

R = percent recovery

Ns = Enterococci (CFU/100 mL) in the spiked sample

Nu = Enterococci (CFU/100 mL) in the unspiked sample

(Even if no colonies are found, the minimum value is 1)

T = true spiked Enterococci (CFU/100 mL) manufacturer's lot mean

11.6.4 Using the percent recoveries of the four analyses, calculate the mean percent recovery and the relative standard deviation (RSD) of the recoveries. The RSD is the standard deviation divided by the mean, multiplied by 100.

11.6.5 Compare the mean recovery and the RSD with the corresponding IPR criteria below:

Recovery (mean percent)	**85% - 106%**
Precision (as maximum RSD)	**14%**

If the mean and the RSD for recovery of Enterococci meet acceptance criteria, system performance is acceptable and analysis of field samples may begin. If the mean or the RSD fall outside of the required range for recovery, system performance is unacceptable. In this event, identify the problem by evaluating each step of the analytical process, media, reagents, and controls, correct the problem and repeat the IPR analysis.

11.7 Ongoing precision and recovery (OPR)

To demonstrate ongoing control of the analytical system, the laboratory must routinely process and analyze spiked **PBS** (Section 8.31) samples. The laboratory must analyze one OPR sample after every 20 field and matrix spike samples or one per week that samples are analyzed, whichever occurs more frequently. OPR samples must be accompanied by an acceptable method blank (sterile phosphate-buffered saline (PBS)) and appropriate media sterility checks. The OPR procedure is as follows:

11.7.1 Spike a 100-mL sample of PBS with *Enterococcus faecalis* ATCC 19433 by aseptically adding one BioBall to the container and mixing by vigorously shaking the sample bottle a minimum of 25 times.

11.7.2 Filter and process each OPR sample according to the procedure outlined in Section 10.5 and calculate the number of Enterococci per 100 mL according to Section 12.0.

11.7.3 Calculate the percent recovery (R) for each OPR sample using the equation in section 11.6.3.

11.7.4 Compare the OPR results (percent recovery) with the corresponding recovery criteria below:

OPR (as percent recovery) 78%-113%

If the OPR result for recovery of Enterococci meets acceptance criteria, method performance is acceptable and analysis of field samples may continue. If the OPR result falls outside of the acceptance criteria for recovery, system performance is unacceptable. In this event, identify the problem by evaluating each step of the analytical process, media, reagents, and controls, correct the problem and repeat the OPR analysis.

11.8 Matrix spikes (MS)

MS analysis is performed to determine the effect of a particular matrix on enterococci recoveries. The laboratory must analyze one MS sample when **disinfected** wastewater samples are first received from a new source. Subsequently, 1 per 20 samples received from a disinfected wastewater must include a MS sample. MS samples must be accompanied by the analysis of an unspiked field sample (duplicate) subsequently collected from the same sampling site. Additionally, an OPR sample must be run along side the field samples. MS samples are performed as follows:

11.8.1 Prepare two 100 mL field samples that were subsequently collected from the same site. One sample will remain unspiked and the other will serve as the spiked sample. If 100 mL volume is not available, use two 10-mL volumes from a single field bottle sample.

11.8.2 Select sample sizes that will yield an enterococci value of 20 - 60 colonies on a membrane.

11.8.3 Spike the MS sample with an *E. faecalis* BioBall (Section 8.34).

11.8.4 Filter the spiked field sample and the unspiked field sample as directed in Section 10.5.

11.8.5 After incubation, count all enterococci colonies on both plates. Adjust the colony count of the spiked sample by subtracting any enterococci colonies found on the membrane of the unspiked sample.

11.8.6 Calculate the percent recovery (R) for the MS sample using the equation in section 11.6.3.

11.8.7 Compare the MS result (percent recovery) with the corresponding recovery criteria below:

MS (as percent recovery) 63%-110%

If the MS result for recovery of Enterococci meets acceptance criteria, system performance is acceptable and analysis of field samples from this disinfected wastewater source may continue. If the MS result is unacceptable and the OPR sample result associated with this batch of samples is acceptable, a matrix interference may be causing the poor results. If the MS recovery is unacceptable, all associated field data must be flagged.

11.9 Laboratories with two or more analysts must compare each analyst's colony counts from one positive field sample per month. Colony counts must be within 10% between analysts. Facilities with a single analyst must have that analyst perform duplicate colony counts of a single membrane filter each month. Duplicate colony counts must be within 5% for a single analyst. If no positive field samples are available, an OPR sample may be substituted for these determinations.

11.10 For additional details of OPR, MS, Duplicate and quality control samples analyses refer to SOP QC0952.

11.11 Immediately bring to the attention of the supervisor or his designee any deviations in expected quality control testing results and refer to SOP QC0516 Deviations in Expected Quality Control Data to institute corrective action procedures.

11.12 As part of the laboratory QA program, method recovery results for OPR and IPR samples should be charted and updated records maintained in order to monitor ongoing method performance. Refer to SOP QC0952 for further information.

11.13 A Demonstration of Capability (DOC) must be completed initially, and each time there is a significant change in instrument type, personnel, or test method. Demonstration must be documented using the form "Demonstration of Capability Certification Statement" as described in SOP QC0499.

11.13.1 DOC may be established with the use of IPR and OPR Study. Document the successful completion of the Initial Demonstration of Capability for each analyst using the "Demonstration of Capability Certification Statement".

11.13.2 Submit all raw data, a spreadsheet summarizing the recoveries and standard deviations, and a completed "Initial Demonstration of Capability Certification Statement" to the QA Director for review, via LIMS immediately upon completion.

11.13.3 Following review and approval by the QA Director, the original Certification Statement and spreadsheet will be maintained in the analyst training files, which are kept in the QA office.

11.14 Corrective actions are taken when nonconforming work or departures from policies and procedures in the management system or technical operations have been identified. Preventive action is a proactive process to identify opportunities for improvement rather than a reaction to the identification of problems or complaints.

- Analytical work may be stopped if necessary during the investigation, and analyses may resume after it is verified that the corrective actions taken have been effective.
- Corrective actions may include, but not limited to instrument repair or maintenance, recalibration of the instrument, resampling, reanalysis of samples, etc.

11.15 Preventive actions may include, but not limited to preventive maintenance, retraining of analysts, change in procedures etc.

12.0 Calculations and Record Keeping

12.1 Compute the count, using membrane filters with 20 to 60 enterococcus colonies or those closest to that, by the following equation:

enterococcus colonies/100 mL=

(enterococcus colonies counted / mL of sample filtered) x 100

Report results as x CFU/100 mL where X represents the number of colonies.

Note: Refer to Section 12.7 for guidance when colony counts are both above and below the upper and lower limits.

12.2 If all MF counts for a given sample are **below the lower acceptable limit** of 20, select the most nearly acceptable count and use the equation in Section 12.1 to obtain enterococcus density.

For example, sample volumes of 100, 10 and 1 mL produced colony counts of 17, 1 and 0, respectively. Calculate on the basis of the most nearly acceptable plate count, 17, and report as 17 CFU/100 mL.

12.3 If the total number of enterococcus colonies are **not distinct enough** for accurate counting (TNTC), use > 60 in the calculation and report the result by using the equation in 12.1. If all membrane counts are above the upper acceptable limit of 60 but countable, calculate the count using the smallest volume filtered.

For example, volumes 1, 0.5, and 0.01 mL all produced plate counts of TNTC. Use the upper range of 60 colonies as the basis of calculation with the smallest filtration volume and estimate the count:

60 / 0.01 X 100 = 600,000 CFU/100 mL

Report this as > 600,000 CFU/100 mL

12.4 If there are counts in the **acceptable range on replicate plates**, carry the counts independently to final reporting units, then calculate the arithmetic mean of those counts to obtain the final reporting value.

Example, if the counts are 24 and 36 for replicate plates of 100 mL each, then the arithmetic mean is calculated as follows:

(24 CFU/100 mL + 36 CFU/100 mL) / 2 = 30 CFU/100 mL

12.5 If there is **more than one dilution having an acceptable range** of counts, carry the counts independently to final reporting units, then average for final reporting value.

For example, volumes 100, 10 and 1 mL produce colony counts of TNTC (too numerous to count), 55, 30, and 1 respectively. Independently carry each MF count to a count of per 100 mL:

55/10 x 100 = 550 CFU/100 mL
30/1 x 100 = 3000 CFU/100 mL

Calculate the arithmetic mean:

(550 CFU/100 mL+ 3000 CFU/100 mL) / 2 = 1775 CFU/100 mL

Report 1775 CFU/10 mL

12.6 If counts from **all membranes are zero**, calculate final result using the largest volume filtered.

For example, sample volumes of 25, 10 and 2 mL produced colony counts of 0, 0 and 0 respectively. Calculate the number of colonies per 100 mL that would have been reported if there had been one colony on the filter representing the largest filtration volume. In this example the largest volume is 25 mL, calculation would be:

1/25 X 100 = 4 CFU/100 mL

Report as <4 CFU/100 mL.

12.7 If colony counts are **both above and below the upper and lower limits**, select the most nearly acceptable count.

For example, colony counts of 64, 6 and 0 from volumes of 100, 10 and 1 mL respectively. Calculate on the basis of the most nearly acceptable plate count, 64, and report 64 CFU/100 mL.

If sample volumes of 100, 10 and 1 mL produced colony counts of 98, 18 and 0 respectively calculate using 18 colonies. This must be reported as an estimated count.

12.8 If there is no result because of confluent growth, >200 atypical colonies (TNTC), lab accident, etc., the data must be reviewed by the Department Manager or his/her designee for any laboratory errors. A result may not be reported; the client must be notified with specific reason for lack of reportable result.

12.9 Documentation of Laboratory work

12.9.1 Enter and initial the date and time sample was taken, received, run, and completed in designated areas on the EQC Chain of Custody form.

12.9.2 Document all laboratory data as outlined in SOP QC0343, Documentation of Laboratory Data.

12.9.3 Immediately bring to the attention of the supervisor or his designee any deviations in expected quality control testing results and refer to SOP QC0516 Deviations in Expected Quality Control Data to institute corrective action procedures.

13.0 Method Performance

13.1 Specificity – The specificity of the medium used in this method is 6.0% false positive and 6.5% false negative for various environmental water samples. The false positive rate was calculated as the percent of colonies, which react typically, but did not verify as members of the enterococcus group. The false negative rate was calculated as the percent of all verified enterococcus colonies not reacting typically.

13.2 Bias – The persistent positive or negative deviation of the results from the assumed or accepted true value is not significant.

13.3 Precision – The precision among laboratories for marine water was 2.2% and for surface water was 18.9%.

14.0 Pollution Prevention/Waste Management

14.1 Keep storage of chemicals in individual departments to a minimum, in order to minimize the potential for large spills and exposure to hazardous substances. Each laboratory manager or designee is required to inspect their department on a semi-annual basis for expired reagents and chemicals. Notify the Safety Director for disposal of expired reagents and chemicals.

14.2 Minimize the amount of waste generated by preparing only the minimum required amount of a reagent.

14.3 Expired hazardous chemicals, reagents, and samples requiring lab packing or other outside disposal/treatment are stored in a designated waste storage facility (such as the chemical shed) until final disposal. This is under the direction and supervision of the Safety Director. Individual analysts may not transfer chemicals or other substances to a waste storage facility without obtaining authorization from the Safety

Director. All microbiological waste generated during the performance of this procedure (including used petri dishes) must be disposed of in accordance to the Laboratory Waste Disposal SOP, QC0479. Additional details regarding specific disposal of chemical waste at EQC are given in the EQC Safety Procedure Manual, which is incorporated herein by reference.

==========

1.0 Scope and Application

1.1 This procedure is used when the number of *E. coli* in water needs to be determined by the membrane filtration (MF) method using modified membrane-thermotolerant *E. coli* agar (modified mTEC). It is to be performed by trained personnel anytime the enumeration of *E. coli* bacteria using this method is required.

1.2 The MF technique provides a direct count of bacteria in water based on the development of colonies on the surface of a membrane filter. It is highly reproducible, can be used to test relatively large sample volumes, and yields results more rapidly than the multiple-tube procedure. However, the MF procedure has limitations, particularly when testing waters with high turbidity or elevated background bacteria.

2.0 Summary and Discussion of Procedure

2.1 Method 1603 is approved for the detection and enumeration of *E. coli* in both disinfected wastewaters and ambient waters. With respect to the latter, a wide variety of pathogenic microorganisms can be transmitted to humans when bathing in such waters. Historically, fecal coliforms have been recommended as the indicator of choice for evaluating the microbiological quality of recreational waters. Recent studies, however, have demonstrated that *E. coli* and enterococci show a stronger correlation with swimming-associated gastroenteritis than do fecal coliforms, and that both indicators were equally acceptable for monitoring fresh water quality.

2.2 The MF procedure for *E. coli* uses a modified mTEC medium and an incubation temperature of 44.5 ± 0.2 °C for selectivity. Samples up to 100 mL are filtered through a sterile, 47 mm, 0.45 micron membrane filter and incubated on modified mTEC agar, first for 2 ± 0.5 hours at 35 ± 0.5 °C, and then for 22 ± 2 hours in a water bath at 44.5 ± 0.2 °C. All red or magenta colonies are counted as *E. coli.*

Typical and atypical *E. coli* colonies may be confirmed using a verification procedure.

3.0 Definitions

3.1 *E. coli* are those bacteria which produce red or magenta colonies on modified mTEC agar.

4.0 Health and Safety Warnings

4.1 Personnel engaged in laboratory analyses at Eurofins QC, Inc. (EQC) must be familiar with and adhere to the policies set forth in the current version of the EQCL Safety Procedure Manual.

5.0 Cautions

5.1 Start microbiological examination of a water sample promptly after collection to avoid unpredictable changes. Hold temperature of all samples at 0 to <10 °C (do not allow to freeze) during transit to the laboratory and prior to testing. The maximum hold time from time of collection to incubation start time must not exceed 8 hours, with the exception of drinking waters for LT2 (The Long Term 2 Enhanced Surface Water Treatment Rule) projects, which have a maximum hold time of 30 hours. Any deviations in transport or analyzing holding times, missing sampling information, sample volume, or test preformed must be communicated to the client representative and notes made in the sample login and history log.

6.0 Interferences

6.1 Water samples containing colloidal or suspended particulate material can clog the membrane filter and prevent filtration, or cause spreading of bacterial colonies that could interfere with enumeration and identification of target colonies.

7.0 Personnel Qualifications

7.1 Before performing this test independent of secondary supervision and review, each analyst must have an approved Demonstration of Capability Certification Statement (DOC) form (see SOP QC0499) on file in the Quality Assurance office.

8.0 Equipment, Apparatus and Materials

8.1 Erlenmeyer flask for mixing media, clean borosilicate

8.2 Forceps with smooth tips.

8.3 Incubator capable of maintaining a temperature of 35 ± 0.5 °C.

8.4 Petri dishes 60 x 15 mm, plastic, presterilized.

8.5 Stereoscopic microscope with fluorescent light source.

8.6 Filtration funnel units: filter funnels 47-mm magnetic (Gelman or equivalent), graduated at 50 and 100 mL, in assembly with base, sterile, re-usable.

Note: As an alternative, disposable, sterile filtration funnel units can be used (Fisher, Catalog # 09-740-30D or equivalent).

8.7 Membrane filters, 47 mm/0.45 micron, sterile (Millipore or equivalent).

8.8 Water-proof plastic bags.

8.9 Water bath capable of maintaining a temperature of 44.5 ± 0.2 °C.

8.10 Vacuum manifold and pump or laboratory house vacuum system.

8.11 Modified mTEC Agar (Difco or equivalent). Used for the detection and enumeration of *E. coli* in water by the MF method.

8.11.1 Suspend 45.6 g of the powder in 1 L of purified water. Mix thoroughly. Heat with frequent agitation and boil for 1 minute to completely dissolve the powder. Autoclave at 121 °C for 15 minutes.

8.11.2 Cool to 45 - 50 °C in a waterbath and aseptically add sterile 1N NaOH to achieve the pH of 7.3 ± 0.2.

8.11.3 Dispense agar in 4 to 6-mL quantities into 60 x 15 mm disposable petri dishes and allow to solidify.

8.11.4 Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Test for sterility and growth promotion properties as directed in SOP QC0448. Store all prepared plates at 2 - 8 °C for up to 2 weeks. The amount of media prepared can be adjusted accordingly to the work load. The positive control for modified mTEC is *E. coli*, negative control is *E. aerogenes*. Media lot comparisons are required for this method. Notify Water Microbiology Manager when a new manufacturer's lot is being used. Record all media preparation data in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.12 Tryptic soy agar (TSA) (BD BBL or equivalent). This medium is used for the cultivation and identification of bacteria.

8.12.1 Suspend 45.7 g of the powder into 1 L of purified water. Mix thoroughly. Heat with frequent agitation and boil for 1 minute to completely dissolve the powder. Autoclave at 121 °C for 15 minutes. Final pH must be 7.3 ± 0.2.

8.12.2 Dispense 15 to 20 mL into 15x100 mm, sterile petri dishes and allow to solidify. Prepared media will be light amber in color. The amount of media prepared can be adjusted accordingly to the work load. Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for TSA is *E. coli*; a negative control is not needed. Store all prepared plates at 2 - 8 °C for up to 2 weeks. Record all media preparation data in the Water Microbiology electronic media book as directed in SOP QC0448.

8.13 Trypticase soy broth (TSB) (BD BBL or equivalent). This medium is used as a general purpose media for cultivation of microorganisms.

8.13.1 Dissolve 30 g of the powder in 1 L of purified water. Mix thoroughly. Warm gently until solution is complete. Dispense 10-mL portions into suitable screw-cap tubes. Autoclave prepared media at 121 °C for 15 minutes. Final

pH must be 7.3 ± 0.2. Prepared media will be clear, yellow to amber in color and free from precipitates. The amount of media prepared can be adjusted accordingly to the work load.

8.13.2 Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for TSB is *E. coli*. No negative control is needed. Store all prepared tubes at 2 - 8 °C for up to 3 months. Record all media preparation data in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.14 Nutrient Agar (Remel or equivalent). Used for the cultivation and enumeration of microorganisms in water.

8.14.1 Suspend 23 g of the medium into 1 L of purified water. Heat to boiling with agitation to completely dissolve the powder. Autoclave prepared media at 121 °C for 15 minutes. Final pH must be 6.8 ± 0.2.

8.14.2 After sterilization, place 12-15 mL into 15 x 100 mm-sterile petri dishes and allow to solidify. Prepared media will be light amber in color and slightly opalescent. The amount of media prepared can be adjusted accordingly to the work load. Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for Nutrient Agar is *E. coli*; a negative control is not needed. Store all prepared plates at 2 - 8 °C for up to 2 weeks. Record all media preparation data in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.15 Lauryl Tryptose Broth (LTB) (Difco or equivalent). Used for detecting coliform bacteria in water and wastewater.

8.15.1 Suspend 35.6 g of the powder in 1 L of purified water. Mix thoroughly. Warm slightly to completely dissolve the powder. Prepare tubes with inverted 10 by 75 mm culture tubes before dispensing media. Dispense 10-mL portions into autoclavable, borosilicate glass tubes of sufficient size to contain both the culture media and the sample without being three quarters full. Autoclave prepared media at 121 °C for 15 minutes. Final pH must be 6.8 ± 0.2. Prepared media will be yellow to gold in color with some haziness. The amount of media prepared can be adjusted accordingly to the work load.

8.15.2 Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for LTB is *E. coli* and the negative control is *P. aeruginosa*. Store all prepared tubes at 2 - 8 °C for up to 3 months. Record all media preparation data in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.16 Simmons Citrate Agar (Acumedia or equivalent). Simmons Citrate will differentiate microorganisms based upon their ability to utilization of citrate.

8.16.1 Suspend 24.2 g of the medium in 1 L of purified water. Heat with frequent agitation and boil for one minute to completely dissolve the medium. Dispense agar into suitable screw cap tubes and autoclave at 121 °C for 15 minutes. Final pH must be 6.9 ± 0.2. After sterilization, slant tubes until media is solid. Prepared media will be forest green in color and slightly hazy. The amount of media prepared can be adjusted accordingly to the work load. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for Simmons citrate is *E. areogenes* and the negative control is *E. coli*. Store all prepared tubes at 2 - 8 °C for up to 3 months. Record all media preparation data in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.17 EC Medium (EC Broth) (Acumedia or equivalent). Used in this method for the detection of *E. coli* at 44.5 °C.

8.17.1 Dissolve 37 g of the medium to 1 L of purified water. Mix thoroughly. Place 10 x 75 mm culture tubes (inverted) into autoclavable, borosilicate glass tubes. Dispense 10 mL of EC broth into the autoclavable, borosilicate glass tubes of sufficient size to contain both the culture media and the sample without being three quarters full. Autoclave prepared media at 121 °C for 15 minutes. Final pH must be 6.9 ± 0.2. The amount of media prepared can be adjusted accordingly to the work load. Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for EC broth is *E. coli* and the negative control is *E. aerogenes*. Store prepared media at 2 - 8 °C for two weeks in tubes with "pop" tops and three months for screw tops. Record all media preparation data in the Water Microbiology electronic media logbook as directed in SOP QC0448.

Note: Do not use tubes if the inverted tubes (durham tubes) are not completely filled with medium after sterilization.

8.18 Cytochrome oxidase reagent (Difco or equivalent).

N,N,N',N'-tetramethyl-*p*-phenylenediamine dihydrochloride, 1% aqueous solution (1 g per 100 mL reagent-grade water).

8.19 Kovacs indole reagent (Difco or equivalent).

p-dimethylaminobenzaldehyde (10 g), amyl or isoamyl alcohol (150 mL) and concentrated (12 M) hydrochloric acid.

8.20 Inoculating loops, sterile, plastic.

8.21 Tryptone Water – Bacto Tryptone (BD or equivalent). Tryptone Water is used to detect *E. coli* based on indole production.

8.21.1 Composition:

Bacto Tryptone	10.0 g
Sodium chloride	5.0 g
Reagent-grade water	1.0 L

8.21.2 Add reagents to 1 L of purified water and mix thoroughly to dissolve. Dispense 5 mL portions into autoclavable, borosilicate glass tubes of sufficient size. Autoclave prepared media for 15 minutes at 121 °C. Final pH must be 7.3 ± 0.2. Prepared media will be light to medium amber and slightly opalescent. The amount of media prepared can be adjusted accordingly to the work load. Label each batch with the date prepared, batch ID, date of expiration, lot number, storage temp, method number and media name. Test for sterility and growth promotion properties as directed in SOP QC0448. The positive control for Tryptone Water is *E. coli* and the negative control is *E. aerogenes*. Store prepared media at 2 - 8 °C for up to 3 months. Record all media preparation data in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.22 Phosphate Buffered Saline (PBS)

8.22.1 Composition:

Sodium dihydrogen phosphate (NaH_2PO_4)	0.58 g
Disodium hydrogen phosphate (Na_2HPO_4)	2.5 g
Sodium Chloride	8.5 g
Reagent-grade water	1.0 L

8.22.2 Dissolve the reagents in 1 L of reagent-grade water and dispense in appropriate amounts for dilutions in screw cap bottles. Autoclave at 121 °C for 15 minutes. Final pH must be 7.4 ± 0.2. Store prepared PBS at room temperature. Record in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.22.3 Ingredients can be modified to prepare larger or smaller amounts of PBS. The following is an example of how to make 10 L of PBS.

8.22.3.1 Measure out the total amount of reagents needed for 10 L. Pour these ingredients into 3 L of reagent-grade water. Boil the mixture to dissolve the salts. Add the solution to 7 L of reagent-grade water contained in a carboy. Dispense into screw cap bottles and/or into containers. Autoclave at 121 °C for 15 minutes. Final pH must be 7.4 ± 0.2.

Note: Use PBS when performing IPR and OPR sample analyses.

8.23 Phosphate Buffered Dilution water

8.23.1 Prepare as directed in SOP QC0500. The amount of dilution water prepared can be adjusted accordingly to the work load. Record media in the Water Microbiology electronic media logbook as directed in SOP QC0448.

8.24 Sample containers, 125 mL, polypropylene, containing Sodium Thiosulfate tablet for chlorine neutralization.

8.25 Positive control culture *Escherichia coli*, ATCC 11775 or equivalent (BioBalls).

8.26 Negative control culture *Enterococcus faecalis*, ATCC 19433 or equivalent (BioBalls), or *Enterobacter aerogenes* (*E. aerogenes*) ATCC 13048.

8.27 White Filter Paper (Whatman or equivalent).

8.28 60 x 15 mm presterilized, plastic petri dishes.

8.29 Carboy capable of holding 20 L.

8.30 Hotplate.

8.31 Water bath capable of maintaining 50 °C to temper agar.

8.32 A computer capable of real time sample analysis via the WM logbook.

8.33 Autoclave indicator tape.

8.34 Autoclave funnel wrap: aluminum foil or kraft paper.

9.0 Calibration

9.1 Calibrate thermometers used to monitor the temperature of incubators and water baths against a NIST thermometer annually according to SOP QC0339. Calibrate all others (digital, infrared, etc.) quarterly.

9.2 Schedule annual calibration and maintenance of balances through the manufacturer or other qualified, contracted personnel.

9.3 Calibrate pH meters according to manufacturer's recommendations and SOP QC0467.

9.4 Check incubator temperatures twice daily, at least four hours apart to ensure temperature requirements are being met. Record readings in the temperature logbooks.

10.0 Sample Preparation and Analysis

10.1 Collect samples as directed in SOP QC0519 Water and Wastewater Sampling for Microbiological Testing. Store collected samples from the field to the laboratory on ice at a temperature between 0 and 10 °C (do not freeze). When samples are stored at the testing laboratory, prior to analysis, store refrigerated between 0.5 and 5 °C (do not freeze). At no time shall the sample be frozen.

10.2 Initiate analysis as soon as possible after collection to minimize changes in bacterial population. The maximum time allowed between collection and analysis of a water sample is 8 hours, with the exception of waters for LT2 projects, which have a maximum holding time of 30 hours from time of collection to analysis.

10.3 Sample size

10.3.1 The size of the sample will be governed by the expected bacterial density based on the previous historical *E. coli* levels of the source. An ideal sample volume will yield 20 to 80 *E. coli* colonies on a membrane filter surface.

10.3.2 **A minimum of 3 dilutions must be used for any new sample source.**

10.3.3 In instances where the bacterial density is expected to be high, turbidity situations exist, no known history of bacterial density or for legal cases, filter at least three appropriate dilutions from 1 to 100 mL using log interval (e.g. 100, 10, 1, 0.1, etc.) or half log intervals (e.g. 100, 30, 10, 3, 1 mL) prepared in phosphate buffered dilution water through a membrane.

Note: When analyzing smaller sample volume (e.g., <20 mL), add 20-30 mL of phosphate buffered dilution water to the funnel prior to filtration. This will allow even distribution of the sample on the membrane.

10.3.4 If a sample is too turbid to filter, use a different technique for analysis, such as an MPN method.

10.4 Sterile filtration units

10.4.1 Use for filtration series

10.4.1.1 Use sterile filtration units to begin each filtration series. A filtration series is considered to be interrupted when an interval of 30 minutes or longer elapses between sample filtrations. After such interruption, treat any further sample filtration as a new filtration series and replace the filter funnels with new sterile filter funnels.

10.4.1.2 Do not process more than ten (10) filtrations on any funnel. That is, after ten filtrations, including samples, rinse water or sample dilutions, change-out the filter funnel to a second, sterile funnel.

10.4.1.3 During testing in the laboratory, multiple funnels may be used for less than 10 field sample filtrations in order to meet holding times or when, in the judgment of the analyst, a new funnel should be used following a sample with a suspected high level of bacteria. **Always complete any funnel use with a filter blank.**

10.4.2 Use for serial diluted single sample (i.e., river samples, etc.)

10.4.2.1 Use separate sterile filtration unit for each sample to be tested. Start filtration from the highest dilution to lowest. Rinse the interior surface of the funnel 3 times with a 20-30 mL of the sterile dilution water after each filtration. Following the third (final) rinse, remove the filter funnel and replace with a new, sterile disposable funnel.

10.5 Sample Filtration

10.5.1 Using sterile forceps, place a sterile membrane filter (grid side up) over the porous plate of the filtration unit. Pour sample into filtration unit and filter under partial vacuum.

10.5.2 With the membrane still in place, rinse the interior surface of the funnel 3 times with a 20-30 mL portion of sterile dilution water from a squeeze bottle. Thorough rinsing is required to prevent cross-contamination.

10.5.2.1 Where the bacterial density is expected to be high and/or turbidity situations exist additional rinses should be employed.

10.5.2.2 Perform at least one additional rinse to prevent cross-contamination to the following sample in the filtration series.

10.5.3 Upon completion of the final rinse, and the filtration process, disengage vacuum, unlock and remove funnel, and immediately remove the membrane filter with sterile forceps. Place the filter on a modified mTEC agar dish which has been allowed to warm to room temperature with a rolling motion to avoid entrapment of air.

10.5.4 The first two samples filtered on any sterile funnel is a "Sterility Blanks". These serves as the 'Initial Sterility Blank', and is a check on the efficiency of the autoclave sterilization for re-usuable funnels. Refer to Section 11.3.

10.5.5 When more than one sample is processed on an individual funnel, the last sample filtered on a funnel is a "Final Sterility Blank". Refer to Section 11.3.

10.5.6 Analyze a Rinse Water check as a sample, one time, for each new bottle of sterile rinse water bottle opened. Rinse water counts as a sample in the filtration series. Refer to Section 11.3.

10.6 Incubate samples at 35 ± 0.5 °C for 2 ± 0.5 hours to rejuvenate injured or stressed bacteria.

10.7 Transfer samples to waterproof plastic bags, seal, and submerge in a water bath at 44.5 ± 0.2 °C for 22 ± 2 hours. Anchor dishes below water surface to maintain critical temperature requirements.

10.8 Counting *E. coli* colonies

10.8.1 Use a colony counter or a low power stereoscopic microscope with a cool white fluorescent light source directed to provide optimal viewing.

10.8.2 Colonies produced by *E. coli* on modified mTEC are red or magenta in color. Red or magenta colonies are considered "typical" *E. coli*.

10.8.3 For samples with multiple volumes tested refer to Section 12.0 for further instructions.

10.9 *E. coli* Verification Procedure

10.9.1 Using sterile, plastic, inoculating loops, transfer growth from the centers of 10 well-isolated typical (red /magenta) colonies and 10 well-isolated atypical colonies to nutrient agar plates or slants and to trypticase soy broth.

10.9.2 Incubate the nutrient agar plates and trypticase soy broth cultures for 24 ± 2 hours at 35 ± 0.5 °C.

10.9.3 After the incubation outlined in 10.9.2, transfer growth from the nutrient agar and perform a cytochrome oxidase test. This test uses a sterile plastic loop to transfer a loop full of growth to a piece of white filter paper. Holding the cytochrome oxidase dropper, gently crush the ampule one time. After tapping the dropper bottle a few times on the bench top turn the dropper upside down and put a few drops of oxidase reagent onto the bacteria already on the filter paper. A positive reaction will take place within 15 seconds. If the area where the bacteria smear is applied turns deep purple within 15 seconds after applying cytochrome oxidase, the test is positive. Disregard any color change after 15 seconds. No color change is a negative reaction. Since *E. coli* is oxidase negative there should be no color change.

10.9.4 Transfer growth from the trypticase soy broth tube (after incubation in Section 10.9.2) to a Simmons citrate agar slant, tryptone water and an EC broth tube as outlined below.

10.9.4.1 Simmons Citrate: Take a loop full of growth from tryptic soy broth and transfer it to Simmons Citrate. To do this; stab the Citrate

with a loop full of bacteria, pushing the loop to the bottom of the tube. While pulling the loop out of the media streak the loop across the slant of the Citrate in a left to right motion. Incubate the Simmons Citrate agar for 4 days at 35 ± 0.5 °C in an aerobic atmosphere. A positive reaction is indicated by growth with an intense blue color on the slant. Since *E. coli* is citrate negative, there should be little or no growth and no change in agar color (i.e., medium remains dark green).

10.9.4.2 EC broth: From the trypticase soy broth tube, take a loop full of growth and inoculate it into EC medium (with an inverted culture tube). Incubate the EC broth tube at 44.5 ± 0.2 °C in a water bath for 24 ± 2 hours. The water level must be above the level of the EC broth in the tube. A positive *E. coli* test is indicated by turbidity and production of gas in the inverted 10 x 75 mm culture tube. No gas in the inverted culture tube is *E. coli* negative. *E coli* is EC positive for growth and gas.

10.9.4.3 Tryptone Water: From the trypticase soy broth, take a loop full of growth and transfer it to Tryptone water. Incubate the tryptone water (broth) for 18-24 hours at 35 ± 0.5 °C with loosened caps. After incubation gently crush the indole ampule one time. After tapping the dropper bottle a few times on the bench top turn the dropper upside down and put 0.5 mL of Kovacs indole reagent into the typtone water tube. Shake the tube gently. Allow the tube(s) to stand for 5-10 minutes at room temperature. A positive *E. coli* test is indicated by a deep red color, which develops in the alcohol layer on top of the broth. *E coli* is indole positive.

10.9.4.4 *E. coli* are oxidase negative, citrate negative, EC growth and gas positive, and indole positive.

10.9.4.5 Adjust results based upon percentage of *E. coli* colonies confirmed. For example, if only a few suspect colonies are verified to be *E. coli* the reported value needs to be adjusted as follows:

Total # of colonies counted = 60

# of colonies selected for verification = 10

# of colonies confirmed = 5

Adjusted final *E. Coli* result = 60 x 5/10 = 30

Note: Alternately, commercially available multi-test identification systems may be used to verify colonies. Refer to Section 12.0 of EPA 1603, July 2006.

10.9.4.6 Record all information (Typical or Atypical colonies, media batch number, incubation times, etc.) into *E.coli* Verification logbook Form #2084. The laboratory manager or his designee must review the Logbook for accuracy.

10.9.5 Frequency Tracking

The main lab and satellites offices must track the number of samples that contain typical and atypical colonies. Verification tests are performed at the main lab.

10.9.5.1 Following plate counting, use the Sample Tracking file for this method (EPA 1603) and bar-code each sample that has either typical or atypical colonies into the file for tracking frequency.

10.9.5.2 For satellites offices, take a picture of the plate. Send the plate and photo to the main lab for verification. Notify the main lab staff when plates are being sent.

Note: The main lab will use the picture as a reference for confirmation of original count of typical and atypical colonies.

10.9.5.3 After receiving plates from a Satellite office, initiate the verification the same day or at a minimum by the following day to ensure the quality of data.

10.9.5.4 Verification must be performed each month based on the following frequency: Verify a minimum of 10 typical (positive) and 10 atypical (negative) *E. coli* colonies or 1 typical and 1 atypical *E. coli* colony from 10% of all plates showing growth, whichever is more frequent.

10.9.5.5 When routine samples do not provide at least 10 typical and at least 10 atypical colonies, a source known to satisfy this requirement must be analyzed and verified. Such sources can include samples from local pounds or streams.

10.9.5.5.1 Collect a sample from local pound or stream and analyzed as a regular sample.

11.0 Quality Control

11.1 Test all microbiological media after preparation as directed in SOP QC0448.

11.2 Check each lot # of membrane filters for sterility by placing a membrane on a tryptic soy agar plate for 24 ± 2 hours at 35 ± 0.5 °C. Absence of growth indicates sterility of the filter. Reject any lot that is found to be non-sterile. Record results in the Water Microbiology quality control book.

11.3 Perform the following checks when using autoclavable (multi-use) funnels.

11.3.1 Analyze an initial sterility blank on TSA, as the first sample for each sterile funnel used as follows:

11.3.1.1 Rinse each funnel with 20-30 mL of phosphate-buffered dilution water as is done during the rinse step for a sample. Do not use additional rinses. Place the filters on TSA plates and incubate for 24 ± 2 hours at 35 ± 0.5 °C. Absence of growth indicates sterility of the phosphate-buffered dilution water and the filtration assembly. Record results in the Water Microbiology Logbook in LIMS.

11.3.2 Analyze an initial sterility blank on modified mTEC, as the second sample for each sterile funnel used as follows:

11.3.2.1 Rinse each funnel with 20-30 mL of phosphate-buffered dilution water as is done during the rinse step for a sample. Do not use additional rinses. Place the filter on a modified mTEC plate and complete the analysis of the sterility blank as a regular sample. Absence of growth indicates sterility of the phosphate-buffered dilution water and the filtration assembly for *E.coli*. Record results in the Water Microbiology Logbook in LIMS.

11.3.3 Analyze a final sterility blank following all samples analyzed with any funnel, WHEN more than one sample is analyzed on a funnel. If only one sample is processed per funnel, a final sterility blank is not required.

11.3.4 Analyze a Rinse Water check as a sample, one time, for each new bottle of sterile rinse water bottle opened. Pour 50 mL of sterile water into filtration unit and filter. Rinsing the interior surface of the funnel 3 times is not required. Complete the analysis of the sterility blank as a regular sample.

11.3.5 For each autoclavable funnel, up to a maximum of ten (10) filtrations may be performed before being replaced with an un-used sterile funnel. A filtration includes any: sample, sample dilution or rinse water check.

11.4 Disposable sterile funnels

11.4.1 When using disposable sterile funnels, an initial sterility check or final sterility blank is not required.

11.4.2 Disposable sterile funnels are lot checked for sterility when received at the laboratory.

11.5 Duplicate analyses. Perform duplicate analyses at a minimum of a 5% (1 out of every 20 samples) frequency or 1 per week, whichever is more frequent. Refer to SOP QC0952 for further information.

11.6 Check each batch of PBS and phosphate-buffered rinse water for sterility by adding 50 mL of PBS or rinse water to 50-mL double strength trypticase soy broth, incubating at 35 ± 0.5 °C for 24 hours and checking for growth. Record results in the Water Microbiology quality control logbook in LIMS.

11.7 On a monthly basis, verify a minimum of 10 typical and 10 atypical *E. coli* colonies (can be from a single membrane) or 1 typical and 1 atypical colony from 10% of all samples with growth, whichever is more frequent. Record results in the Water Microbiology Verification Book.

11.8 Initial precision and recovery (IPR)

The IPR analysis is used to demonstrate acceptable method performance (recovery and precision) by each laboratory before the method is used for monitoring field samples. IPR samples should be accompanied by an acceptable method blank (sterile Phosphate-buffered saline (PBS)) and appropriate media sterility checks. The IPR procedure is as follows:

11.8.1 Prepare four, 100-mL samples of **PBS** (Phosphate Buffered Saline, Section 8.22 above) and spike each sample with *E. coli* ATCC 11775 by aseptically adding 1 BioBall or known density of the laboratory prepared culture spike to each container and mixing by vigorously shaking the sample bottle a minimum of 25 times.

11.8.2 Filter and process each IPR sample according to the procedure outlined in Section 10.0 and calculate the number of *E. coli* per 100 mL according to Section 12.0.

11.8.3 Calculate the percent recovery (R) for each IPR sample using the following equation:

$$R = 100 \times \frac{(Ns - Nu)}{(T)}$$

R = percent recovery

Ns = *E. coli* (CFU/100 mL) in the spiked sample

Nu = *E. coli* (CFU/100 mL) in the unspiked sample (minimum value is 1 even if no colonies are found)

T = true spiked *E. coli* (CFU/100 mL) manufacturer's lot or lab culture spike mean

11.8.4 Using the percent recoveries of the four analyses, calculate the mean percent recovery and the relative standard deviation (RSD) of the recoveries. The RSD is the standard deviation divided by the mean, multiplied by 100.

11.8.5 Compare the mean recovery and the RSD with the corresponding IPR criteria below:

Recovery (mean percent): detect - 144%
Precision (as maximum RSD): 61%

If the mean and the RSD for recovery of *E. coli* meet acceptance criteria, system performance is acceptable and analysis of field samples may begin. If the mean or the RSD falls outside of the required range for recovery, system performance is unacceptable. In this event, identify the problem by evaluating each step of the analytical process, media, reagents, and controls, correct the problem and repeat the IPR analysis.

11.9 Ongoing Precision and Recovery (OPR)

To demonstrate ongoing control of the analytical system, the laboratory shall routinely process and analyze spiked PBS samples. The laboratory shall analyze one OPR sample after every 20 field and matrix spike samples or one per week that samples are analyzed, whichever occurs more frequently. OPR samples shall be accompanied by an acceptable method blank (sterile Phosphate-buffered saline) and appropriate media sterility checks. The OPR procedure is as follows:

11.9.1 Spike a 100-mL sample of **PBS** (Phosphate Buffered Saline, Section 8.22 above) with *E. coli* ATCC 11775 by aseptically adding 1 BioBall to the container and mixing by vigorously shaking the sample bottle a minimum of 25 times.

11.9.2 Filter and process each OPR sample according to the procedure outlined in Section 10.0 and calculate the number of *E. coli* per 100 mL according to Section 12.0.

11.9.3 Calculate the percent recovery (R) for each OPR sample using the equation in Section 11.8.3.

11.9.4 Compare the OPR results (percent recovery) with the corresponding recovery criteria below:

OPR (as percent recovery) detected - 144%

If the OPR result for recovery of *E. coli* meets acceptance criteria, method performance is acceptable and analysis of field samples may continue. If the OPR result falls outside of the acceptance criteria for recovery, system performance is unacceptable. In this event, identify the problem by evaluating each step of the analytical process, media, reagents, and controls, correct the problem and repeat the OPR analysis.

11.10 Matrix spikes (MS)

MS analysis are performed to determine the effect of a particular matrix on *E. coli* recoveries. The laboratory must analyze one MS sample when disinfected wastewater samples are first received from a new source. Subsequently, 1 per 20 samples received from a disinfected wastewater must include a MS sample. MS samples must be accompanied by the analysis of an unspiked field sample (duplicate) subsequently collected from the same sampling site. Additionally, an OPR sample must be run along side the field samples. MS samples are performed as follows:

11.10.1 Prepare two 100-mL field samples that were subsequently collected from the same site. One sample will remain unspiked and the other will serve as the spiked sample. If 100 mL volume is not available, use two 10-mL volumes from a single field bottle sample.

11.10.2 Select sample sizes that will yield an *E. coli* value of 20-80 colonies on a membrane.

11.10.3 Spike the MS sample with an *E. coli* BioBall (Section 8.26).

11.10.4 Filter the spiked field sample and the unspiked field sample as directed in Section 10.5.

11.11 Laboratories with two or more analysts must compare each analyst's colony counts from one positive field sample per month. Colony counts must agree within 10% between analysts. Facilities with a single analyst must have that analyst perform duplicate colony counts of a single membrane filter each month. Duplicate colony counts must be within 5% for a single analyst. If no positive field samples are available an OPR sample may be substituted for these determinations.

11.12 For additional details of OPR, MS, Duplicate and quality control samples analyses refer to SOP QC0952.

11.13 Immediately bring to the attention of the Director of Microbiology or his designee any deviations in expected quality control testing results and refer to SOP QC0516 Deviations in Expected Quality Control Data to institute corrective action procedures.

11.14 As part of the laboratory QA program, method recovery results for OPR and IPR samples should be charted and updated records maintained in order to monitor ongoing method performance. Refer to SOP QC0952 for further information.

11.15 A Demonstration of Capability (DOC) must be completed initially, and each time there is a significant change in instrument type, personnel, or test method. Demonstration must be documented using the form "Demonstration of Capability Certification Statement" as described in SOP QC0499.

11.15.1 DOC may be established with the use of IPR and OPR Study. Document the successful completion of the Initial Demonstration of Capability for each analyst using the "Demonstration of Capability Certification Statement".

11.15.2 Submit all raw data, a spreadsheet summarizing the recoveries and standard deviations, and a completed "Initial Demonstration of Capability Certification Statement" to the QA Director for review, via LIMS immediately upon completion.

11.15.3 Following review and approval by the QA Director, the original Certification Statement and spreadsheet will be maintained in the analyst training files, which are kept in the QA office.

11.16 Corrective actions are taken when nonconforming work or departures from policies and procedures in the management system or technical operations have been identified. Preventive action is a proactive process to identify opportunities for improvement rather than a reaction to the identification of problems or complaints.

- Analytical work may be stopped if necessary during the investigation, and analyses may resume after it is verified that the corrective actions taken have been effective.
- Corrective actions may include, but not limited to instrument repair or maintenance, recalibration of the instrument, resampling, reanalysis of samples, etc.

11.17 Preventive actions may include, but not limited to preventive maintenance, retraining of analysts, change in procedures etc.

12.0 Calculations and Record Keeping

12.1 Compute the count, using membrane filters with 20 to 80 *E. coli* colonies or those closest to that as described below, by the following equation:

$$\textit{E. coli}\ \text{colonies/100 mL} = \frac{\textit{E. coli}\ \text{colonies counted}}{\text{mL sample filtered}} \times 100$$

12.2 If all MF counts for a given sample are **below the lower acceptable limit** of 20, select the most nearly acceptable count and use the equation in 12.1 to obtain *E. coli* density.

12.2.1 For example, sample volumes of 100, 10 and 1 mL produced colony counts of 17, 1 and 0, respectively.

12.2.1.1 Calculate on the basis of the most nearly acceptable plate count, 17, and report as 17 colonies/100 mL.

In this case, because no calculations were done (i.e. this is the count for 100 mL), the count is reported as 17 CFU/100 mL rather than an "estimated count of 17 CFU/100 mL".

12.2.2 As a second example, sample volumes of 10 and 1 mL produced colony counts of 18 and 0, respectively.

12.2.2.1 Calculate on the basis of the most nearly acceptable plate count, 18, and calculate as in Section 12.1 above.

$$\frac{18}{10} \mathrm{X} 100 = 180 \text{ colonies /100 mL}$$

Report this as estimated count 180 CFU/100 mL. Use the "E" qualifier code.

12.3 If the total number of *E. coli* colonies are not distinct enough for accurate counting or too numerous to count (TNTC), record the results as > 80 and report the actual result by using the equation in 12.1.

12.4 If all membrane counts are **above the upper acceptable limit of 80 but countable**, calculate the count using the smallest volume filtered.

12.4.1 For example, sample volumes 1, 0.1, and 0.01 mL, produced colony counts of TNTC, 150, and 110 colonies, respectively, use the colony count from the smallest sample volume filtered.

$$\frac{110}{0.01} \mathrm{X} 100 = 1{,}100{,}000 \text{ colonies /100 mL}$$

Report this as estimated count 1,100,000 CFU/100 mL. Use the "E" qualifier code.

12.5 If there are counts in the **acceptable range on replicate plates**, carry the counts independently to final reporting units, then calculate the arithmetic mean of those counts to obtain the final reporting value.

12.5.1 Example, if the counts are 24 and 36 for **replicate plates** of 100 mL each, then the arithmetic mean is calculated as follows:

$$\frac{(24 \text{col}/100\text{mL} + 36 \text{col}/100\text{mL})}{2} = 30 \text{ colonies/100 mL}$$

12.6 If there is **more than one dilution having an acceptable range** of counts, carry the counts independently to final reporting units, then average for final reported value.

12.6.1 For example, sample volumes 100, 10, 1 and 0.1 mL, produced colony counts of TNTC, 75, 30, and 1, respectively, then two volumes, 10 mL and 1 mL, produced colonies in the acceptable counting range.

12.6.2 Independently carry each MF count to a count per 100 mL:

$$\frac{75}{10}\text{X}100 = 750 \text{ colonies/100 mL}$$

and

$$\frac{30}{1}\text{X}100 = 3000 \text{ colonies/100 mL}$$

12.6.3 Calculate the arithmetic mean as in Section 12.1.

$$\frac{(750\,\text{CFU/100mL} + 3000\,\text{CFU/100mL})}{2} = 1875 \text{ Colonies/100 mL}$$

12.7 If counts from **all membranes are zero**, calculate final result using the largest volume filtered.

12.7.1 For example, sample volumes of 25, 10, and 2 mL, produced colony counts of 0, 0, and 0, respectively. The largest volume filtered was 25 mL, so the calculation would be:

$$\frac{1}{25}\text{X}100 = 4 \text{ Colonies/100 mL}$$

Report this as < (less than) 4 colonies/100 mL.

12.8 If colony counts are **both above and below the upper and lower limits**, select the most nearly acceptable count.

12.8.1 For example, sample volumes of 100, 10, and 1 mL, produced colony counts of 84, 8, and 0, respectively. Calculate on the basis of the most nearly acceptable plate count, 84, and report as 84 colonies/100 mL:

84 colonies/100 mL

In this case, because no calculations were done (i.e. this is the count for 100 mL), the count is reported as 84 CFU/100 mL rather than an "estimated count of 84 CFU/100 mL".

12.8.2 As a second example, sample volumes of 100, 10, and 1 mL, produced colony counts of 98, 18, and 0, respectively. Calculate on the basis of the most nearly acceptable plate count, 18, and calculate as in section 12.1 above.

$$\frac{18}{10}\text{X}100 = 180 \text{ Colonies/100 mL}$$

Report this as estimated count 180 CFU/100 mL. Use the "E" qualifier code.

12.9 If there is **no result** because of confluent growth, >200 atypical colonies, lab accident, etc. **report as No Data** and specify the reason.

12.10 Documentation of Laboratory work

12.10.1 Enter and initial the date and time sample was taken, received, run, and completed in designated areas on the EQCL Chain of Custody form.

12.10.2 Document all laboratory data as outlined in SOP QC0343 Documentation of Laboratory Data.

12.10.3 Immediately bring to the attention of the Director of Microbiology or his designee any deviations in expected quality control testing results and refer to SOP QC0516 Deviations in Expected Quality Control Data to institute corrective action procedures.

12.10.4 Use the Water Micro Electronic Notebook to document all sample, sample duplicate and QC check samples.

12.10.5 Verification documentation is maintained in manual logbooks.

13.0 Method Performance

13.1 Method performance is evaluated by the review of blanks, OPR and MS/MSD. Refer to Section 15.0 of EPA method 1603 for additional information.

14.0 Pollution Prevention/Waste Management

14.1 Keep storage of chemicals in individual departments to a minimum, in order to minimize the potential for large spills and exposure to hazardous substances. Each laboratory manager or designee is required to inspect their department on a semi-annual basis for expired reagents and chemicals. Notify the Safety Director for disposal of expired reagents and chemicals.

14.2 Minimize the amount of waste generated by preparing only the minimum required amount of a reagent.

14.3 Expired hazardous chemicals, reagents, and samples requiring lab packing or other outside disposal/treatment are stored in a designated waste storage facility (such as the chemical shed) until final disposal. This is under the direction and supervision of the Safety Director. Individual analysts may not transfer chemicals or other substances to a waste storage facility without obtaining authorization from the Safety Director. All microbiological waste generated during the performance of this procedure (including used petri dishes) must be disposed of in appropriately labeled biohazardous waste bags and must be autoclaved prior to final disposal. Additional details regarding specific disposal of chemical waste at EQC are given in the EQC Safety Procedure Manual, which is incorporated herein by reference.

1.0 BACKGROUND

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1 (DELCORA, 2017b). The total service area served by DELCORA, as shown on Figure 1-2 (DELCORA, 2017b), is approximately 82,977 acres which illustrates that DELCORA serves a significant and widespread portion of Delaware County.

The combined sewer area simulated in DELCORA's existing Hydrologic and Hydraulic model is located within the City of Chester and consists of a drainage area of approximately 1,510 acres. It comprises approximately half of Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows. The location of Chester City's service area is illustrated on Figure 1-2 (DELCORA, 2017b).

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western service area discharges to DELCORA's Western Regional Treatment Plant (WRTP). The Eastern service area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWDSWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are directed to the PWDSWPCP. As such, dry weather flows and a portion of the wet weather flows (total flow less than 20 MGD) from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

There are a total of 26 combined sewer overflow outfalls listed with 25 discharge points (Outfall #009 and #010 both discharge at Outfall #009) in DELCORA's existing National Pollutant

Discharge Elimination System (NPDES) Permit. Under its NPDES Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow outfalls (#002-#026, #032, #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

2.0 SAMPLING AND ANALYSIS PLAN OVERVIEW

The Sampling and Analysis Plan (SAP) is designed to collect data that will be used to develop and calibrate watershed and receiving water quality models which will be used to assess water quality concerns for the POCs identified in the Identification of Sensitive Areas and Pollutants of Concern Report (DELCORA, 2016a). These POCs are fecal coliform, *E. coli*, and *Enterococcus*. Additional *in situ* parameters, such as salinity, temperature, and conductivity will also be collected to inform the development of the Water Quality Model.

Water quality monitoring will be undertaken at up to thirteen (13) in-stream locations (seven of which are Delaware River sampling locations), four (4) CSO locations in the DELCORA combined sewer system area, and two (2) storm water locations in the City of Chester municipal separate storm sewer system, as shown in Figure 1. Maps of each sample location are also provided in DELCORA, 2017b. Water quality monitoring and sampling will be conducted as follows:

- Eleven (11) in-stream locations in the vicinity of the DELCORA CSO area will be sampled for water quality for (3) dry weather events; one of which will be targeted for collection during a tributary low-flow period (less than 25th percentile flow). The mid-stream and far-shore Delaware River locations will not be sampled during the dry weather surveys because it is expected that water quality in the river will be relatively uniform laterally due to the lack of active sources during dry weather. These dry weather events would preferably be distributed across the sampling season, which is assumed to be March through June of 2017. Grab samples and *in situ* measurements will be collected at each location during each event.
- Thirteen (13) in-stream locations will be sampled for water quality using grab samples and *in situ* monitoring for three (3) discrete wet weather events, according to the surface water quality monitoring program protocols described in this SAP;

- Up to four (4) CSO and two (2) stormwater outfall locations will be sampled for water quality for the same three (3) discrete wet weather events according to the outfall monitoring program protocols described in this SAP. Samples for all outfalls will be collected as grab samples.
- Standard operating procedures (SOPs) referenced in the following sections of this SAP.

The sampling events are planned to be distributed across the sampling season, which is assumed to be March through June 2017. Additionally, bathymetry surveys in the lower portion of the tributaries may be required to inform the development of the Water Quality Model, pending delivery of HEC models with transect information for these portions of the receiving waters.

2.1 SAMPLE LOCATIONS

Monitoring locations have been selected to characterize the watershed at a sub-watershed level, recognizing various political and hydrologic features, land uses and potential pollutant sources. Site selection and analytical parameters are designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. The sampling locations are shown in Figure 1 and listed in Table 1, Table 2, and Table 3.

The tables include summaries of the rationales for each sampling location selected. The Chester Creek and Ridley Creek locations were selected to distinguish, to the extent possible, between upstream, stormwater and Chester CSO pollutant loads. The Delaware River sampling locations will provide a characterization of water quality entering the Chester CSO area from either tidal direction as well as water quality within the CSO discharge area. During wet weather, three samples will be collected across the transect corresponding to the DR-04 sampling location during each sampling round, when sampling across the river is feasible, to characterize lateral variability in the Delaware River during storm events. Delaware River conditions may be too hazardous for safe collection of one or more samples and/or sampling rounds (e.g. during periods of heavy barge traffic, small craft advisories, lightning, etc.). When these conditions occur, sampling will not be conducted in the river for safety reasons.

The CSO sampling locations were selected based on their outfall discharge location, relatively high frequency of overflow, their overflow volume, and their accessibility. The stormwater

sampling locations were selected to characterize the water quality associated with the predominant land uses (residential and commercial/industrial) in the study area. Each stormwater sampling location is in an area that is representative of the land use elsewhere in the City's stormwater area.

Figure 1: Proposed Receiving Water (RW), Combined Sewer (CSO), and Stormwater (SW) Monitoring Locations

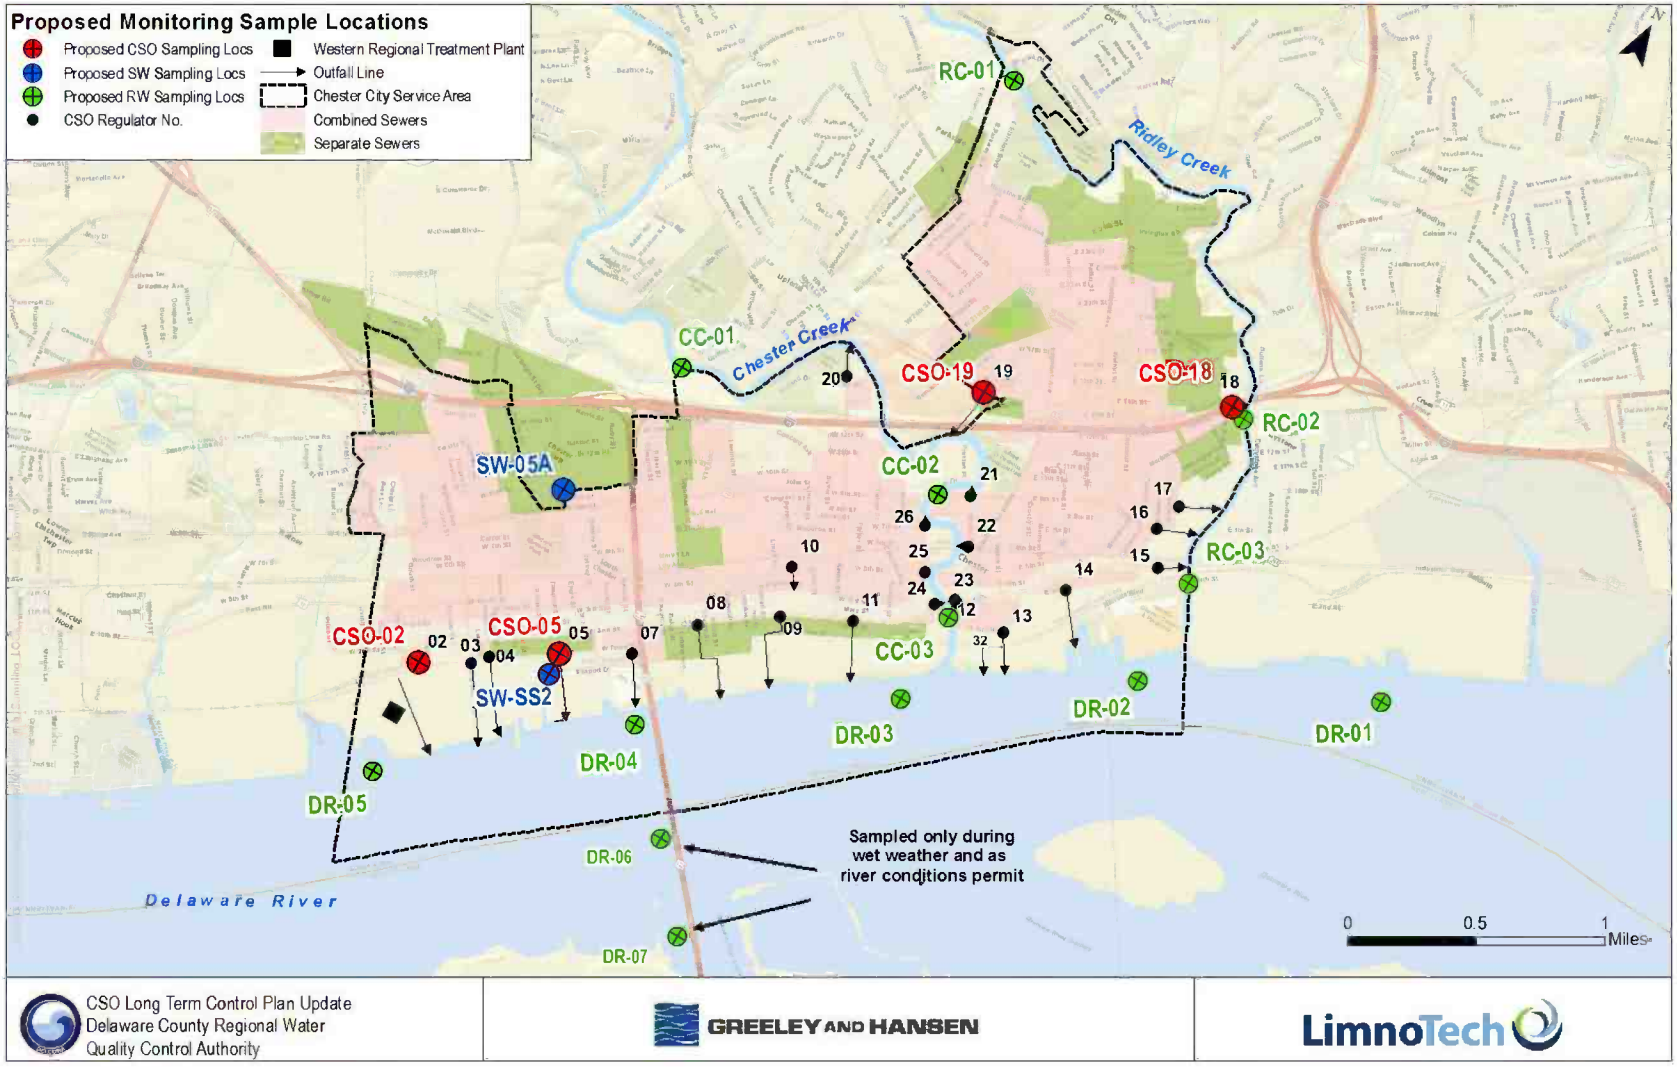

Table 1: Tributary Receiving Water Sampling Locations

Station ID	Sampling Location	Receiving Water	Type	Activity/Notes	Accessibility
CC-01	Upland Rd. / Incinerator Rd. Bridge. **39.850122, -75.386348**	Chester Creek	Tributary	20 ft. from rail to water. Upstream of CSO outfall. Creek is non-tidal.	Upland road access gated from both ends, may need to contact police for access or walk in from gate. Minimal traffic.
CC-02	9th St Bridge (54 W 9th St) **39.850709, -75.365530**	Chester Creek	Tributary	23 ft. from rail to water. Bridge is located next to Chester High School.	Accessible from 9th Street. Can pull vehicle on shoulder or pull into school. Light traffic.
CC-03	Intersection of Edgmont and 2nd street. William Penn's Landing Park (126 E 2nd St) **39.845227, -75.360284**	Chester Creek	Tributary	Site is in William Penn's Landing Park. Sample off of Concrete plaza that overhangs Chester Creek. Tidal influence. Grab samples upstream of bridge.	Can pull vehicle off of 2nd Street and walk into park. Light traffic.
RC-01	Chester Park Drive Bridge (298 East Elkington Blvd) **39.873264, -75.375183**	Ridley Creek	Tributary	19 ft. rail to water. Sample upstream of CSO outfall. Upstream of CSO-33. Creek is non-tidal here.	Can park in lot adjacent to Chester Park Drive Bridge. Minimal traffic.
RC-02	Morton Ave. Bridge (1300 Sun Drive) **39.863016, -75.348686**	Ridley Creek	Tributary	22 ft. rail to water (low tide), with 2 ft. water depth. Site is in same area as CSO-18.	Can park on Sun Drive and use sidewalk when sampling off of bridge. Medium traffic.
RC-03	4th Street (Harrah's) Bridge. Bridge No. 157 (Chester-Eddystone Bridge) (1050 East 4th St Eddystone) **39.853435, -75.346350**	Ridley Creek	Tributary	25 ft. rail to water (low tide) shallow during low tide. Creek is tidal. Lower bottle from bridge using a rope or other means.	Can park on shoulder north of bridge use sidewalk when sampling off of bridge. Medium traffic.

Table 2: Main Stream Receiving Water Sampling Locations

Station ID	Longitude	Latitude	Receiving Water	Type	Description	Rationale
DR-01	39.85282	-75.3299	Delaware River	Main stem	Delaware River between Ridley Creek and Crum Creek	"Upstream" of DELCORA's CSO discharges[1]
DR-02	39.84715	-75.3462	Delaware River	Main stem	Delaware River between CSO-14 and Ridley Creek	Characterize Ridley Creek impacts on Delaware River, in the upper Delaware River (Secondary contact area)
DR-03	39.8398	-75.3606	Delaware River	Main stem	Delaware River between CSO-11 and Chester Creek	Characterize Chester Creek impacts on Delaware River, in the upper Delaware River (Secondary contact area)
DR-04	39.83132	-75.3766	Delaware River	Main stem	Delaware River at the boat launch off Highway 322	Priority area, in the lower Delaware River (Primary contact area)
DR-05	39.82182	-75.3917	Delaware River	Main stem	Delaware River between CSO- 002 and Stoney Creek	"Downstream" of DELCORA's CSO discharges[1], in the Atlantic sturgeon sensitive area
DR-06[2]	39.82636	-75.371	Delaware River	Main stem	Delaware River mid-stream along the transect of DR-04	Characterize lateral variability in the Delaware River during storm events
DR-07[2]	39.82203	-75.3665	Delaware River	Main stem	Delaware River far shore (left descending bank) along the transect of DR-04	Characterize lateral variability in the Delaware River during storm events

Notes:
[1] **"Upstream" and "downstream" subject to tidal conditions at time of sampling**
[2] **These locations will be sampled during the wet weather events only, when river conditions permit. POC concentrations are assumed to be laterally well-mixed during dry weather due to the absence of significant pollutant sources.**

Table 3: CSO and Stormwater Sampling Locations

Station ID	Sampling Location	Receiving Water	Type	Activity/Notes	Accessibility
CSO-02	Front and Booth St (100 Booth St) **39.828334, -75.392570**	Delaware River	CSO	SCADA level sensor installed. Concrete dam diverts flow to right side MH flow to WRTP (has an orifice plate). Overflow over the dam will flow to CSO outfall at Delaware River.	Can park at the end of Booth St. prior to rail tracks. Minimal traffic. MH cover is marked with white dot.
CSO-05	Front and Townsend (101 Townsend St) **39.832598, -75.383958**	Delaware River	CSO	SCADA level sensor and Hach flow meter installed. Concrete dam diverts flow to right side MH flow to WRTP. Overflow over the dam will flow to CSO outfall at Delaware River.	Can park at the end of Townsend St. Minimal traffic. MH cover is marked with white dot.
CSO-18	Hancock St. and Sun Dr. (1310 Sun Dr) **39.863501, -75.349203**	Ridley Creek	CSO	SCADA level sensor and Hach flow meter installed. Concrete dam diverts flow to right side MH flow to WRTP. Overflow over the dam will flow to CSO outfall at Ridley Creek.	Can park at the end of Hancock St. Minimal traffic. MH cover is marked with white dot.
CSO-19	14th and Crozer Hospital (1 Medical Center Blvd) **39.857132, -75.366105**	Chester Creek	CSO	SCADA level sensor and Hach flow meter installed. Concrete dam diverts flow to interceptor MH flow to WRTP. Overflow over the dam will flow to CSO outfall at Chester Creek.	Can park in the cul-de-sac off of 14th St. High traffic. MH cover is on lawn area marked with white dot.
SW-SS2	105 Townsend St **39.832853, -75.384193**	Delaware River	SW	Industrial storm water MH. MH is clear and on gravel area near CSO-05.	Can park at the end of Townsend St. Minimal traffic. MH cover is marked “storm” with white dot.
SW-05A	7th and Engle Street (by tennis courts) **39.838501, -75.387708**	Chester Creek	SW	Residential storm water MH. MH is clear and on grass area off of road.	Can park on 7th St. shoulder and access MH on lawn next to traffic light. Medium traffic. MH cover is on lawn area marked with white dot.

2.2 SAMPLING SCHEDULE

2.2.1 DRY WEATHER SAMPLING

Collection of water quality samples will be performed for three (3) dry weather events; with one dry weather sampling event planned to be collected during a low-flow period (less than 25th percentile flow) in Chester Creek and Ridley Creek (if possible). Two rounds of sampling will be conducted for each dry weather survey: one round to be completed during ebb (outgoing) tide and the second round to be completed during flood (incoming) tide.

Dry weather event samples will be taken at up to eleven (11) locations:

- **Three (3) locations on Chester Creek** that will characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations will also reflect these tidal influences on water quality.
- **Three (3) locations on Ridley Creek** that will characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations will also reflect these tidal influences on water quality.
- **Five (5) locations on the Delaware River** that will characterize water quality in the vicinity of DELCORA's CSO discharges. Sampling locations have been selected to separate to the extent possible the effect of DELCORA's CSOs on water quality from other sources contributing pollutants to the waterways. Sampling will be conducted near the shoreline adjacent to the City of Chester.

The locations of these stations are shown in Figure 1. Details for these stations are provided in Table 1, Table 2, and Table 3. The set of parameters for which the samples will be analyzed is provided in Table 5. In-situ measurements of physical parameters, such as salinity, temperature, and conductivity will be collected at each sampling location with a sonde. In the Delaware River, *in situ* measurements will be made at three depths at each sampling location during each round of sampling.

2.2.2 WET WEATHER SAMPLING

Collection of water quality samples will be performed for three (3) wet weather events. The purpose of the wet weather sampling is to characterize the impact of CSO discharges and non-CSO source runoff on in-stream water quality. The wet weather events will span a range of precipitation, flow and seasonal conditions. Wet weather event samples will be taken at all 13 in-stream locations as well as at up to six source locations in the intervals described below:

- **Six (6) In-Stream Tributary Sampling Locations:** Three (3) locations will be on Chester Creek and three (3) locations on Ridley Creek. The locations will be the same locations used for the dry weather surveys. Tributary locations will be sampled up to five times per event at the following approximate intervals: Hour 0.5-2.5, Hour 4.5-6.5, Hour 8.5-10.5, Hour 14.5-16.5, and Hour 22-24. Sampling intervals will be defined by the start of rainfall rather than CSO or SSO activation. A total of 30 samples will be collected during each wet weather sampling event from in-stream locations. One field blank and one field duplicate will be collected during each event to be used as field quality control (QC).
- **Up to Seven (7) In-Stream Delaware River Locations:** Up to seven locations will be on the Delaware River and will be sampled up to ten times per event at the following approximate intervals: Hour 0, Hour 2, Hour 4, Hour 6, Hour 9, Hour 12, Hour 15, Hour 18, Hour 21, and Hour 24. Sampling intervals will be defined by the start of rainfall rather than CSO or SSO activation. The frequency of sampling is intended to capture in-stream impacts in the vicinity of DELCORA's service area from both DELCORA's CSOs as well as upstream sources. Two additional locations on the Delaware River, one at mid-stream and one near the far shore, have been added to characterize lateral variability in water quality during storm event conditions, when sampling across the river is feasible. The sampling regimen is also designed to allow a semi-quantitative mass balance to be computed over a complete tidal cycle. A total of 70 samples may be collected during each wet weather sampling event. If river conditions are unsafe for sampling (e.g. small craft advisories, heavy barge traffic, etc.), sampling may be suspended for one or more locations and/or sampling rounds. One field blank and one field duplicate will be collected during each event to be used as field QC. Final selection of sampling locations and sampling intervals will be determined prior to the start of the sampling program and will be based on logistic considerations (e.g. can seven locations be sampled and dropped off to a courier within the 3 hour sampling window), safety and accessibility to the Delaware River, and available resources.
- **Up to Six (6) Outfall Locations:** Sampling will be conducted at up to two (2) stormwater outfalls and up to four (4) combined sewer overflow outfalls. The CSO and stormwater sampling locations will be finalized prior to the initiation of the sampling program based on accessibility of sampling, safety of sampling personnel, equipment risk, and available resources. It is assumed that each of the outfall locations will have up to eight sets of samples collected for each event at the following intervals: 1st flush, 30 minutes, and 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, 24 hours. If a location is not flowing, no sample will be collected. As many as 48 samples may be collected during each wet weather sampling event, depending on the number of monitored outfalls and if all monitored

outfalls discharge for 24 hours. However, the actual number of samples is likely to be less than the amount indicated since it is unlikely that all of the monitored outfalls will discharge for the full 24 hour monitoring period. One field blank and one field duplicate will be collected during each event to be used as field QC.

The locations of these stations are shown in Figure 1. Details for these stations are provided in Table 1, Table 2, and Table 3. The set of parameters for which the samples will be analyzed are summarized in Table 5. *In-situ* measurements will not be collected at the outfall locations.

Sampling crews will conduct all wet weather event sampling using the protocols described in the Quality Assurance Project Plan (DELCORA, 2017a). Samples will be delivered to the laboratory where the samples will be analyzed for the laboratory parameters identified in Table 5.

Determination to mobilize for a Wet Weather Event will be a collaborative effort between Greeley and Hansen, LimnoTech, the field sampling contractor and the laboratory contractor personnel. The intent is to identify a 4 to 6 hour window in which a wet weather event may commence 24 hours in advance to assist in mobilization of the sampling crews.

2.3 FIELD SAMPLING METHODS AND PROCEDURES

2.3.1 RECEIVING WATER AND SOURCE SAMPLE COLLECTION METHODS

The physical, microbiological and chemical data that will be collected from the waterbodies are obtained either through direct (*in situ*) measurements or through analysis of a water sample. The microbiological and chemical data collected from the outfall discharges will be obtained through laboratory analysis of the water samples. The general collection procedures for receiving water and outfall sampling are as follows:

1. Clean and decontaminate all sampling equipment prior to and after sample collection according to the procedures in the SOP No. 301.
2. Don appropriate personal protective equipment as required by the Health and Safety Plan (HASP).
3. Collect samples by dipping a container on a pole, into the water. The water is then poured into the clean sample containers pre filled with preservative. The collection container will then be disposed of. Care should be taken to avoid capturing bottom sediment or surface foam/scum during sample collection.
4. Creek water samples collected from bridges higher than 25 ft above the water surface will be collected by bailer, or from a new wide mouth glass jar, connected to new string. The water is then poured into the clean sample containers pre filled with preservative. The

collection container will then be disposed of. Care should be taken to avoid capturing bottom sediment or surface foam/scum during sample collection.

5. CSO samples will be collected using a "clean hands, dirty hands" technique. In accordance with the HASP, atmospheric conditions, such as lower explosive limit, and hydrogen sulfide, will be monitored inside the manhole prior to sample collection, or any other invasive activity. CSO sample collection from CSO-19 (wet weather only), will be screened for radioactivity as there may be the potential for medical treatment waste to be present.
6. Label all sample containers with the date, time, site location, sampling personnel, and other requested information.
7. Record sample collection information on the field logs and then store the samples in a cooler with ice as described in the SOP No. 103.
8. Handle, pack, and ship samples according to the procedures in the SOP No. 103, including the completion of a Chain-of-Custody (COC) form for each cooler shipped to the laboratory for analyses

2.3.2 IN SITU MEASUREMENTS (RECEIVING WATER ONLY)

Instantaneous water quality measurements (such as salinity, temperature, and conductivity) using field instruments will be collected at the receiving water locations as specified in DELCORA, 2017b. These measurements, along with calibration and maintenance, will be conducted following manufacturer's instructions (YSI, 2009)

Field instruments will be calibrated before initiating monitoring activities for each event and a post-monitoring calibration check will be conducted at the end of the event. All calibration and maintenance activities will be documented on the Instrument Calibration Sheet. The field instrument calibration must be conducted in accordance with the manufactures instructions.

Salinity, temperature, and conductivity will be measured at all in-stream sampling locations using a YSI 6920 or similar instrument during both wet and dry sampling events, prior to sample collection. Measurements will be made mid-channel at mid-depth in the tributaries, whenever possible. In the Delaware River, measurements will be made at the surface, mid-depth and near the bottom, whenever possible. Measurements will be documented in the field logs. Documentation will include: date/time, location, type of measurement, personnel, equipment identification, and general site observations (e.g. weather, stream conditions).

2.3.3 SAMPLING EQUIPMENT

The sampling equipment required for the DELCORA monitoring program is included in Table 4.

Table 4: Sampling Equipment list

Sampling Activity	Required Equipment	
General Equipment (Required for all sampling activities)	Field log book with weather-proof paper and pen ("Rite- in-the-Rain") or field data sheets Pens/pencils and Maps Sample bottles and labels Swing sampler/dipper Chain-of-custody Zip lock bag Coolers with ice Amber glass bottles Bailer twine Intrinsically safe headlamps Intrinsically safe flashlight Extra batteries Hydrolab/YSI multi-parameter First Aid Kit and BBP Kit	12" Nitrile gloves Hand spray bottles with Liquinox solution Scrub brush and bucket Distilled water (10 gallons) Sun screen PPE as specified in HASP Phone Emergency Contact List Field Safety Instruction Eye Wash Cell phone Calibration materials and solutions/gases Sonde and instrument (sonde) calibration sheet Sonde instrument manual Sonde service kit Extra batteries for instruments (sondes)
Wet Weather In-Stream Sampling	General Equipment Rain Gear Submersible Marine Radio 16' Jon Boat with motor Tide Charts and Navigation Charts Float Plan Depth Finder Boat Gear (Personal and throwable PFD's, whistle, oars, anchor, line, nav lights, bailer, air horn) Mustang Suits	
Wet Weather CSO & Outfall Sampling	General Equipment Rain Gear RAD meter with pancake probe Multi RAE for LEL and H2S screening	
Dry Weather Sampling	General Equipment	

2.4 SAMPLE IDENTIFICATION

Sample packaging and shipping procedures are designed to ensure that the samples and the chain- of-custody forms will arrive at the laboratory intact and together.

1. All samples collected will be labeled in a clear and precise way for proper identification in the field and for tracking in the laboratory. The laboratory will pre-label each bottle with all information except for the date and time of sample collection using the method described below. The person collecting the sample will complete the label with date and time. No bottle sets will be distributed without the pre-labeling unless specifically agreed upon among Greeley and Hansen, LimnoTech, the field sampling and laboratory contractors prior to the sampling event.

   Use indelible waterproof marking pen and include:

   - ***Sample identification code (ID)***– will include*:*
     - Site designation number - sampling round number, as follows:

       _ _ - _ _ _ - _ - _
       1 2 3 4 5 6 7

       Where,

       Characters 1-5: Sample Site ID (column 1 in Table 1, Table 2 and Table 3)

       Character 6: Sampling round number

       Character 7: B - Blank sample qualifier (if required)

     - Duplicate samples will be labeled with a sample ID of:

       "DUP _ _ _ - _ _".
       1 2 3 4 5

       Where

       Characters 1-3: Duplicate ID number (numbers will be assigned to each sampling crew)

       Characters 4-6: Designation of RW for receiving water sample duplicate or OF for outfall sample duplicate. A blank line will be placed in the location, date and time boxes of the sample label so the laboratory does not know where the sample was collected. The duplicate number in the duplicate sample ID will be assigned in the field and recorded in the field log book.

     - Blank samples will be given a normal sample ID, with a B qualifier at the end of the ID.

       - *Sample type (water);*
       - *Analysis required;*
       - *Date sampled;*

- *Time sampled;*
- *Name or initials of person who collected the sample;*
- *Mode of collection (composite or grab);*
- *Preservation added, if applicable.*

2. Check the caps on the sample containers so that they are tightly sealed.
3. Cover the label with clear packing tape to secure the label onto the container and prevent the label from being illegible if wet.
4. Store samples in coolers with ice to maintain the samples at ≤4 degrees Celsius until they are received in the laboratory.
5. Complete the information needed on the field log book and the chain-of-custody, primarily sample date and time and any notes regarding deviations from the planned sampling protocol (e.g. limited volume precluded collecting the full volume required).

2.5 SAMPLE MANAGEMENT

Samples will be properly packaged for transport to the laboratory as summarized below.

1. Using packaging tape, secure the outside and inside of the drain plug at the bottom of the cooler that is used for sample transport.
2. Place the sealed container upright in the cooler.
3. Place additional cushioning material around the sides of each sample container as needed.
4. Place ice on top of sample containers. Do not pack ice so tightly that it may prevent the addition of sufficient cushioning material. Ensure that bottle caps will not be submerged in water if ice melts.
5. Fill the remaining space in the cooler with vermiculite or other cushioning material if the coolers are being shipped.
6. Place the chain-of-custody forms in a large Ziploc© type bag and tape the forms to the inside of the cooler lid.
7. Close the cooler lid and fasten with packaging tape. Wrap strapping or packaging tape around both ends of the cooler at least twice, if coolers are being shipped.

All shipments will be accompanied by the chain-of-custody form identifying the contents. It is preferred that a separate chain-of-custody form be completed for and placed in each shipping container/cooler. The original form will accompany the shipment and copies will be retained by the sampler for the project records.

During the dry weather and wet weather sampling events, representatives from the laboratory will be responsible for collecting and delivering the samples to the laboratory quickly enough so that

hold times can be achieved for the bacteria parameters (8 hours from the time of sample collection). The Field Manager will manage the coordination of field crews and couriers during the sampling event.

2.5.1 SAMPLE DOCUMENTATION

2.5.2 FIELD DATA COLLECTION FORMS

The field log book will serve as a daily record of events, observations and measurements during all field activities. All information pertinent to sampling activities will be recorded in the field logs and will include:

- Names of field crew and specifically the author of the field log
- Date and time of the sample round beginning and ending
- Location of sampling activity
- Date and time of collection
- Sample identification numbers
- Field measurements

Field observations and details related to analysis or integrity of samples (e.g., weather conditions, noticeable odors, colors, stream flow description, etc.)

The field log book may also include:

- Sampling method
- Sampling equipment used
- Number and volume of samples collected
- Type of sample
- Summary of any meetings or discussions with the public, state agency, etc.
- Levels of safety protection

Field meters will be calibrated daily in accordance with the manufacturer's recommendations. Standards, solutions used, concentrations and readings taken will be recorded daily in Instrument Calibration Sheet.

2.5.3 SAMPLE CHAIN-OF-CUSTODY FORMS

A chain-of-custody is a legally-binding record of the date and time periods that samples were in the possession (e.g. custody) of the parties indicated. Transfers between parties are documented by the custodial party signing over custody to the receiving party and the receiving party signing

for receipt of the samples. Completed chain-of-custody forms will be required for all samples to be analyzed.

Chain-of-custody forms will be prepared in advance by the laboratory for each sampling location and round of sampling. Chain-of-custody forms will be initiated by the sampling crews in the field during the sampling events and must remain with the samples at all times. The samples and signed chain-of-custody form will remain in the possession of the sampling crew until samples are either delivered to the lab or placed in the custody of the personnel responsible for their delivery to the laboratory.

The chain-of-custody form will contain the sample's unique identification number, sample date and time, sample description, sample type and analyses required. Copies will be made prior to shipment for field documentation. The original chain-of-custody form will accompany the samples to the laboratory.

2.5.4 DATA SUBMITTAL

Instrument Calibration Sheets and copies of the field log book will be turned over to the LimnoTech Water Quality Monitoring Program Task Manager following each monitoring event. Following review by the LimnoTech Water Quality Monitoring Program Task Manager, all field logs, photographs and chain-of-custody forms will be included in the project database.

2.5.5 QUALITY CONTROL

The purpose of any quality assurance/quality control (QA/QC) program is to ensure that all sampling protocols and procedures are followed such that samples are representative of the water quality to which they are associated. The monitoring data that will be collected is intended to meet the quality assurance objectives described in the QAPP. Data quality will be measured in terms of accuracy and precision, completeness, representativeness, comparability, and the required detection limits for the analytical methods. Each of these data quality indicators is defined in the QAPP. QC samples will be collected in the field to support the assessment of data quality. The QA/QC program includes the following elements:

- Training of all field staff;
- Field quality control procedures;

- QA/QC samples; and,
- Equipment calibration.

2.6 DECONTAMINATION AND INVESTIGATION-DERIVED WASTE

If sampling equipment, such as buckets, etc., are to be reused at more than one location in the field, they must be cleaned prior to collecting the next sample. Prior to leaving a site, the equipment will be washed with a mild disinfectant solution (1:25 ratio household bleach to tap water), followed by a detergent solution (Alconox, or equivalent) wash, and must be rinsed at least three (3) times with distilled water. A brush may be used to remove deposits of material or sediment if necessary. At the next sampling site, the equipment must be rinsed at least one time at each location with creek water prior to sampling.

Equipment and instruments used for sample collection or monitoring at CSO locations (wet weather only) will be wiped down using a disinfectant wipe, followed by a distilled water rinse.

Decontamination water generated during the sampling events will be collected in 5 gallon buckets and disposed of at the DELCORA treatment facility at the end of the sampling shift.

3.0 ANALYTICAL PARAMETERS AND METHODS

Samples will be analyzed by Eurofins, in their network of accredited laboratories for fecal coliform, E coli, and enterococcus through laboratory analysis by the following methods, or in accordance with 40CFR136.

- Fecal coliform, Membrane Filters Technique for Members of the Fecal Coliform Group, Standard Methods 9222-D, 2006, 22nd Edition
- E. coli, Membrane Filtration Using Modified Membrane- Thermotolerant Escherichia coli Agar by EPA 1603
- Enterococci, EPA Method 1600, Membrane Filter Technique.

Table 5 summarizes the analytical parameters, the matrices, analyses, analytical methods, containers, preservatives, QA/QC samples, and technical holding times for the samples proposed for collection during the sampling event.

Table 5: Guidelines for Water Sample Container and Preparation and Preservation

Parameter	Sample Container	Sample Volume	Storage Requirement	Preservative	Sample Holding Time	Analytical Method	Detection Limit
Fecal coliform	Plastic- Sterile	250 ml	Place on ice, or refrigerate to ≤6°C	None	8 Hours	Standard Methods 9222-D	10 no./100 ml
E coli	Plastic- Sterile	250 ml	Place on ice, or refrigerate to ≤6°C	None	8 Hours	EPA 1603	10 no./100 ml
Enterococcus	Plastic- Sterile	250 ml	Place on ice, or refrigerate to ≤6°C	None	8 Hours	EPA 1600	10 no./100 ml

4.0 QUALITY ASSURANCE AND QUALITY CONTROL PROCEDURES

This section describes the QA and QC procedures for personnel during the site sampling event, including responsibilities, field QC, laboratory QC, data evaluation, and data management.

4.1 FIELD QUALITY CONTROL

The quality of data generated in a laboratory depends primarily on the integrity of the samples that arrive at the laboratory. Consequently, necessary precautions must be taken to protect samples from contamination and deterioration. Procedures detailed in SOP No. 203 for Collection of Discrete Water Samples and instrument manufacturer's instructions (YSI, 2009) will be followed to ensure field quality control.

Field accuracy will be assessed through the use of field or equipment blanks. In order for the accuracy assessment to be relevant, all appropriate protocols concerning sample collection, handling, preservation, and hold times must be maintained. Equipment that is used to collect samples for analysis may become cross-contaminated through the normal course of monitoring. If not properly cleaned and rinsed, samples may be contaminated during sampling from previous locations.

4.1.1 FIELD BLANKS

Field blanks will consist of a reagent grade blank water transferred into separate sample collection containers, transferred into the sample bottle ware, and submitted to the laboratory for

quality control. The laboratory will provide the sampling crews with the water to be used to prepare the field blanks.

Field blanks will be collected at a frequency of one blank during each sampling event per sampling crew.

4.1.2 FIELD DUPLICATES

Precision is a measure of the agreement between two or more measurements. Duplicate or replicate samples will be taken for a portion of the samples to assess field precision. A field duplicate is defined as a sample produced when a single sample is split into two or more aliquots immediately after the sample is collected. Each aliquot is placed into a separate container and analyzed separately.

Field duplicates will be collected at a frequency at least one field duplicate per sampling crew.

4.1.3 CALIBRATION OF FIELD EQUIPMENT

Instantaneous water quality measurements (such as salinity, temperature, and conductivity) using field instruments will be collected as specified in DELCORA, 2017b. Salinity, temperature, and conductivity will be measured at the specified sampling locations using an YSI 6920 or similar instrument, prior to sample collection. All field instruments will be calibrated at the beginning of the day of sampling and checked again at the end of each day, as required by the QAPP. Field instrument calibration and sample measurement data will be recorded on the Instrument Calibration Sheet and in the field log book, respectively.

4.1.4 DATA REPRESENTATIVENESS AND COMPLETENESS

The intent of this SAP is to obtain a complete data set which is representative of site conditions. Data will be reviewed for completeness. If not all samples were collected, resulting in less than 100% completeness, the reason for the data gaps will be identified in the Trip Report. If any data are rejected, the reason for the data rejection will be discussed in the Trip Report. If sampling activities or procedures vary significantly from this SAP due to unexpected conditions in the field or other unforeseeable factors, WESTON will discuss these deviations from the SAP and whether the changes affect data representativeness in the Trip Report.

STANDARD OPERATING PROCEDURES

WESTON SOLUTIONS, INC.
STANDARD OPERATING PROCEDURE

SOP 101 LOGBOOK DOCUMENTATION

Revision 2 December 2015

1.0 INTRODUCTION

The purpose of this Standard Operating Procedure (SOP) is to provide Weston Solutions, Inc. (WESTON®) members with a step-by-step guide for logbook documentation.

2.0 LOGBOOKS

2.1 Personal Logbooks

All WESTON members are required to document daily office activities in personal logbooks. Information in these logbooks shall be factual and objective and must be kept current at all times. Entries should include daily events, such as specific work order numbers, activities, task numbers, phone calls and meetings. It is important to note that all personal logbooks are property of WESTON® and may be reviewed by management at any time. A copy of Attachment A "Logbook Operating Practices" must be affixed to the inside cover of the personal logbook. Personal logbooks must be obtained through WESTON® Administrative support staff and must include a WESTON® logbook tracking number.

2.2 Site Logbooks

All WESTON members are required to document site activities in site logbooks. Information in these logbooks shall be factual and objective and must be kept current at all times. Entries should include daily events, such as site activities, safety meetings, names of personnel entering/exiting site, sampling data, etc. A copy of Attachment A "Logbook Operating Practices" must be affixed to the inside cover of the site logbook. All site logbooks are the property of client and must remain with the site file. Site logbooks will be maintained by the WESTON® Project Team Leader. Information may be entered into the site logbook by any appropriate team member. Entries will be made in waterproof ink. Site logbooks must be obtained through WESTON® Administrative support staff and must include a WESTON® logbook tracking number.

3.0 SPECIFIC PROTOCOL

Adhere to the following protocol for both personal and site logbooks (see Attachment A for additional information):

1. Logbooks are permanently bound, all pages numbered.
2. Entries begin on page 1.
3. Use only blue or black ink (waterproof).
4. Write Weston Solutions, Inc., as well as the mailing address and phone number on the inside covers of both the site and personal logbooks.

5. Print the site name, volume number, and coverage dates on the site logbook cover and inside cover.
6. Do not write in the margins or between written lines, and do not leave blank pages to fill in later.
7. Fill in all pages in all logbooks.
8. Place a single line through mistakes and initial each one.
9. At the end of any partial page, draw a single diagonal line across the page and initial the line to indicate the end of that pages notes.
10. If a line on the page is not completely filled, draw a horizontal line through the blank portion of the line and initial it.
11. Write late notes/entries as soon as possible and identify this entry as such (use "Late Note:" on a new line to begin a late note and "End Late Note" on a new line to finish a late note).
12. Be objective for all logbook entries
13. Ensure that the logbook clearly shows the sequence of the day's events.
14. If an error is made, draw a single line through the error and initial it.
15. Sign or initial all completed pages (typically in the lower right corner) as they are completed.
16. Sign entries at the end of the day, or before someone else writes in the logbook.
17. Maintain control of the logbook and keep in a secure location.

Personal logbooks will contain (see Attachment A for additional information) the following information:

1. Employee's name, work address, and telephone number.
2. Full names and affiliations for all persons cited in the logbook. Be sure to check the spelling of names and affiliations for accuracy.
3. Sequence of daily events.
4. Task numbers, full dates (i.e. 12 January 2012), and military time (i.e. 0800).
5. Initialed daily entries.

Site logbooks will contain (see Attachment A for additional information) the following information:

1. The name and location of the site.

2. Names of Site Leader and Assistant Site Leaders.
3. Site sketches if appropriate. Draw a box around the sketch to separate the sketch from the text in the logbook.
4. Dates of sample collection or event.
5. Time of sample collection or event.
6. Weather conditions on a daily basis.
7. Field observations.
8. Numbers and types of samples collected and sample identification numbers.
9. Description of sampling methodology by referenced Standard Operating Procedures or FSP.
10. Type(s) of laboratory analyses requested.
11. Phone calls and/or contacts with people at the site on a daily basis.
12. Name of subcontractor and excavation equipment.
13. Any modifications in work activities from approved work plans, FSPs, etc. (i.e., sampling locations, deviations from procedures with reasons, etc.).
14. Visual description of samples and test pits, as required. Includes color, texture, moisture, and other physical soil characteristics.
15. Levels of personal protective equipment worn for tasks performed.
16. Significant changes during the day (i.e., stoppage of work during a lightning storm).

3.1 Audits

Personal and Site logbooks are subject to audit by WESTON® Quality Assurance personnel at any time. Logbook audits will be documented and maintained in the site project file and/or personnel file. Attachment B Logbook Auditing Check sheet or another method of documentation will be used to document all logbook audits.

ATTACHMENT A: LOGBOOK OPERATING PRACTICES

Logbook Operating Practices

Procedure

- Logbooks are permanently bound, all pages numbered and entries begin on page 1.
- Use only blue or black ink (waterproof).
- Written Legibly.
- Write Weston Solutions, Inc., as well as the mailing address and phone number on the inside covers of both the site and personal logbooks.
- Print the site name, volume number, and coverage dates on the site logbook cover and inside cover.
- Do not write in the margins or between written lines; do not leave blank pages to fill in later.
- Fill in all pages in all logbooks.
- Include the date on every page.
- At the end of any partial page, draw a single diagonal line across the page and initial the line to indicate the end of that pages notes.
- If a line on the page is not completely filled, draw a horizontal line through the blank portion of the line and initial it.
- Write late notes/entries as soon as possible and identify this entry as such (use "Late Note:" to begin a late note and "End Late Note" to finish a late note).
- Be objective for all logbook entries.
- Ensure that the logbook clearly shows the sequence of the day's events.
- If an error is made, draw a single line through the error and initial it.
- Sign or initial all completed pages (typically in the lower right corner).
- Sign entries at the end of the day, or before someone else writes in the logbook.
- Maintain control of the logbook and keep in a secure location.
- End of Logbook noted on last page ("End of Logbook").

General Information

- Team members listed at beginning of day.
- Other Personnel & Affiliation (e.g. OSC-Smith, OSC-Jones) identified.
- Signatures when change of recorder.
- Team Members' Site Entries and Exits are documented.
- Late Entries Noted Appropriately.

Field Logbooks

- General Information.
- Name, location of site, and work order number.
- Name of the Site Manager or Field Team Leader.
- Names and responsibilities of all field team members using the logbook (or involved with activities for which entries are being made).
- Weather conditions.
- Objective narratives written.
- Field observations.
- Names of any site visitors including entities that they represent.

Sampling (a table in the logbook can be used for sample information)

- Time Collected.
- Grab/Composite.
- Sample Location.
- Type of Analysis.
- CLP Case Number(s)
- Shipping Information.
- Number and types of collected samples.
- Sample identification numbers, including any applicable cross-references to split samples or samples collected by another entity.
- A description of sampling methodology, or reference to any governing document (i.e. Work Plan, QAPP). Any deviations from governing document(s) are identified with reasons for deviations specified.
- Summary of equipment preparation and decontamination procedures.
- Sample description including depth, color, texture, moisture content, and evidence of waste material or staining.
- Air monitoring (field screening) results.
- Types of laboratory analyses requested.

Photo Logs

- Camera and PDA (IDs).
- Date of pictures.
- Time of pictures.
- Directions of photos.
- Description of photos.
- Photographer/Witness.

Safety

- All safety, accident, and/or incident reports.
- Real-time personnel air monitoring results, if applicable.
- Heat/cold stress monitoring data, if applicable.
- Level of protection for tasks.
- Reasons for upgrades or downgrades in personal protective equipment.
- Health and safety inspections, checklists (drilling safety guide), meetings/briefings.
- Equipment make, model, and serial number for monitoring instruments.
- Calibration records for monitoring instruments.
- Site Safety Meeting (time/topics).
- Site Objectives/ Plan of Activities.
- Chemical/Physical Hazards.
- Personnel Attending.

Equipment

- Equipment Type (make, model, a serial numbers).
- Calibration records.
- Background Readings & Locations.
- Monitoring Readings & Locations.
- Sampler(s) initials

Contractor Oversight Activities

- Progress and activities performed by contractors including operating times.
- Deviations of contractor activities with respect to project governing documents (i.e., specifications).
- Contractor sampling results and disposition of contingent soil materials/stockpiles.
- Excavation specifications and locations of contractor confirmation samples.
- General site housekeeping and safety issues by site contractors.
- Equipment and personnel on-site.
- Duration of equipment use vs. standby.
- Inventory of shipments received (or verification of items on packing slip).
- Document inspection of disposal trucks arriving at site (e.g., visual observation of clean tankers or truck trailers, etc.).

Logbook OP_Rev3 December 2015

ATTACHMENT B: SITE LOGBOOK AUDITING CHECKSHEET

Site Name:_____

Work Assignment/TDD No. _____

Site Name:_____ Site Location:_____

Logbook Recorder:_____ Logbook Reviewer:_____

As a part of WESTON's quality assurance program, the following checklist should be used as a guide for items, at a minimum, to include in your logbook. In the future, please make your best effort to thoroughly document all field activities.

LOGBOOK AUDITING CHECKSHEET				
INFORMATION:	***YES***	***NO***	***N/A***	***COMMENTS***
Logbook is permanently bound, all pages numbered and entries begin on page 1.				
Only blue or black ink used.				
Written Legibly.				
"Weston Solutions, Inc." as well as the mailing address and phone number are included on the inside cover.				
The site name, volume number, and coverage dates (if the logbook is completed) are included on the site logbook cover and inside cover.				
No writing in the margins or between written lines.				
No blank pages; all pages are filled in.				
Date is included on every page.				
At the end of any partial page, a single diagonal line is drawn across the page and initialed.				
Where a line on the page is not completely filled, a horizontal line is drawn through the blank portion of the line and initialed.				
Any late notes/entries are identified as such (i.e., "Late Note:" to begin a late note and "End Late Note" to finish a late note).				
Logbook entries are objective.				
The logbook clearly shows the sequence of events.				
If an error was made, a single line was drawn through the error and it was initialed.				
All completed pages are signed or initialed (typically in the lower right corner).				
Signature of author at the end of the day				
Signature of author at change of recorder.				

ATTACHMENT B: SITE LOGBOOK AUDITING CHECKSHEET

LOGBOOK AUDITING CHECKSHEET				
INFORMATION:	***YES***	***NO***	***N/A***	***COMMENTS***
End of Logbook noted on last page ("End of Logbook") for completed logbooks.				
General Information				
Team members are listed at beginning of day.				
Other Personnel & Affiliation (e.g. OSC-Smith, OSC-Jones) are identified.				
Team Members' Site Entries and Exits are documented.				
Name, location of site, and work order number is identified.				
Name of the Site Manager or Field Team Leader is identified.				
Weather conditions are noted.				
Field observations are sufficiently detailed.				
Sampling (a table in the logbook can be used for sample information)				
Sample identification numbers, are noted.				
Time Collected is identified.				
Grab/Composite is identified (or FSP/SAP is referenced).				
Sample Locations are identified (or FSP/SAP is referenced).				
Type of Analysis is identified (or FSP/SAP is referenced).				
CLP Case Number(s) is noted.				
Number and types of collected samples are identified (or FSP/SAP is referenced).				
A description of sampling methodology is included (or FSP/SAP is referenced).				
Any deviations from the FSP/SAP or other governing document(s) are noted, including specified reasons for deviations.				
Summary of equipment preparation and decontamination procedures are noted (or FSP/SAP is referenced).				
Sample description including depth, color, texture, moisture content, and evidence of waste material or staining are noted.				
Air monitoring (field screening) results are included.				
Types of laboratory analyses requested are identified (or FSP/SAP is referenced).				
Logbook is permanently bound, all pages numbered and entries begin on page 1.				

ATTACHMENT B: SITE LOGBOOK AUDITING CHECKSHEET

LOGBOOK AUDITING CHECKSHEET				
INFORMATION:	***YES***	***NO***	***N/A***	***COMMENTS***
Only blue or black ink used.				
Written Legibly.				
"Weston Solutions, Inc." as well as the mailing address and phone number are included on the inside cover.				
The site name, volume number, and coverage dates (if the logbook is completed) on the site logbook cover and inside cover.				
No writing in the margins or between written lines				
No blank pages; all pages are filled in.				
Date is included on every page.				
At the end of any partial page, a single diagonal line is drawn across the page and initialed.				
Where a line on the page is not completely filled, a horizontal line is drawn through the blank portion of the line and initialed.				
Any late notes/entries are identified as such (i.e., "Late Note:" to begin a late note and "End Late Note" to finish a late note).

WESTON SOLUTIONS, INC.
STANDARD OPERATING PROCEDURE

SOP 103 CHAIN-OF-CUSTODY DOCUMENTATION

August 2011

1.0 INTRODUCTION

The purpose of this Standard Operating Procedure (SOP) is to provide Weston Solutions, Inc. (WESTON®) team members with a step-by-step guide for chain-of-custody documentation.

2.0 SCOPE

This SOP describes the minimum requirements for sample chain-of-custody procedures. These procedures permit traceability from the time of sample collection to generation of the analytical data report.

These procedures are intended to document sample possession from the time of sample collection to sample disposal (i.e., sample shipment, sample storage, sample analysis).

3.0 GENERAL PROTOCOL

A chain-of-custody record will be maintained from the time of sample collection until final disposition.

For the case of the chain-of-custody forms and the traffic report chain-of-custody forms, every transfer of custody will be noted and signed. The distribution of the chain-of-custody forms will be done in accordance with the distribution list at the bottom of each form. The chain-of-custody record shall contain, at a minimum, the following information:

- Project identification
- Project identification number
- Sample number
- Sample type and description
- Sample location
- Time and date of sample collection (military time)
- Requested analyses
- Sample information (e.g., no. of bottles, preservatives, etc.)
- Names and signatures of samplers
- Signatures of individuals who have had sample custody
- The name of the carrier and the airbill number, if the sample is shipped

4.0 PROTOCOL FOR SHIPMENTS

All pertinent data must be recorded legibly in black or blue ink. Mistakes can only be corrected by drawing a single line through the mistake and then initialing and dating the correction.

Listed below are the information needed in each section of the chain-of-custody record:

- The PROJ. NO. section of the form will always contain the site Project Control System (PCS) number.
- The PROJECT NAME section of the form will contain the Site name only if the samples are being analyzed by the EPA Region III Laboratory, otherwise it will contain the START Analytical Technical Directive Document (TDD) number or the DAS project number.
- The SAMPLERS (Signature) section should contain the printed name and signature of samplers.
- The TIME section should be in military time.
- The LOCATION section should give a description of the sample location (note: never put resident's names or full addresses in this section).
- The diagonal lines on the top of the form should contain the analyses to be performed for each sample. An X should be placed in the block beneath the analyses to be performed for each sample.
- The airbill number and shipper should be identified in the REMARKS section at the bottom of the form.

Every time the samples are relinquished to a different individual the current sample custodian is required to relinquish the custody to the new individual.

5.0 SAMPLE LABELS AND CUSTODY SEALS

In addition to chain-of-custody forms, sample labels and custody seals are needed to ensure sample custody has been maintained. Sample labels should contain the same information contained on the chain-of-custody record to ensure the proper analyses are being performed on the samples. Custody seals ensure that the samples have not been tampered with during sample shipment. Below is a description of the information needed for the labels and custody seals.

5.1 Sample Labels

The following information will be recorded on the sample labels affixed to each container:

- Project identification number
- Sample number
- Time and date of sample collection
- Sample type (composite/grab)

- Sample location
- Analyses requested
- Preservatives used

5.2 Custody Seals

Custody seals confirm that samples have not been tampered with. The individual who has custody of the samples will sign, date, and affix the seals to the cooler or shipping box which contains the samples so that it cannot be opened without breaking the seal. A wide clear tape will be placed over the seals to ensure that the seals are not accidentally broken during transportation.

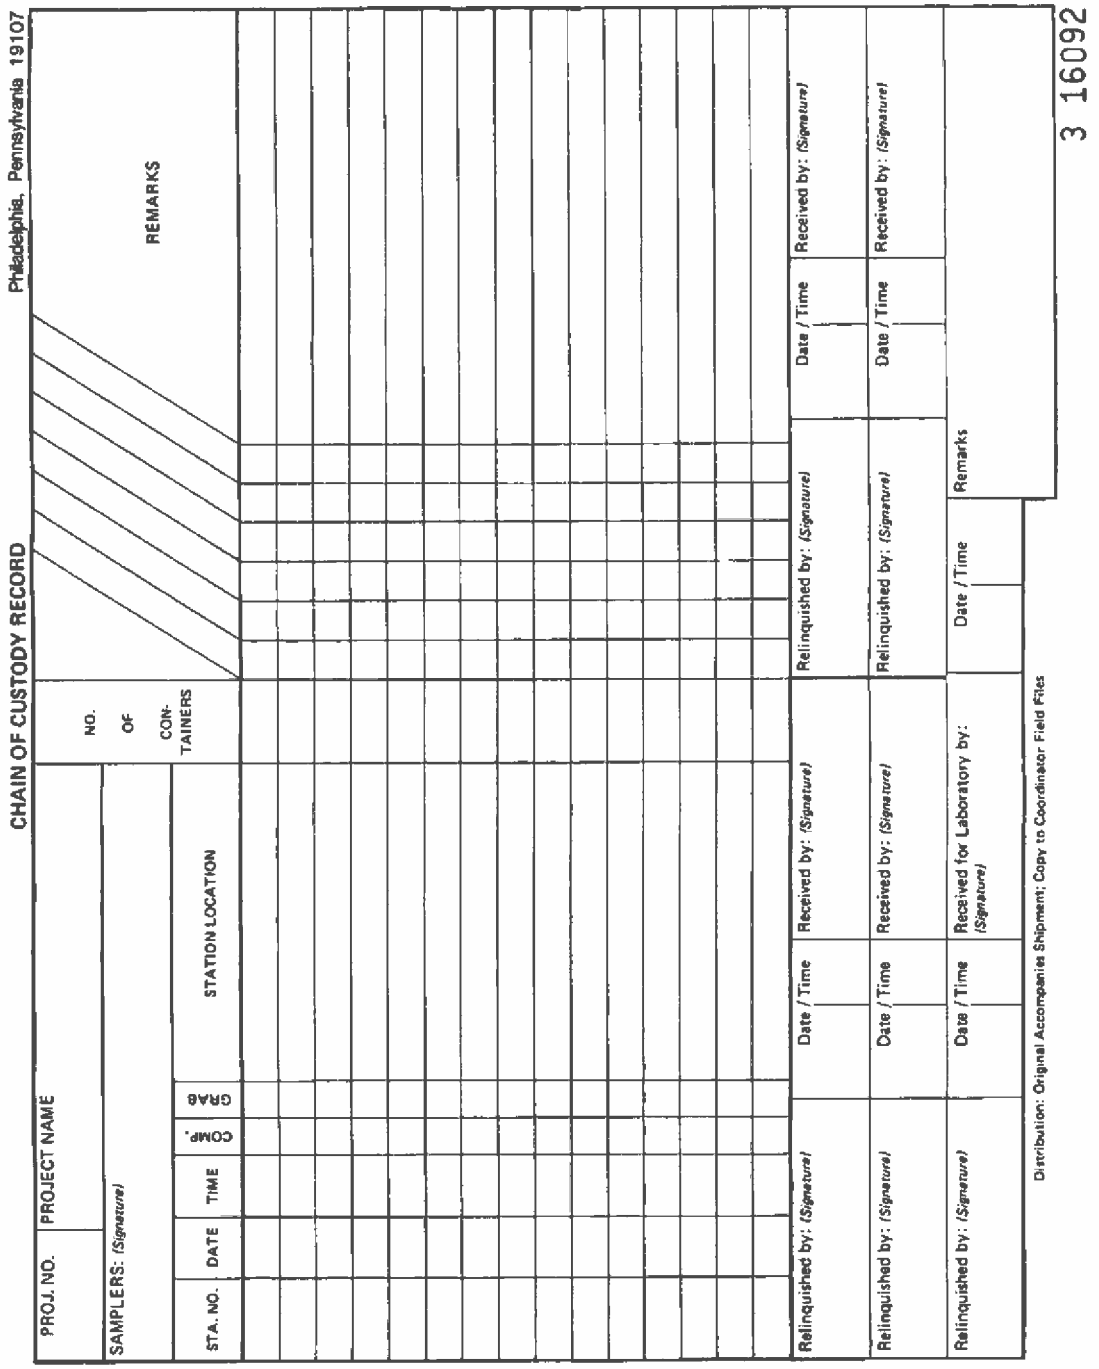
August 2011

ATTACHMENT 1: CHAIN-OF-CUSTODY RECORD



WESTON SOLUTIONS, INC
STANDARD OPERATING PROCEDURE

SOP 104 PHOTOGRAPHIC AND VIDEO DOCUMENTATION

Revised November 2015

1.0 INTRODUCTION

The purpose of this Standard Operating Procedure (SOP) is to provide Weston Solutions, Inc. (WESTON®) team members with a step-by-step guide for photographic and video documentation. Photographs/videos should be used to document field activities including initial site conditions during assessments and emergencies prior to, during and after removal and remedial actions, during enforcement actions, and at special events and outreach programs.

2.0 PHOTOGRAPHIC AND VIDEO DOCUMENTATION

2.1 Photographs

Unless specifically requested otherwise, WESTON will document all site, sampling and special events using digital photographs.

Date and time should be accurately set for all digital cameras to document the date of the photography. Descriptions of the photograph subject, date, time, site name and location should be documented in the site logbook for all photographs. This information can also be documented in the digital camera or other electronic data collection device; however, written logbook descriptions should be maintained.

2.2 Video

If requested WESTON team members will document site activities using hand-held digital video cameras. Film video will only be taken if specifically requested, and such documentation, as well as High-definition digital video or other specialized video services, may require subcontractor support.

Date and time should be accurately set for all digital video cameras to document the date of the video. Descriptions of the video subject, date, time, site name and location should be documented in the site logbook for all video. This information can also be documented in the digital camera or other electronic data collection device; however, written logbook descriptions should be maintained.

3.0 SPECIFIC PROTOCOL

Adhere to the following protocol for both photographic and video documentation:

- Enter description of filming activities in the site logbook documenting type of camera, time (military time) and date, filming individual, and orientation angle of the viewing angle.

- Print the site name, the project number, and coverage dates on each storage media that has been used.
- Prepare a photographic log and label all photographs with the following information: the project number, site name, site location, date and time, description of photograph, orientation, and photographer.
- Store all storage media (SandDisk [SD] or other memory card, MicroSD, Digital tape, Universal Serial Bus [USB] flash drive, site negatives, original videos or other media) in the official site file.
- Be objective for all photographs/video. Ensure the purpose of the photograph is entered into the site log (e.g., documenting labels for enforcement, or condition of neighboring properties prior to the initiation of a removal action, or documenting an exposure pathway).

WESTON SOLUTIONS, INC.
STANDARD OPERATING PROCEDURE

SOP 203 SURFACE WATER SAMPLING

Revised November 2015

1.0 SCOPE AND APPLICATION

This Standard Operating Procedure (SOP) is applicable to the collection of representative liquid samples from streams, rivers, lakes, ponds, lagoons, and surface impoundments. It includes samples collected from depth, as well as samples collected from the surface.

2.0 METHOD SUMMARY

Sampling situations vary widely and therefore no universal sampling procedure can be recommended.

However, sampling of liquids from the above mentioned sources is generally accomplished through the use of one of the following samplers or sampling techniques:

- Kemmerer bottle
- Van dorn sampler
- bacon bomb sampler
- dip sampler
- direct method

These sampling techniques will allow for the collection of representative samples from the majority of surface waters and impoundments encountered.

3.0 SAMPLE PRESERVATION, CONTAINERS, HANDLING, AND STORAGE

Once samples have been collected, follow these procedures:

1 Transfer the sample(s) into suitable labeled sample containers.
2 Preserve the sample if appropriate, or use pre-preserved sample bottles.
3 Cap the container, put it in a resealable plastic bag and place it on ice in a cooler.
4 Record all pertinent data in the site logbook and on a field data sheet.
5 Complete the chain-of-custody form.
6 Attach custody seals to the cooler prior to shipment.
7 Decontaminate all sampling equipment prior to the collection of additional samples.

4.0 INTERFERENCES AND POTENTIAL PROBLEMS

There are two primary interferences or potential problems with surface water sampling. These include cross-contamination of samples and improper sample collection.

- Cross-contamination problems can be eliminated or minimized through the use of dedicated sampling equipment. If this is not possible or practical, then decontamination of sampling equipment is necessary.

- Improper sample collection can involve using contaminated equipment, disturbance of the stream or impoundment substrate, and sampling in an obviously disturbed area.

Following proper decontamination procedures and minimizing disturbance of the sample site will eliminate these problems.

5.0 EQUIPMENT/APPARATUS

Equipment needed for collection of surface water samples includes:

- Kemmerer bottles
- Van Dorn sampler
- Bacon bomb sampler
- Dip sampler
- Line and messengers
- Sample bottles and preservatives
- pH paper
- Resealable plastic bags
- Ice for sample preservation
- Coolers
- Ball-point pen, permanent marker, grease pencil, marking spray paint
- Chain of custody forms, EPA custody seals, field data sheets
- Sample bottle labels/tags
- Decontamination equipment (brushes, buckets, garden sprayer, alconox or liquinox, water, etc.)
- Paper towels
- Plastic sheeting
- Map/plot plan/sketches
- Personal protective equipment and monitoring equipment (as specified in the Health and Safety Plan)
- Field data measurement equipment as specified in the FSP (such as YSI)
- Compass
- Tape measure (up to 300 ft)
- Survey stakes, flags, or buoys and anchors
- Global positioning system (GPS) unit with sub-meter accuracy or better
- Digital camera with adequate storage media
- Logbook/waterproof pen and field data sheets
- Plastic garbage bags
- Scissors

- Nitrile or latex sample gloves
- Shipping documents (Federal Express forms/shipping labels/etc.)
- Strapping/packing tape

6.0 REAGENTS

Reagents will be utilized for preservation of samples and for decontamination of sampling equipment. The preservatives required are specified by the analysis to be performed. Decontamination solutions are specified in SOP No. 301, Decontamination Procedures.

7.0 PROCEDURES

7.1 Preparation

- Determine the extent of the sampling effort, the sampling methods to be employed, and which equipment and supplies are needed.
- Obtain necessary sampling and monitoring equipment.
- Decontaminate or pre-clean equipment, and ensure that it is in working order.
- Prepare scheduling and coordinate with staff, clients, and regulatory agency, if appropriate.
- Perform a general site survey prior to site entry in accordance with the site specific health and safety plan.
- Use stakes, flags, or buoys to identify and mark all sampling locations. If required, the proposed locations may be adjusted based on site access, property boundaries, and surface obstructions.

7.2 Sampling Considerations

7.2.1 Representative Samples

In order to collect a representative sample, the hydrology and morphometrics (e.g., measurements of volume, depth, etc.) of a stream or impoundment should be determined prior to sampling. This will aid in determining the presence of phases or layers in lagoons or impoundments, flow patterns in streams, and appropriate sample locations and depths.

Water quality data should be collected in impoundments to determine if stratification is present. Measurements of dissolved oxygen, pH, and temperature can indicate if strata exist that would affect analytical results. Measurements should be collected at one-meter intervals from the substrate to the surface using an appropriate instrument, such as a YSI (or equivalent).

Water quality measurements such as dissolved oxygen, pH, temperature, conductivity, and oxidation-reduction potential can assist in the interpretation of analytical data and the selection of sampling sites and depths anytime surface water samples are collected.

Generally, the deciding factors in the selection of a sampling device for sampling liquids in streams, rivers, lakes, ponds, lagoons, and surface impoundments are:

- Will the sample be collected from the shore or from a boat on the impoundment?
- What is the desired depth at which the sample is to be collected?
- What is the overall depth and flow direction/flow rate of river or stream?

7.2.2 Sampler Composition

The appropriate sampling device must be of a proper composition. Samplers constructed of glass, stainless steel, polyvinyl chloride (PVC) or Polytetrafluoroethylene (PFTE such as Teflon®) should be used based upon the analyses to be performed.

7.3 Sample Collection

Photograph sample locations with landmarks in view. Keep in mind that sample locations may need to be referenced in the future, often years after your sampling event.

7.3.1 Kemmerer Bottle

Kemmerer bottle may be used in most situations where site access is from a boat or structure such as a bridge or pier, and where samples at depth are required. Sampling procedures are as follows:

1. Using a properly decontaminated Kemmerer bottle, set the sampling device so that the sampling end pieces are pulled away from the sampling tube, allowing the substance to be sampled to pass through the tube.
2. Lower the pre-set sampling device to the predetermined depth. Avoid bottom disturbance.
3. When the Kemmerer bottle is at the required depth, send down the messenger, closing the sampling device.
4. Retrieve the sampler and discharge the first 10 to 20 mL to clear any potential contamination on the valve. Transfer the sample to the appropriate sample container.

7.3.2 Van Dorn Sampler

A Van Dorn sampler is used to collect surface water from a very specific sampling depth or from a shallow water body. Since the sampler is suspended horizontally, the depth interval sampled is the diameter of the sampling tube. The sampling procedure is as follows:

1. Use a properly decontaminated Van Dorn sampler. Set the device so that the end stoppers are pulled away from the body allowing surface water to enter the tube.
2. Lower the pre-set sampling device to the predetermined depth. Avoid disturbance of the bottom.
3. When the Van Dorn is at the required depth, send the weighted messenger down the suspension line, closing the sampling device.
4. Retrieve the sampler and discharge the first 10-20 milliliters (mL) from the drain to clear potential contamination from the valve. This procedure may be repeated if additional sample volume is needed to fulfill analytical requirements. Subsequent grabs may be composited or transferred directly to appropriate sample containers.

7.3.3 Bacon Bomb Sampler

A bacon bomb sampler may be used in similar situations to those outlined for the Kemmerer bottle. Sampling procedures are as follows:

1. Lower the bacon bomb sampler carefully to the desired depth, allowing the line for the trigger to remain slack at all times. When the desired depth is reached, pull the trigger line until taut.
2. Release the trigger line and retrieve the sampler.
3. Transfer the sample to the appropriate sample container by pulling the trigger.

7.3.4 Dip or Swing Sampler

A dip sampler and/or a swing sampler are useful for situations where a sample is to be recovered from an outfall pipe or along a lagoon bank where direct access is limited. The long handle on such a device allows access from a discrete location. Sampling procedures are as follows:

1. Assemble the device in accordance with the manufacturer's instructions.
2. Extend the device to the sample location and collect the sample.
3. Retrieve the sampler and transfer the sample to the appropriate sample container.

7.3.5 Direct Method

For streams, rivers, lakes and other surface waters, the direct method may be utilized to collect water samples from the surface. This method is not to be used for sampling lagoons or other impoundments where contact with contaminants are a concern.

Using adequate protective clothing, access the sampling station by appropriate means. For shallow stream stations, collect the sample under the water surface, pointing the sample container upstream. The container must be upstream of the collector. Avoid disturbing the substrate. For lakes and other impoundments, collect the sample under the water surface avoiding surface debris and the boat wake.

When using the direct method, do not use pre-preserved sample bottles as the collection method may dilute the concentration of preservative necessary for proper sample preservation.

8.0 QUALITY ASSURANCE/QUALITY CONTROL

The following general QA/QC procedures apply:

- Field QA/QC samples (e.g., field blanks, equipment rinsate blanks, trip blanks, duplicate samples, MS/MSD, etc.) must be collected in accordance with the FSP and QAPP
- All data must be documented in site logbooks.
- All sample locations should be recorded using a GPS unit.
- All instrumentation must be operated in accordance with operating instructions as supplied by the manufacturer, unless otherwise specified in the work plan. Equipment checkout must occur prior to sampling/operation and should be documented.

9.0 HEALTH AND SAFETY

When working with potentially hazardous materials, follow U.S. EPA, OSHA and specific health and safety procedures.

More specifically, when sampling lagoons or surface impoundments containing known or suspected hazardous substances, take adequate precautions. The sampling team member collecting the sample should not get too close to the edge of the impoundment, where bank failure may cause him or her to lose their balance. The person performing the sampling should be on a lifeline and be wearing adequate protective equipment, including a Type II PFD.

Sampling over and around water can be dangerous, be sure to follow all HAS procedures and have an approved HASP. Whenever boats are to be used to collect samples, a Float Plan must be prepared and included as part of the approved HASP. When working around and over cold water, appropriate survival suits are required (such as Mustang suits), as specified in the approved HASP.

STANDARD OPERATING PROCEDURE

SOP 301 DECONTAMINATION PROCEDURES

Revised November 2015

1.0 PURPOSE

To provide guidance for the decontamination of equipment used to sample, install sample points (monitor wells, soil borings and test pits), and make field measurements. This operating practice is not intended to be site specific or equipment specific, but to provide guidance in place of non-existent state or federal guidelines or in cases where the site-specific work plan or Field Sampling Plan does not provide additional detail on decontamination procedures.

2.0 DISCUSSION

2.1 Introduction

The objective of decontamination procedures is to provide clean equipment for the retrieval of representative environmental samples. Decontamination procedures differ depending on the nature of the equipment used. The three categories of decontamination procedures are discussed below:

- Intrusive equipment used to install sample points including drilling (tools, augers, rods, etc.) and excavation equipment (backhoes, excavators, etc.).
- Equipment used to measure the characteristics of the media to be sampled including water level, pH, specific conductivity, and temperature probes. This category also includes pumps to purge water.
- Equipment that has contact with the sample to be submitted for laboratory analysis including bailer, split-spoons, hand auger, stainless steel bowls and scoops.

Because items from the first two categories do not contact the sample media that is sent to a laboratory for analysis, the decontamination procedures are less stringent. Dedicated and disposable equipment will be used whenever feasible to limit decontamination and the possibility of cross-contamination. This includes rope, tubing, filterware and, in some cases, soil scoops, pans, and bailers.

3.0 PROCEDURES

3.1 Intrusive Equipment

Drilling tools, including augers, rods, drill bits, hand tools, etc. will be steam cleaned prior to use and after each location. Split spoons will also be steam cleaned if not used for sample collection. Backhoe buckets and arms will also be steam cleaned prior to use and between each sample location.

3.2 Field Measurement Equipment

Water level probes will be cleaned using the following procedures:

- Wipe the probe with a paper towel.
- Alconox®, Liquinox®, or other appropriate cleaning solution and potable water wash.
- Deionized water rinse.

Other measurement equipment should be rinsed with deionized water between readings. Pumps used for well purging shall be decontaminated using the following procedures:

- Alconox®, Liquinox®, or other appropriate cleaning solution and potable water scrub and pump through.
- Potable water rinse and pump through.

Rope and tubing used with the pump will be made of polyethylene and be dedicated (and disposable) to one sample location.

3.3 Sampling Equipment

Equipment used for sample collection include but are not limited to:

- Teflon bailers
- Stainless steel scoops and bowls
- Hand augers
- Split spoons

This equipment will be cleaned using the following procedures:

- Alconox®, Liquinox®, or other appropriate cleaning solution and potable water scrub.
- Thorough potable water rinse.
- Deionized water rinse.
- Specialized decontamination fluid rinse, if necessary for the type of sampling and level of analyses.
- Deionized water rinse, if a specialized decontamination fluid rinse is used.
- Total air dry (only if sample is to be analyzed for organics).

Sampling instruments should be wrapped in aluminum foil after decontamination to keep clean before sampling. Note that this may be eliminated if low level metals analyses are being

conducted and aluminum is a potential contaminant of concern. Also note that aluminum foil should not be used if sampling for Perfluorinated Compounds.

4.0 DOCUMENTATION

Decontamination efforts should be documented in the field logbook. Decontamination fluids should be disposed of properly. Depending on site conditions, it may be appropriate to contain spent decontamination fluids. In that case, the appropriate vessel (i.e., drum) should be used depending on the ultimate disposition of the material. See *SOP 019 Investigative Derived Waste Compliance Plan* for more detailed information on handling and disposal of these wastes.

5.0 INTERPRETATION

If there are questions on the interpretation or applicability of items in this operating practice, the Project Manager, Technical Manager or Quality Manger should be consulted.

REGION III
1650 Arch Street
Philadelphia, Pennsylvania 19103-2029

APR 16 2018

RECEIVED
APR 19 2018
By 2018-0503

Mr. Robert Willert, Executive Director
Delaware County Regional Quality Control Authority
100 East Fifth Street
Chester, PA 19013

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Water Quality Modeling and Monitoring Work Plan Update WQMMWP dated July 31, 2017. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). This letter served to iterate the original approval and formally notify you that EPA accepted the updated WQMMWP and is approved.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

Executive Summary

Introduction

The DELCORA Consent Decree requires that a Water Quality Model be developed to support the Long Term Control Plan Update. This report describes DELCORA's receiving water quality model, including the development and calibration of the model, and the initial application of the model to quantify baseline pollutant of concern (POC) water quality conditions in the receiving waters for the typical period. The POCs include Fecal coliform, *E.coli*, and *Enterococcus*. The objective of the water quality modeling was to compute POC concentrations in the tidal portions of Chester Creek and Ridley Creek, and in the Delaware River, by accounting for all major POC sources within the model domain. The intended use of the water quality modeling framework is to evaluate the water quality under typical year conditions and to evaluate CSO control alternatives.

Model Development

Three types of models, which comprise the modeling framework, were jointly applied to compute POC concentrations in Chester and Ridley Creeks and the Delaware River:

- A watershed model which simulates flows and POC loads from the Chester and Ridley Creeks watersheds;
- CSO models to simulate flows and POC loads from the DELCORA and Philadelphia Water Department (PWD) combined sewer systems (CSS) to the streams; and,
- A receiving water quality model that computes POC concentrations in Chester and Ridley Creeks and the Delaware River resulting from the various sources of POCs to the streams.

The watershed and CSS models were developed using the EPA Stormwater Management Model (SWMM) and the receiving water quality model was developed using the EPA Environmental Fluid Dynamics Code (EFDC) model.

Model Calibration

Site specific data was used for calibrating the various models, including USGS flow data, NOAA tide data, wet and dry weather water quality data obtained by DELCORA, and ambient water quality data obtained from the Delaware River Basin Commission (DRBC). The water quality data obtained by DELCORA proved particularly useful in calibration the water quality model, as it contained both wet and dry weather data at various locations within the study area, including both upstream and downstream of the DELCORA CSO discharges.

Calibration of the various models was evaluated using metrics such as total runoff volume, peak flow rates, timing of the flow response, frequency of discharge, water levels, water velocities, and

in-stream water quality concentration. The calibration approach was to adjust model parameters and evaluate changes in model results against the entire calibration dataset, and identify the model values that were most consistent with the central tendencies of the dataset by stream. Each model within the framework was developed and calibrated using the best available data, and found to be reasonably consistent with observed data and therefore reliable to be applied for the Long Term Control Plan Update.

Model Application

The water quality model was applied for the typical year hydrologic period of 1994-1996, which includes one relatively dry year, a relatively wet year, and an average year (DELCORA, 2016b). Modeled POC concentrations were compared to the currently applicable and potential future water quality standards, as described in the table below. The Upper Delaware River and the tidal zones of Chester and Ridley Creek currently have secondary contact water quality standards whereas the Lower Delaware River currently has primary contact water quality standards for bacteria. The boundary between the Upper and Lower Delaware River occurs at river mile 81.8, which is just downstream of Chester Creek and CSO-11.

Table ES-1: Water Quality Standards for Comparisons with Model Results

Segment	*Enterococcus* (#/100 mL)	Fecal Coliform (#/100 mL)	*E.coli*[1] (#/100 mL)
Upper Delaware River and Tidal Zones of Creeks	Monthly Geomean: 88 #/100 mL	Monthly Geomean: 770 #/100 mL	n/a
Lower Delaware River	Monthly Geomean: 33 #/100 mL	Monthly Geomean: 200 #/100 mL	Monthly Geomean: 126 #/100 mL Statistical Threshold Value: 410 #/100 mL

1. *E.coli* (EC) standards likely to be codified by PADEP 12-24 months from July 2017. These criteria would apply to the non-tidal tributaries and Delaware River below R.M. 81.8, during recreational months only (May 1 - September 30).

Model results were summarized over the stream reaches that receive CSO discharges, and that occur within Pennsylvania water. Generally, the modeling indicated that the *Enterococcus* standards are the most stringent (relative to current concentrations) among the three POCs. Excursions above the WQS are frequent in the two Creeks and infrequent in the Delaware River. The excursions are almost always due to background sources coming from upstream of the DELCORA CSO area. DELCORA CSOs have a relatively smaller (less than 10%, on average) impact on monthly geometric mean concentrations than background sources.

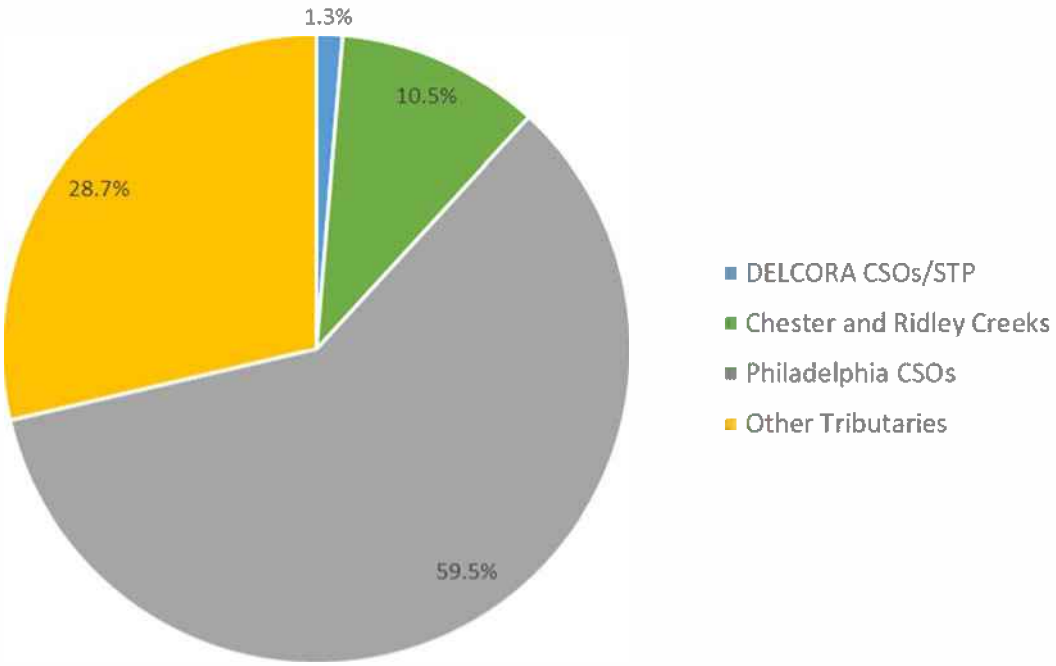
Findings and Implications

A water quality model was developed to compute POC concentrations in the tidal sections of Chester Creek and Ridley Creek, as well as in the Delaware River. Major findings of the modeling are as follows:

- The model is deemed adequate to assess the local water quality conditions in the DELCORA project area, including in the tidal portions of Chester and Ridley Creek, and in the Delaware River from roughly river mile 80 near Marcus Hook Creek, to river mile 85 near Crum Creek.
- Outputs of the hydrologic and hydraulic model relative to volumes and loadings were adequate for utilization as inputs for the development of the water quality model.
- The monitoring data shows that wet weather concentration at the most upstream monitoring locations (located upstream of CSO influence) in Chester Creek and Ridley Creek often exceed the monthly geometric mean WQS concentration for the three POCs. Wet weather exceedances are also observed in the most upstream monitoring location for the Delaware River, but less frequently as compared to the creeks. The *E.coli* statistical threshold value WQS[1] concentration (410 #/100 mL) was exceeded once under wet weather conditions during the sampling periods in the Delaware River.
- The modeling results show that when water quality standards are exceeded during wet weather events, upstream and background sources typically prevent the attainment of both the monthly geometric mean and STV water quality standards.
- The modeling results show that CSOs by themselves do not cause water quality violations in any of the stream segments.
- The DELCORA CSO loads are small compared to upstream and background loads entering the DELCORA project area (Figure ES-1).

[1] E.coli (EC) standards likely to be codified by PADEP 12-24 months from July 2017. These criteria would apply to the non-tidal tributaries and Delaware River below R.M. 81.8, during recreational months only (May 1 - September 30).

Figure ES-1: Percent of Bacteria Load by Source



Further, each model within the framework was developed and calibrated using the best available data, and found to be reasonably consistent with observed data and therefore reliable to be applied for the LTCPU. Two major observations can be made from the water quality modeling application results. One is that background sources dominate the modeled POC concentrations (and by extension, DELCORA CSO loads are small compared to background loads, as shown in the figure above), and the second is that the DELCORA CSOs by themselves do not cause non-attainment, or preclude the attainment, of WQS. Moreover, the modeling results show that regardless of additional CSO controls, even complete separation, water quality standards would still be exceeded under current conditions because background sources typically prevent compliance with WQS. While the Consent Decree addresses the issue of background sources by requiring CSO controls to also be assessed assuming that background sources are reduced to 75% of the applicable WQS, it is not clear that imposing CSO controls under these conditions is reasonable given that there is no current plan for reducing background loads in Chester and Ridley Creeks. The CSO Policy states that "where WQS and designated uses are not met in part because of natural background conditions or pollution sources other than CSOs, a total maximum daily load, including a wasteload allocation and a load allocation, or other means should be used to apportion pollutant loads". Such apportionment of loads does not currently exist for Ridley and Chester Creeks for bacteria.

The intended use of the water quality modeling framework is to evaluate CSO control alternatives with respect to applicable water quality standards and demonstrate that alternatives selected for the LTCPU program will meet the water quality-based requirements of the Clean Water Act and Consent Decree. The water quality model is adequate to assess presumption levels of control to show that the CSOs after controls are in place do or do not preclude the attainment of water quality standards. The model framework could also be used to assess the demonstration approach, however, as explained in this report, the modeling shows that CSOs alone do not cause WQS violation and do not preclude the attainment of WQS, and background loads are currently causing WQS violations upstream of the CSOs and the CSO influence. Without a State plan for estimating the cost and practicality for controlling the background load upstream of DELCORA's CSO area, it is difficult to justify the demonstration approach.

As such, DELCORA will utilize the presumption approach, which is shown in this report to be reasonable in light of the data and analysis as called for in the National CSO Policy.

Section 1 Introduction

1.1 Background of DELCORA's Facilities

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1. The total service area served by DELCORA, as shown on Figure 1-2, is approximately 82,977 acres which illustrates that DELCORA serves a significant and widespread portion of Delaware County.

The combined sewer area simulated in DELCORA's existing Hydrologic and Hydraulic model is located within the City of Chester and consists of a drainage area of approximately 1,510 acres. It comprises approximately half of Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows. The location of Chester City's service area is illustrated on Figure 1-2.

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western service area discharges to DELCORA's Western Regional Treatment Plant (WRTP). The Eastern service area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWD-SWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are directed to the PWDSWPCP. As such, dry weather flows and a portion of the wet weather flows (total flow less than 20 MGD) from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

There are a total of 26 combined sewer overflow outfalls listed with 25 discharge points (Outfall #009 and #010 both discharge at Outfall #009) in DELCORA's existing National Pollutant Discharge Elimination System (NPDES) Permit. Under its NPDES Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four stormwater outfalls at the WRTP (028-031) and from 26 combined sewer overflow outfalls (#002-#026, #032, #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

DELCORA'S SERVICE AREA

Part C – Other Requirements, Section V – Combined Sewer Overflows of the NPDES Permit details DELCORA's responsibilities with respect to the CSO system including reporting, continued implementation of and continued compliance with the Nine Minimum Controls (NMC), and implementation of the existing Long-Term Control Plan (LTCP) dated April 1999 and the July 2008 addendum to the LTCP until the updated LTCP is approved.

1.2 Consent Decree Requirements

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated LTCP to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. The Consent Decree specifies that within sixty (60) days after the approved Water Quality Model Plan is fully implemented according to the schedule included in the Modeling Work Plan, DELCORA shall submit to EPA and PADEP a Water Quality Model Report for review and approval pursuant to Section VI (Review and Approval of Submittals) which shall specifically address each item set forth in Paragraph 15(a)(i)-(vi).

The work plan was first submitted in January 11, 2017 and a revision was submitted in July 31, 2017.

1.3 CSO and Receiving Water System Description

The combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's serviced area. The combined wastewater/stormwater system in the City of Chester is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, and CSO regulators and CSO outfalls. The City owns, operates and maintains the inlets, stormwater-only sewers that connect to the combined sewer system and any stormwater-only outfalls. The City is also responsible for the maintenance and cleaning of the streets, planning, zoning, and development controls. The Chester CSO system contains 26 permitted outfalls and they discharge to three receiving water bodies: the Delaware River, Chester Creek, and Ridley Creek. However, there are only 25 CSO discharge locations, as CSO #010 discharges to the Delaware River through CSO #009. Figure 1-3 depicts the locations of CSO regulators and outfalls that are DELCORA's responsibility. Figure 1-3 also provides a sewer system characterization and illustrate the breakdown of each outfall and how each drainage area has combined sewers and separate sewers. Figure 1-4 is a schematic of the Chester CSO system and shows the outfalls and the interceptors that are connected to each CSO. Note that CSO #033 does not appear to overflow during the typical year period. This CSO will be evaluated in the LTCP but, as a practical matter, it does not cause or contribute to WQS being exceeded.

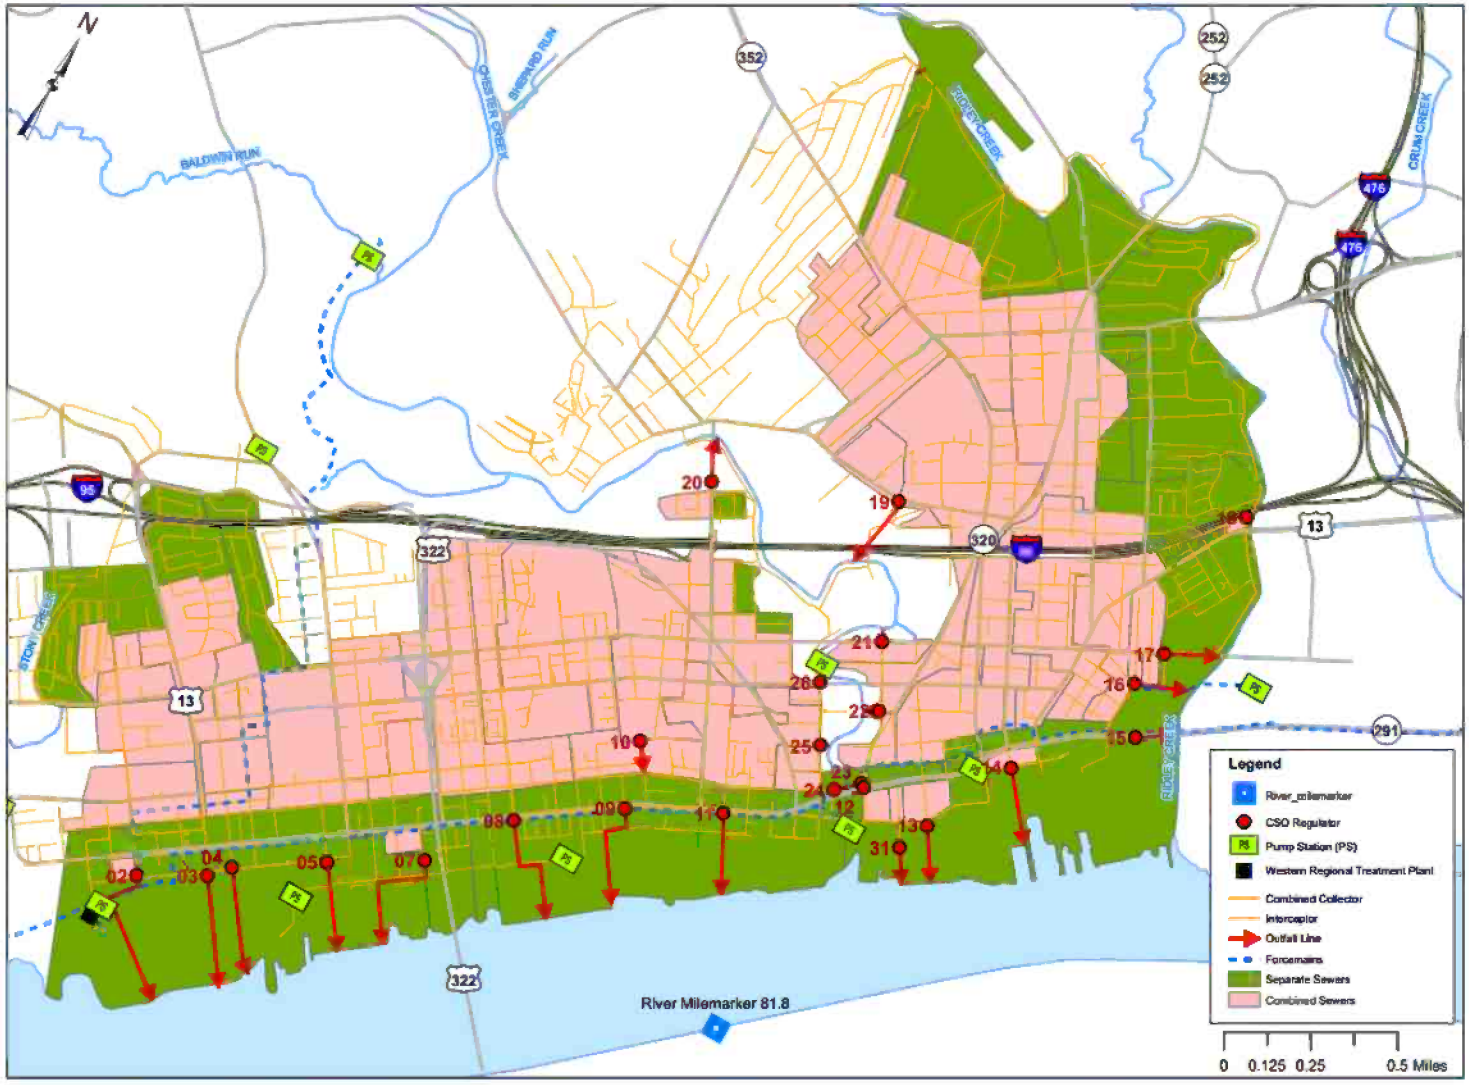

Figure 1-4: Schematic of Chester CSO System

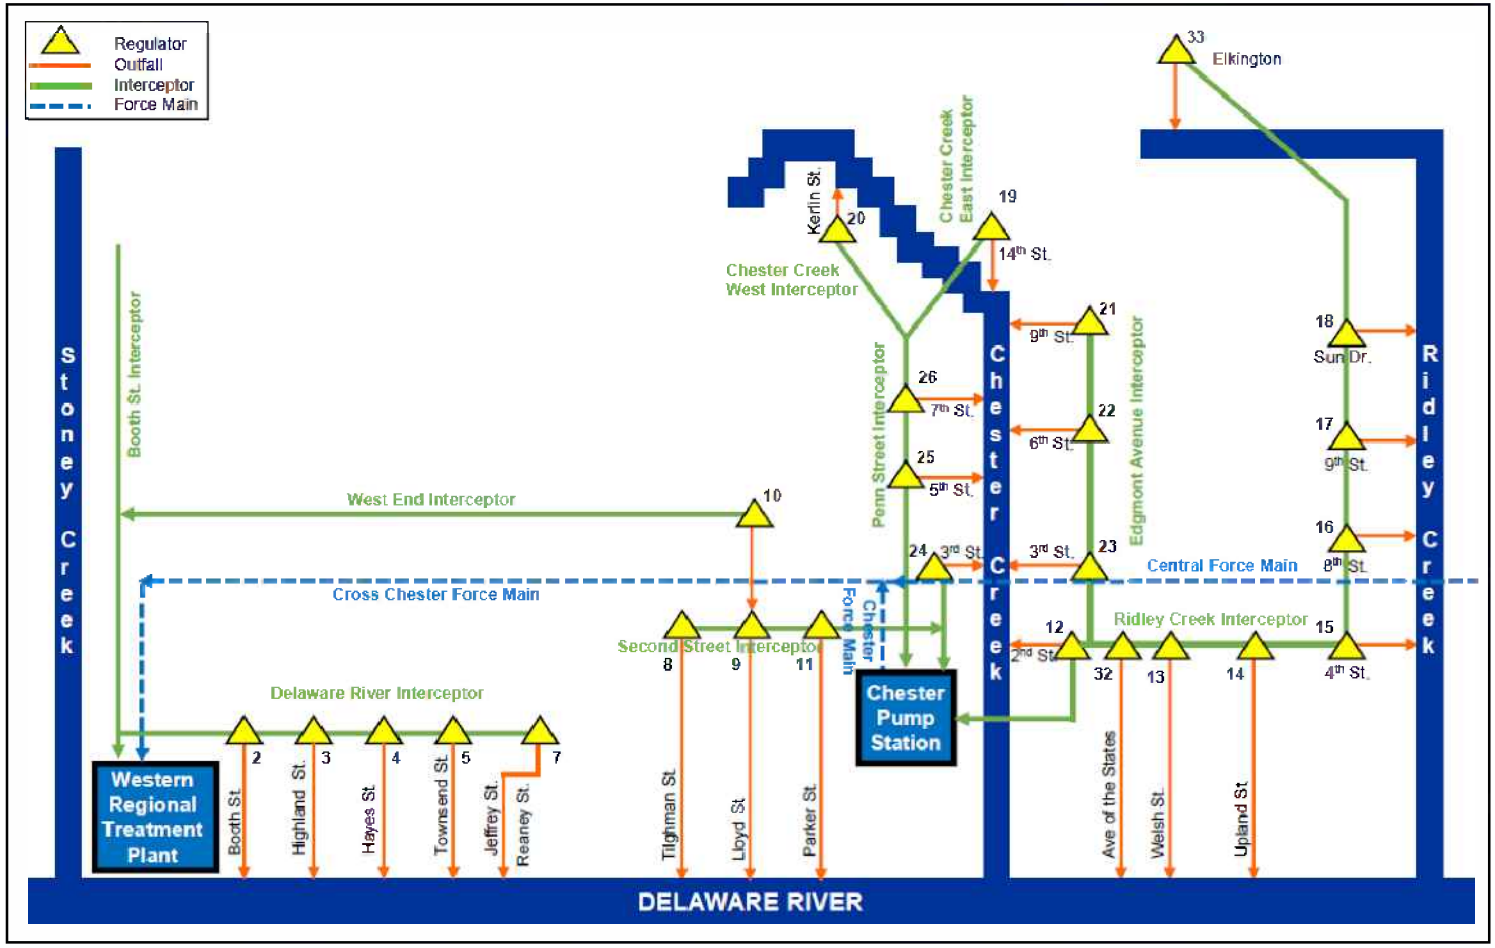

CSO Long-Term Control Plan
Delaware County Regional Water Quality Control Authority

GREELEY AND HANSEN

Figure 1-4
SCHEMATIC OF CHESTER CSO SYSTEM

The pollutants of concern (POC) in the receiving waters are described in the "Identification of Sensitive Areas and Pollutants of Concern Report" (DELCORA, 2016a), and include Fecal coliform, *E.coli*, and *Enterococcus*.

DELCORA conducted an extensive wet and dry weather monitoring program between March and June 2017 to better characterize the POC loads within the project area. Site selection and analytical parameters were designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. More information on the DELCORA Water Quality Monitoring Program can be found in Section 4.1.3 as well as in Appendix B.

1.4 Report Purpose and Objectives

This report describes DELCORA's receiving water quality model, which will support the Long Term Control Plan update (LTCPU). Specifically, the report describes the development and calibration of the model, and the initial application of the model to quantify baseline POC water quality conditions in the receiving waters for the typical period. The objective of the water quality modeling was to compute POC concentrations in Chester Creek, Ridley Creek, and the Delaware River, by accounting for all major POC sources within the model domain. Furthermore, the objective of the water quality model is to produce results for the typical period that will serve as the basis for evaluating CSO control alternatives. The primary focus of the water quality model is on the local water conditions, including the tidal zones of Chester and Ridley Creeks, and the Delaware River from roughly river mile 80 near Marcus Hook Creek to river mile 85 near Crum Creek. The intended use of the water quality modeling framework is to evaluate the water quality under typical year conditions and for the LTCP CSO control alternatives.

Page intentionally left blank for double-sided printing

Section 2 Water Quality Modeling Software

Three types of models, which comprise the modeling framework, were jointly applied to compute pollutant of concern (POC) concentrations in Chester and Ridley Creeks and the Delaware River:

- A watershed model which simulates flows and POC loads from the Chester and Ridley Creeks watersheds;
- CSO models to simulate flows and POC loads from the DELCORA and Philadelphia Water Department (PWD) combined sewer systems (CSS) to the streams; and,
- A receiving water quality model that computes POC concentrations in Chester and Ridley Creeks and the Delaware River resulting from the various sources of POCs to the streams.

The watershed model framework for this project is the EPA Stormwater Management Model (SWMM), which is supported by the USEPA. SWMM is a dynamic rainfall-runoff simulation model used for single event or continuous simulation of runoff quantity and quality from primarily urban areas (USEPA, 2014). The watershed model is based upon the EPA SWMM, Version 5.1.010, which is consistent with the version used for the CSS model. A variety of enhanced SWMM platforms are available that integrate the EPA SWMM software with user friendly interfaces and GIS capabilities. For this project, PCSWMM, developed by Computational Hydraulics International (CHI), was used.

The DELCORA combined sewer system hydrologic and hydraulic (H&H) model used for this study was developed by Greeley and Hansen (GH) to support DELCORA's Long Term Control Plan Update (LTCPU). The CSS model is based upon the EPA SWMM, Version 5.1, Build 5.1.012 and was applied through the proprietary software InfoSWMM Version 14.5 Update 4, developed by Innovyze (DELCORA, 2017).

A simplified Philadelphia combined sewer system model was developed by LimnoTech to estimate Philadelphia CSO flow and POC load contributions. The reason for including these loads is because large contributions of POCs occur upstream of DELCORA that impact the water quality in the DELCORA project area. The Philadelphia CSS model is also based on the EPA SWMM, Version 5.1.010 model using PCSWMM. Unlike the DELCORA CSS model, it does not represent hydraulics of the Philadelphia combined sewer system; instead it represents the storage capacity of the system and the frequency and magnitude of combined sewer overflows.

The receiving water quality model was developed based on USEPA's EFDC (Environmental Fluid Dynamics Code) modeling framework. This model has been applied to support numerous CSO water quality projects (Lynchburg, VA; Northern Kentucky; Evansville, IN; Cincinnati, OH) and is suitable for representing hydrodynamic and water quality conditions occurring in the Delaware River and its tributaries. EFDC is a state-of-the-art finite difference model that can be used to simulate hydrodynamic and water quality behavior in one, two, or three dimensions in riverine, lacustrine, and estuarine environments (TetraTech, 2007). The model has been applied to hundreds of water bodies across the United States, including in the Delaware Bay and Chesapeake Bay.

Page intentionally left blank for double-sided printing

Section 3 Model Configuration and Development

Model configuration and development is the process of configuring a model to represent certain conditions of interest (e.g. combined sewer overflows, or bacteria concentrations) at a particular site. The model development process for DELCORA's water quality modeling framework included definition of 1) important physical and chemical processes, 2) model inputs and assumptions influencing the modeled processes, 3) the spatial extent of model calculations, and 4) the time span of model calculations. This process is described below for each of the components of the modeling framework.

3.1 Watershed Model

3.1.1 Purpose and Description

The purpose of the Chester and Ridley Creek watershed model is to estimate flow conditions in the creeks for periods when USGS flow data for the two creeks are unavailable for the application period. Gage data are available through much of the typical period, except for a long data gap in Ridley Creek (9/22/1995 through 12/31/1996) and some shorter periods at both gages. The watershed model is used to fill in those data gaps, as well as to estimate the flow contribution of the separate storm sewer areas within the DELCORA project area as represented in Figure 1-3.

The watershed model consists of a set of subcatchments representing the hydrology of the system. The subcatchments are connected to a network of stream segments representing the hydraulics of the system. During wet weather events, runoff and associated pollutants are transported from the subcatchments to the stream network, and ultimately discharge to Chester Creek, Ridley Creek, or the Delaware River.

To set up the watershed model in SWMM, processes influencing the system's hydrology and hydraulics were characterized. Several different types of data were used for this characterization. The processes that were modeled and the relevant data that were collected and analyzed for setting up the watershed model are further described below.

3.1.2 Model Processes

The first step in model development is determining what hydraulic and water quality processes should be included. SWMM is capable of modeling six processes: rainfall/runoff, infiltration, snow melt, groundwater, flow routing, and water quality. To meet the objectives of this model three of these processes were used: rainfall/runoff, infiltration, and flow routing. The other three processes were not used or were modified as follows:

- Snow melt: it was assumed that snow melt typically does not generate significant runoff in the DELCORA area, so this process was not included.

- Groundwater: the contribution of groundwater to stream flow was approximated using a base flow time pattern for select model nodes as well as the RTK model for faster interflow response (See Section 3.1.2.3), so explicitly modeling groundwater was not necessary.
- Water quality: water quality was modeled by assigning wet weather and dry weather flow bacteria concentration to the modeled flows. These concentrations were calculated based on the results from the dry and wet weather monitoring program. Explicitly modeling pollutant loads through build-up/wash-off functions was therefore not necessary.

Site-specific watershed data were used to define key inputs and to represent the local relationship between precipitation, runoff, and in-stream flow conditions. These data include area, slope, percent impervious, soil type (infiltration), depression storage, base flow, and Manning's roughness coefficient. General watershed model characteristics for each watershed and the source of information are provided in Table 3-1, and are further explained in the subsections following the table. The modeled hydraulic and runoff response was further refined through the calibration process.

Table 3-1: Watershed Model Characteristics

	Chester Creek	Ridley Creek	Data Source
Annual Precipitation (in)	41.6	41.6	NOAA NCDC (Philadelphia International Airport)[2]
Drainage Area (sq. miles)	65.6	38.2	USGS Streamstats[3]
Imperviousness (%)	13.2	8.5	USGS Streamstats[2]
Average Overland Slope (%)	7.5	7.5	USGS Streamstats[2]
Top Three Land Uses (%)	Residential (45%)	Residential (44%)	Delaware Valley Regional Planning Commission[4]
	Wooded (24%)	Wooded (29%)	
	Agriculture (7%)	Agriculture (13%)	
Dominant Hydrologic Soil Group	HSG B	HSG B	USDA NRCS SSURGO 2016[5]
Average Watershed Yield (MG/mi^2)	10.4	9.2	USGS Gage Data[6]

3.1.2.1 Subwatershed Delineations

The watershed model consists of a set of subcatchments representing the drainage area of the Chester Creek and Ridley Creek watershed. For modeling purposes, each tributary's watershed was subdivided into smaller subwatersheds using the hydrologic unit code (HUC) delineations developed by the USGS[7] as the initial basis for the delineation. These HUC 10 subwatersheds were then divided into smaller subcatchments through interpretation of a digital elevation model (DEM) in ArcGIS, and consideration of tributary confluences, flow metering stations, water quality monitoring stations, road planimetric data, and the delineation of the Chester City separate sewer area as well as the combined sewer area. The separate sewer area and combined sewer area were previously delineated by the City of Chester and Greeley & Hansen respectively. Overall, the drainage areas downstream of the USGS gages were divided into smaller subcatchments compared to the upstream areas because more information was available to facilitate the delineations at the subcatchment level. Additionally, the majority of drainage area downstream of the USGS gages also coincides with the focus area of the modeling. The delineation of the two watersheds are shown in Figure 3-1.

3.1.2.2 Meteorology

SWMM requires two meteorological inputs: a precipitation time series to generate runoff, and temperature data to calculate evaporation. Several meteorological stations are located in or near the Ridley and Chester Creek Watershed, as shown in Figure 3-2.

Complete time series for precipitation (hourly and daily), daily minimum and maximum temperatures were available at Philadelphia International Airport from 1948 through current conditions, including the watershed calibration time period of 2006 through 2016. All meteorological data at this station was obtained from NCDC, which is operated by the National Oceanic and Atmospheric Administration (NOAA). The other stations either have incomplete data sets, recordings that do not overlap with the complete calibration period, or the recorded time steps are too coarse (larger time step than hourly). These stations are therefore not suitable for the watershed hydrology calibration.

[7] https://water.usgs.gov/GIS/huc.html

Figure 3-1: Extent of Watershed Model

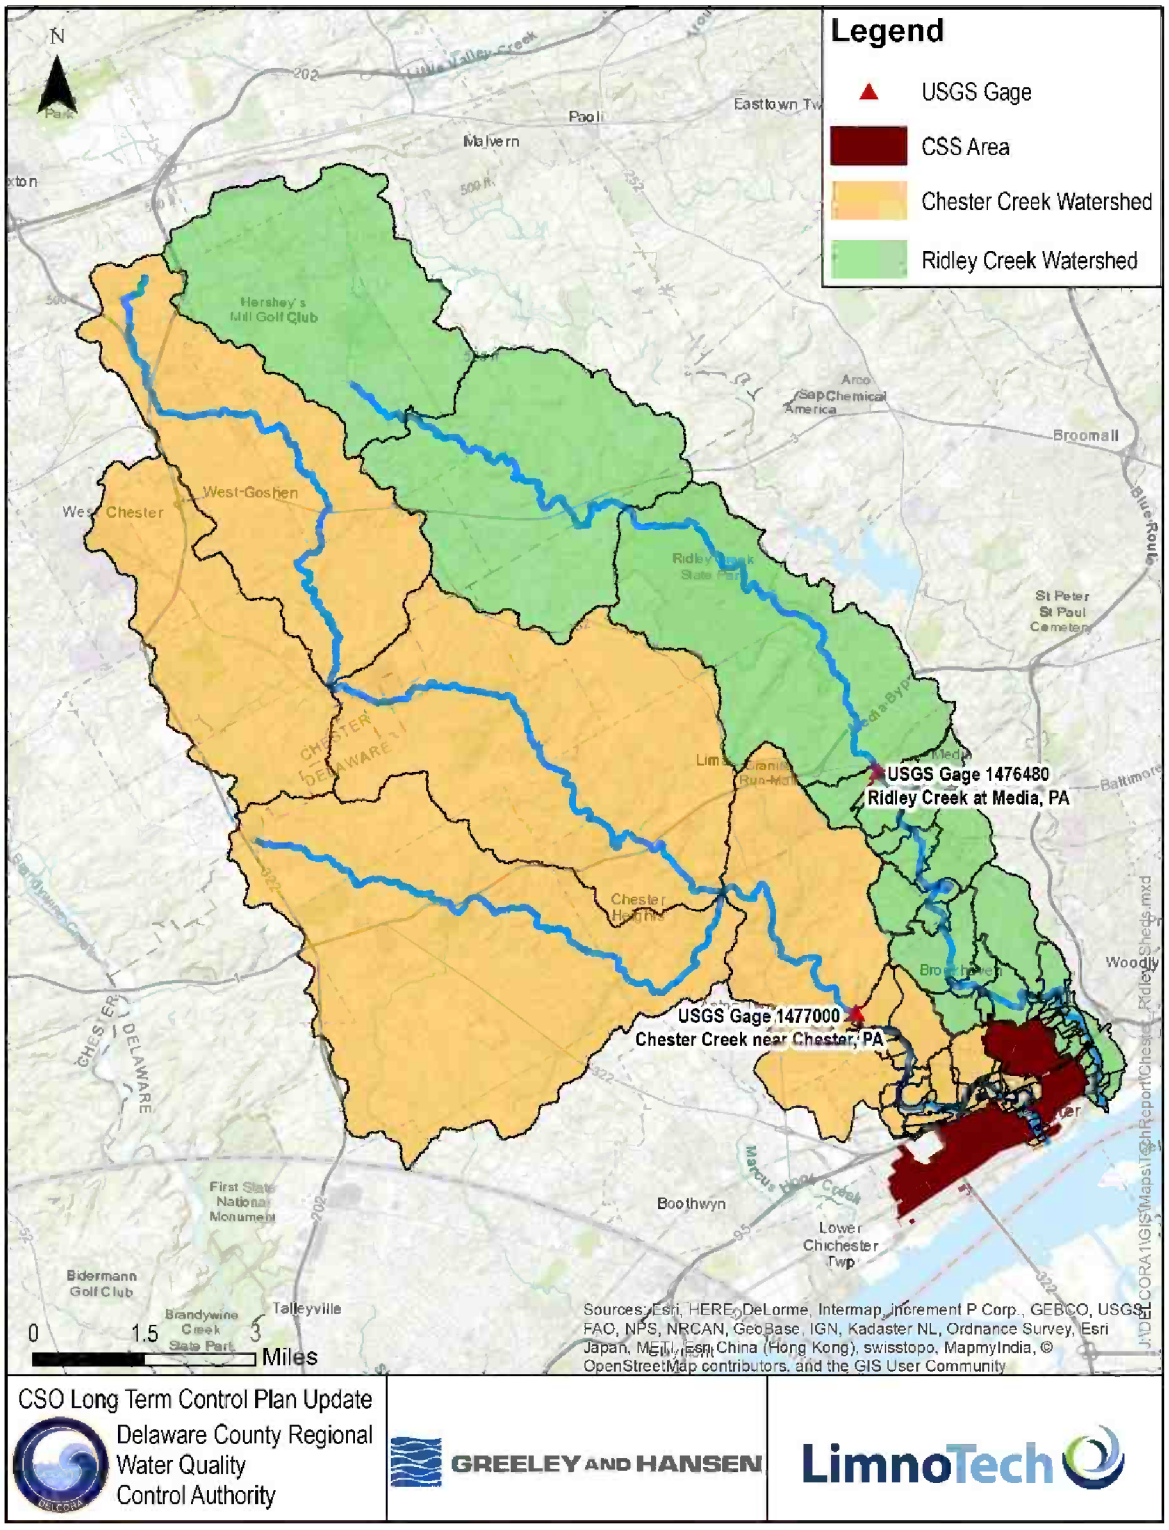

Figure 3-2: Location of Meteorology Stations

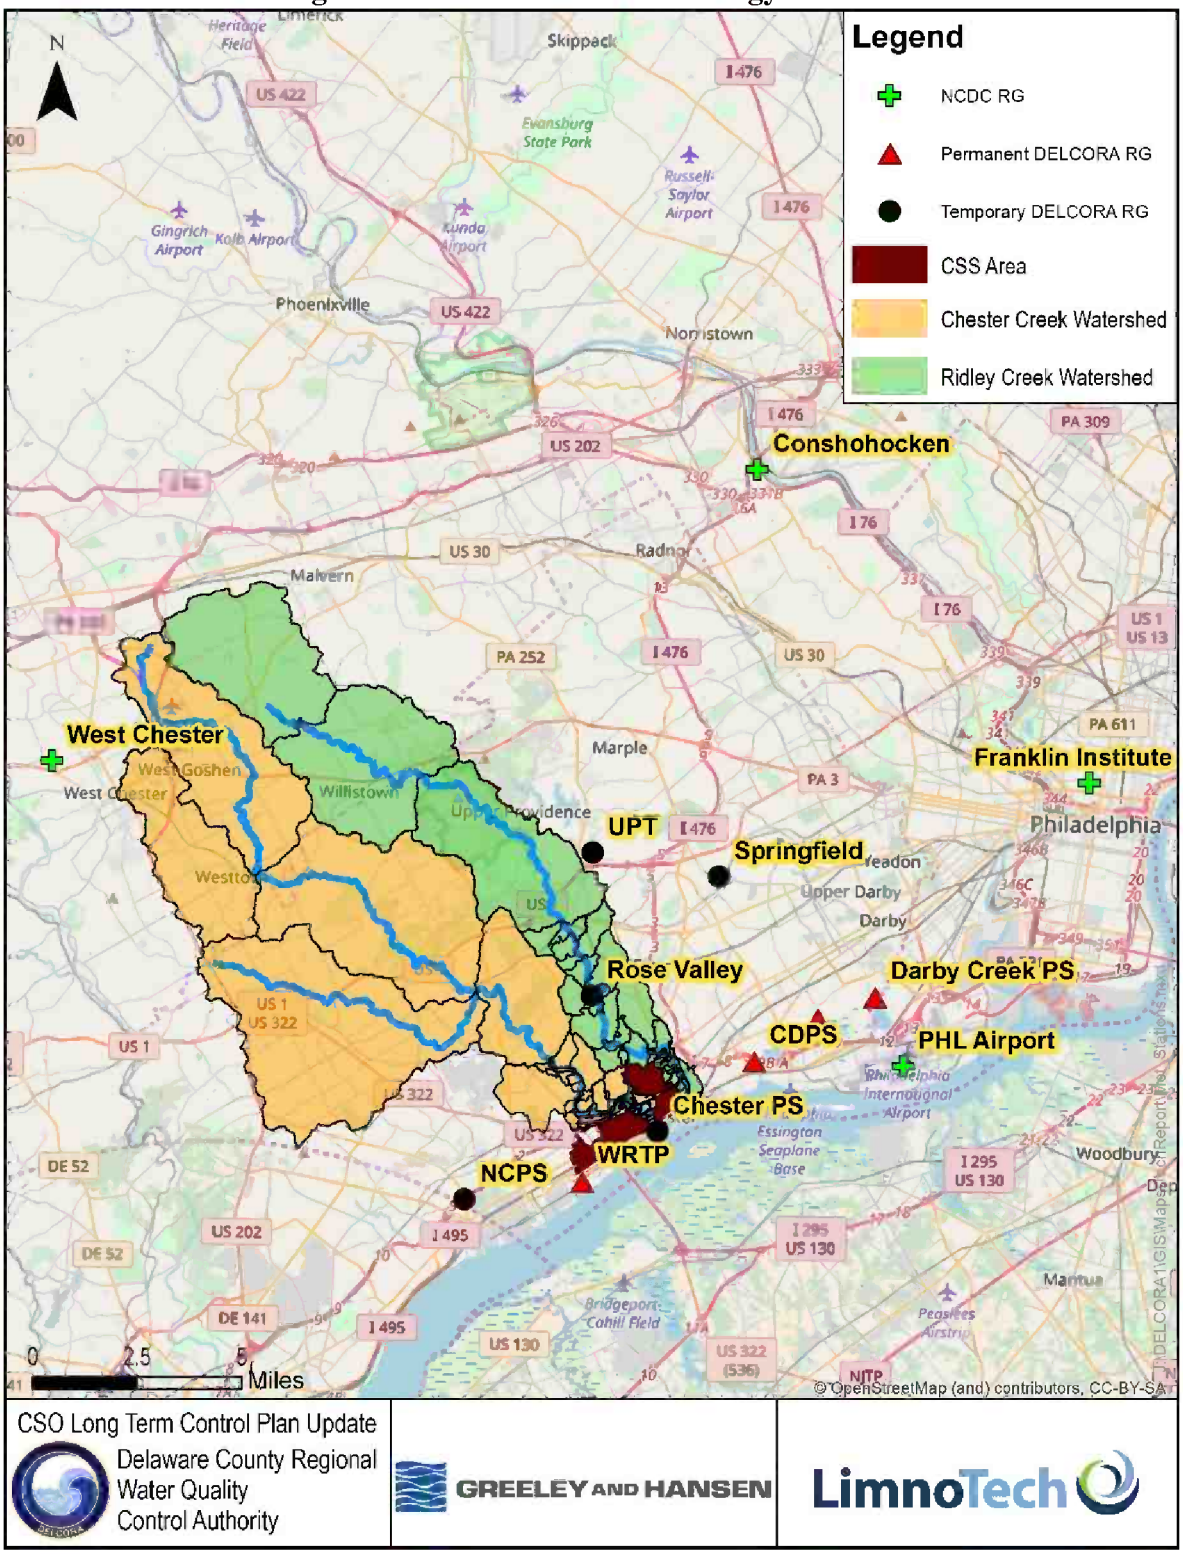
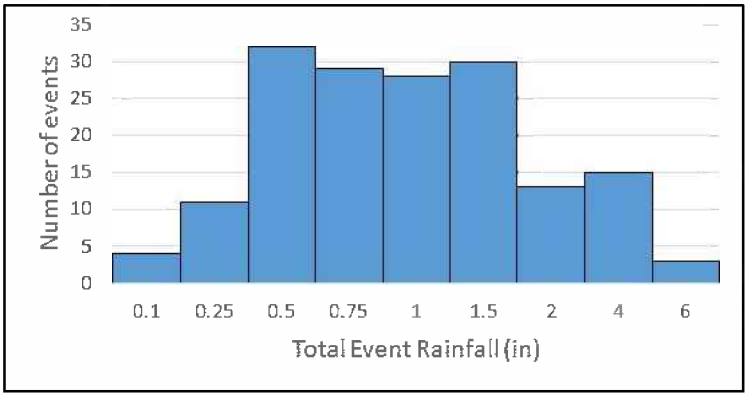


The availability of only one gage for the watershed calibration means that the model may be less accurate for rainfall patterns that vary across the watershed. In order to minimize the effect of this spatial variability on the calibration, a set of 165 rainfall events were chosen from the 10-year calibration period when there was consistency between the total rainfall depth at Philadelphia International Airport and the observed flow runoff depth at the Ridley and Chester Creek USGS gages. Two criteria were used to evaluate "consistency" between observed precipitation and flow: (1) precipitation events must increase baseflow by at least 3 times, and (2) the observed flow response occurs within 4 hours of the precipitation event. The selected rainfall events vary in intensity, duration, and overall rainfall depth, as shown in Figure 3-3 below.

Figure 3-3: Watershed Calibration Events: Rainfall Depths



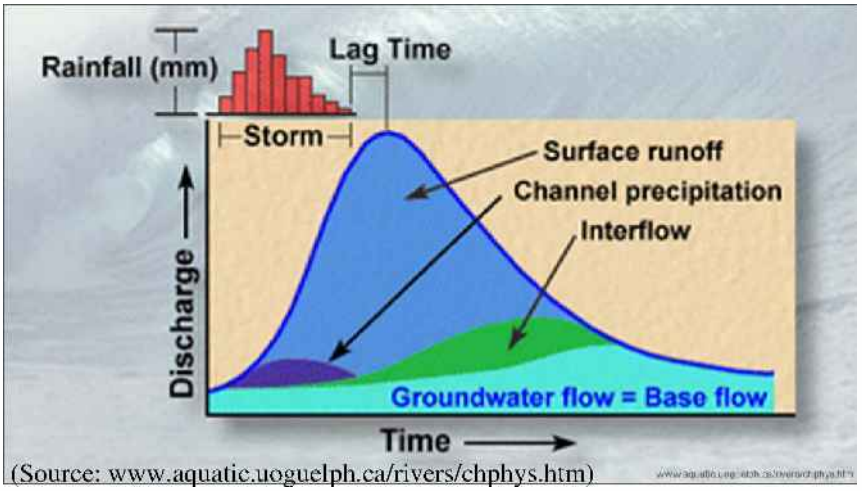
3.1.2.3 Hydrology

The total observed stream discharge relative to a rain event can be separated into different categories of flow, including:

- Channel precipitation: This is flow from rain that falls directly on streams. It represents a very small portion of the total stream flow, but produces an almost instantaneous increase in flow relative to the beginning of a rain event.
- Direct surface runoff: This represents the portion of rain that lands on the ground surface and becomes stormwater runoff. This flow builds up quickly (i.e.: short lag time) relative to the beginning of a rain event, especially in urban areas. Direct runoff can enter streams through overland flow (flow moving over the top of the ground surface) or through a sewer pipe conveyance system.
- Interflow: This is the flow from the portion of rain that infiltrates into the ground and moves laterally through the shallow unsaturated soils towards streams. This flow has a more delayed response compared to surface runoff.
- Groundwater or base flow: This is flow entering the creek from the groundwater table. This flow has a much slower response time to rainfall compared to direct surface runoff and interflow.

A generalized streamflow response to a rainfall event is shown in Figure 3-4 below.

Figure 3-4: Generic Streamflow Hydrograph



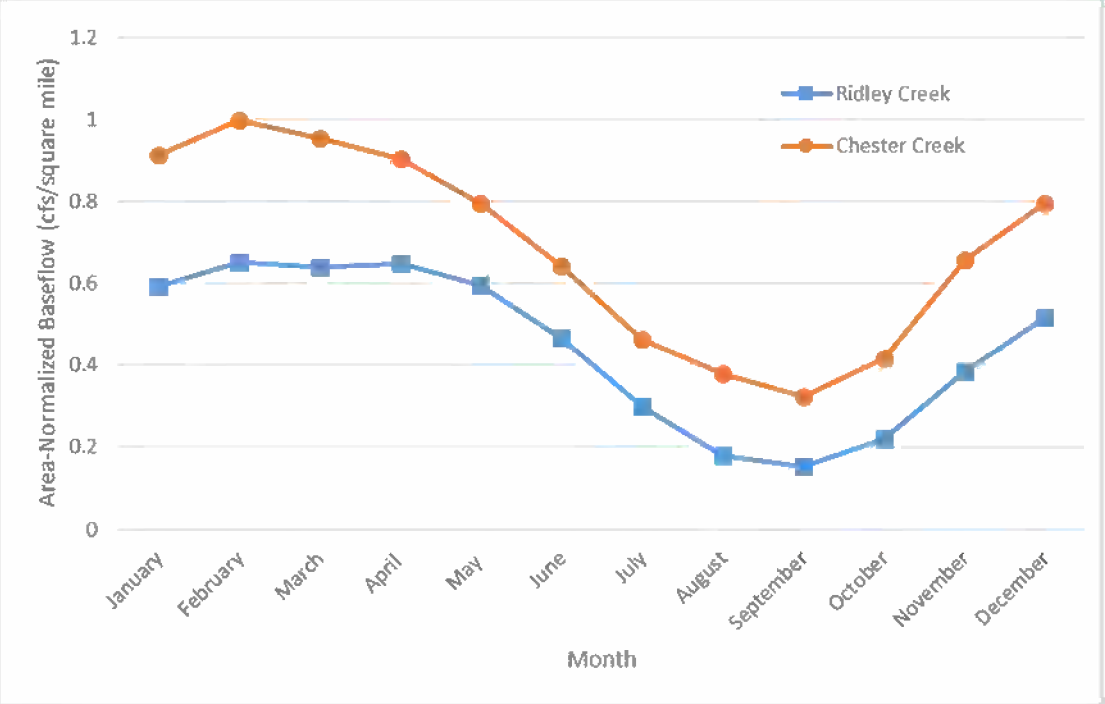
The watershed model simulates the direct surface runoff via the SWMM runoff block using a nonlinear reservoir method. Parameters that influence the surface runoff are explained in the subsections below.

Initial model results and comparisons with observed stream flows at the USGS gages indicated a significant interflow response during wet weather. Interflow was therefore simulated using the RTK approach in the SWMM model since sufficient data for explicit groundwater modeling within SWMM was not available. RTK is an application of the synthetic unit hydrograph method and is based on fitting up to three triangular unit hydrographs to an observed hydrograph to estimate the fast, medium, and slow stream responses (EPA 2008; Lai, 2017).

Surface Runoff and Channel precipitation are represented by one of the three RTK hydrographs that is generally used to represent inflow to sewers. Interflow is represented by the RTK hydrograph that is used to represent short term infiltration. Base flow is represented by the RTK hydrograph that is used to estimate groundwater flow.

Base flow comprises the majority of stream flow during extended periods of dry weather, and can be estimated from measured flow data time series. The flow records from the two USGS gages at Ridley and Chester Creek were used to approximate base flow within each creek. Using 10 years of flow data, monthly 7Q10 flows were calculated using methods from Risley et al (2008). The 7Q10 flows represent flows in a stream during dry periods and can be estimated on a monthly basis to capture the seasonal variability in these dry flows. These values were then normalized to watershed area (in mi^2) and applied to subcatchments that contribute to the streams and creeks that are included in the watershed model (Figure 3-5). Base flow was added to the watershed model as a constant inflow with monthly variations based on the area of the contributing subwatershed.

Figure 3-5: Area-Normalized Base Flow Values for Ridley and Chester Creek



3.1.2.4 Soil infiltration

SWMM offers several methods for soil infiltration (listed in order of increasing complexity): Curve Number, Horton's, and Green-Ampt. The curve number methodology is a fairly coarse representation of soil infiltration and does not allow for time-and-rain variable soil infiltration variations. The Green-Ampt method requires very site-specific knowledge to characterize infiltration parameters, which were not readily available for this project. Therefore, the Horton method was selected as most appropriate for the watershed model. Horton's method uses a set of parameters that defines the maximum infiltration rate, the minimum infiltration rate, the decay rate for transitioning from maximum to minimum infiltration rates, a recovery rate for transitioning from minimum to maximum infiltration rates, and an overall maximum infiltration volume. These parameters are determined based on the hydrologic soil groups that are present in the watershed model extent.

The hydrologic properties of soils influence how quickly and how much precipitation is converted to runoff. In general, soils can be classified by hydrologic soil group (HSG). There are four basic HSGs, called HSG A, HSG B, HSG C, and HSG D. Soils in group A have the lowest runoff potential, while soils in group D have the greatest runoff potential (Mockus et al., 2004). These four basic classifications can then be broken down into dual classifications such as A/D or B/D. Dual classifications represent soils that are classified as group D because of a high water table, causing them to have a high runoff potential. However, if the water table were lowered, these soils would have a lower runoff potential (such as group A or B).

To characterize the soils within the model extent, data were downloaded from the 2016 Soil Survey Geographic (SSURGO) database provided by the National Resources Conservation Service (NRCS). A wide range of HSGs are represented within the SWMM model extent (Table 3-2). In addition to the four standard categories (HSG A through D), several dual classifications are also represented. These dual classifications were assumed to be undrained, and were therefore assigned the same soil properties as HSG D. Any soil types with no official hydrologic soil group classification were also assumed to be mainly poorly drained and would have a high potential for runoff. Therefore, they were assigned the same soil properties as HSG D.

The soil infiltration parameters associated with each HSG were estimated from tables provided in the *User's Guide to SWMM 5* (James et al., 2010). An average minimum and average maximum value from the suggested range was used for the infiltration rate. In the absence of detailed soil data, the decay constant and drying time were assumed to be the same for all soil types within the model extent, and a maximum infiltration volume was not specified.

Table 3-2: Description of Hydrologic Soil Groups within Watershed Model Extent

Hydrologic Soil Group	Description	Ridley Creek		Chester Creek	
		Area (acres)	% of Total	Area (acres)	% of Total
A	Soils with low runoff potential	7.3	19%	7.0	11%
A/D	Soils with high runoff potential unless drained. Otherwise classified as HSG A.	0.0	0%	0.0	0%
B	Soils with moderately low runoff potential	12.6	33%	27.8	42%
B/D	Soils with high runoff potential unless drained. Otherwise classified as HSG B.	2.0	5%	4.1	6%
C	Soils with moderately high runoff potential	12.0	32%	18.8	29%
C/D	Soils with high runoff potential unless drained. Otherwise classified as HSG C.	3.2	8%	6.8	10%
D	Soils with high runoff potential	1.1	3%	1.1	2%
	TOTAL	38.2	100.0%	65.6	100.0%

3.1.2.5 Impervious Area and Slope

Percent impervious area and percent slope strongly influence the amount of precipitation that runs off to the streams. Large amounts of impervious area and/or high slopes can lead to high-volume and "flashy" runoff. To estimate median percent impervious area for each subcatchment, a high-

resolution land cover raster was downloaded from the Chesapeake Conservancy[8]. Percent slope for each subcatchment was estimated using the National Elevation Dataset (NED) (Gesch et al., 2002). The average percent imperviousness for Chester and Ridley creek are 10% and 8.5% respectively.

3.1.2.6 Other Subcatchment Parameters

In addition to the major subcatchment parameters listed in the sections above, there are five additional parameters that were characterized for each subcatchment: Manning's n coefficient for overland flow over pervious and impervious areas, depression storage for pervious and impervious areas, and percent of impervious area with zero depression storage (Table 3-3). These parameters can be used to adjust the shape and the timing of the hydrograph. For simplicity, these parameters were set to constant values for all subcatchments. The values were selected based on literature values from the SWMM5 manual (James et al., 2010).

Table 3-3: Additional SWMM Subcatchment Parameters

Parameter	Value	Description	Source
Manning's n for overland flow over impervious area	0.018	Average value	Mc Cuen et al. (1996)
Manning's n for overland flow over pervious area	0.25	Dense grass	Mc Cuen et al. (1996)
Depression storage for impervious area	0.075	Average value for impervious surfaces	ASCE (1992)
Depression storage for pervious areas	0.15	Average value for lawns	ASCE (1992)
Percent of impervious area with no depression storage	25%	Default value in SWMM	-

3.1.2.7 Hydraulics and Routing

SWMM offers three methods for routing water through the stream network (listed in order of increasing complexity): steady flow, kinematic wave, and dynamic wave. Dynamic wave was selected for the routing portion of the model. The dynamic wave model can account for channel storage, backwater, entrance/exit losses, flow reversal, and pressurized flow. The dynamic wave model allows for more complex flow conditions than the other routing methods, but requires the use of smaller computational time steps, so choosing this method generally increases the model run times. This method was selected because it has the potential to produce more accurate results.

[8] https://chesapeakeconservancy.org/conservation-innovation-center/high-resolution-data/land-cover-data-project/.

3.1.2.8 Stream Network

The stream network that makes up Chester and Ridley Creek upstream of Chester City were developed using two sources. Hydrography data were acquired from the National Hydrography Dataset (NHD Plus), which is developed by USEPA Office of Water and the US Geological Survey (USGS)[9]. This dataset includes nationwide spatial information about a variety of waterbodies, including streams, rivers, lakes, and ponds. NHD Plus was modified using a digital elevation model developed from LiDAR mass points. Modifications of the NHD Plus flow lines were made to align with the lowest nearby digital elevation model (DEM) elevation and with aerial photographs. No bathymetric data was available for the stream network upstream of Chester City, so the channels were assumed to be trapezoidal channels with a connected floodplain. The geometry of the channels were first estimated using the available DEM data, and then modified during the hydrology calibration process. In the tidal regions of the two Creeks, bathymetric data was collected through a field survey and was used to specify the channel geometry in the receiving water model. The bathymetric field survey of Chester and Ridley Creek was conducted in March of 2017, and the results are described in Appendix A.

3.1.2.9 Water Quality

To estimate tributary water quality concentrations, modeled tributary flows were separated into base flow and runoff components. Event mean concentrations for each component were then estimated based on sampling data (see Section 4.1), then later refined during the water quality model calibration process, which is described in Section 4.2. These event mean concentrations were then associated with each flow component (i.e. runoff and base flow) to estimate POC loads in the tributaries. This method allowed for time-variable POC concentrations that are consistent with the timing of the wet weather flow response.

3.1.2.10 Linkage to the EFDC Water Quality Model

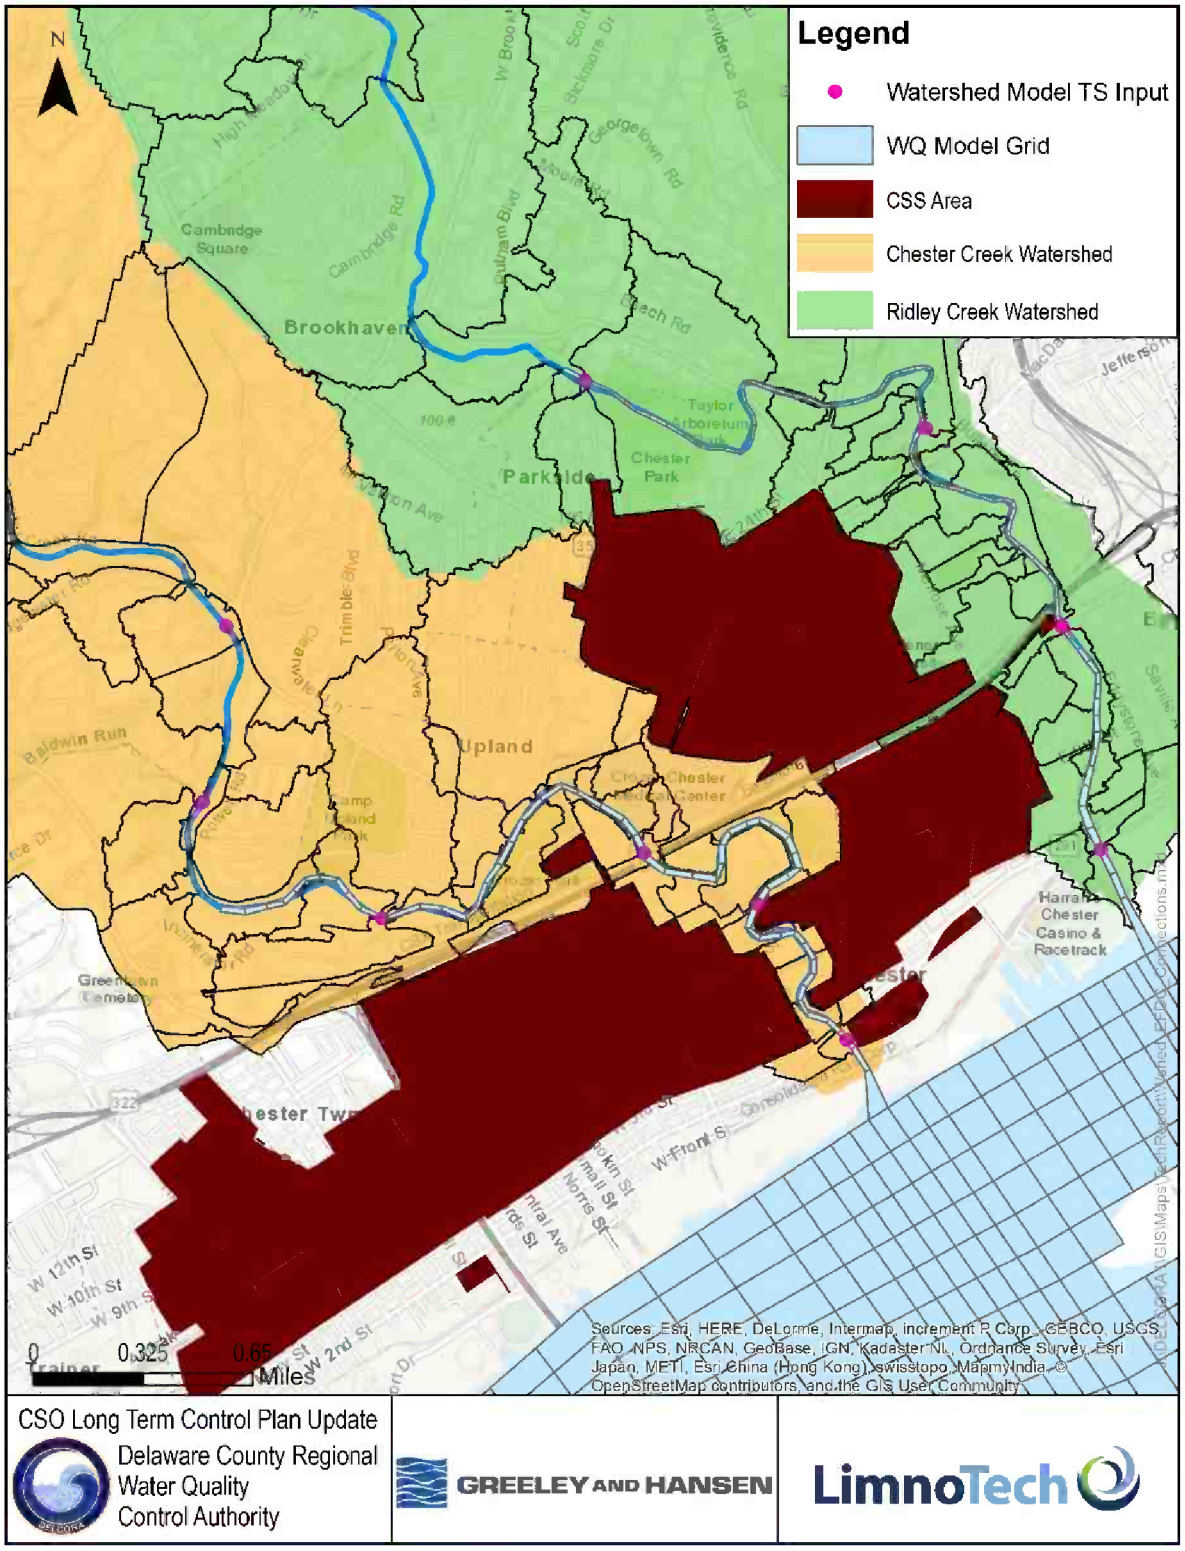
The hydrograph time series (TS) produced by the watershed model were tied into the EFDC at the most appropriate geographic location. These linkages are shown in Figure 3-6.

3.2 DELCORA Combined Sewer System Model Development

The DELCORA combined sewer system (CSS) hydrologic and hydraulic (H&H) model used for this study was developed by Greeley and Hansen (GH) to support the DELCORA Long Term Control Plan Update (LTCPU). This model has been documented in detail in the Sewer System Hydrologic and Hydraulic Model Report (DELCORA, 2017).

[9] https://nhd.usgs.gov/

Figure 3-6: Watershed-Receiving Water Model Connections



3.3 Philadelphia Simplified CSO Model

3.3.1 Purpose and Description

The Philadelphia CSO system is a complex sewer system network managed by the Philadelphia Water Department. It has CSO outfalls located along the Western shore of the Delaware River, the Schuylkill River, Frankford Creek, Pennypack Creek, Tacony Creek, and Cobbs Creek. The bacteria loads from these outfalls contribute to the overall bacteria concentrations in the Delaware River upstream of the DELCORA project area. The Philadelphia CSO model developed for the purpose of this project is a simplified model that approximates the storage volume within the CSO network and magnitude and frequency of Philadelphia CSO discharges and associated POC loads, thereby accounting for Philadelphia CSO POC water quality impacts on the downstream DELCORA service area.

3.3.2 Model Processes

Due to the limited amount of publically available information related to the Philadelphia sewer network, and no publically available calibration data such as metered flows, the Philadelphia CSO model constructed for the purposes of this project is a simplified hydrologic model. It does not explicitly represent the hydraulics of the Philadelphia combined sewer network but rather uses hydrologic functions and parameters available in the SWMM software to approximate the storage volume and flow characteristics within the CSO sewer network, thereby simulating the magnitude (volume) and frequency (timing) of Philadelphia CSO discharges.

Development and calibration of this model relied principally on information from the 2015 and 2016 annual reports of Philadelphia CSO model overflows (PWD, 2015-2016). A summary of information available from these this reports are is shown in Table 3-4. Data from the 2015 annual report was then used to verify the developed model.

Table 3-4: Information Available from the 2016 Philadelphia CSO Model Annual Reports

Receiving Stream	Number of Outfalls (#)	Total Annual Overflow Events (#)	Total Annual Overflow Duration (hours)	Total Annual Overflow Volume (MG)
Cobbs Creek	34	21	46	667
Delaware River	54	33	135	5,025
Frankford Creek	16	39	111	1,000
Pennypack Creek	5	30	165	617
Schuylkill River	41	42	117	2,811
Tacony Creek	15	42	122	2,314

The information presented in the reports helped to constrain model inputs related to the CSS sewersheds, including the total subwatershed area, depression storage, average surface slope, and subwatershed width and length. These parameters were defined for each combined sewer outfall.

Section 4.3 describes how these model inputs were calibrated so that the model accurately computes the volume and frequency of Philadelphia CSOs.

3.4 Receiving Water Model Development

3.4.1 Purpose and Description

The receiving water quality model simulates POC concentrations in the tidal reaches of Chester and Ridley Creeks, as well as in the Delaware River near the DELCORA service area. These modeled POC concentrations will be compared to water quality standards to assess the influence of DELCORA CSO loads on present day water quality compliance. CSO control scenarios will then be simulated within the modeling framework to describe the associated improvements to water quality.

3.4.2 Model Processes

To compute POC concentrations in the receiving waters, the receiving water quality model integrates different known flow and POC contributions, the subsequent transport and mixing of these sources, and the decay of the POCs. Key features represented in the model include upstream Delaware River flows; tributary dry and wet weather flows, tidal conditions, and POC loads from the tributaries, the DELCORA CSOs, and the Philadelphia CSOs. The processes that were modeled and the relevant data that were collected and analyzed for setting up the receiving water quality model are further described below.

Figure 3-7 and Figure 3-8 illustrate the elements related to the development and calibration of the receiving water quality model. These are also further explained in the following subsections.

Figure 3-7: Water Quality Model Extent and Related Features

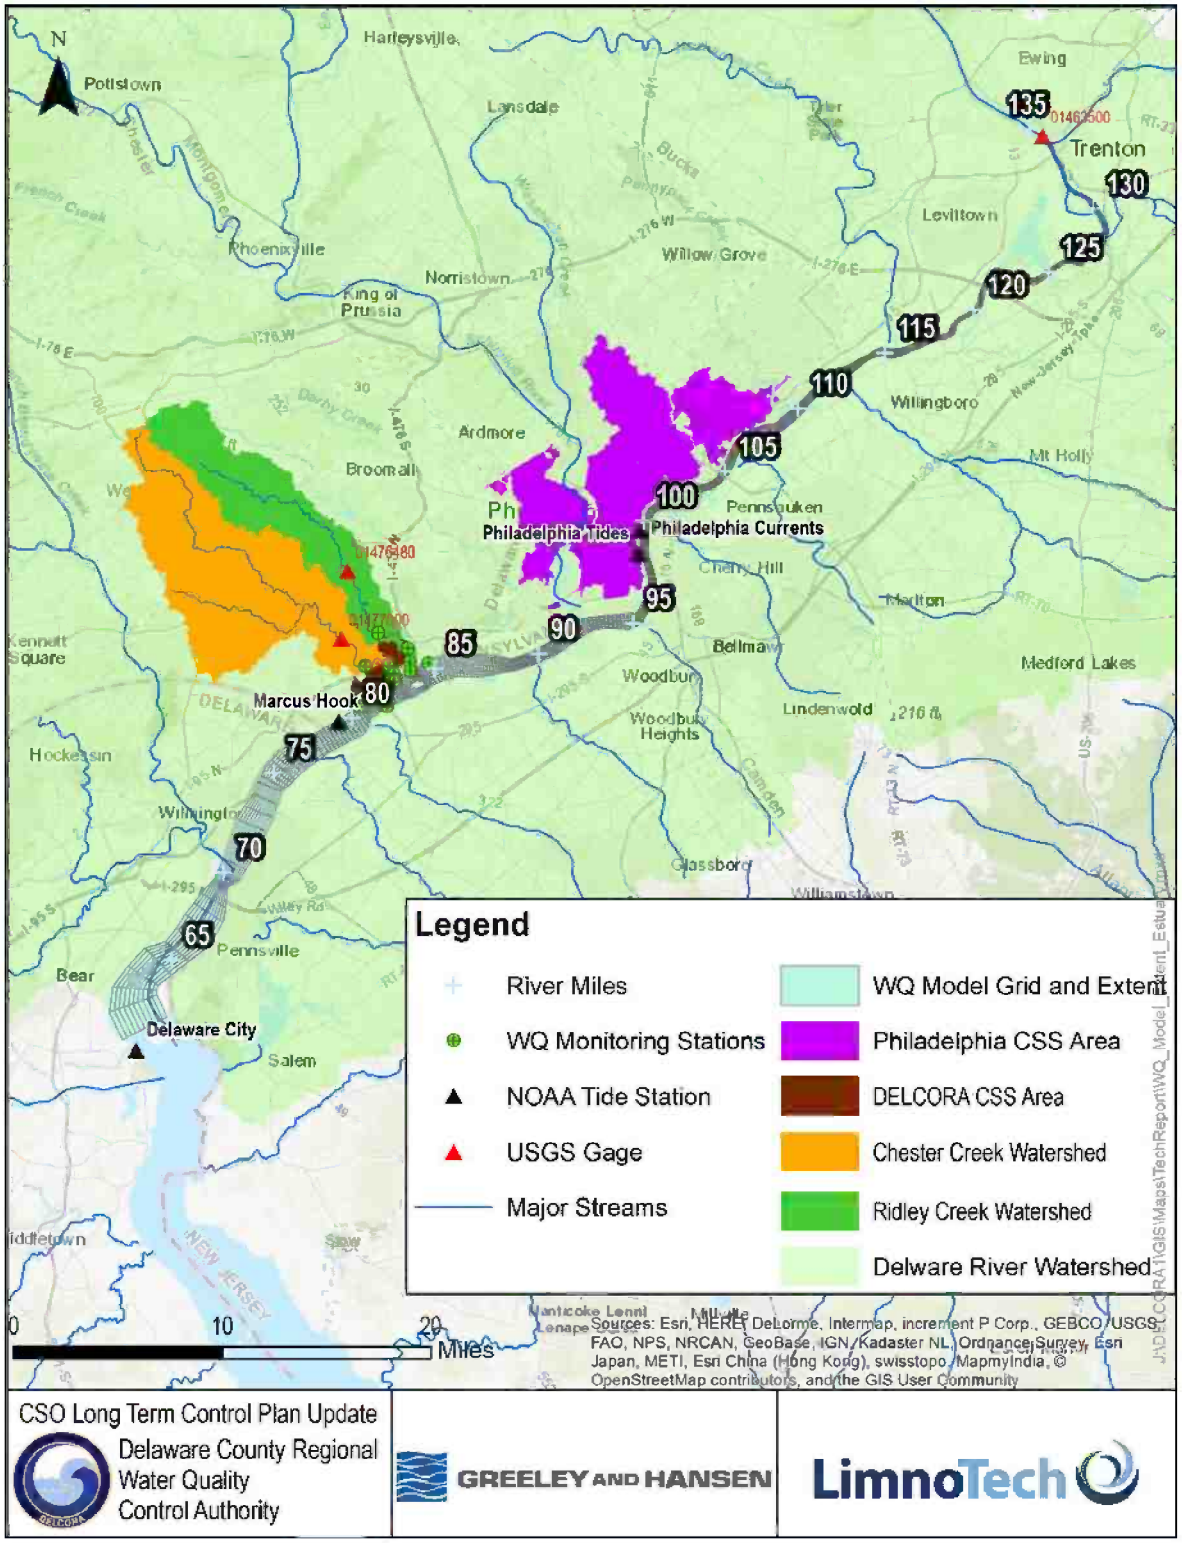


Figure 3-8: Water Quality Model and Related Features near DELCORA System

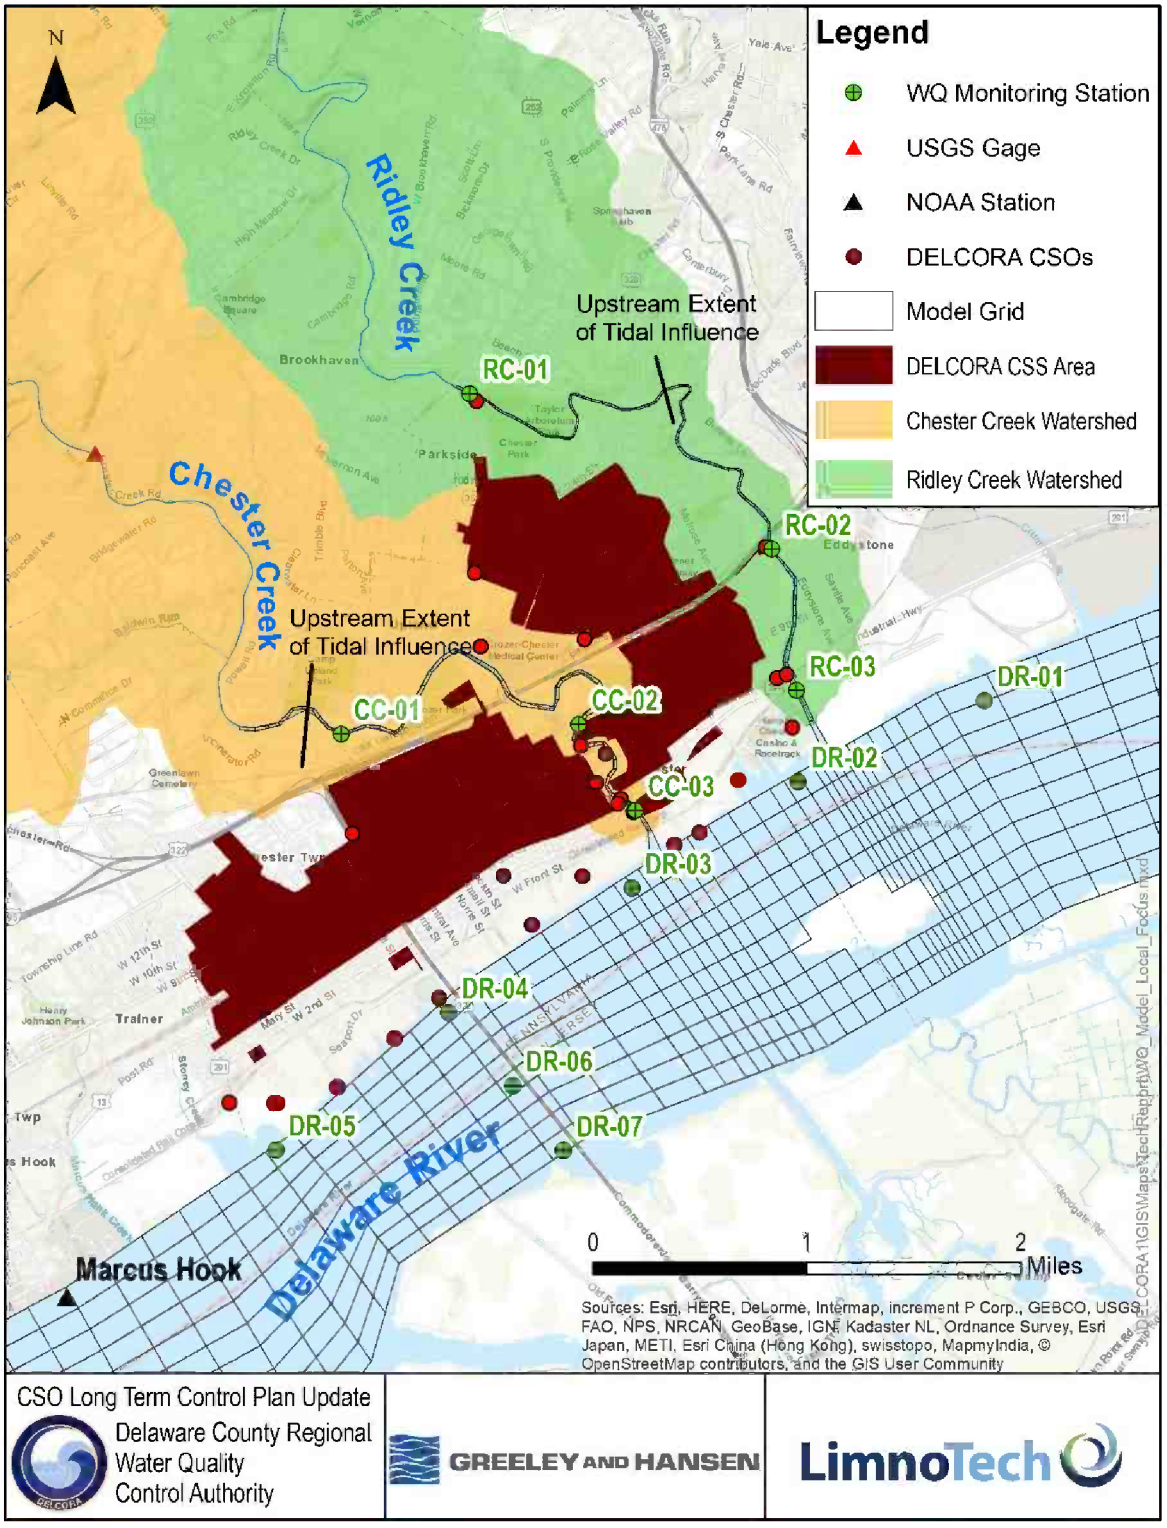


3.4.2.1 Model Extent and Grid Development

The intended use of the water quality model is to predict the local water quality near the DELCORA combined sewer outfalls. However, the extent of the model is much greater than this localized area in order to appropriately represent the mixing of DELCORA POC sources with background POC sources, and the back-and-forth tidal movement that occurs in the Delaware River. The DELCORA water quality model extends from the head of tide in Trenton, NJ to Delaware City, DE. The upstream limit was chosen because that is the limit of the tidal influence and because there is a USGS flow gage present. The downstream limit was chosen because it is well below the DELCORA CSO discharges and because there is a NOAA tidal station present. Both the USGS flow gage and the NOAA tidal station are used as boundary conditions to the model, as further described in Section 3.4.2.1.

The stream lengths that are represented in the model, along with the average grid cell dimensions are shown in Table 3-5. The model grid has the greatest detail near DELCORA CSOs to describe near-field concentration patterns during periods of CSO discharge, and less detail farther from DELCORA CSOs. Grid cell dimensions in Chester and Ridley Creeks were chosen to be long enough that they would not overly constrain the model time step and short enough that they would follow the sinuous paths of the creeks.

Table 3-5: EFDC Water Quality Model Grid Summary

	Miles of Stream Represented	Average Grid Cell Dimensions (LxWxD)*	Total Number of Cells Used	Average Number of Cells Across Stream Width	Average Number of Layers Through Stream Depth
Delaware River	73	1,000ft x 300ft x 23ft	3,766	10	4
Chester Creek	3.5	320ft x 90ft x 4ft	55	1	1
Ridley Creek	3.5	230ft x 60ft x 2ft	80	1	1

* Cell dimensions vary greatly across the model extent depending on the physical properties of the river.

3.4.2.2 Flow and POC Contributions

The EFDC water quality model includes flows and POC loads from a variety of sources, including:

- DELCORA CSOs, represented by the DELCORA H&H model and entered as flow and bacteria concentration time series at each location where DELCORA CSOs discharge into Ridley Creek, Chester Creek, and the Delaware River.
- Philadelphia CSOs, represented by the simplified Philadelphia CSO model, and entered as flow and bacteria concentration time series at the mouth of the tributaries where CSO discharges occur, or directly to the CSO discharge location along the Delaware River.

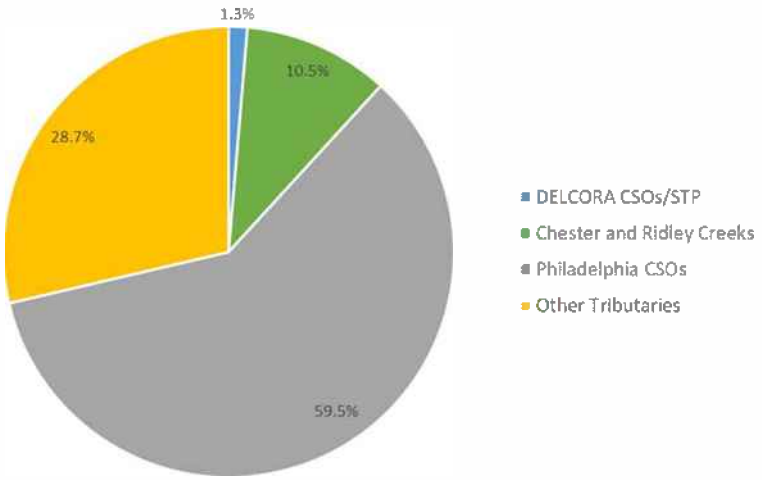
- Ridley and Chester Creek watershed sources, represented by the watershed model or USGS gage data, and entered as flow and bacteria time series at various locations along the two creeks, as explained in Section 3.1.2.9.
- Tributaries along the Delaware River but outside of the DELCORA project area, including, for examples, the Schuylkill River and Darby Creek. These are entered as flow and bacteria time series at the confluence of the tributaries and the Delaware River. The contributions from these tributaries were based on available USGS flow data. Average drainage area ratios were used for the ungaged portions of tributaries, including some tributaries which are entirely ungaged. Bacteria concentrations were estimated as they were for Ridley and Chester Creeks; by separating base flow and runoff and associating EMCs with each flow component, as explained in Section 3.1.2.9.

The respective percent contribution of modeled bacteria load from the different sources are shown in the figure below. The principle loads include the following:

- DELCORA CSO/STP: 1.3% of total load
- Chester and Ridley Creek above the CSO area: 10.5% of total load
- Philadelphia CSO: 59.5% of total load
- Other tributary loads: 28.7% of total load

These modeled bacteria loads were calculated by summing up the total flow contributions from each of the four major sources during both wet and dry weather conditions for the 3-year "Typical Year" application period. These volumes were multiplied by the respective EMC values to calculate the 3-year modeled load and relative percent contribution from each source. It should be noted that the relative contribution from the "Other Tributaries" source is the least constrained by actual monitoring data and is likely much higher in reality than what is shown in the figure. This load has little impact on the water quality and the calibration results near the DELCORA focus area.

Figure 3-9: Percent of Bacteria Load by Source



3.4.2.3 Hydrodynamic Processes

To quantify rates of transport and mixing, the receiving water model represents tidal hydrodynamics in the lower reaches of the creeks and in the Delaware River estuary. The main processes that effect river hydrodynamics include tidal phasing and amplitude, river velocities, flow contributions from tributaries along the Delaware River, and sediment bed resistance (roughness). To simulate the loss of POCs within the receiving water, a first-order, in-stream net decay rate was applied within the model.

Two boundary conditions are used to specify the hydrodynamic and water quality conditions at the upstream and downstream ends of the water quality model. At the upstream end of the model, near Trenton, NJ, flow from USGS gage #01463500 was used to specify the flow coming into the system. At the downstream end of the model, near Delaware City, DE, the Reedy Point NOAA gage #8551910 was used to specify the tidal water surface elevation. Constant bacteria concentrations of 10 #/100 mL were assumed at the upstream and downstream model boundaries, and model tests showed that the boundary conditions had a negligible influence on concentrations near the project area due to the long distances between the boundaries and the project area, and due to bacterial decay. Table 3-6 below summarizes the primary water quality model inputs and supporting data sources.

Table 3-6: Receiving Water Quality Model Inputs and Data Sources

Model Input	Data Source	Notes
Delaware River Bathymetry	NOAA bathymetric soundings	Used most contemporary data available for each reach of the Delaware River
Chester and Ridley Creek Bathymetry	LimnoTech bathymetric soundings	Survey conducted in 2017 (See appendix A)
Tributary Flow Rates	USGS gaged flow data	Used drainage area ratios to estimate flows in ungaged areas
Water Surface Elevations	NOAA 6-minute tidal water level data	Used NOAA gages within the model extent
Water Temperature	USGS daily water temperature data	Delaware River at Chester station (#01477050) Delaware River at Reedy Island Jetty (#1482800)
Meteorological Inputs (e.g. atmospheric pressure)	NOAA hourly meteorological data	Philadelphia International Airport
Upstream Boundary Condition	USGS gaged flow data	Delaware River at Trenton (#01463500)
Downstream Boundary Condition	NOAA 6-minute tidal water level data	Reedy Point station (#8551910)

Page intentionally left blank for double-sided printing

Section 4 Model Calibration

Model calibration is described in USEPA guidance (USEPA, 1994) as the "process of adjusting model parameters within physically defensible ranges until the resulting predictions give the best possible fit to the observed data." Model parameters and assumptions were initially defined to the extent possible based on site specific data. However, if site-specific data were not available, model parameters and assumptions were initially defined based on literature values. The calibration process fine-tuned these parameters, within reasonable bounds, to improve model calculations.

4.1 Site Specific Calibration Data

Site specific data used for calibrating the various models include USGS flow data, NOAA tide data, wet and dry weather monitoring within the DELCORA project area, and Delaware River Basin Commission (DRBC) monitoring data. These datasets are explained in further detail in the sections below. Water quality data was organized in a Microsoft (MS) Access database system to ensure consistency in naming and unit conventions, and for ease of extracting information for calibration purposes.

4.1.1 USGS Data

USGS flow data were used to calibrate the watershed model. The information is available through the USGS[10]. Two stations were used for calibration: Ridley Creek gage (#01476480) and Chester Creek gage (#01477000). The time period of 2006 to 2016 was used for watershed calibration, flow data from 2017 was used for the receiving water quality modeling calibration, and the time period of 1994-1996 was used for the typical period application. Availability of gage data during the typical period is variable, with a long period of data missing in Ridley Creek (9/22/1995 through 12/31/1996) and a few multi-day periods missing at both gages during the three year period. A third station at Trenton, NJ (#01463500) was used to specify the upstream boundary condition for the Delaware River portion of the water quality model. The locations of the USGS gages are shown in Figure 3-7.

4.1.2 NOAA Tide Data

Tide data representing tidal phasing (timing), amplitude (variations in water surface elevation), and current velocity (water speed and direction) were used to calibrate the hydrodynamic component of the water quality model. This information is available through NOAA[11]. Two tidal stations were used for calibration: the Philadelphia station (#8545240) and the Marcus Hook (#8540433) station. A third station at Reedy Point (#8551910) was used to specify the downstream boundary condition for the Delaware River portion of the water quality model. NOAA data from

[10] https://waterdata.usgs.gov/nwis
[11] https://tidesandcurrents.noaa.gov/

2017 was used to calibrate the hydrodynamics of the water quality model. The locations of the NOAA gages are shown in Figure 3-7.

4.1.3 DELCORA Wet and Dry Weather Monitoring Program

DELCORA conducted an extensive wet and dry weather monitoring program between March and June of 2017. Water quality data from this monitoring program was used to calibrate the water quality component of the water quality model and to set initial values for the dry weather, stormwater, and CSO POC event mean concentrations (EMCs). Monitoring was undertaken at thirteen (13) in-stream locations (seven on the Delaware River, three on Ridley Creek, and three on Chester Creek), four (4) CSO locations in the DELCORA combined sewer system area, and two (2) stormwater locations in the City of Chester municipal separate storm sewer system, as shown in Figure 3-7 and in more detail in Figure 4-1.

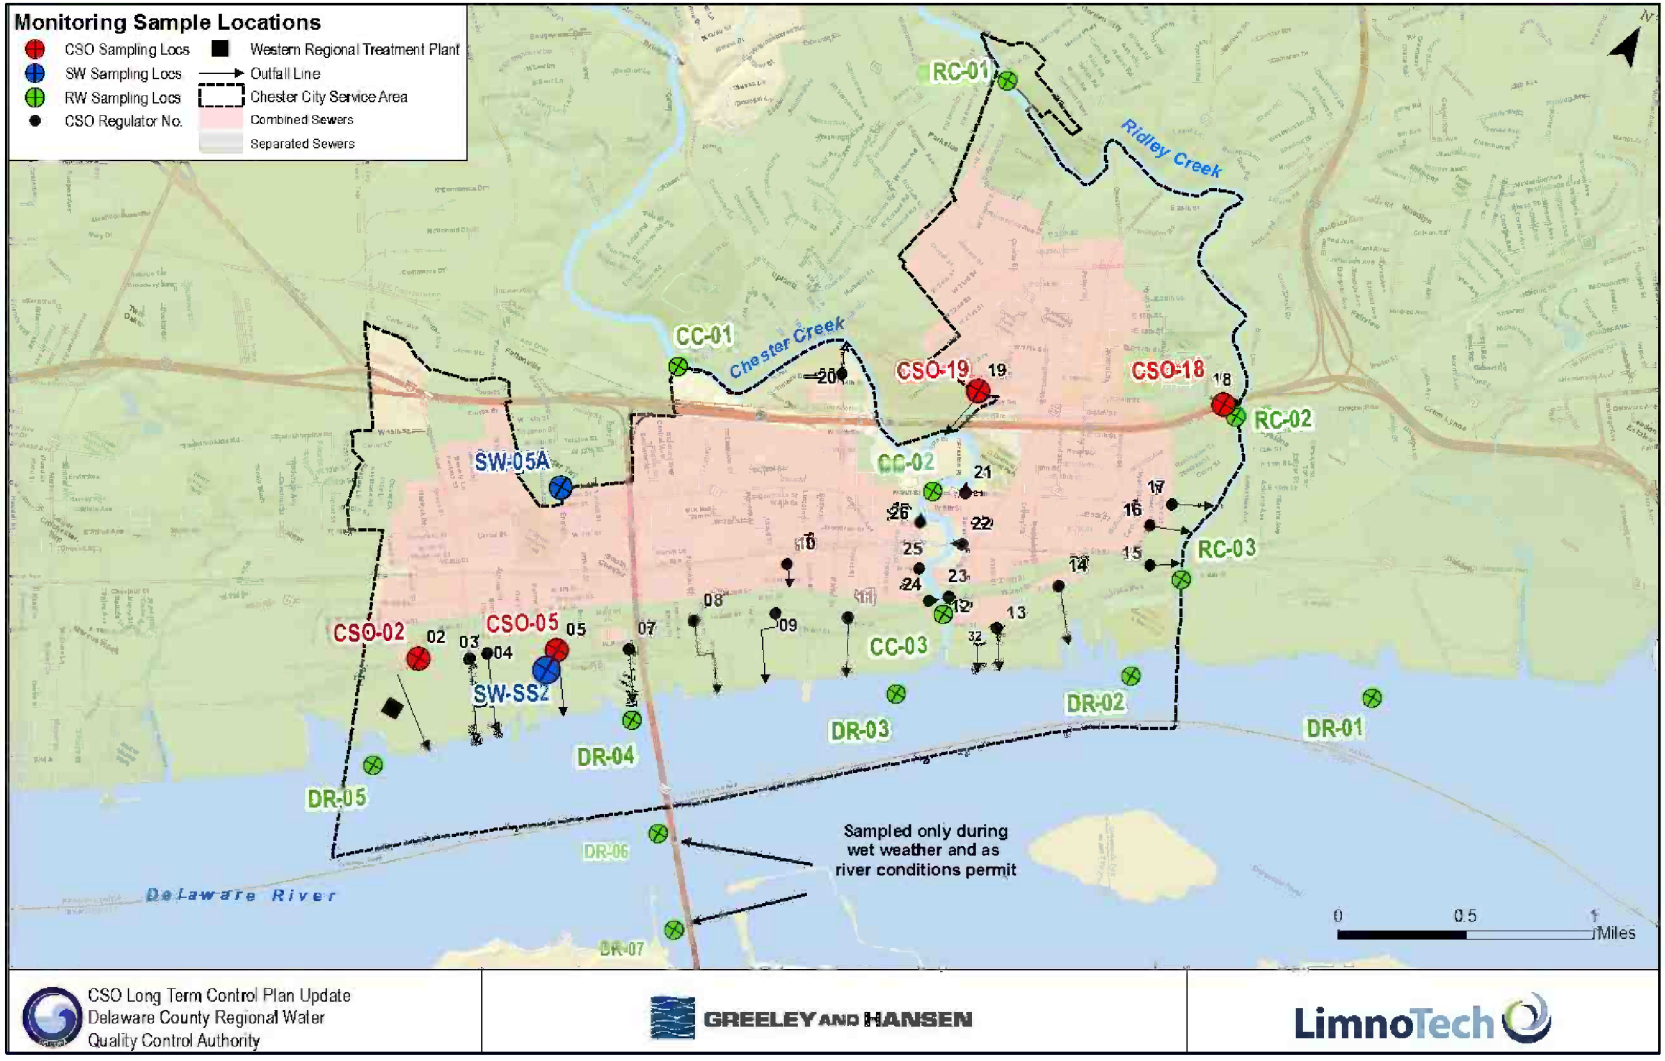
Monitoring locations were selected to characterize the watershed at a sub-watershed level, recognizing various political and hydrologic features, land uses and potential pollutant sources. Site selection and analytical parameters are designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. The POCs sampled were Fecal coliform, *E.coli*, and *Enterococcus*.

Water quality monitoring and sampling was conducted as follows:

- Eleven (11) in-stream locations in the vicinity of the DELCORA CSO area were sampled for water quality for (3) dry weather events. The mid-stream and far-shore Delaware River locations were not sampled during the dry weather surveys because the water quality in the river is found to be relatively uniform laterally due to the lack of active sources during dry weather. These dry weather events were distributed across the sampling season, which was from March through June of 2017. Grab samples and *in situ* measurements were collected at each location during each event.
- All thirteen (13) in-stream locations were sampled for water quality using grab samples and *in situ* monitoring for three (3) discrete wet weather events.
- Up to four (4) CSO and two (2) stormwater outfall locations were sampled for water quality for the same three (3) discrete wet weather. Samples for all outfalls were collected as grab samples.

The sampling events were planned and distributed across the sampling season, which was from March through June 2017.

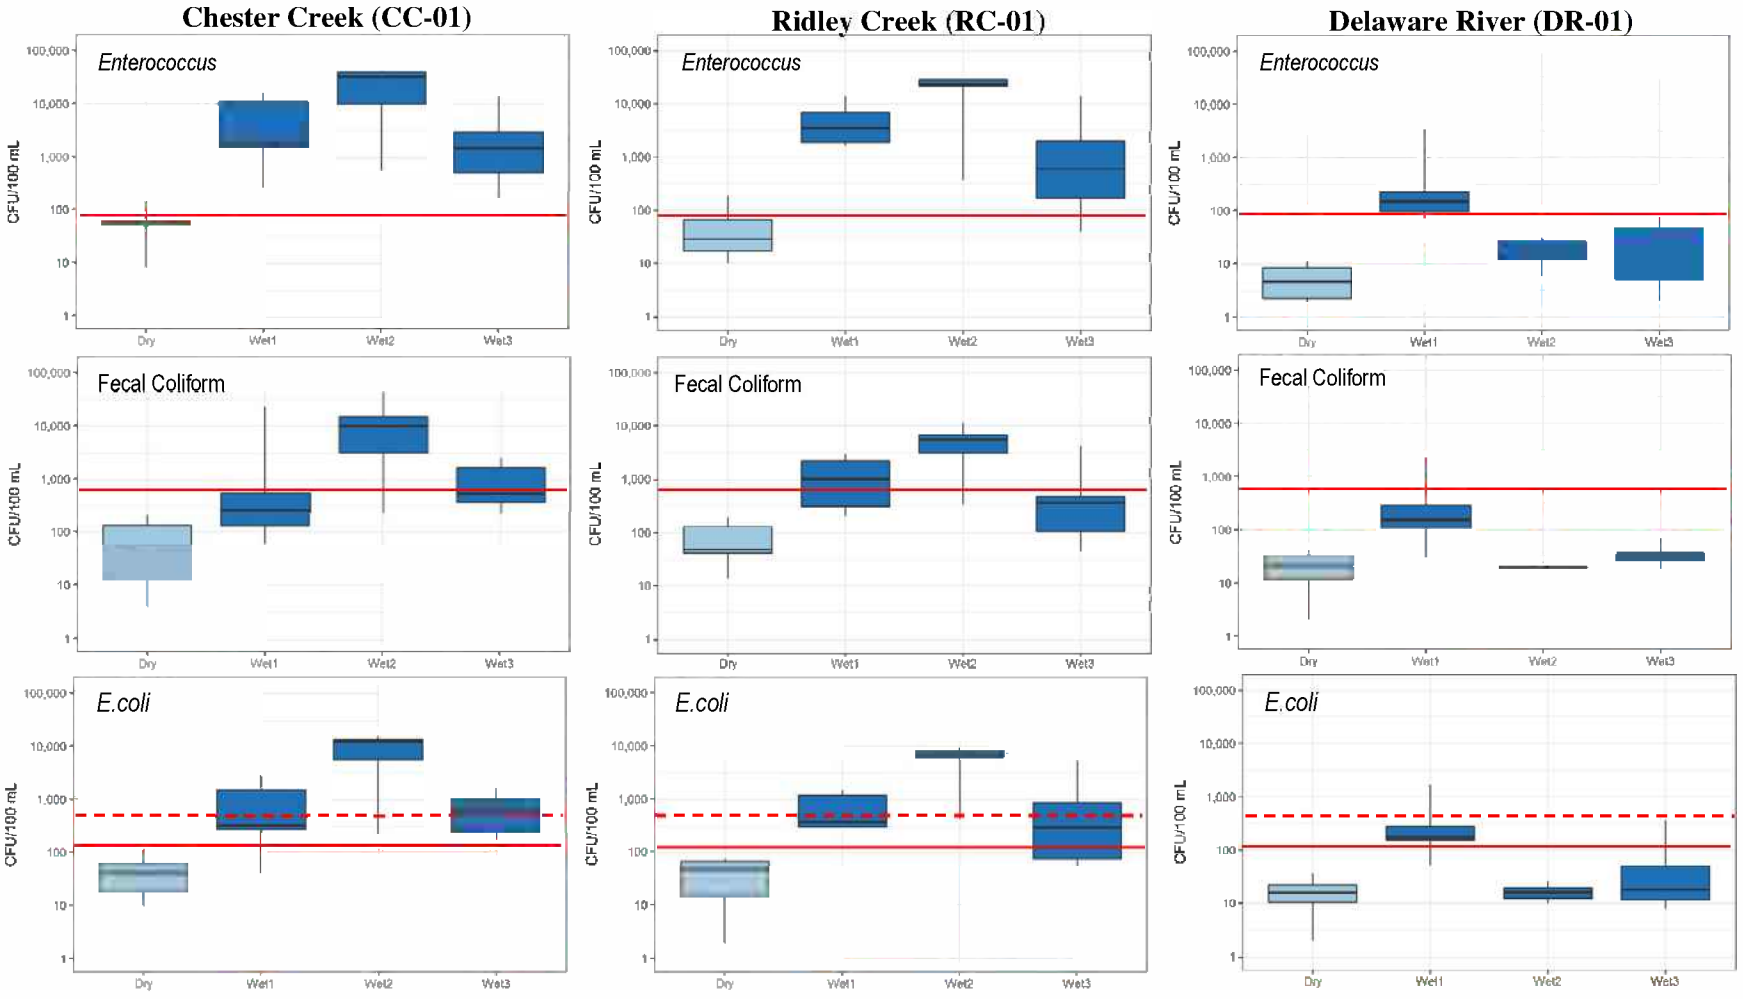
Figure 4-1: Receiving Water, Combined Sewer (CSO), and Stormwater (SW) Monitoring Locations



Detailed information on the results and observations from the DELCORA Water Quality Monitoring Program can be found in Appendix B. Some general observations are summarized below and shown in Figure 4-2.

- Dry weather POC concentrations at the most upstream locations (RC-01, CC-01, DR-01) in the creeks tended to be similar to each other;
- Dry weather concentrations at the most upstream locations (RC-01, CC-01) were mostly, but not always, below numeric thresholds used for water quality standard (WQS) criteria in the tributaries, and were well below WQS numeric thresholds in the Delaware River (DR-01);
- An increase in dry weather POC concentration from upstream to downstream was observed in each of the tributaries, suggesting there may be significant but currently unknown bacteria sources impacting these tributaries during dry weather. This occurs between sampling stations RC-01 and RC-02 in Ridley Creek and between CC-01 and CC-02 in Chester Creek, and is most pronounced for Fecal Coliform and *E.coli*;
- Wet weather concentrations at the most upstream monitoring locations in Chester Creek (CC-01) and Ridley Creek (RC-01) often exceed the monthly geometric mean WQS criteria for the three POCs. These stations are located upstream of the tidal influence, and the exceedances indicate that upstream areas of Ridley and Chester Creeks do not currently meet WQS (Figure 4-2). These data furthermore indicate the practical impossibility of meeting WQS through downstream CSO control.
- Wet weather concentrations at the most upstream monitoring location in the Delaware River sometimes also exceed numeric thresholds used for the monthly geometric mean water quality standard criteria, but less frequently as compared to the creeks. The E.coli statistical threshold value WQS was exceeded once under wet weather conditions during the sampling periods.
- The time series profiles in the Chester Creek and Ridley Creek waterbodies indicate that DELCORA's CSO discharges and Chester's stormwater discharges are not the only sources impacting these tributaries during wet weather. Upstream sources also contribute to high bacteria concentrations during wet weather events.

Figure 4-2: Sampling Results at Most Upstream Sampling Locations in the Creeks and the Delaware River



STV WQS (E.coli: 410 CFU/100ml (proposed); Fecal Coliform and Enterococcus: no STV standard)

4.1.4 DRBC Monitoring Data

The Delaware River Basin Commission conducts regular monitoring of bacteria through its "Delaware Estuary Boat Run" program[12]. Ambient samples are collected monthly along the navigational channel from the head of tide at Trenton, N.J. to the mouth of the Delaware Bay. Samples are collected at 22 stations, once monthly from April to October. Data collected in 2012 were used to validate the water quality component of the water quality model, especially outside of the DELCORA project area, to evaluate the accuracy of modeled POC loads from the Philadelphia CSOs and the Schuylkill River, which are estimated to be the largest POC loads to the estuary. The locations of the DRBC monitoring locations are shown in Figure 3-7.

4.2 Watershed Model Calibration

The modeled hydraulic and runoff response was refined through the calibration process. In this process, the percent impervious, Manning's roughness, RTK interflow and base flow parameters were adjusted within defensible (literature) ranges so that modeled runoff volumes and peak flows were consistent with the observed flow data. Runoff response was calibrated using 165 wet weather events from 2006 to 2016. The rainfall events were chosen to represent a range of different intensities, duration, and rainfall depth. Moreover, these events were chosen when there was consistency between the total rainfall depth at Philadelphia International Airport and observed flow at the Ridley and Chester Creek USGS gages. Two criteria were used to evaluate "consistency" between observed precipitation and flow: (1) precipitation events must increase baseflow by at least 3 times, and (2) the observed flow response occurs within 4 hours of the precipitation event. Calibrating to this subset of events helps minimize the effect of issues with spatial variability of rainfall.

Calibration was evaluated both on total runoff volume, peak flow rates, and timing of the flow response. Various types of plots were used to help assess the calibration, including 1-to-1 plots, event-based time-series hydrographs, and bar charts. To evaluate the overall reasonableness of the watershed calibration, a weight of evidence approach (USEPA, 2015b; Donigian, 2002) was applied using several evaluation metrics, including:

1. Goodness of fit based on correlation coefficients for a wide range of calibration events;
2. Visual checks on continuous time series hydrograph data; and
3. Long term annual performance.

The performance of the model was first evaluated using 1-to-1 plots for comparisons of wet weather event flow volume and peak flows. This is illustrated in Figure 4-3. Both the correlation coefficient (R^2) and the Integral Square Error (ISE) can be used as measures of goodness-of-fit between observed and modeled hydrographs (Sarma, 1969). Overall, the watershed model performed satisfactorily for the total event volume and for the peak flow rates, as shown in the

[12] http://www.state.nj.us/drbc/quality/datum/boat-run.html#3

table below. The slope of each trend line is nearly 1, indicating that the modeled runoff response is unbiased.

Table 4-1: Watershed Model Performance Metrics

	Ridley Creek		Chester Creek	
	R^2	ISE	R^2	ISE
Total Event Volume	0.778 (Good)	5.6 (Very Good)	0.778 (Good)	4.61 (Very Good)
Peak Flow Rate	0.61 (Fair)	8.84 (Good)	0.605 (Fair)	7.2 (Good)

In addition to 1-to-1 plots, a visual check of flow time series (hydrographs) was conducted for the time period of March through May of 2017, when wet weather water quality sampling was conducted. Figure 4-4 and Figure 4-5 compare the observed and modeled flow hydrographs for Chester and Ridley Creeks respectively. The modeled response to the rainfall at the Philadelphia Airport closely tracks the gaged response observed at the two USGS gages. The timing of the peaks occur as expected relative to the occurrence of the rainfall event and to the observed data, providing confidence that the routing parameters used were adequately calibrated. The hydrograph figures also support the previous conclusion that overall, the model predicts volume well, but slightly over predicts peak flow rates. The hydrographs show that the model tends to under predict the effect of baseflow and interflow, despite using the SWMM RTK function.

The hydrograph figures show that there was a notable discrepancy between the observed data and modeled results for the event labeled as "Wet Weather Event 3". This event and other specific wet weather events like this where the modeled runoff volume differed significantly from the observed runoff volume were reviewed more closely. Based upon this review, it was concluded that notable deviation between modeled and observed runoff volumes can occur when rainfall is not uniform over the watershed (e.g. when rainfall is concentrated in a small portion of the watershed) due to the fact that a single rain gage (Philadelphia Airport) is used in the watershed model to represent rainfall conditions over the entire watershed.

In the case of Wet Weather Event 3, the rainfall was concentrated in the vicinity of the City of Chester and areas east of the Delaware River (Figure 4-6). So while the observed rain at the Philadelphia Airport is significant (0.51 inches), very little rainfall fell in the upstream areas of the Ridley and Chester watersheds (less than 0.1 inches), and consequently, very little wet weather flow was observed at the two USGS flow gages (consistent with what would be expected from a small (<0.1-inch) rainfall event) whereas the model predicted more flow (consistent with what would be expected from a 0.5-inch storm).

While the limited number of rainfall gages is a constraint on the accuracy of the watershed model for a single wet weather event, on a long term basis (such as the three year typical hydrologic period) the model provides reasonably accurate estimates of creek flow, as demonstrated in Figure 4-3 on the previous page. In other words, even if an individual event was modeled too high or too low, on a long term basis, the model produces a typical response to rainfall conditions and yearly modeled creek flows during dry weather and wet weather are consistent with the observed data.

Figure 4-3: 1 to 1 Watershed Model Wet Weather Calibration Plots

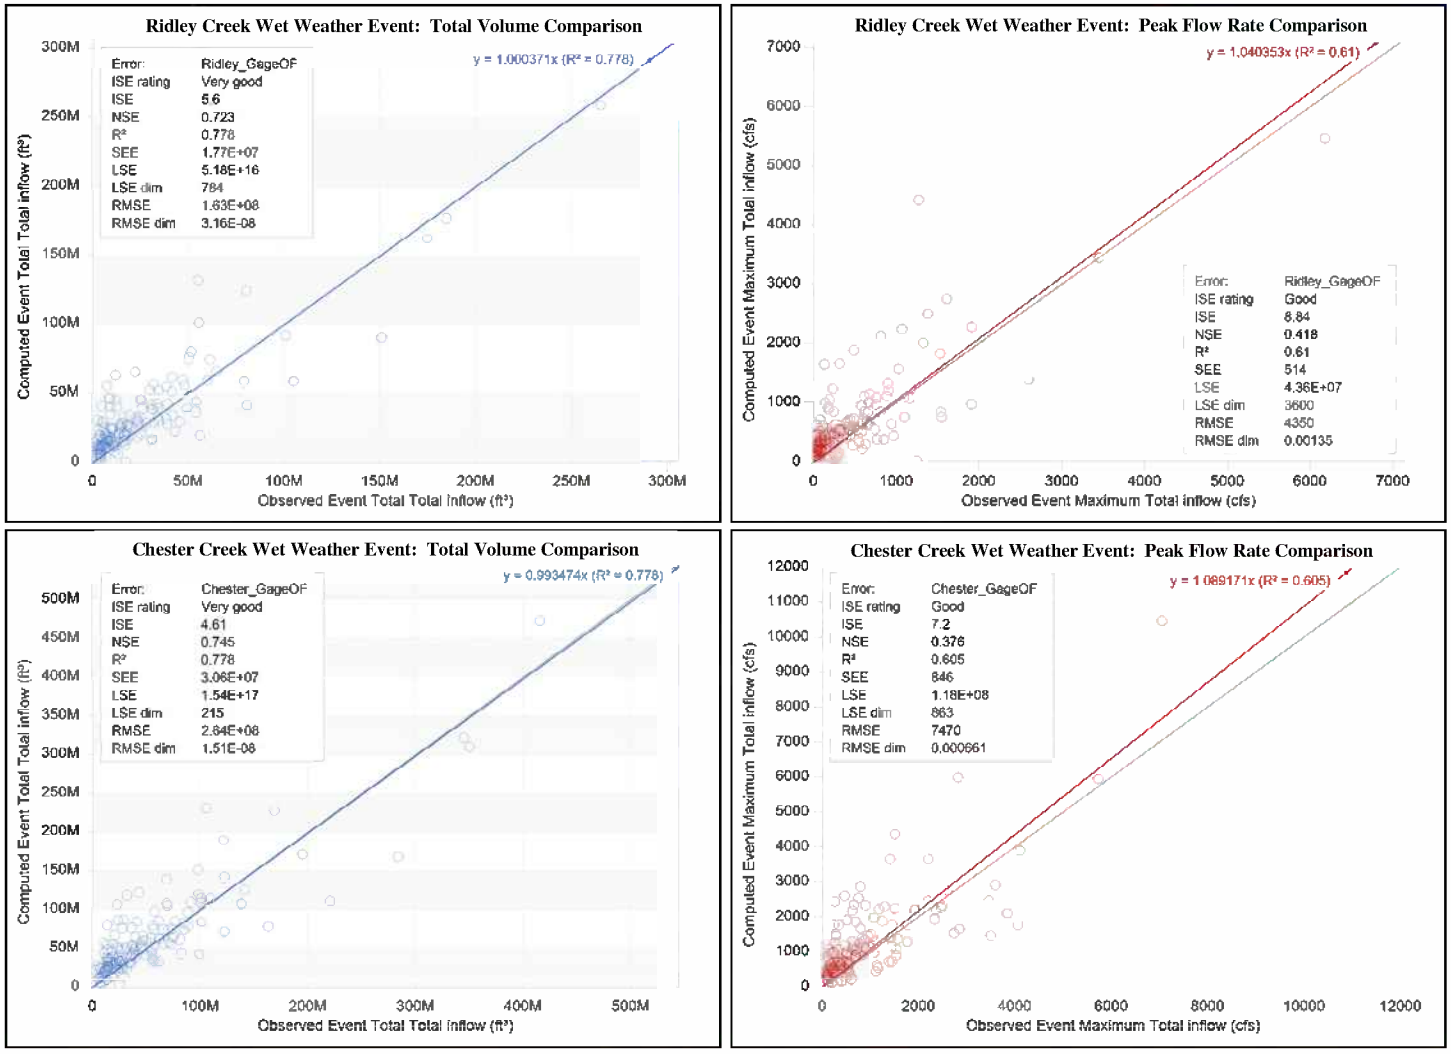

Figure 4-4: Chester Creek - Comparison of Modeled vs. Observed Flow Hydrograph

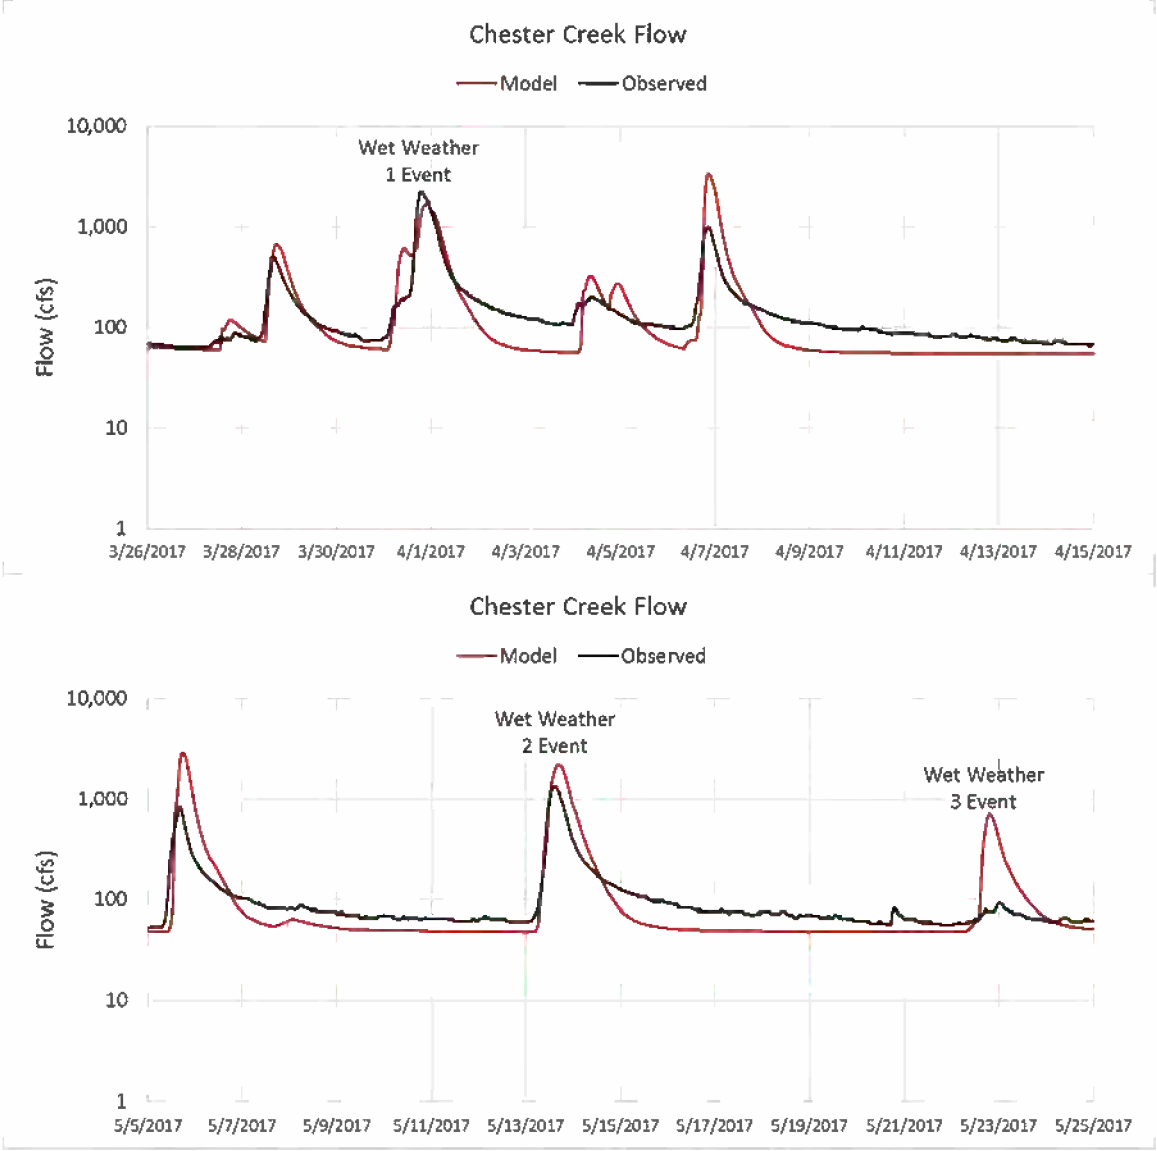

Figure 4-5: Ridley Creek - Comparison of Modeled vs. Observed Flow Hydrograph

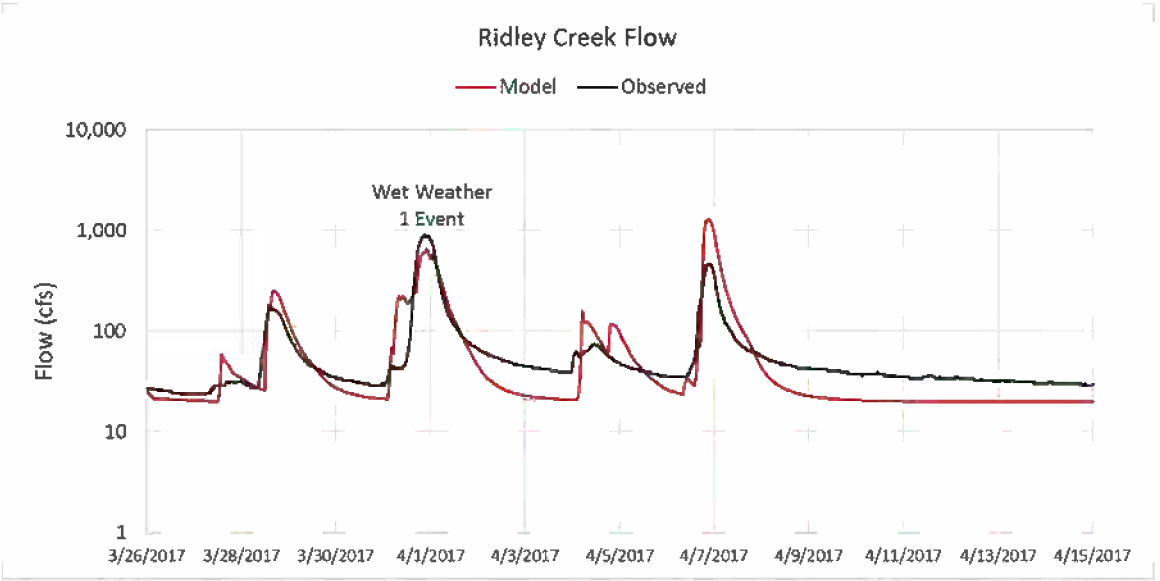

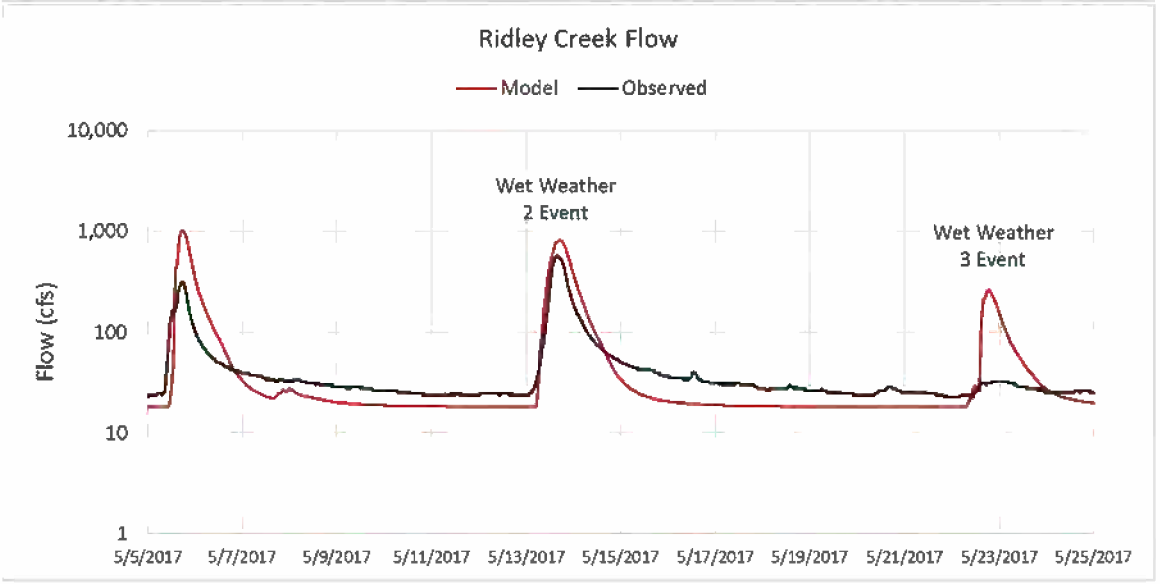

Figure 4-6: Rainfall Distribution for Wet Weather Event 3 (May 22, 2017)

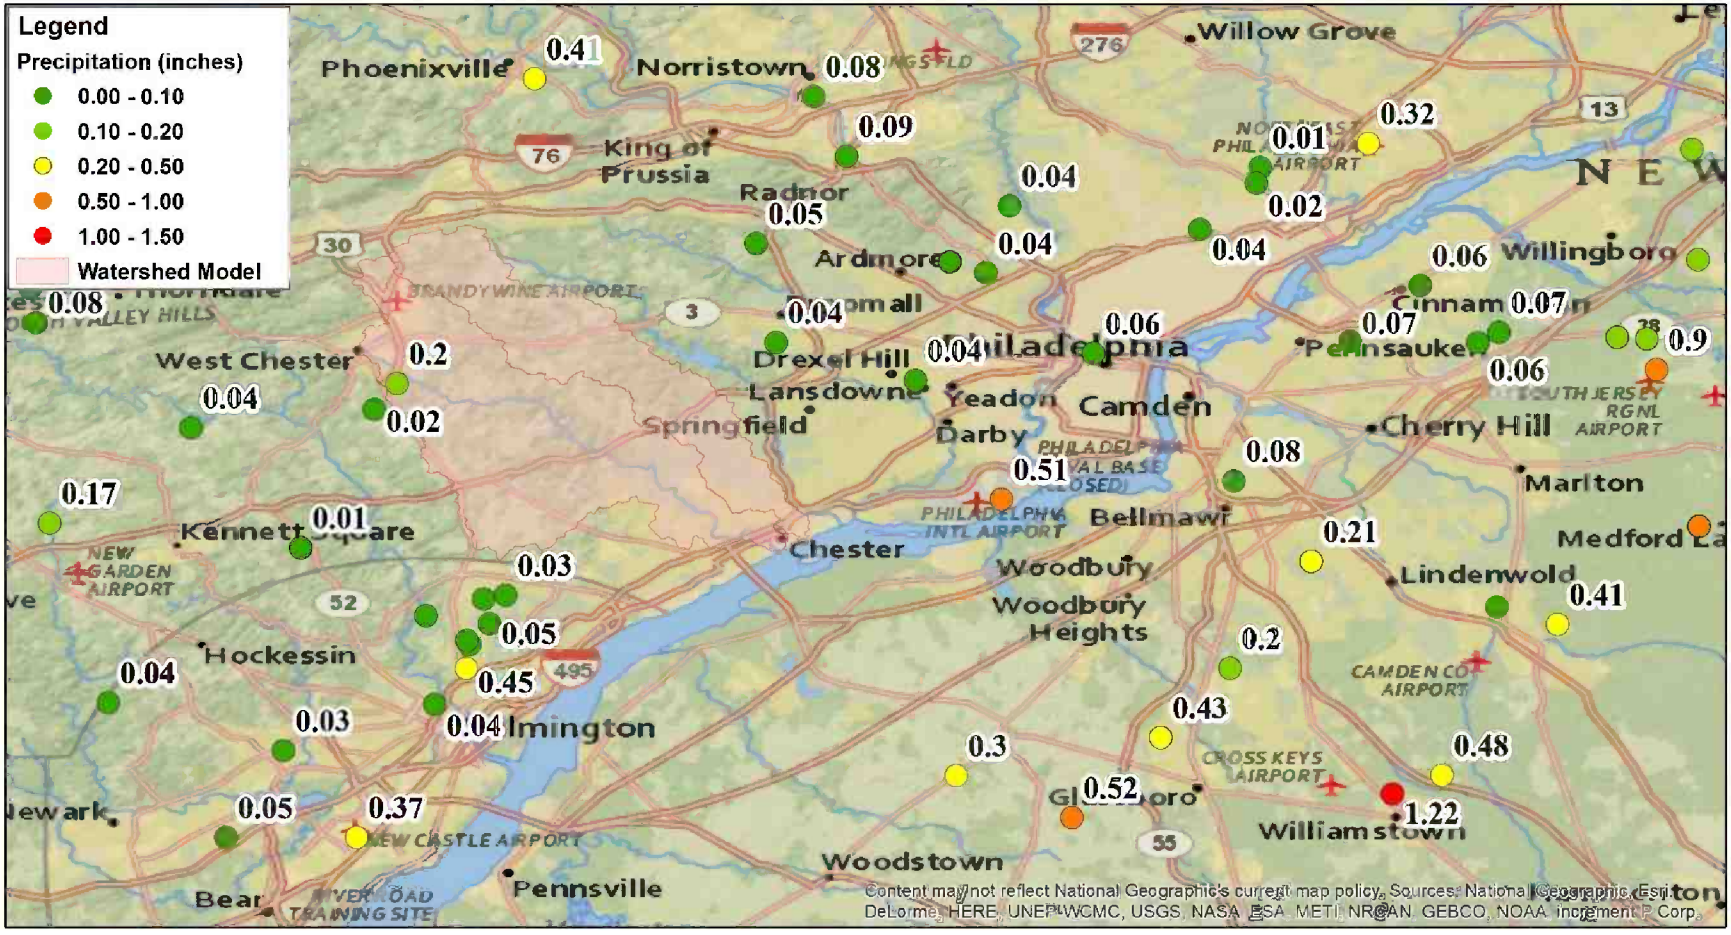


In addition to evaluating the performance of the watershed model on an event basis, the overall annual performance was evaluated. This analysis accounts for contributions from base flow, interflow, and runoff, and compares the model performance against observed flow volume at the USGS gages. The results are shown in the table below and in Figure 4-7.

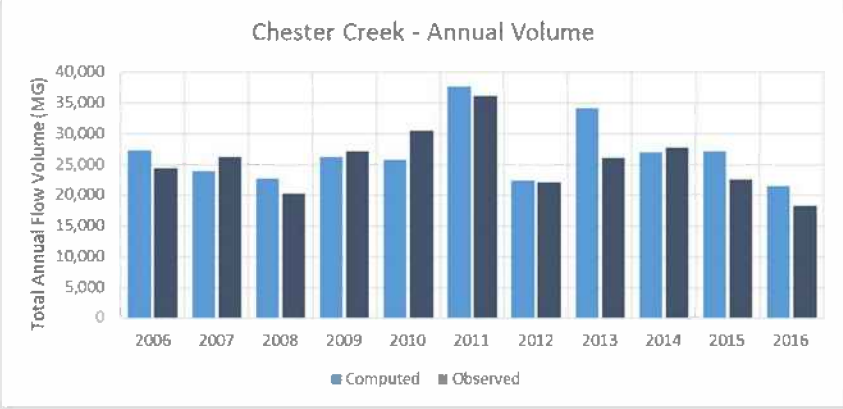
Table 4-2: Watershed Model Overall Annual Performance

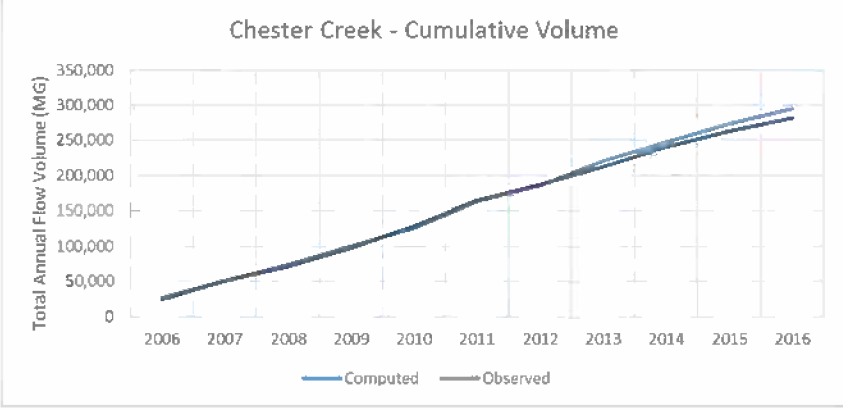
	Chester Creek			Ridley Creek		
Year	Modeled Volume (MG)	Observed* Volume (MG)	Percent Difference	Modeled Volume (MG)	Observed* Volume (MG)	Percent Difference
2006	27,324	24,340	12%	13,093	10,865	21%
2007	23,999	26,172	-8%	11,086	12,005	-8%
2008	22,674	20,278	12%	10,460	8,101	29%
2009	26,255	27,175	-3%	12,486	11,540	8%
2010	25,762	30,512	-16%	12,234	13,539	-10%
2011	37,727	36,184	4%	18,844	16,794	12%
2012	22,375	22,068	1%	10,297	9,390	10%
2013	34,210	26,094	31%	16,981	11,234	51%
2014	26,980	27,722	-3%	12,890	12,093	7%
2015	27,108	22,639	20%	12,948	8,513	52%
2016	21,487	18,226	18%	9,845	7,555	30%

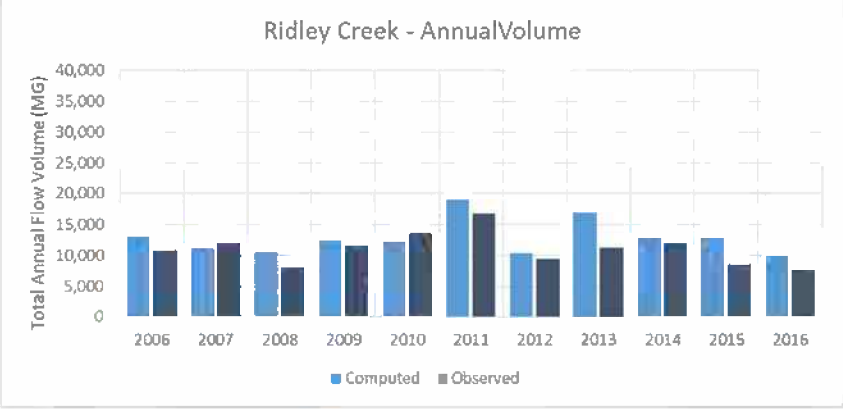
*Missing gage data periods were interpolated using the average flow over the whole time series.

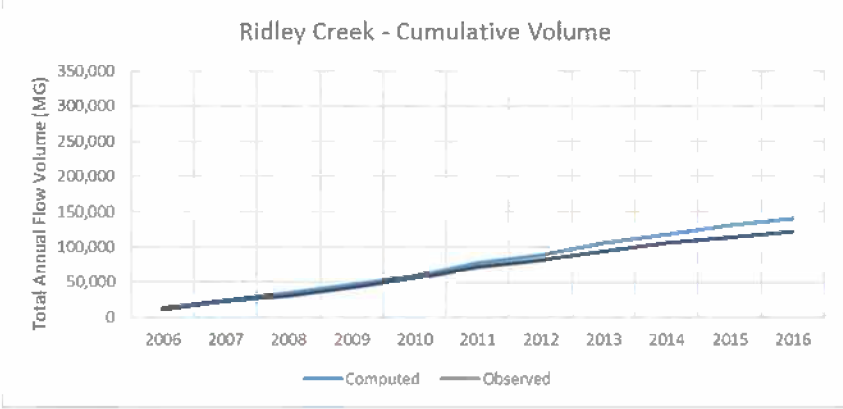
This table shows that the model response is variable from year to year, sometimes over predicting and sometimes under predicting total volume. Our understanding is that these over- and under-predictions are largely driven by rainfall variations over the watershed that are not represented in the watershed model because of lack of limited precipitation data over the entire watersheds. In other words, if the total rainfall observed at the Philadelphia Airport is larger than what was observed in the upper portions of the watershed, then the model would likely over predict total flow volume compared to the observed total flow volume. Conversely, if the total rainfall observed at the Philadelphia Airport is smaller than what was observed in the upper portions of the watershed, then the model would likely under predict total volume compared to the observed total volume. For example, in 2010, less rain was recorded at the Philly Airport than at the West Chester Rain Gage, which is located north of the Chester Creek Watershed, and the model accordingly under predicted total volume in that year. And in 2013, more rain was recorded at the Philly Airport than at the West Chester Rain gage, and the model over predicted volume in that year.

Figure 4-7: Comparison of Modeled vs. Observed Annual Flow Volume and Cumulative Flow Volume









This pattern was observed for some but not all of the years, suggesting that other factors may contribute too. One of those factors may be that there was missing flow data at the two USGS gages during the calibration period. The missing data was replaced by the average flow for the purpose of this specific evaluation, but that may have also led to some over or under prediction in the observed flow volumes. Due to the uncertainty related to rainfall and flow data, this evaluation was not used to fine-tune the calibration because it would compromise the calibration of the individual calibration events and hydrographs.

Taking into account the results from the 1-to-1 plots that showed satisfactory correlation coefficients (see Table 4-1 and Figure 4-3) and the visual checks of the flow time series that confirmed satisfactory responsiveness of the model to rainfall data, the watershed model was deemed sufficiently calibrated, consistent with observed data, and reliable to be applied for the purpose of predicting flows when observed data are not available during the typical year period. As explained in Section 4.1.1, availability of gage data during the typical period is variable, with a long period of data missing in Ridley Creek (9/22/1995 through 12/31/1996) and a few shorter periods (of a few days at a time) missing at both gages during the three year period.

To estimate tributary water quality concentrations, modeled tributary flows were separated into dry and wet weather flow components based on the methodology described in Section 3.1.2.3. Dry weather is the sum of base flow and interflow, while wet weather is represented by the direct runoff and channel precipitation. Statistical reference concentrations for the POC event mean concentrations were initially estimated based on the sampling data obtained from the DELCORA Wet and Dry Weather Monitoring Program (See section 4.1.3). These reference concentrations are shown in Table 4-3. It was somewhat surprising that the *enterococcus* results tended to be higher than the fecal coliform and *E.coli* data. However, there is very little data in the literature for *enterococcus* so it was difficult to assess whether these results are unusual. The fecal coliform concentrations however, are within the range of urban storm water bacteria concentrations reported in the literature (EPA 2004). It should also be noted that, as previously shown in Section 4.1.3, the monitoring data shows that wet weather concentration at the most upstream monitoring locations (located upstream of CSO influence) in Chester Creek and Ridley Creek often exceed the applicable monthly geometric mean or STV WQS concentration for all three POCs.

Table 4-3: Reference POC Concentrations Used to Develop EMCs for Modeled Flows

	Enterococcus (#/100 mL)			Fecal Coliform (#/100 mL)			*E.coli* (#/100 mL)		
	25th %ile	75th %ile	Geo-mean	25th %ile	75th %ile	Geo-mean	25th %ile	75th %ile	Geo-mean
Dry Weather Flow	19	65	39	22	180	40	13	69	28
Wet Weather Flow	8,500	59,500	31,784	799	22,750	4,516	668	18,750	3,042

The POC concentration assumptions were further refined during the water quality model calibration process, which is described in Section 4.5.2. Event mean concentrations were applied to each dry and wet weather flow component to estimate POC loads in the tributaries. This method allows for time-variable POC concentrations that are consistent with the timing of the wet weather flow responses. The final EMCs were determined based on the results of the receiving water model calibration, as explained in Section 4.5. The selected dry weather EMC (30 #/100 mL) is consistent with the geometric mean of the observed data. It was also not varied by POC because the dry weather sampling data were variable but had similar central tendencies. The final calibrated EMC values used in the watershed model are shown in the table below.

Table 4-4: Calibrated POC EMC values for Ridley and Chester Creek

Model Input	*Enterococcus* (#/100 mL)	Fecal Coliform (#/100 mL)	*E.coli* (#/100 mL)
Dry Weather Flow	30	30	30
Wet Weather Flow	20,000	8,000	4,000

4.3 DELCORA Combined Sewer System Model

DELCORA CSO flows were obtained from the calibrated DELCORA CSS H&H Model. The calibration and application of the CSS H&H model is discussed in detail in the H&H model report (DELCORA, 2016).

To model the POC loads from the CSO system, Statistical reference concentrations for the POC event mean concentrations were initially estimated based on the sampling data obtained from the DELCORA Wet and Dry Weather Monitoring Program (See section 4.1.3). These reference concentrations are shown in Table 4-5. Measured concentrations were within the range of CSO bacteria concentrations reported in the literature (EPA, 2004) but tended to be lower than the median concentrations measured in other communities. Several potential explanations for this include: 1) the highly industrialized nature of the DELCORA service area may result in a smaller bacteria load via runoff to the combined system than communities with less industrial land; 2) DELCORA may have a relatively high percentage of stormwater in the combined system.

The data presented a challenge in that the *E.coli* values are generally higher than the fecal coliform values, which is not physically possible since *E.coli* is a subset of fecal coliform. These data were therefore used as initial estimates, but then further refined and adjusted during the water quality model calibration process so as to reflect both the physical constraints (i.e.: *E.coli* EMCs that are smaller than Fecal Coliform EMCs) and the observed ranges.

Table 4-5: Reference POC Concentrations Used to Develop EMCs for the Modeled DELCORA CSOs

	Enterococcus (#/100 mL)			Fecal Coliform (#/100 mL)			*E.coli* (#/100 mL)		
	25th %ile	75th %ile	Geo-mean	25th %ile	75th %ile	Geo-mean	25th %ile	75th %ile	Geo-mean
CSO Concen-tration	42,250	191,750	81,510	53,000	157,000	95,310	66,000	265,500	129,920

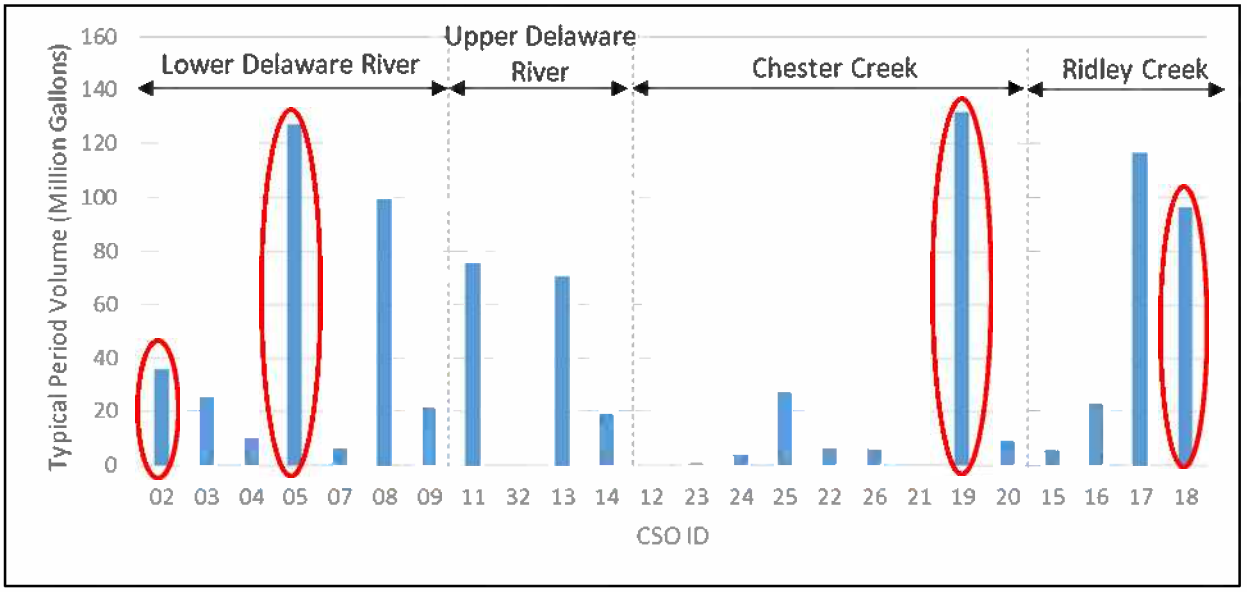
The water quality model was ultimately calibrated using the CSO EMCs shown in Table 4-6 below.

Table 4-6: Calibrated POC EMC Values for the DELCORA CSOs

Model Input	*Enterococcus* (#/100 mL)	Fecal Coliform (#/100 mL)	*E.coli* (#/100 mL)
CSO EMC	125,000	150,000	125,000

Figure 4-8 illustrates the distribution of CSO volumes among the various outfalls by receiving water. The CSOs that were part of the wet weather monitoring program are circled in red.

Figure 4-8: CSO Volumes for Typical Period (1994-1996)



POC loads associated with DELCORA CSOs are estimated by multiplying modeled CSO flow rates by POC EMC concentrations.

4.4 Philadelphia Simplified CSO Model

Calibration of this SWMM model relied principally on information from annual reports of Philadelphia CSO model overflows (PWD, 2017). Tables from these reports, which describe the annual overflow volume, number of overflow events, and total overflow duration per CSO, helped to constrain model inputs related to the combined sewersheds, including the total impervious area, depression storage, average surface slope, and sewershed width and length.

Model parameters described above were first calibrated to reported overflow volumes and frequencies from the 2016 annual CSO reports, then validated using the 2015 annual CSO reports. Modeled and reported overflow volumes and frequencies were in close agreement for the 165 CSO locations in both 2015 and 2016, as shown in Figure 4-9 and Figure 4-10. However, at one overflow location, identified as "F_FRFG," the reported overflow changed significantly between 2015 (1,250 million gallons) and 2016 (<1 million gallons), indicating that some change occurred in the Philadelphia sewer system that eliminated overflows at that discharge location. The SWMM model was configured for the 2016 condition for the water quality calibration. Overall, the model provides reliable estimates of Philadelphia CSO overflow volume and frequency of discharge.

The process for calibration of the model was as follows:

1. Gather CSO information from the Philadelphia CSO Annual Reports[13], including total annual overflow volumes, number of overflow events, and overflow event durations.
2. Develop annual rainfall event statistics, including total rainfall depth and duration for Philadelphia Airport rain gage.
3. Rank the developed rainfall events by total depth and distribute the reported overflow volume over the reported number of overflow events for each CSO. This method assumes that overflows occur during the highest volume rainfall events and that the overflow volume is proportional to the total rainfall depth.
4. Parameterize the SWMM runoff model relying principally on the total assumed rainfall depth which cause overflows, and the reported overflow characteristics (volume, number of overflows and duration).
5. Use the SWMM runoff model to compute the hourly CSO response for each rainfall event and CSO location.
    a. Assume 100% impervious sewersheds and calculate necessary sewershed area for each CSO by dividing the reported annual overflow volume by the assumed total rainfall depth causing overflow.
    b. Set depression storage input equivalent to largest rainfall depth that does not result in an overflow. Further, a constant evaporation rate was used to deplete the depression storage between rainfall events.

[13] http://www.phillywatersheds.org/what_were_doing/documents_and_data/CSO_SW_AnnualReports

c. Adjust sewershed width-to-length ratio, which influences runoff dynamics, for consistency with reported number of overflow events and reported overflow duration.

4.5 Receiving Water Model Calibration

The receiving water model calibration was comprised of two components: calibration of the hydrodynamic calculations (water movement), and calibration of the water quality calculations. These are explained in the following sections.

4.5.1 Hydrodynamic Model Calibration

Calibration of tidal hydrodynamics occurred first. Modeled tidal propagation is principally influenced by sediment bed resistance which varies due to changes in sediment grain size and bed forms. Model inputs related to bed resistance (roughness) were calibrated for consistency with NOAA tidal data at multiple stations near DELCORA CSOs, including the Marcus Hook Station (only water level measured) and Philadelphia Station (water level and currents measured). Modeled and observed water levels were compared for the 2017 water quality sampling period (March through June 2017). The model's representation of changes in tidal phasing and amplitude along the Delaware River estuary, which influence rates of pollutant transport and mixing, were refined during the calibration process.

Figure 4-11 and Figure 4-12 illustrate the hydrodynamic model performance relative to observations. These figures show good agreement between modeled and observed water levels and sufficient agreement between modeled and observed current velocities. Modeled current velocities tend to be low relative to observed current velocities, which is likely due to differences in scale between the observations and the model output. Model output represent average velocities over approximately a 200 foot width and 1,400 foot length, while the observations represent velocities at a much smaller scale (i.e. tens of feet laterally and vertically). Consistency between modeled and observed water levels is a strong indication that at larger spatial scales (i.e. the scale of the model grid and larger scales), the model accurately computes tidal current velocities.

4.5.2 Water Quality Calibration and Validation

4.5.2.1 Approach

The water quality model component was calibrated to sampling data collected in 2017 by DELCORA (see section 4.1.3) and validated to water quality data collected in 2012 by the Delaware River Basin Commission (DRBC). The intent of the calibration is to refine initial POC load (EMC and flow) estimates and the assumed first-order, in-stream POC net decay rate. The POC loads control the amount, the timing, and the intensity of the bacteria loads from the various sources to the receiving water. The decay rate then controls how quickly bacteria decays (decreases in concentration due to the net effects of multiple bacterial processes) over time. The calibration approach was to adjust POC load and decay rate values, evaluate changes in model results against the entire calibration dataset, and identify the model values that were most consistent with the central tendencies of the dataset by stream.

The central tendencies are evaluated through the use of event-based pollutographs and 1-to-1 plots. The pollutographs were evaluated using visual checks for individual events at relevant water quality stations. These visual checks include an evaluation for goodness of fit with respect to the modeled vs observed concentrations, and the time-response of the POC concentrations. The 1-to-1 plots were evaluated with respect to how closely the modeled data could replicate the observed

data within a certain range to account for the typical variability observed with bacteria data. The intent of the water quality calibration was to find the overall best fit across all of the different sampling events and all the relevant monitoring stations, with more emphasis placed on the water quality stations within the DELCORA CSO area. This approach invariably leads to calibration results that are better at some locations or for some events than others. Using different POC load assumptions may improve results for some stations and events, but may diminish results for other stations and events. Model assumptions were refined to obtain the best fit across all of the stations.

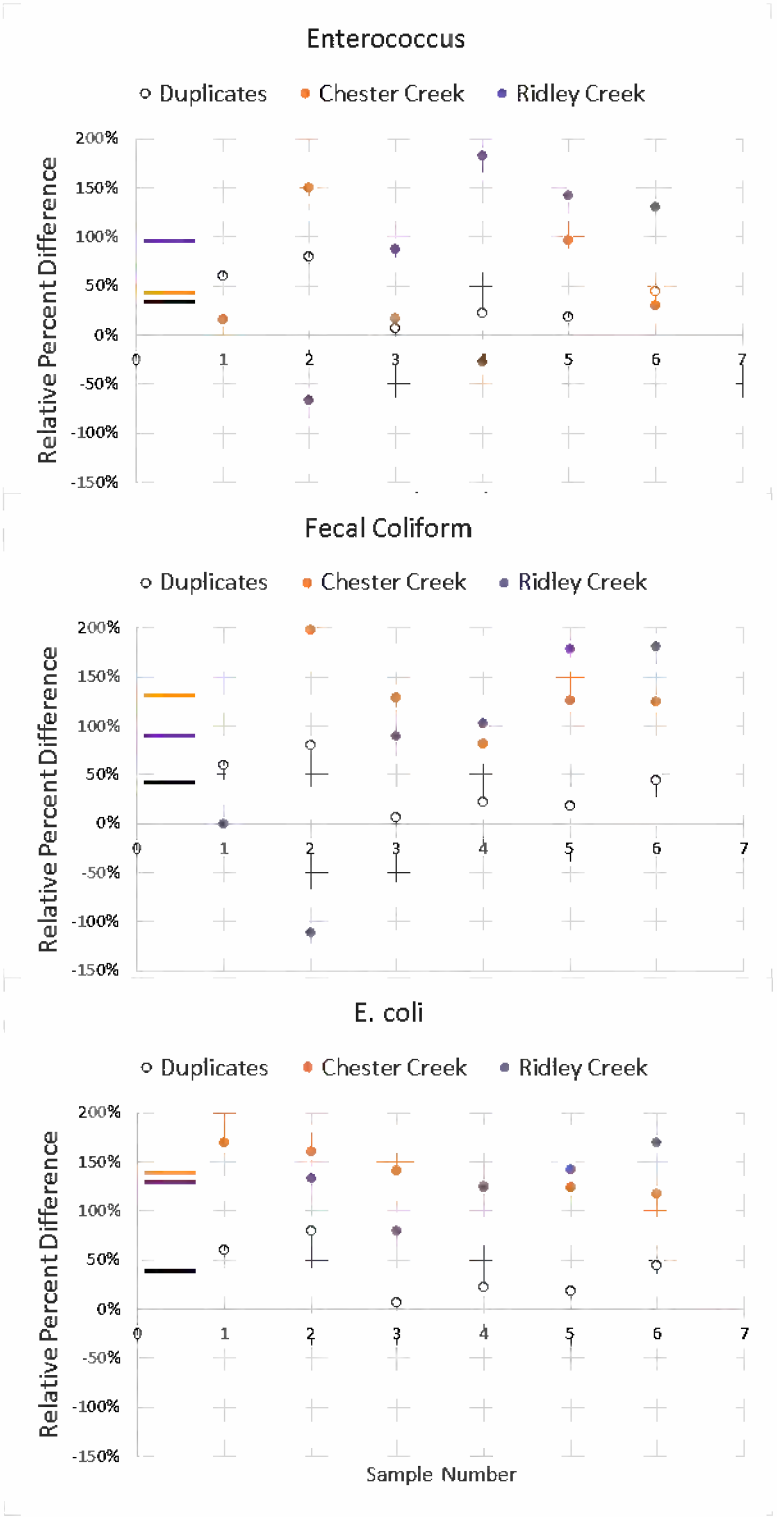
The approach focused first on establishing the appropriate dry weather model values, followed by the wet weather model values. Based on this approach, the decay rate was calibrated to 1.0 per day (1/day), dry weather flow POC concentrations were set to 30 #/100 mL, and wet weather POC EMCs for the tributaries and CSOs were calibrated to the values listed in the table below.

Table 4-7: Model Inputs for POC EMC Concentrations

Model Input	*Enterococcus* (#/100 mL)	Fecal Coliform (#/100 mL)	*E.coli* (#/100 mL)
Background Tributary Runoff POC Concentration	20,000	8,000	4,000
DELCORA and Philadelphia CSOs POC Concentration	125,000	150,000	125,000

As discussed in Section 4.1.3, the results from DELCORA's monitoring program showed an increase in POC concentration from upstream to downstream in each of the tributaries, indicating there may be bacteria sources entering these tributaries during dry weather. Dry weather POC concentrations generally appreciably increase from the most upstream sampling stations (RC-01 and CC-01) to the next downstream sampling stations (RC-02 and CC-02), as illustrated in the figure on the next page. This figure shows the relative percent difference in concentrations from the upstream to downstream sampling locations. When the relative difference is positive, it indicates an increase in concentration from upstream to downstream. While small (+/- 50%) changes could be due to the typical variability observed in sampling data, larger increases (>50%) could be indicative of a bacteria source entering the tributary somewhere between CC-01 and CC-02, and between RC-01 and RC-02. These unknown sources were included in the water quality model and were calibrated for consistency with the central tendency of the dry weather POC data at stations RC-02 and CC-02. The final calibrated loads of the unknown sources ranged from 1.1e6 to 9.1e6 cfu/s depending on POC and stream. Such a source was not included in the model of *Enterococcus* in Chester Creek because no consistent *Enterococcus* concentration increase was observed in the sampling data.

Figure 4-13. Difference in POC Concentration in Upstream vs Downstream Station



Horizontal bars represent mean relative percent difference of paired observations

4.5.2.2 Calibration and Validation Results

The results from the dry weather calibration is shown in Figure 4-14 and Figure 4-15 for Fecal Coliform for dry weather event 2. Model results are shown with the red line and observed data are shown using the gray squares. The figure also shows how the model performs for 50% higher and 50% lower POC load assumptions. Showing the +/- 50% results helps demonstrate that the model represents the central tendencies of the observed water quality data. Generally speaking, the model reasonably predicts dry weather Fecal Coliform concentrations for dry weather event 2, over predicts for dry weather event 1 and under predicts for dry weather event 3. Performance for the other POCS is shown in the table below. A complete set of figures for model calibration for all dry weather events and all POCs can be found in Appendix C.

Table 4-8: Assessment of Dry Weather Events Water Quality Calibration

		Enterococcus	Fecal Coliform	*E.coli*
Dry Weather Event 1	Ridley	Biased High	Biased High	Biased High
	Chester	Biased High	Biased Low	Reasonable fit
	Delaware	Biased High	Biased High	Biased High
Dry Weather Event 2	Ridley	Reasonable fit	Reasonable fit	Reasonable fit
	Chester	Reasonable fit	Reasonable fit	Reasonable fit
	Delaware	Biased High	Reasonable fit	Reasonable fit
Dry Weather Event 3	Ridley	Reasonable fit	Biased Low	Reasonable fit
	Chester	Reasonable fit	Biased Low	Reasonable fit
	Delaware	Reasonable fit	Reasonable fit	Reasonable fit

After calibrating the model to the dry weather events, attention turned to calibrating the wet weather events. Figure 4-16 illustrates the water quality model calibration for fecal coliform during the first wet weather event at select stations in the tributaries and the Delaware River, along with sensitivity tests that show how the model performs for 50% higher and 50% lower POC load assumptions. The objective of the in-stream calibration is to provide the overall best fit across all stations, thus providing consistency with the central tendency along the length of the modeled river. Modeled POC concentrations are consistent with the range of observed concentrations from the DELCORA monitoring program and the model performance is reasonable compared to the observed data. Performance for the other POCS is shown in the table below. A complete set of figures for model calibration for all wet weather events and all POCs can be found in Appendix C.

Table 4-9: Assessment of Wet Weather Events Water Quality Calibration

		Enterococcus	Fecal Coliform	*E.coli*
Wet Weather Event 1	Ridley	Reasonable fit	Biased High	Biased High
	Chester	Reasonable fit	Reasonable fit	Reasonable fit
	Delaware	Biased High	Biased High	Reasonable fit
Wet Weather Event 2	Ridley	Biased Low	Biased Low	Reasonable fit
	Chester	Biased Low	Biased Low	Reasonable fit
	Delaware	Reasonable fit	Reasonable fit	Reasonable fit
Wet Weather Event 3	Ridley	Reasonable fit	Reasonable fit	Reasonable fit
	Chester	Reasonable fit	Biased Low	Biased Low
	Delaware	Reasonable fit	Biased High	Reasonable fit

Following calibration of the dry and wet weather events using the data from the DELCORA Monitoring Program, the water quality model was subsequently validated to water quality data collected in 2012 by the Delaware River Basin Commission (DRBC). Seven samples per location were taken between April and November of 2012 in the Delaware River from Trenton to the mouth of the Delaware River. These data are primarily useful for evaluating accuracy of modeled POC loads from the Philadelphia CSOs and the Schuylkill River, which are estimated to be the largest POC loads to the estuary. Figure 4-17 illustrates the water quality model validation for fecal coliform at stations near Delaware County, starting at river mile 87.9 which is upstream of the DELCORA CSO area. Modeled POC concentrations are consistent with the range and timing of observed concentrations in the DRBC data, and the model performance is reasonable compared to the observed data. Modeled results are also consistent with the observed pattern of higher concentrations near Philadelphia and lower concentrations near DELCORA. A complete set of figures for all POCs and stations used for model validation can be found in Appendix C.

Figure 4-14. Fecal Coliform Dry Weather Calibration at Ridley and Chester Creek (Dry Weather Event #2, 5/10/17)

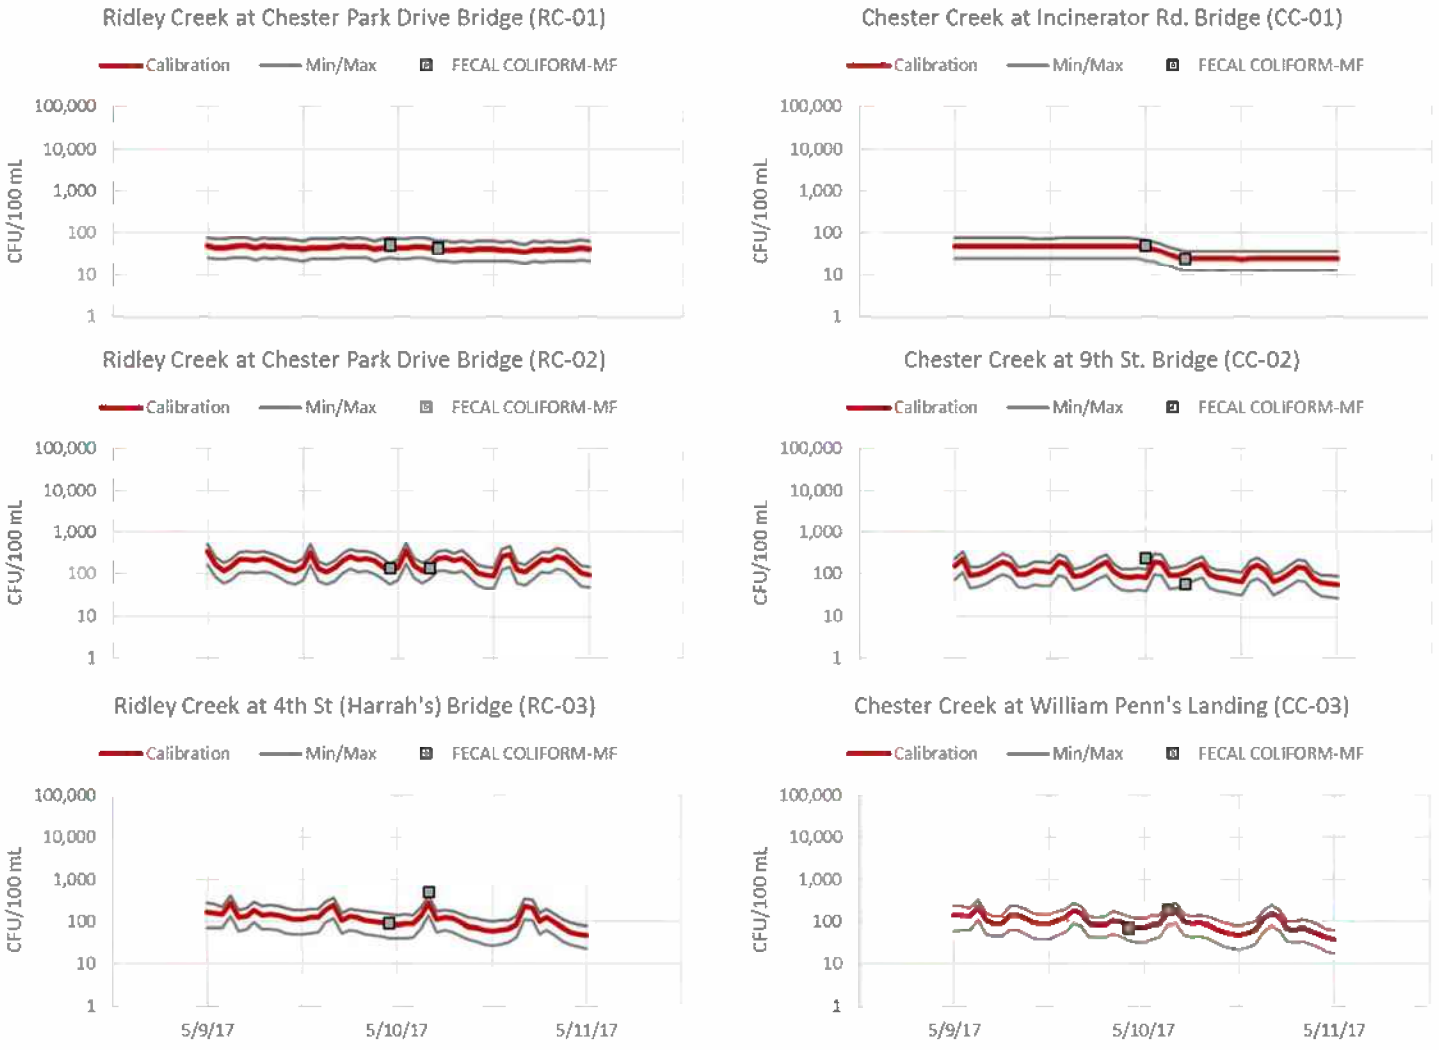


Figure 4-15. Fecal Coliform Dry Weather Calibration at Delaware River Stations (Dry Weather Event #2, 5/10/17)

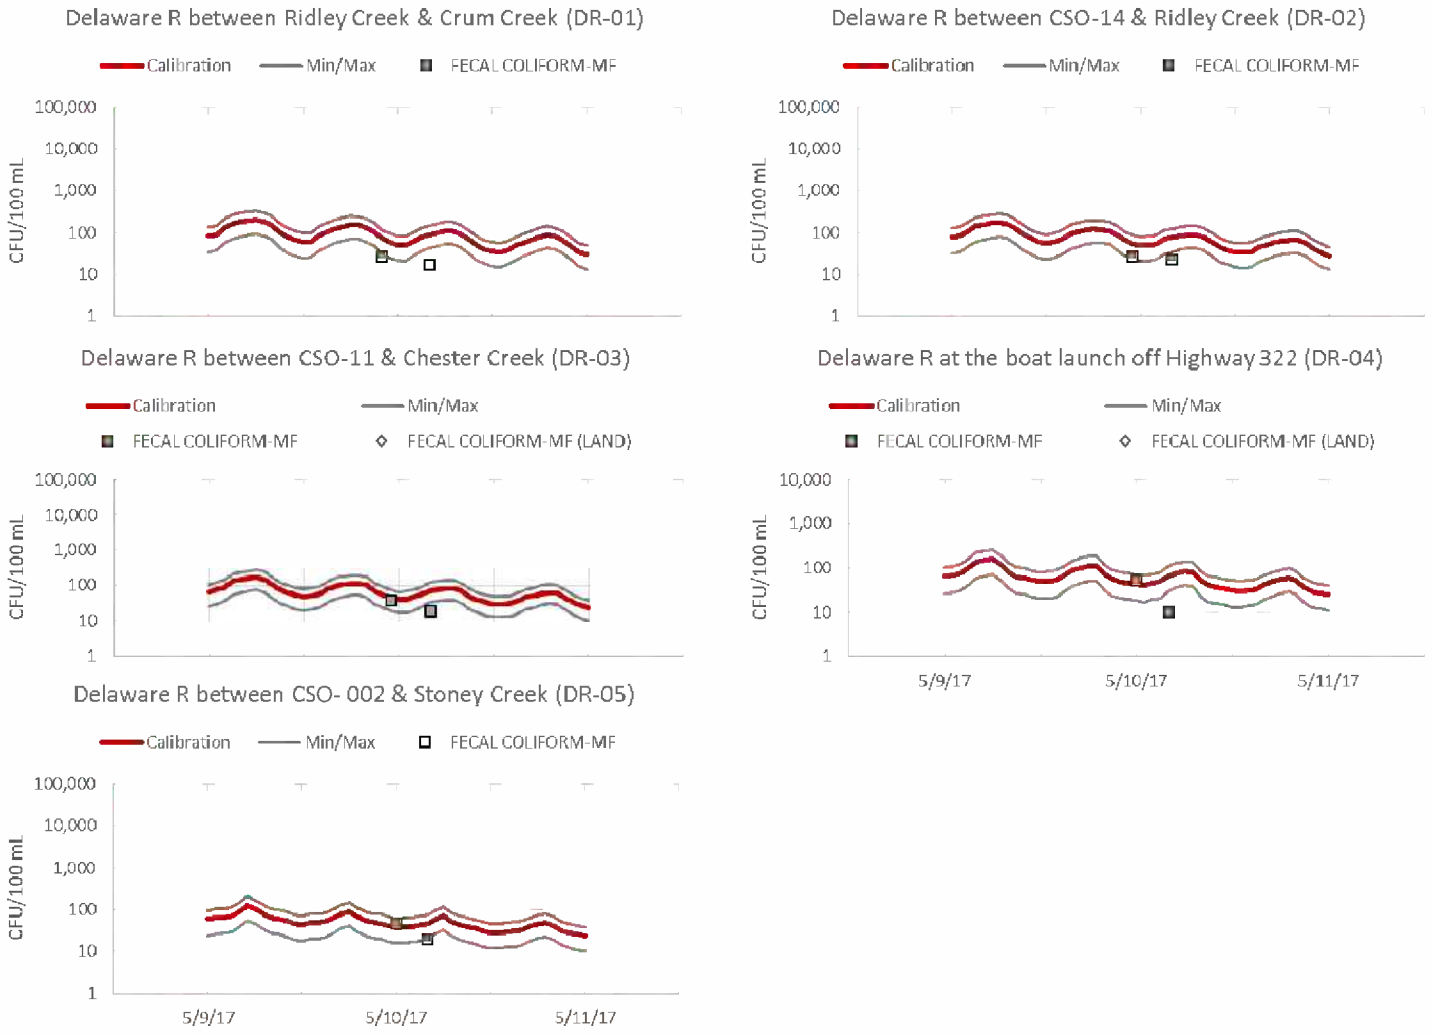

Figure 4-16. Fecal Coliform Calibration at Ridley Creek, Chester Creek, and Delaware River Stations (Wet Weather Event #1, 3/30/17-4/1/17)

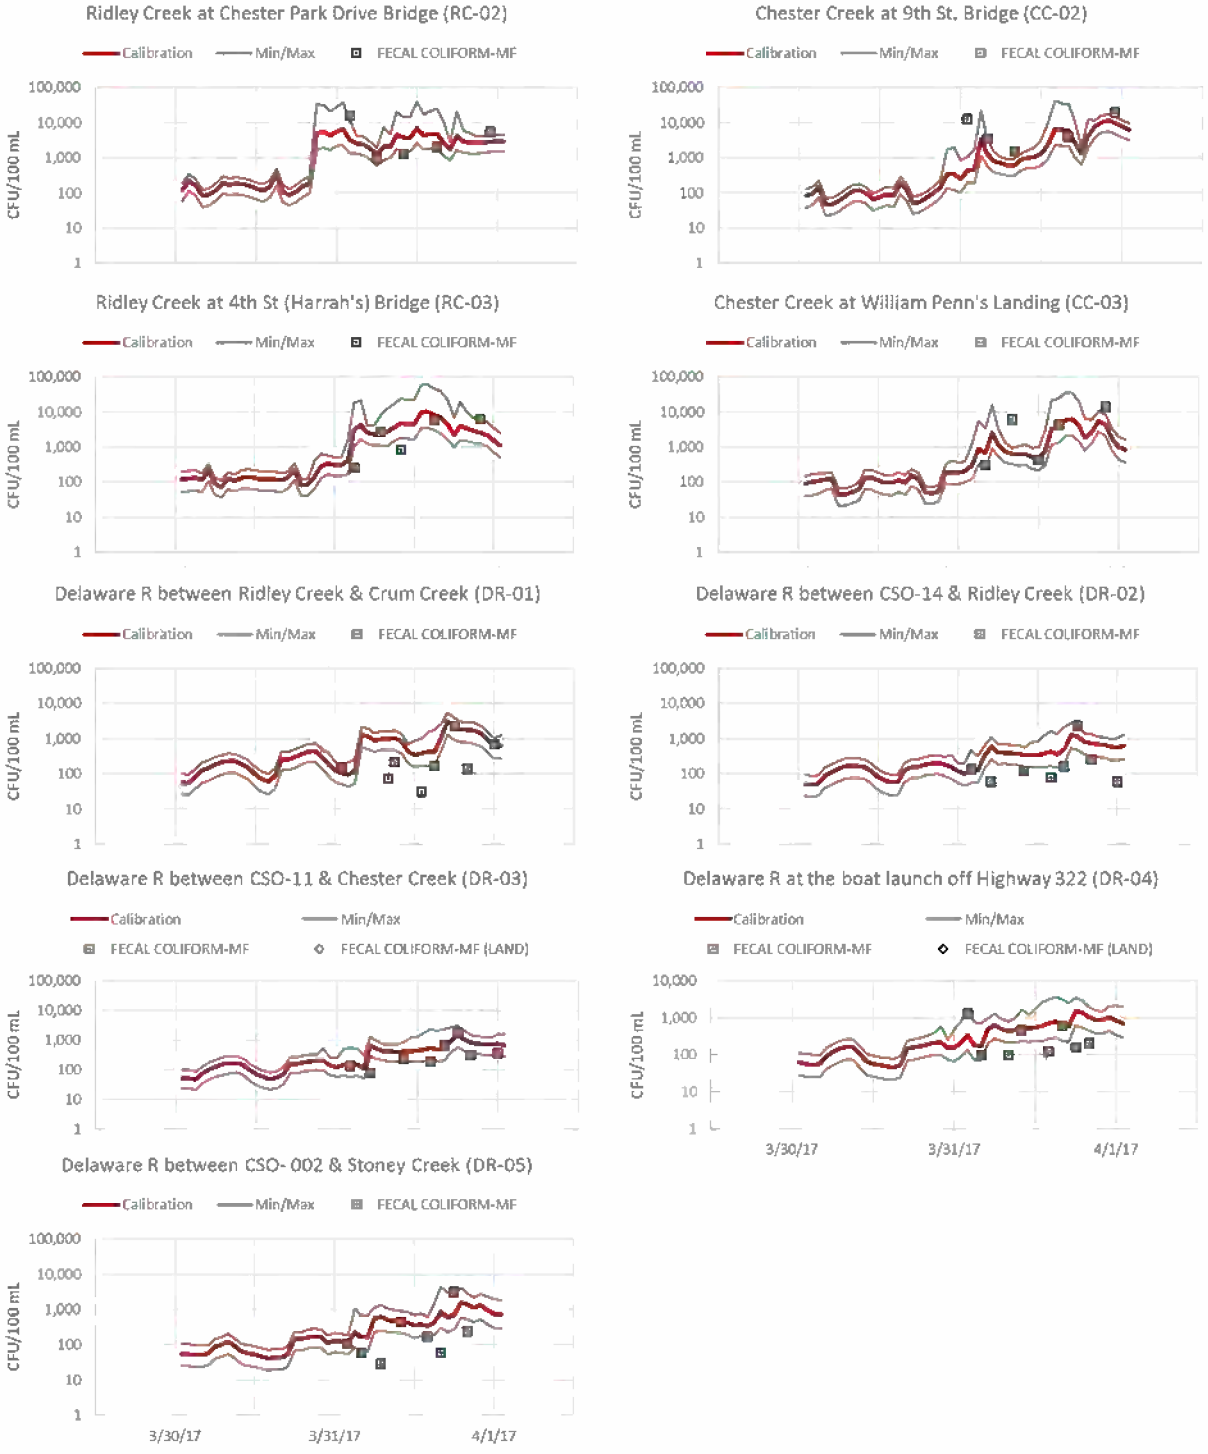

Figure 4-17: Fecal Coliform Model Validation Results near Delaware County

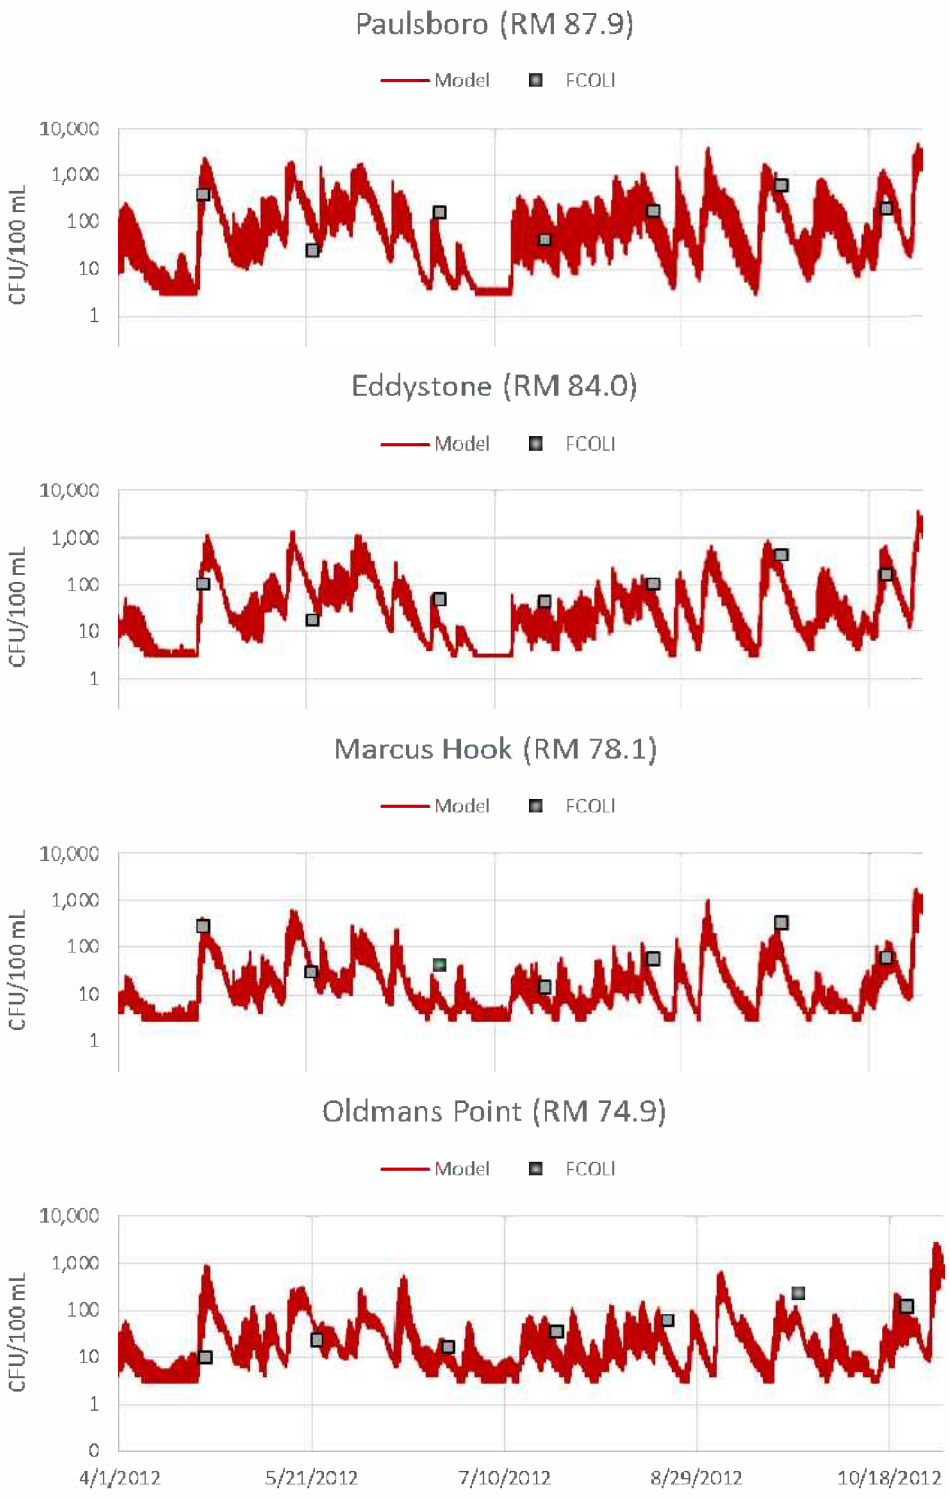

One-to-one plots were also used to assess model performance relative to all observed data at all stations. This is shown in Figure 4-18, Figure 4-19, and Figure 4-20 for the three POCs. These figures pair observed POC concentrations with their associated modeled concentrations for both wet and dry weather events. To account for the natural variability that can occur when sampling POCs, two additional sets of lines were added to the 1-to-1 plot to represent confidence intervals. The first set of dashed lines represent a two times (2x) confidence interval representing the variability in monitoring data results associated with field-collection efforts. The second set of dotted lines represents a ten-time (10x) confidence interval which represents the possible variability in monitoring data results associated with the combination of field and laboratory factors. This confidence interval is based on best professional judgement and variability with field and analytical duplicate results. The majority of points on the one-to-one plots fall within the 10x confidence interval for all stations, however the creek predictions are biased slightly low whereas the Delaware River has an overall reasonable fit, as shown in the table below. Overall, even if an individual event was modeled too high or too low, on a long term basis, the model produces a fairly typical response to POC loads that follow the central tendencies observed.

Table 4-10: Assessment of Overall Water Quality Calibration and Validation

	Enterococcus	Fecal Coliform	*E.coli*
Creeks Calibration	Biased Slightly Low	Biased Slightly Low	Biased Slightly Low
Delaware Calibration	Reasonable fit	Biased Slightly High	Biased Slightly High
Delaware Validation	Reasonable fit	Reasonable fit	Reasonable fit

4.6 Overall Calibration Observations

A water quality modeling framework has been developed and calibrated, and is ready for application to compute POC concentrations in the tidal portions of Chester and Ridley Creeks and in the Delaware River adjacent to DELCORA, for the typical year period. Each model within the framework was developed and calibrated using the best available data, and found to be reasonably consistent with the central tendencies of the observed data and therefore reliable to be applied for the Long Term Control Plan Update.

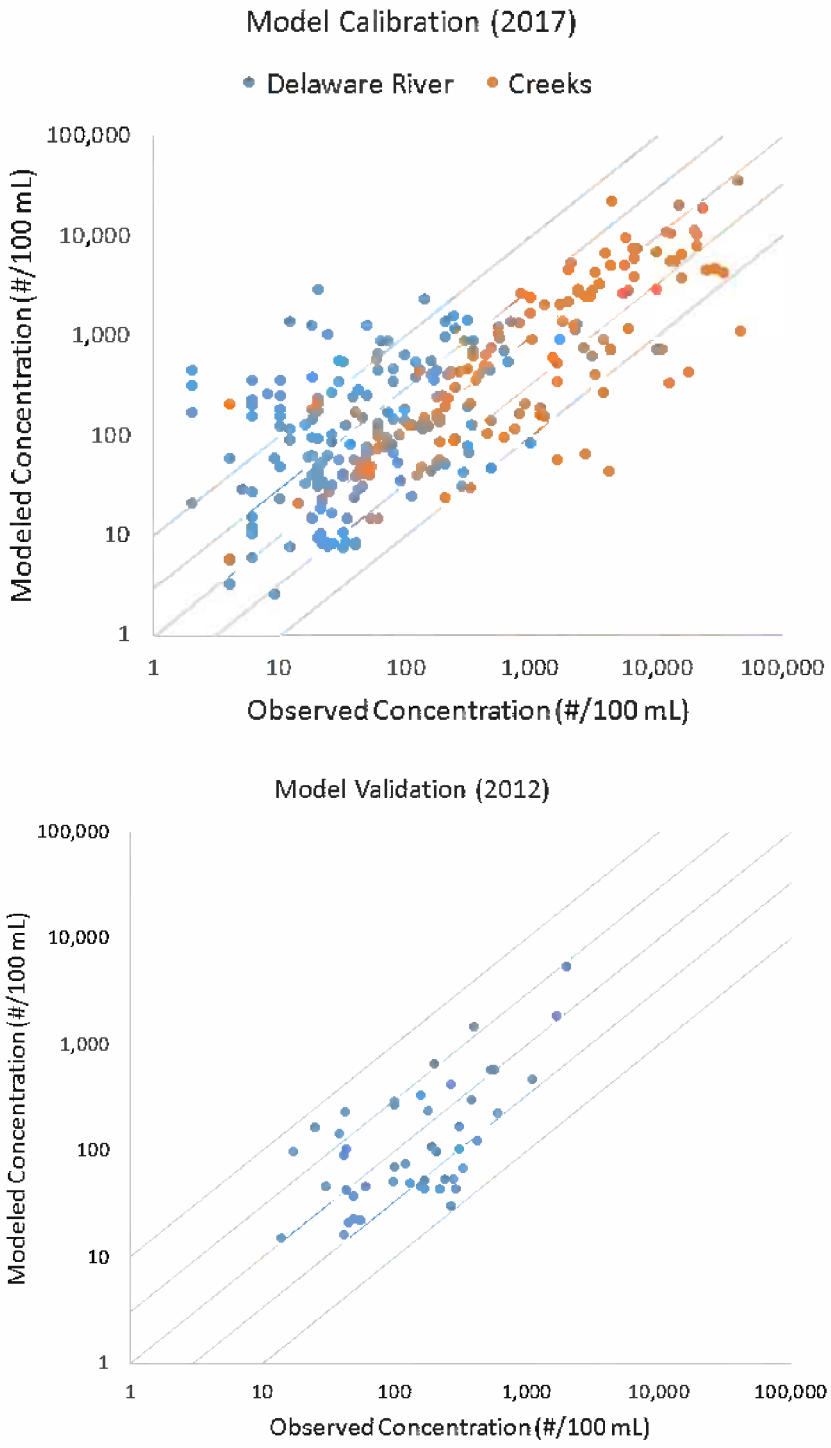

Figure 4-20: *E.coli* Model Calibration and Validation Summary

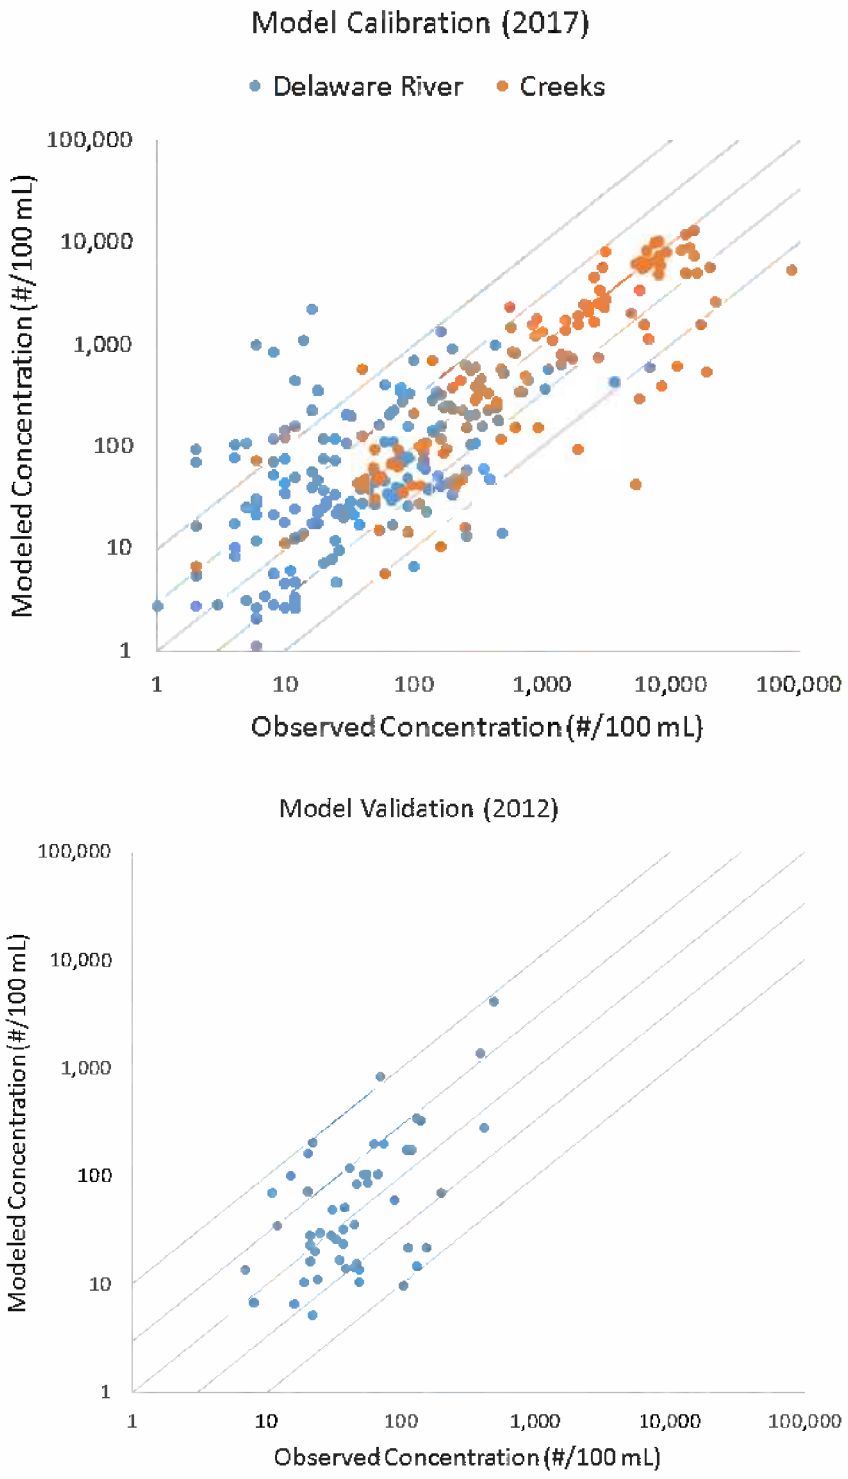


Section 5 Water Quality Model Application to Evaluate Typical Year Condition

5.1 Typical year simulation description

The purpose of the DELCORA water quality model is to compute water quality concentrations for a baseline scenario and potential future control scenarios, and to quantify the water quality benefits of potential future infrastructure projects. The baseline conditions represent the in-stream water quality conditions using the most recent and appropriate data to represent current watershed, tributary, and CSO loads, including the existing DELCORA combined sewer system configuration and operation. The water quality model was applied for the typical year hydrologic period of 1994-1996. This period was identified as being representative of longer-term hydrologic conditions, and includes one relatively dry year, a relatively wet year, and an average year (DELCORA, 2016b).

5.2 Relevant Water Quality Standards

Modeled POC concentrations were compared to the currently applicable and potential future water quality standards. The standards vary by POC and by stream segment, and are summarized in the table below (Table 5-1). The Upper Delaware River and the tidal zones of Chester and Ridley Creek currently have secondary contact WQS whereas the Lower Delaware River currently has primary contact WQS for bacteria. The boundary between the Upper and Lower Delaware River occurs at river mile 81.8, which is just downstream of Chester Creek and CSO-11 (Figure 5-1). Generally, the modeling work indicated that the *enterococcus* standards are the most stringent (relative to current concentrations) among the three POCs.

Table 5-1: Water Quality Thresholds for Comparisons with Model Results

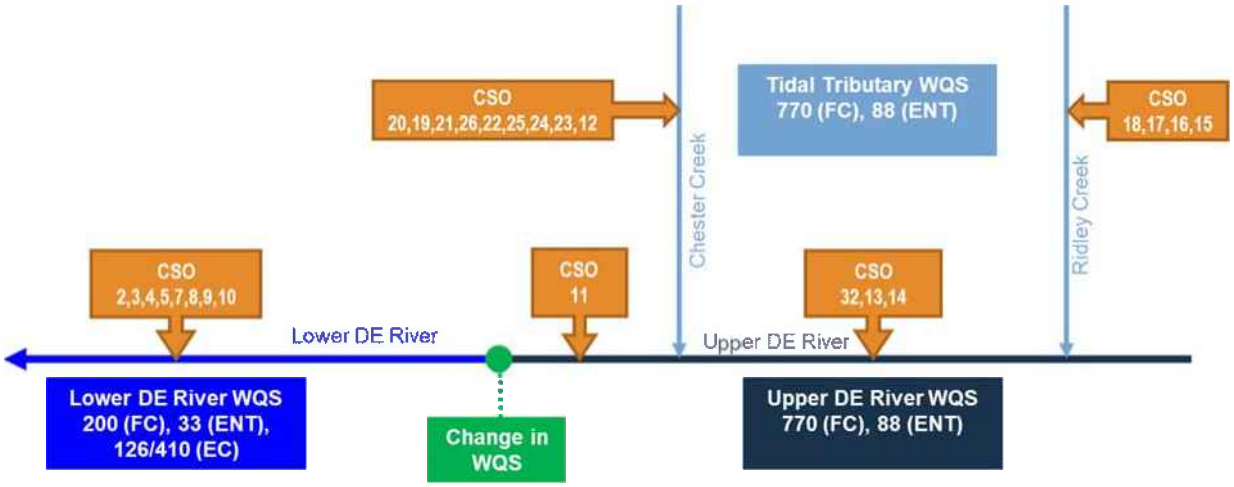
Segment	*Enterococcus* (#/100 mL)	Fecal Coliform (#/100 mL)	*E.coli*[1] (#/100 mL)
Upper Delaware River and Tidal Zones of Creeks	Monthly Geomean: 88 #/100 mL	Monthly Geomean: 770 #/100 mL	n/a
Lower Delaware River	Monthly Geomean: 33 #/100 mL	Monthly Geomean: 200 #/100 mL	Monthly Geomean: 126 #/100 mL Statistical Threshold Value: 410 #/100 mL

1. *E.coli* (EC) standards likely to be codified by PADEP 12-24 months from July 2017. These criteria would apply to the non-tidal tributaries and Delaware River below R.M. 81.8, during recreational months only (May 1 - September 30).

E.coli standards similar to the Lower Delaware River are also proposed for the non-tidal tributaries, which are located upstream of DELCORA's CSO discharges. Outfall CSO-033 is located in the non-tidal portion of Ridley Creek, but this outfall does not appear to overflow during

the typical year period. CSO-033 will be evaluated in the LTCP but, as a practical matter, it does not cause or contribute to WQS being exceeded.

Figure 5-1: Schematic of Applicable POC Water Quality Standards

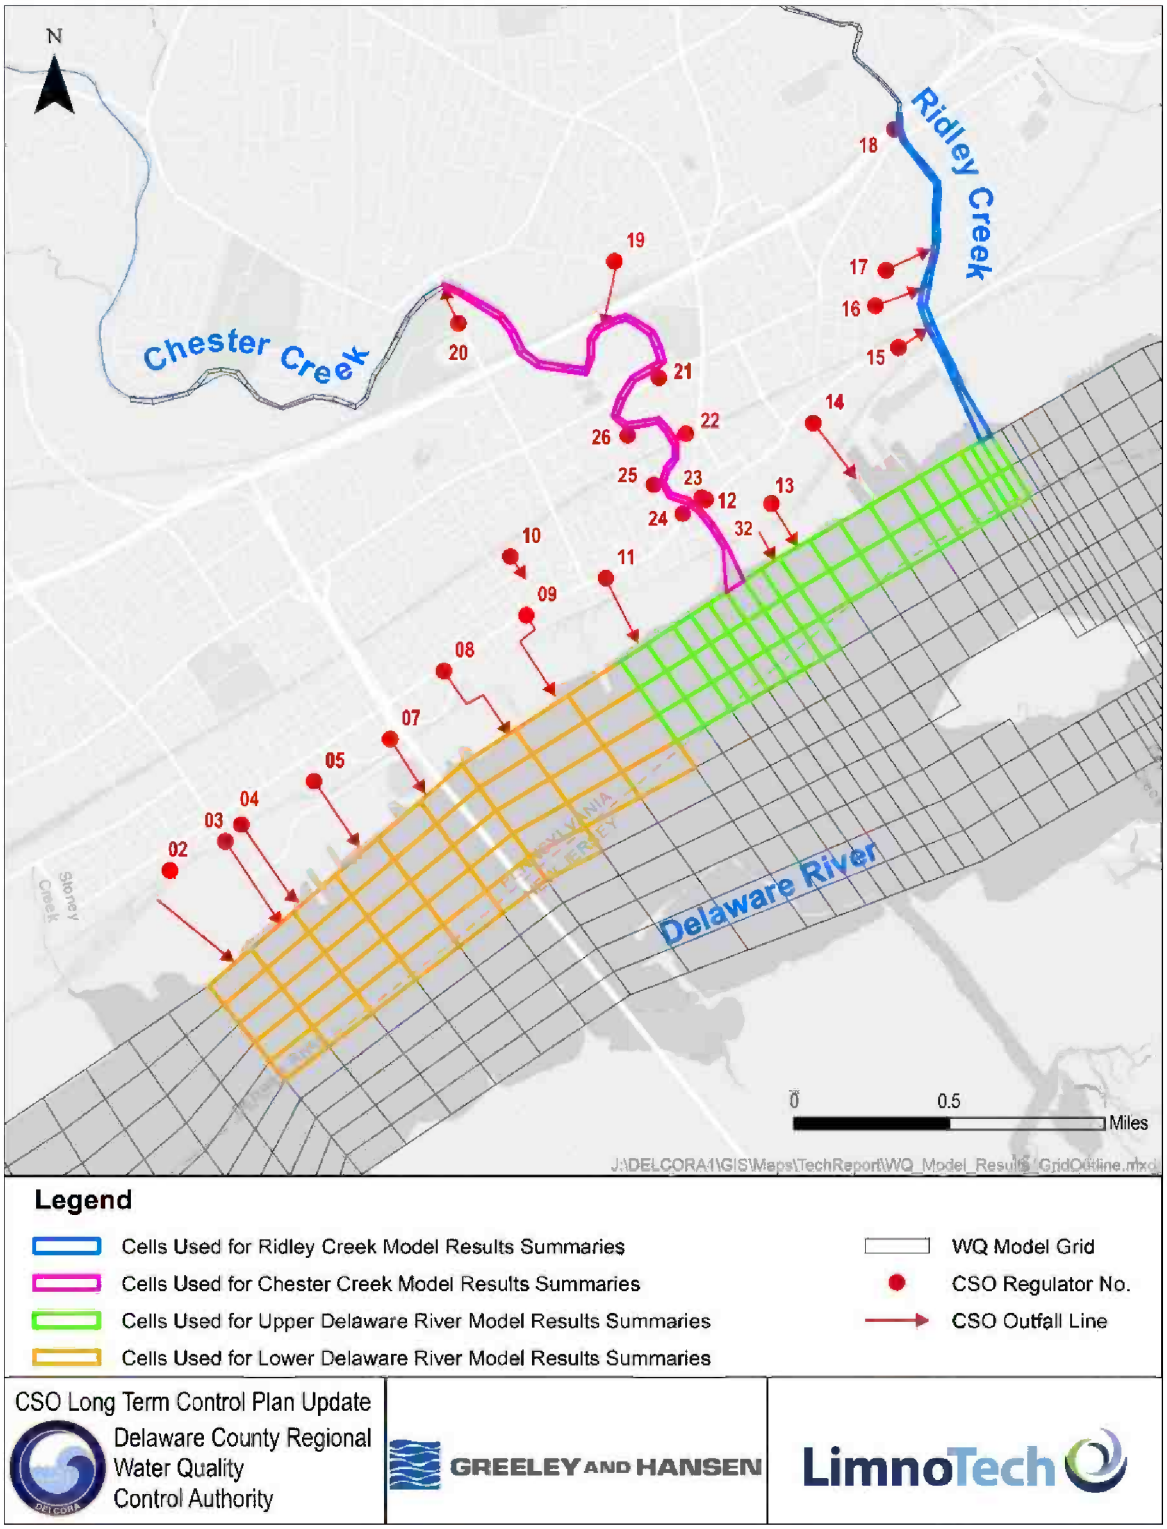


The model has been configured to separately track the in-stream concentration associated with background sources from the in-stream concentration associated with DELCORA sources (CSO and WWTP). This separate accounting will allow for background and non-background sources to be reduced independently from each other. Non-background sources include the DELCORA CSOs and DELCORA STP.

5.3 Typical year simulation results

Model results were summarized for comparison with the applicable water quality standards, which include monthly geometric mean (GM) and statistical threshold value (STV) standards. Model results were summarized over the stream reaches that receive CSO discharges, and that occur within Pennsylvania water as shown in Figure 5-2 below. Monthly geometric mean concentrations and exceedances of the STV standard are computed from hourly model output within each of the selected model grid cells. Model results for the typical year are presented in the sections below.

Figure 5-2: Model Grid Cells Used for Presenting Model Results



5.3.1 Ridley and Chester Creek Observations

Excursions above the *Enterococcus* monthly geomean water quality standards occur in the tidal zone of Ridley Creek almost every single month of the simulation period, and about one third of the time in Chester Creek. No excursions above the Fecal Coliform monthly geomean WQS are observed in either creek. The tidal zone of these creeks do not have a current or proposed *E.coli* WQS.

The excursions are largely due to background sources. As shown in Section 4.1.3, the water quality monitoring data shows that wet weather concentration at the most upstream monitoring locations (located upstream of CSO influence) in Chester Creek and Ridley Creek often exceed the monthly geometric mean and STV WQS concentration for the three POCs. DELCORA CSOs have a relatively smaller impact (less than 10%, on average) on monthly geometric mean concentrations than background sources, because they are intermittent discharges that are only active for short time periods within a monthly geometric mean evaluation period. The assimilative capacity of Ridley Creek is less than in Chester Creek due to its smaller stream flows, so DELCORA CSOs have a larger relative impact on in-stream water quality in Ridley Creek versus Chester Creek. Table 5-2 below shows the number of months where water quality standards are exceeded for each of the three POCs in the creeks. Results are shown for all sources (background and CSOs) and for CSO-only sources. This table shows that CSOs by themselves do not cause water quality violations in the Creeks and are not precluding the attainment of WQS.

5.3.2 Delaware River Observations

Occasional (less than 10%) excursions above the *Enterococcus* monthly geomean water quality standards occur in the Upper Delaware River within the DELCORA LTCPU focus area. No excursions above the Fecal Coliform monthly geomean WQS are observed for the Upper Delaware River. The Upper Delaware River does not have a current or proposed *E.coli* WQS.

Occasional (less than 10%) excursions above all three POC monthly geomean and STV water quality standards occur in the Lower Delaware River within the DELCORA LTCPU focus area. Excursions are somewhat more frequent in the Lower Delaware River than in the Upper Delaware due to the significantly lower water quality standard in the Lower Delaware. Background concentrations near DELCORA are similar in both zones because upstream background sources have a large influence on concentrations in both the upper and lower segments. DELCORA CSOs have a greater impact on the Lower Delaware zone than the Upper Delaware zone because more CSO volume discharges to the Lower Delaware. However, the DELCORA contribution to monthly geometric mean concentrations is generally low (less than 7%, on average) relative to background sources. As shown in Section 4.1.3, the water quality monitoring data shows that wet weather exceedances are observed in the most upstream monitoring location for the Delaware River (DR-01).

Table 5-2 shows the number of months where water quality standards are exceeded for each of the three POCs in the Upper and Lower Delaware River. Results are shown for all sources (background and CSOs) and for CSO-only sources. This tables shows that CSOs by themselves do not cause

water quality violations in the upper or lower Delaware River and are not precluding the attainment of WQS.

Table 5-2: Number of Months Exceeding the Monthly Geomean Water Quality Standard

	Enterococcus Monthly Geomean	Fecal Coliform Monthly Geomean	*E.coli*[1] Monthly Geomean	*E.coli*[1] STV
Ridley Creek				
All Sources	35/36	27/36	n/a	n/a
CSO only	0/36	0/36	n/a	n/a
Chester Creek				
All Sources	14/36	0/36	n/a	n/a
CSO only	0/36	0/36	n/a	n/a
Upper Delaware				
All Sources	2/36	0/36	n/a	n/a
CSO only	0/36	0/36	n/a	n/a
Lower Delaware				
All Sources	5/36	2/36	2/36	12/36
CSO only	0/36	0/36	0/36	0/36

1. No *E.coli* standard currently exists or has been proposed for the tidal portions of Ridley and Chester Creeks or for the upper Delaware River, therefore results for these segments are marked as "n/a" in this table.

5.4 Intended Application of the Water Quality Model

The water quality model is deemed adequate to evaluate compliance with the WQS and the degree to which DELCORA CSOs contribute to non-attainment of WQS. The water quality model will be used to help assess the water quality benefits of potential infrastructure projects considered for the LTCPU (i.e.: CSO alternative scenarios). These CSO alternatives will be simulated by the DELCORA hydrologic and hydraulic (H&H) model (i.e. CSS model) and then evaluated with the receiving water quality model. Resulting changes to in-stream POC concentrations will be compared to the applicable water quality standards as well as to the concentrations observed under the baseline conditions. Water quality model output will be used to summarize the predicted reduction to in-stream POC concentrations.

Two major observations can be made from the water quality modeling application results. One is that background sources dominate the modeled POC concentrations (and by extension, DELCORA CSO loads are small compared to background loads), and the second is that the

DELCORA CSOs by themselves do not cause non-attainment, or preclude the attainment, of WQS. Moreover, the modeling results show that regardless of additional CSO controls, even complete separation, water quality standards would still be exceeded under current conditions because background sources typically prevent compliance with WQS. The modeling results are supported by the water quality data results from the wet weather sampling program, which shows that wet weather concentrations at the most upstream monitoring locations (located upstream of CSO influence) in Chester Creek and Ridley Creek (and to a lesser extent in the Delaware River) often exceed the monthly geometric mean and STV WQS concentration for the three POCs. These monitoring and modeling data taken together indicate the upstream bacteria loads result in a practical impossibility of meeting Water Quality standards in the tidal waters through CSO control. While the Consent Decree addresses the issue of background sources by requiring CSO controls to also be assessed assuming that background sources are reduced to 75% of the applicable WQS, it is not clear that imposing CSO controls under these conditions is reasonable given that there is no current plan for reducing background loads in Chester and Ridley Creeks. The CSO Policy states that "*where WQS and designated uses are not met in part because of natural background conditions or pollution sources other than CSOs, a total maximum daily load, including a wasteload allocation and a load allocation, or other means should be used to apportion pollutant loads*". Such apportionment of loads does not currently exist for Ridley and Chester Creeks for bacteria.

As stated previously, the intended use of the water quality modeling framework is to evaluate CSO control alternatives with respect to applicable water quality standards and demonstrate that alternatives selected for the LTCPU program will meet the water quality-based requirements of the Clean Water Act and Consent Decree. The water quality model is adequate to assess presumption levels of control to show that the CSOs after controls are in place do or do not preclude the attainment of water quality standards. The model framework could also be used to assess the demonstration approach, however, as explained in this report, the modeling shows that CSOs alone do not cause WQS violation and do not preclude the attainment of WQS, and background loads are currently causing WQS violations upstream of the CSOs and the CSO influence. Without a State plan for estimating the cost and practicality for controlling the background load upstream of DELCORA's CSO area, it is difficult to justify the demonstration approach.

As such, DELCORA will utilize the presumption approach, which is shown in this report to be reasonable in light of the data and analysis as called for in the National CSO Policy.

5.4.1 Interpretation of Section 19.b.iv of the Consent Decree

The typical year simulation results show that background sources prevent compliance with the applicable water quality results during some months, and the CSOs are not precluding the attainment of WQS. DELCORA's consent decree requires that if DELCORA uses the demonstration approach and background sources prevent compliance with water quality standards, then DELCORA must also run its water quality model assuming that background sources have

been controlled to 75% of the applicable water quality standards (EPA, 2015). More specifically, section 19.b.iv of the DELCORA Consent Decree states that "*If background sources currently prevent compliance with the water quality standards, DELCORA shall also assess the impact of each size of the CSO controls assuming background pollutant levels are reduced such that in-stream concentrations upstream of the CSO Outfalls are no more than seventy-five (75) percent of the applicable water quality standard.*"

"*Background sources*" are generally understood to be the sources that would not be controlled through the LTCPU, and includes watershed sources of intermittent POCs (e.g. from washoff of POCs from wildlife and pets due to rainfall) as well as continuous sources (e.g. failing septic tanks, etc.), and CSOs from other communities. In other words, background sources are all sources accounted for in the model except for DELCORA CSOs and the DELCORA WWTP. Based on our interpretation of this consent decree language, we could reduce background sources to 75% of the water quality standard during months when there is an excursion above the water quality standard and background sources exceed 75% of the water quality standard.

The Consent Decree states that simulations be conducted with background sources set to seventy-five percent of the water quality standards "*upstream of the CSO outfalls*". However the water quality standard upstream of the outfalls (i.e. in the Upper Delaware) is higher than the standard in the Lower Delaware. So if background sources are reduced to seventy-five percent of the Upper Delaware standard, then the Lower Delaware background concentration would still exceed the Lower Delaware standard (i.e. 75% of the *Enterococcus* Upper Delaware River WQS is 66 #/100ml, which is higher than the Lower Delaware River WQS of 33#/100ml).

The assumed intent of this Consent Decree requirement is to provide some assimilative capacity in the river such that the water quality benefits of potential DELCORA LTCPU infrastructure projects can be more readily identified. With that understanding, the proposed approach to reducing background sources is to separately evaluate CSO controls in the Lower and Upper Delaware zones. First, background sources would be controlled to 75% of the Upper Delaware and Tidal Tributary standard, and control scenarios would be evaluated for CSOs discharging directly to the Upper Delaware and to Chester and Ridley Creeks (which discharge to the Upper Delaware). Second, background sources would be controlled to 75% of the Lower Delaware standard, which would require a larger reduction in background sources, and control scenarios would be evaluated for CSOs discharging directly to the Lower Delaware.

The model has been configured to separately track the in-stream concentration associated with background sources from the in-stream concentration associated with DELCORA sources (CSO and WWTP). This separate accounting will allow for background sources to be reduced independently from non-background sources. Using the time series output from the model, the background sources will be scaled back in the tributaries and in the Upper Delaware River to 75% of the Tidal Tributaries & Upper Delaware River WQS using scaling factors that are specific to each water segment and each month such that background sources are at 75% of the applicable water quality standard for months when non-compliance can be demonstrated.

SUBJECT: Bathymetric Survey of Chester and Ridley Creeks

This memo summaries field work activities conducted by LimnoTech the week of March 27, 2017. An elevation (bathymetric) survey was completed in support of water quality model development on the lower portions of Chester and Ridley Creeks. The creeks are located in the city of Chester, Pennsylvania and are tidally influenced tributaries to the Delaware River. The field crew was made up of LimnoTech employees Cullen O'Brien and Robert Betz.

Survey methods consisted of acquiring cross sectional bank and bed elevation data. Reaches surveyed included the lower 2.75 miles of Chester Creek and 3.25 miles of Ridley Creek to their discharge into the Delaware River. The most upstream transect location corresponds to the most upstream water quality sampling location included in the 2017 wet and dry weather monitoring program conducted by Weston, Greeley and Hansen, and LimnoTech. Transects were collected on ¼-mile interval spacing. Access to the creeks on the upper portions, generally greater than 1 mile upstream, was by wading where the bottom was shallow and firm. The portions below 1 mile were too deep and soft to be accessed on foot and a john boat with tagline was utilized.

Survey position and elevation was collected using Real Time Kinematic-Global Positioning System RTK-GPS techniques. This technique utilizes satellite positioning with real-time corrections for accurate georeferencing spatial locations and reference information to convert measured depths to elevations. GPS equipment consisted of a Trimble GeoXH centimeter edition with external Hurricane antenna. Real-time position corrections were accessed through cellular connection with the Pennsylvania Virtual Reference Station (VRS) network, ensuring high accuracy position data. Each creek cross section was surveyed at approximately five locations across the bed, water surface, bank toe, and bank top. Access to the entire upland bank at transect locations was not always possible; so the closest points safely accessed to the bank toe were surveyed. Elevation measurements collected from the boat were completed by marking the location at the water surface and subsequently measuring the water depth.

Quality control for horizontal and vertical position was verified with a local National Geodetic Survey (NGS) benchmark. A benchmark is an established survey monument with a known lateral and longitudinal (X, Y) position and elevation (Z) position that is stable. An approximate error estimate of +/- 0.5 feet in the vertical and less than 0.5 feet for horizontal position was observed at some transects, but the majority of locations surveyed were considerably more accurate. The observed errors are due to applying GPS technology in a challenging environment with overhead obstructions such as tree cover, buildings, and local thunderstorms that can dilute or interfere with the GPS signal.

The map below (Figure 1) shows the transect locations where elevation measurements were collected.

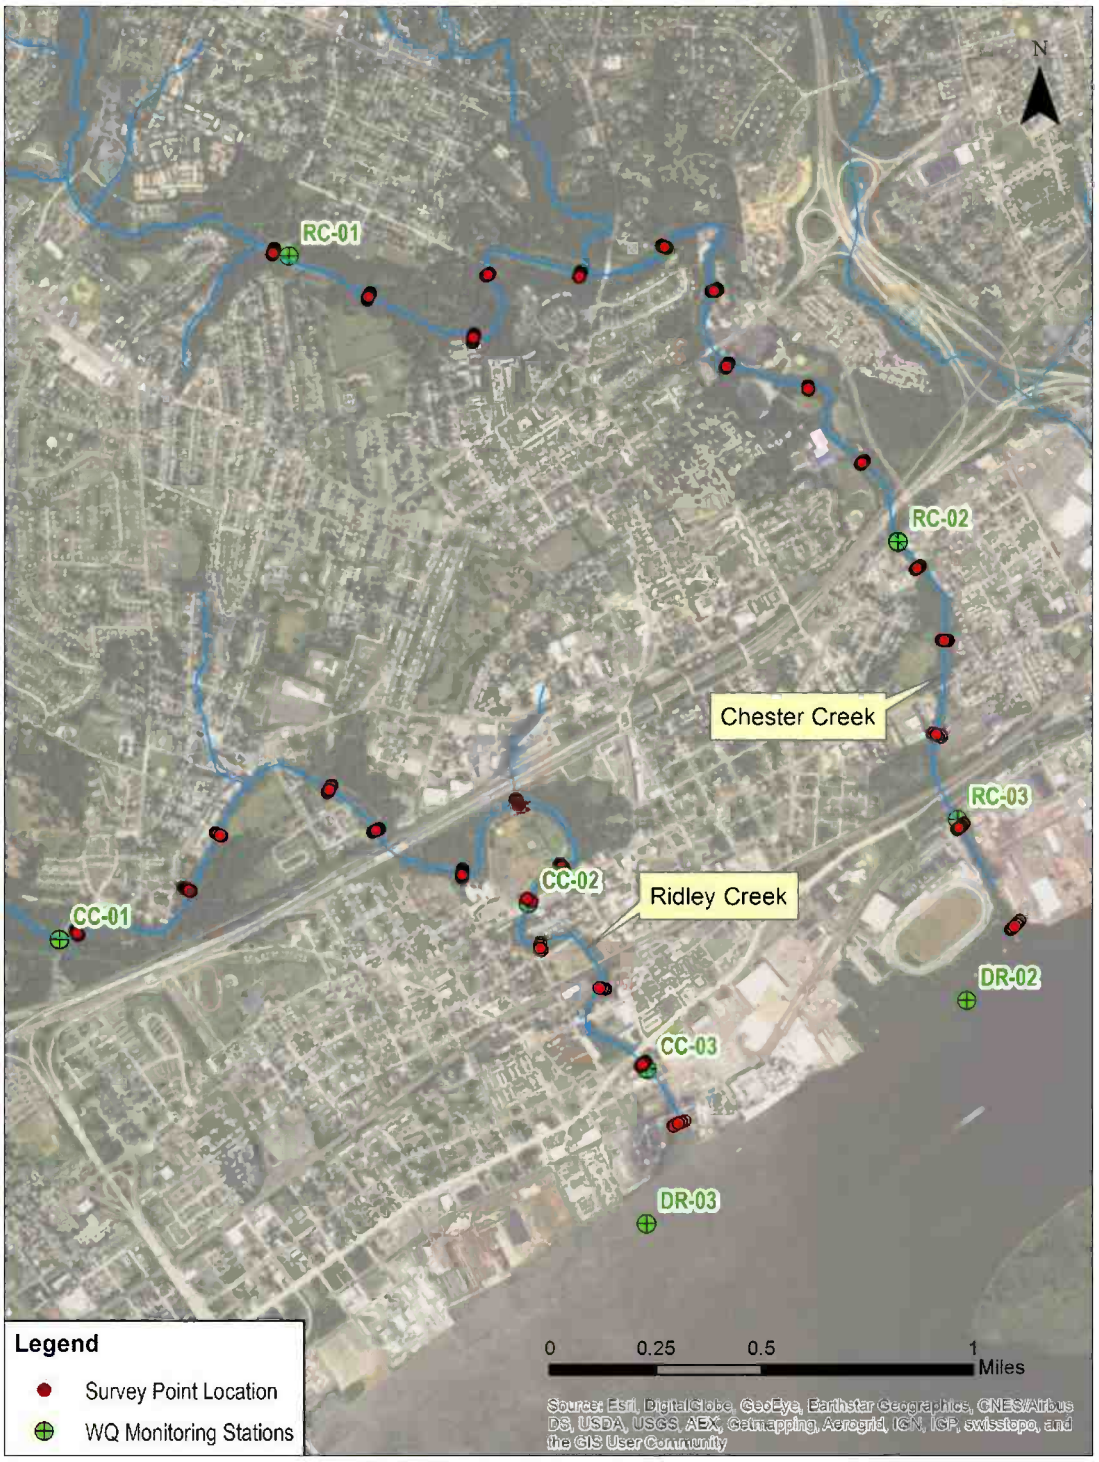

Figure 1: Locations of Creek Elevation Measurements in Chester and Ridley Creeks

Elevation measurements from this survey were compared with similar elevation data from a 1977 Federal Emergency Management Agency (FEMA) Flood Insurance Study (FIS) of the creeks (FEMA, 2015). Though the FEMA study was completed several decades ago, it serves as a useful check on the accuracy and sufficiency of the bathymetric survey data. Figures 1 and 2 compare the LimnoTech survey data with the FEMA data.

A few characteristics of these figures are relevant to the water quality modeling of the creeks. In Chester Creek, the LimnoTech bed elevations are substantially higher (about five to ten feet) than FEMA elevations. Higher contemporary creek elevations influence both the degree of tidal exchange in the lower reaches of the creeks, and travel times of upland runoff and base flow to the Delaware River.

To check for potential bias in the LimnoTech measurements, the LimnoTech measurements of water surface elevation were compared to similar data maintained by NOAA at a nearby tide gage (Philadelphia gage, #8545240). These measurements of water surface elevation agreed well (within two inches) which is a strong indication that the LimnoTech creek bed elevations are not biased high.

Higher creek bed elevations near the Chester Creek mouth are an indication that soft sediments have accumulated there since the 1970s. The highest observed peak flow in Chester Creek occurred a few years before the FEMA survey (in 1971, peak flow of 21,000 cfs) while recent peak flows have been significantly lower (average peak flow of 4,000 cfs in the last ten years) (USGS, 2017). Lower contemporary peak flows may have allowed for the accumulation of soft sediments in the lower reaches of Chester Creek.

Another significant observation from the LimnoTech data is that a pipe crossing near river mile 1.0 in Chester Creek created a high point in the creek bed profile. This high point acts to slightly reduce upstream water currents during lower flow conditions. This would tend to lengthen travel times of bacteria.

In Ridley Creek the LimnoTech data show a more constant bed slope between river miles 2.0 and 3.5 than the FEMA data. This is because low head dams existed in the 1970s near river miles 2.0 and 3.0, but are no longer in place. These dams previously acted to accumulate sediments in their shallow upstream pools, but when the dams were no longer present these accumulated sediments were likely washed away downstream.

These comparisons between the LimnoTech survey data, the historical FEMA data, and the NOAA tide gage, show consistency and provide confidence in the data collected. These comparison also help to identify locations where the creek bed has changed in the last several decades in ways that would influence creek hydraulics and pollutant transport.

Section 1 Introduction

1.1 Background of DELCORA's Facilities

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1. The total service area served by DELCORA, as shown on Figure 1-2, is approximately 82,977 acres which illustrates that DELCORA serves a significant and widespread portion of Delaware County.

The combined sewer area simulated in DELCORA's existing Hydrologic and Hydraulic model is located within the City of Chester and consists of a drainage area of approximately 1,510 acres. It comprises approximately half of Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer regulated outfalls controlling storm overflows. The location of Chester City's service area is illustrated on Figure 1-2.

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western Service Area discharges to DELCORA's Western Regional Treatment Plant (WRTP). The Eastern Service Area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWDSWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. As such, dry weather flows and a portion of the wet weather flows (total flow less than 20 MGD) from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP. Flows above 20 MGD are directed to the PWDSWPCP.

1.2 CSO and Receiving Water System Description

The Chester Combined Sewer Overflow (CSO) system contains 26 permitted outfalls and they discharge to three receiving water bodies: the Delaware River, Chester Creek, and Ridley Creek. However, there are only 25 CSO discharge locations, as CSO #010 discharges to the Delaware River through CSO #009. Figure 1-3 depicts the locations of CSO regulators and outfalls that are DELCORA's responsibility. Figure 1-3 also provides a sewer characterization and illustrates the breakdown of each outfall and how each drainage area has combined sewers and separate sewers. Figure 1-4 is a schematic of the Chester CSO system and shows the outfalls and the interceptors that are connected to each CSO.

1.3 NPDES Permit Requirements

There are a total of 26 combined sewer overflow outfalls listed with 25 discharge points (Outfall #009 and #010 both discharge at Outfall #009) in DELCORA's existing National Pollutant Discharge Elimination System (NPDES) Permit. Under its NPDES Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow outfalls (#002-#026, #032, #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

Part C - Other Requirements, Section V - Combined Sewer Overflows of the NPDES Permit details DELCORA's responsibilities with respect to the CSO system including reporting, continued implementation of and continued compliance with the Nine Minimum Controls (NMC), and implementation of the existing Long-Term Control Plan (LTCP) dated April 1999 and the July 2008 addendum to the LTCP until the updated LTCP is approved.

1.4 Consent Decree Requirements

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated LTCP to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. Consent Decree Paragraph V.A.15 (Water Quality Model Plan) requires that within ninety (90) days after EPA reviews and approves the Alternatives Evaluation Approach, DELCORA shall submit to EPA and PADEP a Water Quality Model Plan for review and approval.

The Alternatives Evaluation Approach Report was approved by US EPA on October 13, 2016. The "Demonstration Approach" was selected for each CSO, receiving streams based on the methodology outlined in the Alternatives Evaluation Report.

1.5 Water Quality Sampling Program Purpose and Objectives

The "Demonstration Approach" requires that a Water Quality Model be developed for each receiving stream. The Water Quality Modeling effort will require calibration and validation of the model and therefore Water Quality Sampling is required. The Water Quality Sampling Program will gather data required for this effort. The three water bodies that receive overflows from DELCORA's CSS include the Delaware River, Chester Creek and Ridley Creek.

1.6 Water Quality Sampling Report Purpose and Objectives

The purpose and objective of the Water Quality Sampling Report is to provide a detailed description of the water quality sampling task undertaken to gather field data as required to build and calibrate the Water Quality Model in accordance with the Water Quality Monitoring and Modeling Work plan (Greeley and Hansen / Limnotech, Revised July 2017). The data gathered through sampling efforts on the Creeks, River, Combined Sewer Outfalls (CSO) and Stormwater (SW) locations has been analyzed and is discussed at length in this report. The report also provides a summary of the sampling activities for each

Dry and Wet weather sampling event along with laboratory testing results and in-situ field data collected on-site for each sampling event.

Section 2 Sampling and Analysis Plan Overview

2.1 Existing Water Quality Monitoring Overview

The Water Quality Monitoring Program (WQMP) was designed to collect data that will be used to assess water quality concerns identified in the Delaware River watershed and its tributaries, Chester Creek and Ridley Creek, in the vicinity of Chester, PA. Pollutants of concern (POCs) are identified in the Identification of Sensitive Areas and Pollutants of Concern Report (Greeley and Hansen, 2016c) which was approved by US EPA on October 13, 2016. Table 2-1 below lists the POCs that were identified which exceeded the maximum water quality standards (WQS) in the receiving streams and were approved for further investigation through water quality monitoring and modelling. The POCs are Fecal coliform, *E. coli*, and *Enterococcus* and are the primary focus of the WQMP. Figure 2-1 shows the water quality standards in the receiving streams.

Table 2-1: List of Pollutants of Concern (POC)

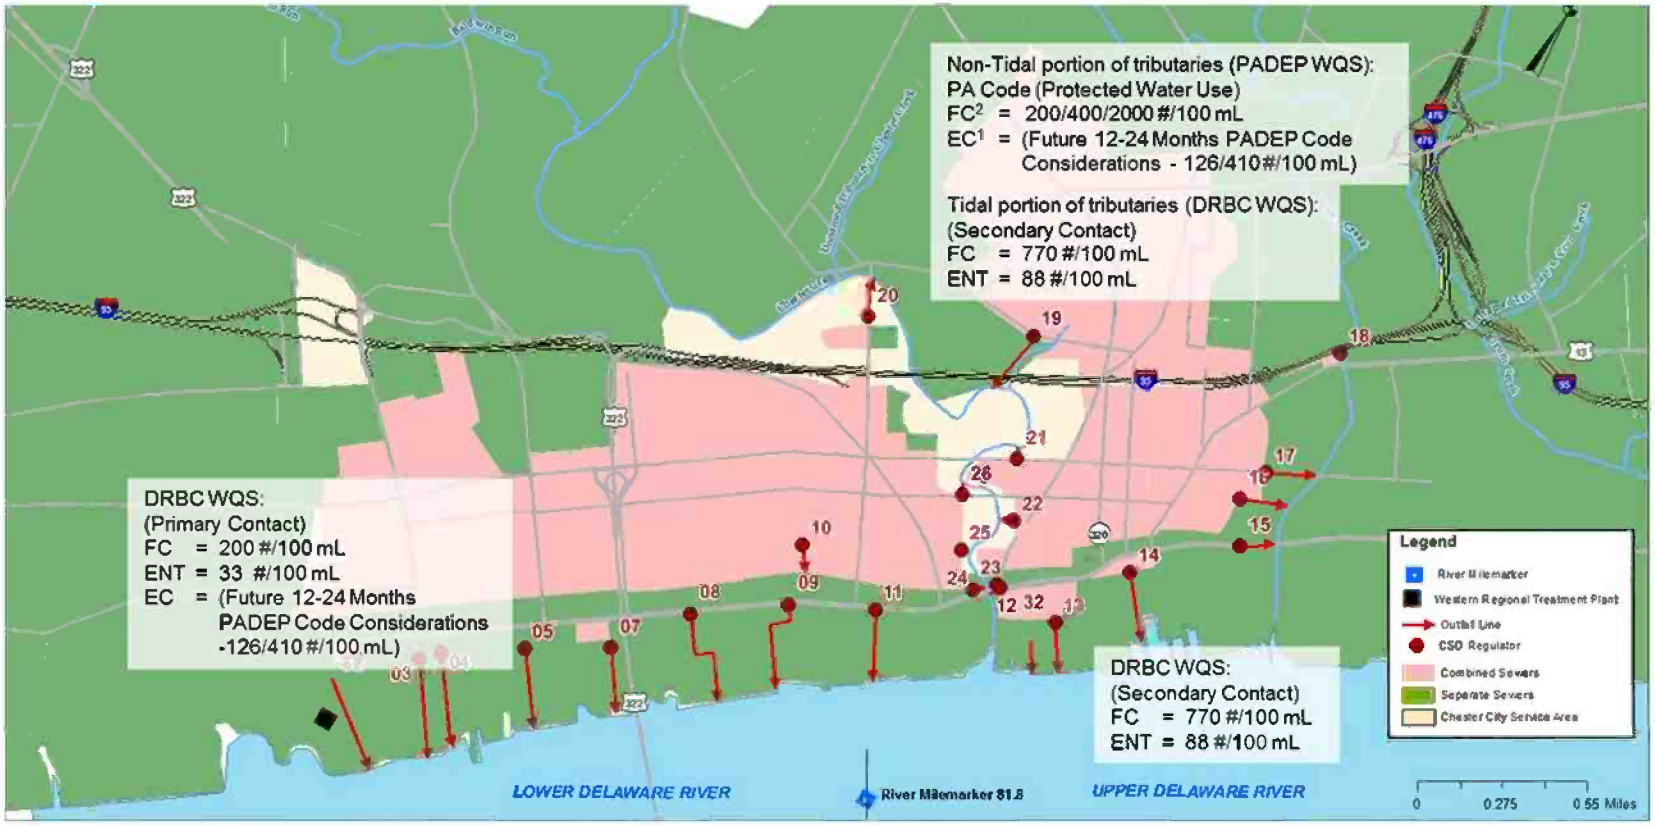
No.	Upper Delaware River		Lower Delaware River		Chester Creek		Ridley Creek	
Pollutants of Concern (>10% of observed samples exceed WQS)								
1	Fecal Coliform[b]	100%	Fecal Coliform[b]	100%	Fecal Coliform[a],[b]	100%	Fecal Coliform[a],[b]	100%
2	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%
3	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%

[a] Based on historical sampling conducted in 2010 upstream and downstream of CSO outfalls only on Chester and Ridley Creeks.

[b] Fecal Coliform and Enterococcus are listed as POCs due to both being parameters typically associated with CSOs.

[c] DRBC regulations are available for Enterococcus and it is typically associated with CSOs and therefore it is included as a POC. However, in consultation with PADEP Enterococcus could be replaced with E. coli bacteria in the future (based on the anticipation that national standards on E. coli will be adopted in Pennsylvania) and therefore E.coli is also included as a POC.

Figure 2-1: Water Quality Standards in the Receiving Streams



[1] E.coli (EC) standards likely to be codified by PADEP 12-24 months from July 2017. These criteria would apply to the non-tidal tributaries and Delaware River below R.H. 81.8, during recreational months only (May 1 - September 30). First value is a geometric mean standard, second is a statistical threshold value (STV) standard (no more than 10% of concentrations can be above this value).

[2] First value is a geometric mean standard, second is a statistical threshold value (STV) standard (no more than 10% of concentrations can be above this value), third value is a non-recreational season standard (October 1 - April 31).

2.2 Sampling and Analysis Plan Overview

Water quality sampling was undertaken at thirteen (13) in-stream locations (seven of which are Delaware River sampling locations), four (4) CSO locations in the DELCORA combined sewer system area, and two (2) stormwater locations in the City of Chester municipal separate storm sewer system, as shown in Figure 2-1. Water quality sampling was conducted as follows:

- Eleven (11) in-stream locations in the vicinity of the DELCORA CSO area were sampled for water quality for (3) dry weather events; one of which was targeted for collection during a tributary low-flow period (less than 25th percentile flow). The mid-stream and far-shore Delaware River locations were not sampled during the dry weather surveys because the water quality in the river is found to be relatively uniform laterally due to the lack of active sources during dry weather. These dry weather events were distributed across the sampling season, which was from March through June of 2017. Grab samples and *in situ* measurements were collected at each location during each event.
- All thirteen (13) in-stream locations were sampled for water quality using grab samples and *in situ* monitoring for three (3) discrete wet weather events, according to the surface water quality monitoring program protocols described in the Water Quality Monitoring and Modeling Work Plan (Greeley and Hansen / Limnotech, Revised July 2017);
- Up to four (4) CSO and two (2) stormwater outfall locations were sampled for water quality for the same three (3) discrete wet weather events according to the outfall monitoring program protocols described in the Water Quality Monitoring and Modeling Work Plan (Greeley and Hansen / Limnotech, Revised July 2017). Samples for all outfalls were collected as grab samples.

The sampling events were planned and distributed across the sampling season, which was from March through June 2017.

2.3 Sampling Locations

Sampling locations were selected to characterize the watershed at a sub-watershed level, recognizing various political and hydrologic features, land uses and potential pollutant sources. Site selection and analytical parameters are designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. The sampling locations are shown in Figure 2-2.

Tables 2-2, 2-3 and 2-4 include summaries of the rationales for each sampling location selected. The Chester Creek and Ridley Creek locations were selected to distinguish, to the extent possible, between upstream, stormwater and Chester CSO pollutant loads. The Delaware River sampling locations provided a characterization of water quality entering the Chester CSO area from either tidal direction as well as water quality within the CSO discharge area. During wet weather, three samples were collected across the transect corresponding to the DR-03 sampling location during each sampling round, when sampling across the river was feasible, to characterize lateral variability in the Delaware River during storm events.

The CSO sampling locations were selected based on their outfall discharge location, relatively high frequency of overflow, their overflow volume, and their accessibility. The stormwater sampling locations

Figure 2-2: Receiving Water, Combined Sewer (CSO), and Stormwater (SW) Sampling Locations

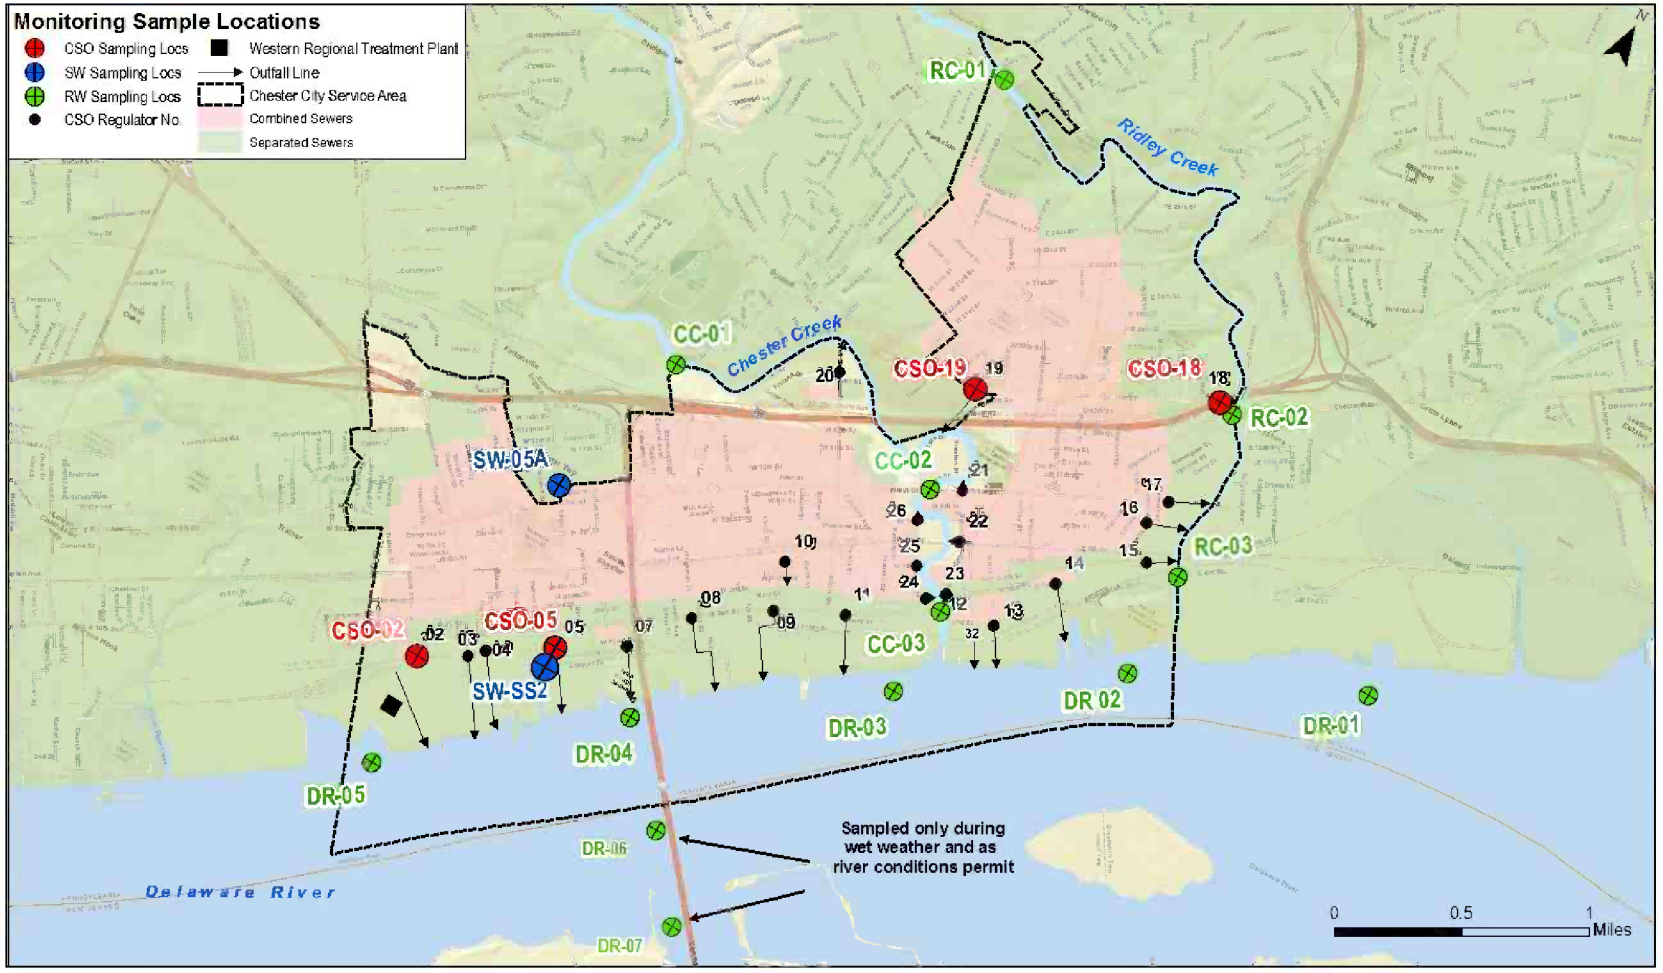


Table 2-2: Tributary Receiving Water Sampling Locations

Station ID	Latitude[1]	Longitude[1]	Receiving Water	Type	Description	Rationale

SW-SS2	39.832853	-75.384193	Delaware River	SW	Front and Townsend; 105 Townsend St	Characterize runoff quality from predominantly commercial/industrial area representative of the commercial/industrial portion of the study area

Notes:
[1] **GPS Coordinates, WGS 1984**

were selected to characterize the water quality associated with the predominant land uses (residential and commercial/industrial) in the study area. Each stormwater sampling location is in an area that is representative of the land use elsewhere in the City's stormwater area.

2.4 Analytical Parameters

All of the in-stream dry and wet weather samples was analyzed for the parameters shown in Table 2-5. The outfall samples was analyzed for *E. coli*, *Enterococcus* and Fecal coliform.

Table 2-5: Analytical and Field Parameters

Parameter	Description	Sampling Program	Type of Measurement
E. coli	Escherichia coli	Dry, Wet	Grab
Enterococcus	Enterococcus sp.	Dry, Wet	Grab
Fecal coliform	Fecal coliform	Dry, Wet	Grab
Temp	Water temperature	Dry, Wet, Receiving Water Only	In-situ
Cond	Conductivity	Dry, Wet, Receiving Water Only	In-situ
Salinity	Salinity	Dry, Wet, Receiving Water Only	In-situ

2.5 Sampling Schedule

2.5.1 Dry Weather Sampling

Collection of water quality samples was performed for three (3) dry weather events; with one dry weather sampling event collected during a low-flow period (less than 25th percentile flow) in Chester Creek and Ridley Creek.

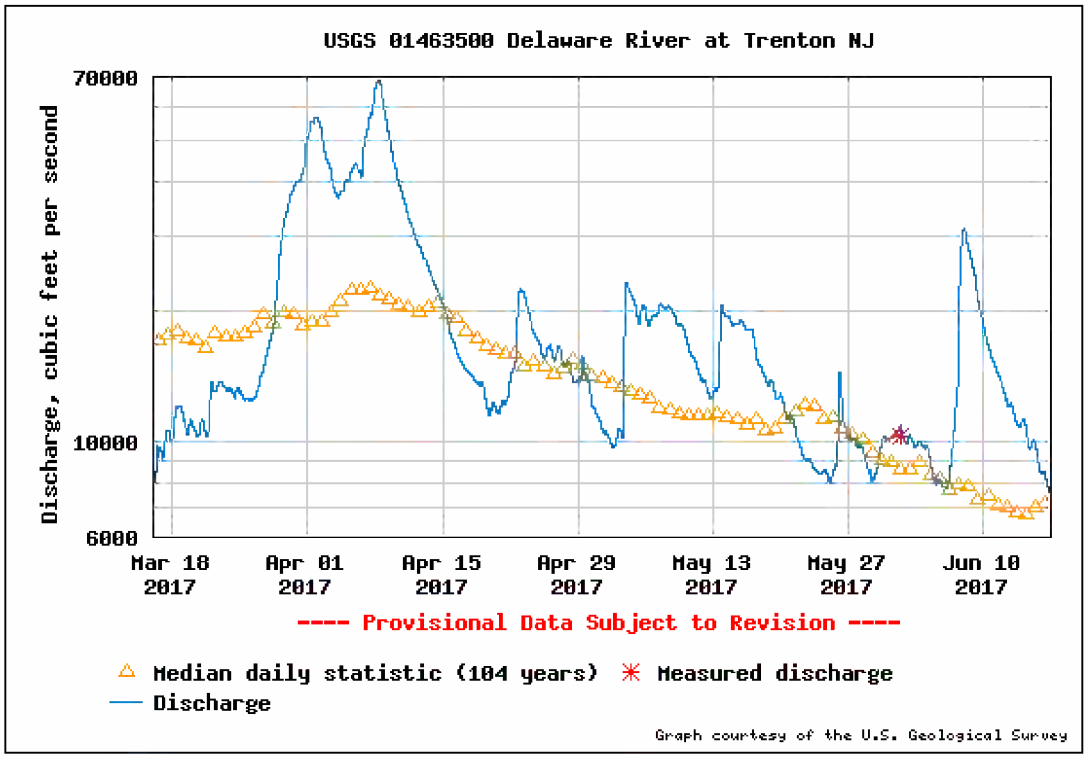
The values and statistics in Tables 2-6 and 2-7 were obtained from the United States Geological Survey (USGS). The USGS StreamStats (https://streamstats.usgs.gov/ss/) website provided the 25th percentile for the period of record for each water body and the National Water Information System (NWIS) provided current flow data. For each Dry Weather Event, the flow listed was reported as the average for the time of the sampling event calculated from 15-minute recorded observations not the average daily flow.

Table 2-6: Gage Information

Water Body	Gage Identification	Gage Description	Latitude	Longitude	Period of Record	StreamStats Weblink	NWIS Weblink
Delaware River	USGS 01463500	Delaware River at Trenton, NJ	40°13'18"	-74°46'41"	1912-2015	https://streamstatsags.cr.usgs.gov/gagepages/html/01463500.htm	https://nwis.waterdata.usgs.gov/nwis/inventory/?site_no=01463500
Chester Creek	USGS 01477000	Chester Creek near Chester, PA	39°52'08"	-75°24'31"	1931-2015	https://streamstatsags.cr.usgs.gov/gagepages/html/01477000.htm	https://nwis.waterdata.usgs.gov/nwis/inventory/?site_no=01477000
Ridley Creek	USGS 01476480	Ridley Creek at Media, PA	39°54'58"	-75°24'13"	1986-2015	https://streamstatsags.cr.usgs.gov/gagepages/html/01476480.htm	https://nwis.waterdata.usgs.gov/nwis/inventory/?site_no=01476480

A graph of the stream flow for each gage over the duration of the sampling program is shown below in Figures 2.3 - 2.5. The percentile for the streamflow during each event was interpolated from the statistical data provided on the StreamStats page.

Figure 2-3: Delaware River Flow, USGS Gage at Trenton, NJ



https://nwis.waterdata.usgs.gov/nwisweb/graph?agency_cd=USGS&site_no=01463500&parm_cd=00060&begin_date=2017-03-16&end_date=2017-06-16

Table 2-7: Receiving Waters 25th Percentile Flow

Water Body	Gage Identification	Gage Description	25th Percentile Flow	Dry Weather Event 1 Average Flow		Dry Weather Event 2 Average Flow		Dry Weather Event 3 Average Flow

Two rounds of sampling were conducted for each dry weather survey: one round was completed during ebb (outgoing) tide and the second round was completed during flood (incoming) tide.

Dry weather event samples were taken at eleven (11) locations:

- **Three (3) locations on Chester Creek** that characterizes water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations used reflect these tidal influences on water quality.
- **Three (3) locations on Ridley Creek** that characterizes water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations used reflect these tidal influences on water quality.
- **Five (5) locations on the Delaware River** that characterizes water quality in the vicinity of DELCORA's CSO discharges. Sampling locations used are selected to separate to the extent possible the effect of DELCORA's CSOs on water quality from other sources contributing pollutants to the waterways. Sampling was conducted near the shoreline adjacent to the City of Chester

The locations of these stations are shown in Figure 2-1. Details for the parameters for which the samples were analyzed is provided in Table 2-5. In-situ measurements of physical parameters, such as salinity, temperature, and conductivity were collected at each sampling location with a YSI sonde. In the Delaware River, *in situ* measurements were collected at three depths at each sampling location during each round of sampling.

2.5.2 Wet Weather Sampling

Collection of water quality samples were performed for three (3) wet weather events. The purpose of the wet weather sampling was to characterize the impact of CSO discharges and non-CSO source runoff on in-stream water quality. The wet weather events spanned a range of precipitation, flow and seasonal conditions.

Wet weather event samples were taken at all 13 in-stream locations as well as at up to six source locations in the intervals described below:

- **Six (6) In-Stream Tributary Sampling Locations:** Three (3) locations were on Chester Creek and three (3) locations on Ridley Creek. The locations were the same locations used for the dry weather surveys. Tributary locations were sampled up to five times per event at the following approximate intervals: Hour 0.5-2.5, Hour 4.5-6.5, Hour 8.5-10.5, Hour 14.5-16.5, and Hour 22-24. Sampling intervals were defined by the start of rainfall rather than CSO or SSO activation. A total of 30 samples were collected during each wet weather sampling event from in-stream locations. One field blank and one field duplicate were collected during each event to be used as field quality control (QC).

- **Up to Seven (7) In-Stream Delaware River Locations:** Up to seven locations were on the Delaware River and were sampled up to ten times per event at the following approximate intervals: Hour 0, Hour 2, Hour 4, Hour 6, Hour 9, Hour 12, Hour 15, Hour 18, Hour 21, and Hour 24. Sampling intervals were defined by the start of rainfall rather than CSO or SSO activation. The frequency of sampling was intended to capture in-stream impacts in the vicinity of DELCORA's service area from both DELCORA's CSOs as well as upstream sources. Two additional locations on the Delaware River, one at mid-stream and one near the far shore, were added to characterize lateral variability in water quality during storm event conditions, when sampling across the river is feasible. The sampling regimen was also designed to allow a semi-quantitative mass balance to be computed over a complete tidal cycle. When the river conditions were unsafe for sampling (e.g. small craft advisories, heavy barge traffic, etc.), sampling was suspended for one or more locations and/or sampling rounds. One field blank and one field duplicate were collected during each event to be used as field QC. Final selection of sampling locations and sampling intervals were determined prior to the start of the sampling program and were based on logistic considerations (e.g. can seven locations be sampled and dropped off to a courier within the 3 hour sampling window), safety and accessibility to the Delaware River, and available resources.
- **Up to Six (6) Outfall Locations:** Sampling was be conducted at up to two (2) stormwater outfalls and up to four (4) combined sewer overflow outfalls. The CSO and stormwater sampling locations were finalized prior to the initiation of the sampling program based on accessibility of sampling, safety of sampling personnel, equipment risk, and available resources. It was assumed that each of the outfall locations will have up to eight sets of samples collected for each event at the following intervals: 1st flush, 30 minutes, and 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, 24 hours. If a location was found to be not flowing, no sample was collected. One field blank and one field duplicate were collected during each event to be used as field QC.

The locations of these stations are shown in Figure 2-2. The set of parameters for which the samples will be analyzed are summarized in Table 2-4. *In-situ* measurements was not collected at the outfall locations.

Sampling crews conducted all wet weather event sampling using the protocols described in the Water Quality Monitoring and Modeling Quality Assurance Project Plan (Greeley and Hansen / Limnotech, Revised July 2017). Crews were required to keep a City of Chester Map with sampling locations clearly marked as well as a letter from DELCORA permitting the crews access to manholes, shorelines, outfalls, and surface waters (see Appendix J). Samples were delivered to the laboratory where the samples were analyzed for the laboratory parameters identified in Table 2-5.

Determination to mobilize for a Wet Weather Event was a collaborative effort between Greeley and Hansen, LimnoTech, the field sampling contractor and the laboratory contractor personnel. The intent was to identify a 4 to 6 hour window in which a wet weather event that commenced 24 hours in advance to assist in mobilization of the sampling crews.

Section 3 Dry and Wet Weather Sampling Activities

3.1 Dry Weather Sampling Event 1

Dry Weather Sampling Event-1 occurred on March 23, 2017. See Table 2-7 for receiving water flows and percentiles based on USGS gages.

3.1.1 Activity on Creeks

Sampling was conducted on Chester Creek (CC) and Ridley Creek (RC). On this date, the observed daily average flows for Chester Creek and Ridley Creek were 75.7 cfs and 29.4 cfs, respectively, at the locations indicated in Table 2-7.

3.1.1.1 Sample Type and Locations

Grab samples were collected from the following locations on the Creeks:

- Three (3) on Chester Creek - CC-01, CC-02, CC-03
- Three (3) on Ridley Creek - RC-01, RC-02, RC-03

A single in-situ measurement was collected at every location and sampling round.

See Figure 2-2 for map of sampling locations. See Appendix K for sampling photos.

3.1.1.2 Sampling Round and Sampling Time

An incoming tide and outgoing tide sample was collected at each of the three Chester Creek and three Ridley Creek locations described above along with the required Field Blanks and Duplicates. Field Blanks were collected at the first sampling location for each event regardless of tide condition. Samples from the downstream end of the creeks were collected first to capture the outgoing tide at the earliest. The samples on creeks were collected in the following order for each sampling round - CC-03, RC-03, RC-02, RC-01, CC-02 and CC-01. The number and type of samples collected from the Creeks for Dry Event 1 are shown in Appendix A - Dry Weather Event 1 - Field Logs and Lab Results Summary.

The sampling event started on March 23, 2017 at 1:00 PM and ended at 7:30 PM. The sampling times were selected so that they were in between the high tide and low tide time data. The outgoing tide samples were collected first followed by the incoming tide later in the evening. The tide data for that date showed a range of high tide to low tide from 9:15 AM to 4:22 PM and a range of low tide to high tide from 4:22 PM to 9: 54 PM. The sample collection times from the Creeks for Dry Weather Event 1 are shown in Appendix A - Dry Weather Event 1 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.1.1.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) (Weston Solutions, Inc., March 2017) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event 1 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site, and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix A - Dry Weather Event 1 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of Dry Weather Event 1 Chain of Custody Forms are shown in Appendix A - Dry Weather Event 1 - Field Logs and Lab Results Summary.

3.1.2 Activity on Delaware River

Sampling was conducted on Delaware River (DR) with 5 locations on the Pennsylvania side of the river. On this date, the observed daily average flow for the Delaware River was 13,323 cfs at the location indicated in Table 2-7.

3.1.2.1 Sample Type and Locations

Grab samples were collected from the following locations on the Delaware River:

- Five (5) on Delaware River – DR-01, DR-02, DR-03, DR-04, DR-05

A single in-situ measurement was collected at every location at surface, mid and near bottom depths.

See Figure 2-2 for map of sampling locations.

3.1.2.2 Sampling Round and Sampling Time

There was an incoming tide and outgoing tide sample collected at each of the five Delaware River locations along with the required Field Blanks and Duplicates. The samples on the river were collected in the following order for each sampling round - DR-01, DR-02, DR-03, DR-04 and DR-05. The number and type of samples collected from the river for Dry Weather Event 1 are shown in Appendix A - Dry Weather Event 1 - Field Logs and Lab Results Summary.

The sampling event started on March 23, 2017 at 12:55 PM and ended at around 6:30 PM. The sampling times were selected so that they were in between the high tide and low tide time data. The outgoing tide samples were collected first followed by the incoming tide later in the afternoon/evening. The tide data for that date showed a range of high tide to low tide from 9:15 AM to 4:22 PM and a range of low tide to high tide from 4:22 PM to 9:54 PM. The sample collection times from the Creeks for Dry Weather Event 1 are shown in Appendix A - Dry Weather Event 1 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.1.2.3 Field Observation and Sample Management

The grab sample was collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event 1 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde at surface, mid and near bottom depths of the river. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix A - Dry Weather Event 1- Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of Dry Weather Event 1 Chain of Custody Forms are shown in Appendix A - Dry Weather Event 1 - Field Logs and Lab Results Summary.

3.2 Dry Weather Sampling Event 2

Dry Weather Sampling Event-2 occurred on 5/10/2017. See Table 2-7 for receiving water flows and percentiles based on USGS gages.

3.2.1 Activity on Creeks

Sampling was conducted on Chester Creek (CC) and Ridley Creek (RC). On this date, the observed daily average flows for Chester Creek and Ridley Creek were 63.9 cfs and 25.0 cfs respectively at the locations indicated in Table 2-7.

3.2.1.1 Sample Type and Locations

Grab samples were collected from the following locations on the Creeks:

- Three (3) on Chester Creek – CC-01, CC-02, CC-03
- Three (3) on Ridley Creek – RC-01, RC-02, RC-03

A single in-situ measurement was collected at every location and sampling round.

See Figure 2-2 for map of sampling locations.

3.2.1.2 Sampling Round and Sampling Time

An incoming tide and outgoing tide sample was collected at each of the three Chester Creek and three Ridley Creek locations described above along with the required Field Blanks and Duplicates. Field Blanks were collected at the first sampling location for each event regardless of tide condition. Samples

from the downstream end of the creeks were collected first to capture the outgoing tide at the earliest. The samples on creeks were collected in the following order for each sampling round – CC-03, RC-03, RC-02, RC-01, CC-01 and CC-02. The number and type of samples collected from the Creeks for Dry Weather Event 2 are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

The sampling event started on May 10, 2017 at 10:00 AM and ended at 5:45 PM. The sampling times were selected so that they were in between the high tide and low tide time data. The incoming tide samples were collected first followed by the outgoing tide later in the afternoon. The tide data for that date showed a range of low tide to high tide from 7:35 AM to 12:56 PM and a range of high tide to low tide from 12:56 PM to 7: 45 PM. The sample collection times from the Creeks for Dry Weather Event 2 are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

See Appendix G for Sample Collection Matrix.

3.2.1.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event 2 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of Dry Weather Event 2 Chain of Custody Forms are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

3.2.2 Activity on Delaware River

Sampling was conducted on Delaware River (DR) with 5 locations on the Pennsylvania side of the river. On this date, the observed daily average flow for the Delaware River was 16,306 cfs at the location indicated in Table 2-7.

3.2.2.1 Sample Type and Locations

Grab samples were collected from the following locations on the Delaware River:

- Five (5) on Delaware River – DR-01, DR-02, DR-03, DR-04, DR-05

A single in-situ measurement was collected at every location at surface, mid and near bottom depths.

See Figure 2-2 for map of sampling locations.

3.2.2.2 Sampling Round and Sampling Time

There was an incoming tide and outgoing tide sample collected at each of the five Delaware River locations along with the required Field Blanks and Duplicates. The samples on river were collected in the following order for each sampling round - DR-01, DR-02, DR-03, DR-04 and DR-05. The number and type of samples collected from the river for Dry Weather Event 2 are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

The sampling event started on May 10, 2017 at 10:00 AM and ended at 5:45 PM. The sampling times were selected so that they were in between the high tide and low tide time data. The incoming tide samples were collected first followed by the outgoing tide later in the afternoon. The tide data for that date showed a range of low tide to high tide from 7:35 AM to 12:56 PM and a range of high tide to low tide from 12:56 PM to 7: 45 PM. The sample collection times from the Creeks for Dry Weather Event 2 are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.2.2.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event 2 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde at surface, mid and near bottom depths of the river. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Dry Weather Event 2 Chain of Custody Forms are shown in Appendix B - Dry Weather Event 2 - Field Logs and Lab Results Summary.

3.3 Dry Weather Sampling Event 3

Dry Weather Sampling Event-3 occurred on 6/13/2017. See Table 2-7 for receiving water flows and percentiles based on USGS gages.

3.3.1 Activity on Creeks

Sampling was conducted on Chester Creek (CC) and Ridley Creek (RC). On this date, the observed flows for Chester Creek and Ridley Creek were 46.8 cfs and 19.0 cfs, respectively, at the locations indicated in Table 2-7.

3.3.1.1 Sample Type and Locations

Grab samples were collected from the following locations on the Creeks:

- Three (3) on Chester Creek – CC-01, CC-02, CC-03
- Three (3) on Ridley Creek – RC-01, RC-02, RC-03

A single in-situ measurement was collected at every location and sampling round.

See Figure 2-2 for map of sampling locations.

3.3.1.2 Sampling Round and Sampling Time

An incoming tide and outgoing tide sample was collected at each of the three Chester Creek and three Ridley Creek locations described above along with the required Field Blanks and Duplicates. Field Blanks were collected at the first sampling location for each event regardless of tide condition. Samples from the downstream end of the creeks were collected first to capture the outgoing tide at the earliest. The samples on creeks were collected in the following order for each sampling round - CC-03, RC-03, RC-02, RC-01, CC-01 and CC-02. The number and type of samples collected from the Creeks for Dry Weather Event -3 are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

The sampling event started on June 13, 2017 at 12:50 AM and ended at 20:06 PM. The sampling times were selected so that they were in between the high tide and low tide time data. The incoming tide samples were collected first followed by the outgoing tide later in the evening. The tide data for that date showed a range of low tide to high tide from 10:33 AM to 3:42 PM and a range of high tide to low tide from 3:42 PM to 10:24 PM. The sample collection times from the Creeks for Dry Weather Event 3 are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.3.1.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event-3 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Dry Weather Event 3 Chain of Custody Forms are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

3.3.2 Activity on Delaware River

Sampling was conducted on Delaware River (DR) with 5 locations on the Pennsylvania side of the river. On this date, the observed flow for the Delaware River was 10,862 cfs at the location indicated in Table 2-7.

3.3.2.1 Sample Type and Locations

Grab samples were collected from the following locations on the Delaware River:

- Five (5) on Delaware River – DR-01, DR-02, DR-03, DR-04, DR-05

A single in-situ measurement was collected at every location at surface, mid and near bottom depths.

See Figure 2-2 for map of sampling locations.

3.3.2.2 Sampling Round and Sampling Time

There was an incoming tide and outgoing tide sample collected at each of the five Delaware River locations along with the required Field Blanks and Duplicates. The samples on river were collected in the following order for each sampling round - DR-01, DR-02, DR-03, DR-04 and DR-05. The number and type of samples collected from the river for Dry Weather Event 3 are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

The sampling event started on June 13, 2017 at 12:50 PM and ended at 20:06 PM. The sampling times were selected so that they were in between the high tide and low tide time data. The incoming tide samples were collected first followed by the outgoing tide later in the evening. The tide data for that date showed a range of low tide to high tide from 10:33 AM to 3:42 PM and a range of high tide to low tide from 3:42 PM to 10:24 PM. The sample collection times from the Creeks for Dry Weather Event 3 are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

3.3.2.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event-3 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde at surface, mid and near bottom depths of the river. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Dry Weather Event 3 Chain of Custody Forms are shown in Appendix C - Dry Weather Event 3 - Field Logs and Lab Results Summary.

3.4 Wet Weather Sampling Event 1

Wet Weather Sampling Event 1 occurred on 3/31/2017. See Table 2-7 and Figures 2-2 thru 2-4 for receiving water flows based on USGS gages.

3.4.1 Activity on Creeks

Sampling was conducted on Chester Creek (CC) and Ridley Creek (RC). The observed flows for Chester Creek were 79.1 cfs at the beginning of the sampling event, reached a peak flow of 2,260 cfs at 6:45PM, and was 1,330 cfs when the sampling event concluded. For Ridley Creek, flow was 28.8 cfs at the beginning of the sampling event, reached a peak flow of 898 cfs at 9:30PM, and was 790 cfs when the sampling event concluded. The flow gauge locations are shown on Figure 3-1 - Flow Gauge Locations.

3.4.1.1 Sample Type and Locations

Grab samples were collected from the following locations on the Creeks:

- Three (3) on Chester Creek – CC-01, CC-02, CC-03
- Three (3) on Ridley Creek – RC-01, RC-02, RC-03

A first grab sample collected on creek was during T=0 at the beginning for the rainfall event. Time T=0 for collection of the in-stream sample was initiated approximately 0.5 hours after the start of rainfall, or when 0.1 inches of rain had fallen or when CSO discharges start occurring (whichever occurs first). Significant rainfall began at 11:45 PM and sampling personnel were already in place to begin sampling within the first half hour. Accordingly, the first storm water sample was taken at location SW-SS2 at 11:50 PM and the first creek sample was collected on Chester Creek at CC-03 at midnight 0:00 hours. The sampling round intervals for all sampling locations are shown in the sampling collection matrix in Appendix G. See Figure 2-2 for map of sampling locations.

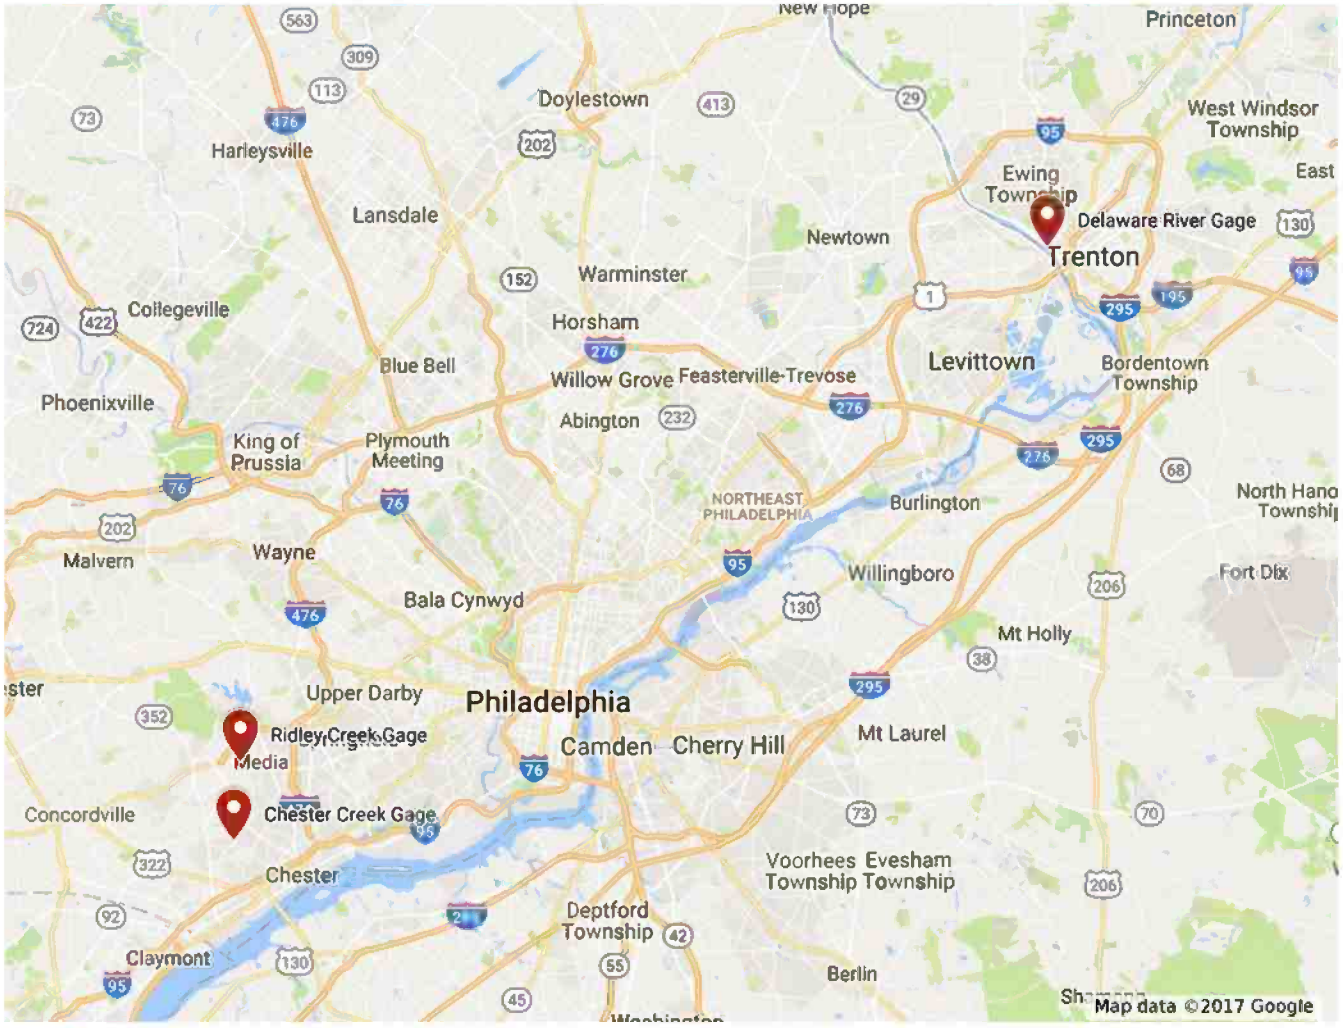
A single in-situ measurement was collected at every location and sampling round.

3.4.1.2 Sampling Round and Sampling Time

The grab samples collected on the Creeks as shown above were collected in intervals. The sampling intervals spanned over a 24 hour rain event. The intervals for sampling on creeks were at hour 0.5-2.5, hour 4.5-6.5, hour 8.5-10.5, hour 14.5-16.5, and hour 22-24. The samples also included the required Field Blanks and Duplicates as indicated in the Sampling collection matrix shown in Appendix G. Field Blanks were collected at the first sampling location. Samples from the downstream end of the creeks were collected first to capture the outgoing tide at the earliest. The samples on creeks were collected in the following order for each sampling round - CC-03, RC-03, RC-02, RC-01, CC-02 and CC-01. The number and type of samples collected from the Creeks for Wet Weather Event 1 are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

The sampling event started on March 31, 2017 at 12:30 AM and ended on April 1, 2017 at 12:30 AM. There were a total of five (5) rounds of sampling conducted on the creeks. The sampling intervals were selected to capture the earlier part of the rainfall event and any impact of CSOs and Storm water runoff on the Creeks water quality. All samples from each location and from each sampling round were collected

Figure 3-1: Flow Gauge Locations



for analysis. The sample collection times from the Creeks for Wet Weather Event 1 are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.4.1.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event 1 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix D – Wet Weather Event 1 – Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 1 Chain of Custody Forms are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

3.4.2 Activity on Delaware River

Sampling was conducted on Delaware River (DR) with 5 locations on the Pennsylvania side of the river and 2 locations, mid-channel and New Jersey side, on a transect near the Commodore Barry Bridge. On this date, the observed flow for the Delaware River was 44,100 cfs at the location shown on Figure 3-1.

3.4.2.1 Sample Type and Locations

Grab samples were collected from the following locations on the Delaware River:

- Seven (7) on Delaware River – DR-01, DR-02, DR-03, DR-04, DR-05, DR-06, DR-07

A first grab sample collected on river was during T=0 at the beginning for the rainfall event. Time T=0 for collection of the in-stream sample was initiated approximately 0.5 hours after the start of rainfall, or when 0.1 inches of rain had fallen or when CSO discharges start occurring (whichever occurs first). The sampling round intervals for all sampling locations are shown in the sampling collection matrix in Appendix G. See Figure 2-2 for map of sampling locations.

A single in-situ measurement was collected at every location at surface, mid and near bottom depths.

3.4.2.2 Sampling Round and Sampling Time

The grab samples collected on the Creeks as shown above were collected in intervals. The sampling intervals spanned over a 24 hour rain event. The intervals for sampling on creeks were at hour 0, hour 2, hour 4, hour 6, hour 9, hour 12, hour 15, hour 18, hour 21, and hour 24. The samples also included the required Field Blanks and Duplicates as indicated in the Sampling collection matrix shown in Appendix G. The samples on river were collected in the by two boat crews. One of the boat crews were assigned to sample the northern sampling locations DR-01, DR-02, DR-03 and the other boat crew was assigned to sample the southern sampling locations and points across the river at DR-04, DR-05, DR-06 and DR-07. The two boat crews were used to collect samples during the first five (5) sampling rounds to provide enough time to return the samples to the lab and complete the entire sampling loop on the river within the decided sampling intervals. After the first five (5) rounds only one boat crew was required to sample at all locations due to the availability of more time between sampling intervals after completing the entire loop. The number and type of samples collected from the river for Wet Weather Event 1 are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

Boat activities became too hazardous as determined by the boat captain and all on-water activities were halted at 4:45 AM. A couple of shore grabs were collected at near locations DR-04, DR-05 between 7:00 AM and 7:30 AM. Conditions improved allowing for the resumption of boat activities after a period of approximately 4 hours. Delaware River loop was behind by one (1) entire set due to skipped locations because of boat motor issues, ship docking on river near sampling location and hazardous conditions on river.

See Appendix G for Sample collection matrix.

3.4.2.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Dry Weather Event-1 samples on the creeks was held within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site, and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde at surface, mid and near bottom depths of the river. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 1 Chain of Custody Forms are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

3.4.3 Activity at Combined Sewer Overflow (CSO) Locations

3.4.3.1 Sample Type and Locations

Grab samples were collected from the following CSO locations:

- Four (4) locations – CSO-02, CSO-05, CSO-18, CSO-19

See Figure 2-2 for map of sampling locations.

3.4.3.2 Sampling Round and Sampling Time

The samples were collected at each of the CSO locations along with the required Field Blanks and Duplicates. The samples at the CSOs were collected in the following order for each sampling round - first flush, 30 minutes, 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, and 24 hours. The samples were collected only if there was any active overflow occurring over the weir at the CSO location. The number and type of samples collected from the river for Wet Weather Event 1 are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

The sampling event started on March 30, 2017 at 12:30 AM and ended on April 1, 2017 at around 12:30 AM. The sampling was started at time T=0 at the start of rain fall event to collect the first flush sample. The sampling intervals were distributed over a 24 hour sampling period. If it was found that a CSO was not active then no samples were collected at those locations during those sampling rounds. It was observed that CSO-02 activated very fast whereas CSO-05 took longer to activate compared to CSO-18 and CSO-19. Any samples that were not collected in the previous round were recaptured in the next round so as to have the desired number of samples for analysis. The sample collection times from the CSO locations for Wet Weather Event 1 are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.4.3.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 1 samples at the CSO locations was held within the recommended time for lab analysis. While collecting the samples the sample was collected on the downstream side of the overflow for an active overflow at the CSO locations. The sampling equipment was used and then decontaminated using DI water at every sampling location. The field observations and Field Blanks and Duplicate information is provided in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 1 Chain of Custody Forms are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

3.4.4 Activity at Storm Water (SW) Locations

3.4.4.1 Sample Type and Locations

Grab samples were collected from the following storm water locations:

- Two (2) locations – SW-05A, SW-SS2

See Figure 2-2 for map of sampling locations.

3.4.4.2 Sampling Round and Sampling Time

Samples were collected at both of the storm water locations along with the required Field Blanks and Duplicates. The samples on were collected in the following order for each sampling round - SW-SS2 and SW-05A. The number and type of samples collected for Wet Weather Event 1 are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

The sampling event started on March 30, 2017 at 12:30 AM and ended on March 31 at 12:30 PM. The sampling times were distributed to cover the storm over 24 hour period and samples were collected whenever there was active storm flow occurring. The sample collection times from the Storm water locations for Wet Weather Event 1 are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.4.4.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate equipment and protective gear. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 1 samples at the Storm water locations was held within the recommended time for lab analysis. The sampling equipment was used and decontaminated using DI water at every sampling location. The number of samples, Field Blanks and Duplicates are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 1 Chain of Custody Forms are shown in Appendix D - Wet Weather Event 1 - Field Logs and Lab Results Summary.

3.5 Wet Weather Sampling Event 2

Wet Weather Sampling Event 2 occurred on 5/5/2017. See Table 2-7 and Figures 2-2 through 2-4 for receiving water flows based on USGS gages.

3.5.1 Activity on Creeks

Sampling was conducted on Chester Creek (CC) and Ridley Creek (RC). The observed flows for Chester Creek were 54.8 cfs at the beginning of the sampling event, reached a peak flow of 841 cfs at 4:15PM, and was 160 cfs when the sampling event concluded. For Ridley Creek, flow was 24.5 cfs at the beginning of the sampling event, reached a peak flow of 315 cfs at 5:30PM, and was 60.8 cfs when the sampling event concluded. The flow gauge locations are shown on Figure 3-1.

3.5.1.1 Sample Type and Locations

Grab samples were collected from the following locations on the Creeks:

- Three (3) on Chester Creek – CC-01, CC-02, CC-03
- Three (3) on Ridley Creek – RC-01, RC-02, RC-03

A first grab sample collected on creek was during T=0 at the beginning for the rainfall event. Time T=0 for collection of the in-stream sample was initiated approximately 0.5 hours after the start of rainfall, or when 0.1 inches of rain had fallen or when CSO discharges start occurring (whichever occurs first). Significant rainfall began at 7:00 AM and sampling personnel were already in place to begin sampling within the first half hour. Accordingly, the first creek sample was taken at 7:20 AM. The sampling round intervals for all sampling locations are shown in the sampling collection matrix in Appendix G. See Figure 2-2 for map of sampling locations.

A single in-situ measurement was collected at every location and sampling round.

3.5.1.2 Sampling Round and Sampling Time

The grab samples collected on the Creeks as shown above were collected in intervals. The sampling intervals spanned over a 24-hour period. The intervals for sampling on creeks were at hour 0.5-2.5, hour 4.5-6.5, hour 8.5-10.5, hour 14.5-16.5, and hour 22-24. The samples also included the required Field Blanks and Duplicates as indicated in the sampling collection matrix shown in Appendix G. Field Blanks were collected at the first sampling location. Samples from the downstream end of the creeks were collected first to capture the outgoing tide at the earliest. The samples on creeks were collected in the following order for each sampling round - CC-03, RC-03, RC-02, RC-01, CC-02 and CC-01. The number and type of samples collected from the Creeks for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

The sampling event started on May 5, 2017 at 7:00 AM and ended on May 6, 2017 at 7:00 AM. There were a total of five (5) rounds of sampling conducted on the creeks. The sampling intervals were selected to capture the earlier part of the rainfall event and any impact of CSOs and Storm water runoff on the Creeks water quality. All samples from each location and from each sampling round were collected for analysis. The sample collection times from the Creeks for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

See Appendix G for sample collection matrix.

3.5.1.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protection equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 2 samples on the creeks was within the recommended time for lab analysis. While collecting the samples, field observations were noted to indicate any specific weather, water body, site, and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 2 Chain of Custody Forms are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

3.5.2 Activity on Delaware River

Sampling was conducted on Delaware River (DR) with 5 locations on the Pennsylvania side of the river and 2 locations, mid-channel and New Jersey side, on a transect near the Commodore Barry Bridge. On this date, the observed flow for the Delaware River was 19,900 cfs at the location shown on Figure 3-1.

3.5.2.1 Sample Type and Locations

Grab samples were collected from the following locations on the Delaware River:

- Seven (7) on Delaware River – DR-01, DR-02, DR-03, DR-04, DR-05, DR-06, DR-07

A first grab sample collected on river was during T=0 at the beginning for the rainfall event. Time T=0 for collection of the in-stream sample was initiated approximately 0.5 hours after the start of rainfall, or when 0.1 inches of rain had fallen or when CSO discharges start occurring (whichever occurs first). The sampling round intervals for all sampling locations are shown in the sampling collection matrix in Appendix G. See Figure 2-2 for map of sampling locations.

A single in-situ measurement was collected at every location at surface, mid and near bottom depths.

3.5.2.2 Sampling Round and Sampling Time

The grab samples collected on the Creeks as shown above were collected in intervals. The sampling intervals spanned over a 24-hour period. The intervals for sampling on the Delaware River were at hour 0, hour 2, hour 4, hour 6, hour 9, hour 12, hour 15, hour 18, hour 21, and hour 24. The samples also included the required Field Blanks and Duplicates as indicated in the sampling collection matrix shown in Appendix G. The samples on the river were collected by two boat crews. One of the boat crews was assigned to sample the northern sampling locations DR-01, DR-02, DR-03 and the other boat crew was assigned to sample the southern sampling locations and points across the river at DR-04, DR-05, DR-06 and DR-07. The two boat crews were planned for sample collection during the first five (5) sampling rounds, to provide enough time to return the samples to the lab and complete the entire sampling loop on

the river within the decided sampling intervals. After the first three (3) rounds, only one boat crew would be required to sample at all locations because of the availability of more time between sampling intervals after completing the entire loop.

As Round 2 was being completed, lightning was observed in the area. Safety protocols required that both boats be removed from the water and that 30 minutes elapse with no lightning before resumption of boat activities. This resulted in a 35-minute delay in the start of Round 3. After the third round of sampling, several punctures were discovered in one of the boat's hull causing water to inundate the boat see Appendix K - Sampling Photos). For safety and maneuverability concerns, this boat was pulled from the river. As the second boat began Round 4, it also encountered mechanical issues when its engine could not propel the boat forward. After inspection, a problem with the transmission was identified and this boat was also removed from the river. It was suggested to switch out the engine so that sampling on the Delaware River could continue, but was unsuccessful due to the incompatibility of the steering systems between the two boats. At this point two (2) rounds were missed, hour 6 and hour 9. As an alternative option (to get as much data as possible) the remainder of sampling on the Delaware River for rounds six through ten were taken from shore locations close to DR-03 and DR- 04. There were no accessible points along Chester City shoreline to collect grab samples for DR-01, DR-02 and DR-05. Grab sample for DR-03 was collected from shore on Norris Street and that for DR-04 was collected from the boat launch ramp near the stadium. Grab samples were collected using bailer and rope along with insitu readings for both locations. For reference, the number and type of samples collected from the river for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

The sampling event started on May 5, 2017 at 7:00 AM and ended on May 6, 2017 at 7:00 AM. There were a total of eight (8) rounds of sampling conducted on the Delaware. The sampling intervals were selected to capture the earlier part of the rainfall event and any impact the CSOs and storm water runoff had on river water quality. The sample collection times from the Creeks for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

See Appendix G for sample collection matrix.

3.5.2.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protective equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 2 samples on the Delaware River was within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site, and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde at surface, mid and near bottom depths of the river. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples.

Copies of the Wet Weather Event 2 Chain of Custody Forms are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

3.5.3 Activity at Combined Sewer Overflow (CSO) Locations

3.5.3.1 Sample Type and Locations

Grab samples were collected from the following CSO locations:

- Four (4) locations – CSO-02, CSO-05, CSO-18, CSO-19

See Figure 2-2 for map of sampling locations.

3.5.3.2 Sampling Round and Sampling Time

Grab samples were collected at each of the CSO locations along with the required Field Blanks and Duplicates. The samples at the CSOs were collected in the following order for each sampling round - first flush, 30 minutes, 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, and 24 hours. The samples were collected only for the first five (5) rounds for all CSO locations because there was not any active overflow occurring over the weir after 6 hours. The number and type of samples collected from the river for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

The sampling event started on May 5, 2017 at 7:00 AM and ended on May 6, 2017 at around 7:00 AM. The sampling was started at time T=0, the beginning of an active overflow, to collect the first flush sample. The sampling intervals were distributed over a 24 hour sampling period, but before sampling rounds six through eight, it was found that no CSOs were actively discharging, therefore no samples were collected at those locations during those sampling rounds. Because of the precipitation intensity for this particular round of sampling, all CSOs discharged within minutes of each other. The sample collection times from the CSO locations for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.5.3.3 Field Observation and Sample Management

The samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protective equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 2 samples at the CSO locations was within the recommended time for lab analysis. Samples were collected on the downstream side of the overflow for an active overflow at the CSO locations. The sampling equipment was used and then decontaminated using DI water at every sampling location. The field observations, Field Blanks, and Duplicate information is provided in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples.

Copies of the Wet Weather Event 2 Chain of Custody Forms are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

3.5.4 Activity at Storm Water (SW) Locations

3.5.4.1 Sample Type and Locations

Grab samples were collected from the following storm water locations:

- Two (2) locations – SW-05A, SW-SS2

See Figure 2-2 for map of sampling locations.

3.5.4.2 Sampling Round and Sampling Time

Samples were collected at both of the storm water locations along with the required Field Blanks and Duplicates. The samples at SW-05A and SW-SS2 were collected in the following order for each sampling round - first flush, 30 minutes, 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, and 24 hours. The samples were collected only for the first five (5) rounds for both storm water locations because there was not any flow occurring in the storm sewers after 6 hours. The number and type of samples collected from the river for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs, Chain of Custody Forms, and Lab Results.

The sampling event started on May 5, 2017 at 7:00 AM and ended on May 6, 2017 at around 7:00 AM. The sampling was started at time T=0, the beginning of an active flow, to collect the first flush sample. The sampling intervals were distributed over a 24 hour sampling period, but before sampling rounds six through eight, it was found that neither storm sewer had active flow occurring, therefore no samples were collected at those locations during those sampling rounds. The sample collection times from the CSO locations for Wet Weather Event 2 are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.5.4.3 Field Observation and Sample Management

The samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protective equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 2 samples at the storm water locations was within the recommended time for lab analysis. The sampling equipment was used and decontaminated using DI water at every sampling location. The number of samples, Field Blanks and Duplicates are shown in Appendix E – Wet Weather Event 2 – Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 2 Chain of Custody Forms are shown in Appendix E - Wet Weather Event 2 - Field Logs and Lab Results Summary.

3.6 Wet Weather Sampling Event 3

Wet Weather Sampling Event 3 occurred on 5/22/2017

3.6.1 Activity on Creeks

Sampling was conducted on Chester Creek (CC) and Ridley Creek (RC). The observed flows for Chester Creek were 58.1 cfs at the beginning of the sampling event, reached a peak flow of 92.1 cfs at 12:15AM, and was 70.4 cfs when the sampling event concluded. For Ridley Creek, flow was 23.6 cfs at the beginning of the sampling event, reached a peak flow of 32.5 cfs at 8:15PM, and was 28.8 cfs when the sampling event concluded. The flow gauge locations are shown on Figure 3-1.

3.6.1.1 Sample Type and Locations

Grab samples were collected from the following locations on the Creeks:

- Three (3) on Chester Creek – CC-01, CC-02, CC-03
- Three (3) on Ridley Creek – RC-01, RC-02, RC-03

A first grab sample collected on creek was during T=0 at the beginning for the rainfall event. Time T=0 for collection of the in-stream sample was initiated approximately 0.5 hours after the start of rainfall, or when 0.1 inches of rain had fallen or when CSO discharges started occurring (whichever occurs first). Significant rainfall began at 10:20 AM and sampling personnel were already in place to begin sampling within the first half hour. Accordingly, the first creek sample was taken at 10:42 AM. The sampling round intervals for all sampling locations are shown in the sampling collection matrix in Appendix G. See Figure 2-2 for map of sampling locations.

A single in-situ measurement was collected at every location and sampling round.

3.6.1.2 Sampling Round and Sampling Time

The grab samples collected on the Creeks as shown above were collected in intervals. The sampling intervals spanned over a 24 hour period. The intervals for sampling on creeks were at hour 0.5-2.5, hour 4.5-6.5, hour 8.5-10.5, hour 14.5-16.5, and hour 22-24. The samples also included the required Field Blanks and Duplicates as indicated in the sampling collection matrix shown in Appendix G. Field Blanks were collected at the first sampling location. Samples from the downstream end of the creeks were collected first to capture the outgoing tide at the earliest. The samples on creeks were collected in the following order for each sampling round - CC-03, RC-03, RC-02, RC-01, CC-02 and CC-01. The number and type of samples collected from the Creeks for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

The sampling event started on May 22, 2017 at 9:00 AM and ended on May 23, 2017 at 10:30 AM. There were a total of five (5) rounds of sampling conducted on the creeks. The sampling intervals were selected to capture the earlier part of the rainfall event and any impact of CSOs and Storm water runoff on the Creeks water quality. All samples from each location and from each sampling round were collected for analysis. The sample collection times from the Creeks for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

See Appendix G for sample collection matrix.

3.6.1.3 Field Observation and Sample Management

The samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protection equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 3 samples on the creeks was within the recommended time for lab analysis. While collecting the samples, field observations were noted to indicate any specific weather, water body, site, and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde. The sonde was used and decontaminated using DI water at every sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 3 Chain of Custody Forms are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

3.6.2 Activity on Delaware River

Sampling was conducted on Delaware River (DR) with 5 locations on the Pennsylvania side of the river and 2 locations, mid-channel and New Jersey side, on a transect near the Commodore Barry Bridge. On this date, the observed flow for the Delaware River was 9,180 cfs at the location shown on Figure 3-1 - Flow Gauge Locations.

3.6.2.1 Sample Type and Locations

Grab samples were collected from the following locations on the Delaware River:

- Seven (7) on Delaware River – DR-01, DR-02, DR-03, DR-04, DR-05, DR-06, DR-07

A first grab sample collected on river was during T=0 at the beginning for the rainfall event. Time T=0 for collection of the in-stream sample was initiated approximately 0.5 hours after the start of rainfall, or when 0.1 inches of rain had fallen or when CSO discharges started occurring (whichever occurs first). Very light precipitation had occurred intermittently throughout the early morning hours (2:00 AM to 9:00 AM). Steady rainfall began after 9:00 AM, by which time 0.05 inches of rain had fallen, according to the WRTP rain gauge. Sampling personnel were already in place to begin sampling immediately. Accordingly, the first river sample was taken at 9:05 AM. The sampling round intervals for all sampling locations are shown in the sampling collection matrix in Appendix G. See Figure 2-2 for map of sampling locations.

A single in-situ measurement was collected at every location at surface, mid and near bottom depths.

3.6.2.2 Sampling Round and Sampling Time

The grab samples collected on the Creeks as shown above were collected in intervals. The sampling intervals spanned over a 24 hour period. The intervals for sampling on the Delaware River were at hour 0, hour 2, hour 4, hour 6, hour 9, hour 12, hour 15, hour 18, hour 21, and hour 24. The samples also included the required Field Blanks and Duplicates as indicated in the sampling collection matrix shown in Appendix G. The samples on the river were collected by two boat crews. One of the boat crews was assigned to sample the northern sampling locations DR-01, DR-02, DR-03 and the other boat crew was assigned to sample the southern sampling locations and points across the river at DR-04, DR-05, DR-06 and DR-07. The two boat crews were planned for sample collection during the first five (5) sampling rounds, to provide enough time to return the samples to the lab and complete the entire sampling loop on the river within the decided sampling intervals. After the first five (5) rounds, only one boat crew would be required to sample at all locations because of the availability of more time between sampling intervals after completing the entire loop.

In actuality, two boat crews were used for 3 rounds, due to mechanical issues with the boats. After the third round of sampling, several small punctures were discovered in one of the boat's hull causing water to inundate the boat. For safety and maneuverability concerns, the boat was pulled from the river. The second boat also encountered issues at this time when its engine could not propel the boat forward. After inspection, a problem with the transmission was identified and this boat was also removed from the river. An attempt to switch out the engine was made so that sampling on the Delaware River could continue, but was unsuccessful. At this point two (2) rounds were missed, hour 6 and hour 9. As an alternative option (to get as much data as possible) the remainder of sampling on the Delaware River for rounds six through ten were taken from shore locations close to DR-03 and DR- 04. There were no accessible points along Chester City shoreline to collect grab samples for DR-01, DR-02 and DR-05. Grab sample for DR-03 was collected from shore on Norris Street and that for DR-04 was collected from the boat launch ramp near the stadium. Grab samples were collected using bailer and rope along with in-situ readings for both locations. For reference, the number and type of samples collected from the river for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

The sampling event started on May 22, 2017 at 9:00 AM and ended on May 23, 2017 at 10:30 AM. There were a total of ten (10) rounds of sampling conducted on the Delaware. The sampling intervals were selected to capture the earlier part of the rainfall event and any impact the CSOs and storm water runoff had on river water quality. The sample collection times from the Creeks for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

See Appendix G for sample collection matrix.

3.6.2.3 Field Observation and Sampling Management

The samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protective equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 3 samples on the Delaware River was within the recommended time for lab analysis. While collecting the samples the field observations were noted to indicate any specific weather, water body, site, and sample conditions. In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde at surface, mid and near bottom depths of the river. The sonde was used and decontaminated using DI water at every

sampling location. The field observations and in-situ field measurements including water salinity readings, temperature and conductivity are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 3 Chain of Custody Forms are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

3.6.3 Activity at Combined Sewer Overflow (CSO) Locations

3.6.3.1 Sample Type and Locations

Grab samples were collected from the following CSO locations:

- Four (4) locations – CSO-02, CSO-05, CSO-18, CSO-19

See Figure 2-2 for map of sampling locations.

3.6.3.2 Sampling Round and Sampling Time

Samples were collected at each of the CSO locations along with the required Field Blanks and Duplicates. The samples at the CSOs were collected in the following order for each sampling round - first flush, 30 minutes, 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, and 24 hours. The samples were collected only for the first five (5) rounds for all CSO locations because there was not any active overflow occurring over the weir after 6 hours. The number and type of samples collected from the river for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

The sampling event started on May 22, 2017 at 9:00 AM and ended on May 23, 2017 at around 10:30 AM. The CSO sampling was started at time T=0, the beginning of an active overflow, to collect the first flush sample. Significant rainfall began at 10:20 AM and sampling personnel were already in place to begin CSO sampling at first flush, which occurred at 10:25 AM. Because of the precipitation intensity for this particular round of sampling, all CSOs discharged within minutes of each other. The sampling intervals were distributed over a 24-hour sampling period, but before sampling rounds six through eight, it was found that no CSOs were actively discharging, therefore no samples were collected at those locations during those sampling rounds. The sample collection times from the CSO locations for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.6.3.3 Field Observation and Sample Management

The grab samples were collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protective equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 3 samples at the CSO locations was within the recommended time for lab analysis. Samples were collected on the

downstream side of the overflow for an active overflow at the CSO locations. The sampling equipment was used and then decontaminated using DI water at every sampling location. The field observations, Field Blanks, and Duplicate information is provided in Appendix F - Wet Weather Event 3 - Field Logs, Chain of Custody Forms, and Lab Results.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 3 Chain of Custody forms are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

3.6.4 Activity at Storm Water (SW) Locations

3.6.4.1 Sample Type and Locations

Grab samples were collected from the following storm water locations:

- Two (2) locations – SW-05A, SW-SS2

See Figure 2-2 for map of sampling locations.

3.6.4.2 Sampling Round and Sampling Time

Samples were collected at both of the storm water locations along with the required Field Blanks and Duplicates. The samples at SW-05A and SW-SS2 were collected in the following order for each sampling round - first flush, 30 minutes, 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, and 24 hours. The samples were collected only for the first five (5) rounds for both storm water locations because there was not any flow occurring in the storm sewers after 6 hours. The number and type of samples collected from the river for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs, Chain of Custody Forms, and Lab Results.

The sampling event started on May 5, 2017 at 7:00 AM and ended on May 6, 2017 at around 7:00 AM. The sampling was started at time T=0, the beginning of active flow, to collect the first flush sample. Significant rainfall began at 10:20 AM and sampling personnel were already in place to begin SW sampling at first flush, which occurred at 10:30 AM. The sampling intervals were distributed over a 24-hour sampling period, but before sampling rounds six through eight, it was found that neither storm sewer had active flow occurring, therefore no samples were collected at those locations during those sampling rounds. The sample collection times from the CSO locations for Wet Weather Event 3 are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

See Appendix G for Sample collection matrix.

3.6.4.3 Field Observation and Sample Management

The sample was collected as per the requirements of the Sampling and Analysis Plan (SAP) using appropriate sampling and personal protective equipment. The samples were preserved immediately on ice for transfer to laboratory for further analysis. The hold time for all the Wet Weather Event 3 samples at the storm water locations was within the recommended time for lab analysis. The sampling equipment

was used and decontaminated using DI water at every sampling location. The number of samples, Field Blanks and Duplicates are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

The samples were handed over the laboratory for analysis with their respective Chain of Custody Forms. The Chain of Custody Forms included details on the sample IDs, type of sample and release of samples. Copies of the Wet Weather Event 3 Chain of Custody Forms are shown in Appendix F - Wet Weather Event 3 - Field Logs and Lab Results Summary.

Section 4 Laboratory Results

The Sampling Program succeeded in acquiring the volume and range of pollutant data needed to construct, calibrate and validate the water quality model. Table 4-1 provides a summary of the number of samples collected for each of the sampling events at each sampling station. Table 4-2 provides a summary of the range of observed pollutant concentrations collected during the dry and wet weather sampling events.

The pollutants of concern (POCs) analyzed in the samples collected in the Sampling Program include fecal coliform, *Escherichia coliform (E. coli)*, and enterococcus. The coliform group has been used to assess sanitary quality in recreational waterways for decades (Standard Methods, 1980). Fecal coliform is a member of the coliform group present in the gut and feces of warm-blooded animals and is used as an indicator of fecal contamination and associated pathogens. The fecal coliform group includes many genera, including *Enterobacter, Klebsiella, Citrobacter, and Escherichia* (Standard Methods, 1998). E. coli is a one member of the fecal coliform group that provides more specificity than fecal coliform as a potential indicator of pathogenic organisms (USEPA, 1986), particularly in freshwater systems (USEPA, 2012). Enterococcus is a subgroup of the fecal streptococcus group, another type of bacteria found in the gastrointestinal tract of warm-blooded animals (Standard Methods, 1998). Enterococci have been found to be the best pathogenic indicator of fecal contamination in marine waters (USEPA, 2012). Because the DELCORA service area includes both freshwater and tidal/marine waterways, all of these indicators are pertinent to assessing water quality conditions in the local waterways and comparing to corresponding water quality standards.

This section describes the laboratory results for each of the individual sampling events. The environmental conditions of each of these sampling events were described in Section 3. Plots of concentrations over time are presented in this section for a subset of locations, and plots for all locations are included in Appendix H. For the tributaries, the flow at the upstream USGS gage is also included in the figures. However, for the Delaware River, no flow values are shown because the nearest flow gage is in Trenton, NJ, which is too far away (~80 miles upstream) to be indicative of local conditions.

The quality of the data with respect to the QAPP objectives are described in additional detail in Section 5. Additional analysis of the data, such as developing Event Mean Concentrations (EMCs) for the CSOs and stormwater locations are described in Section 6.

4.1 Dry Weather Sampling – Event 1 Results

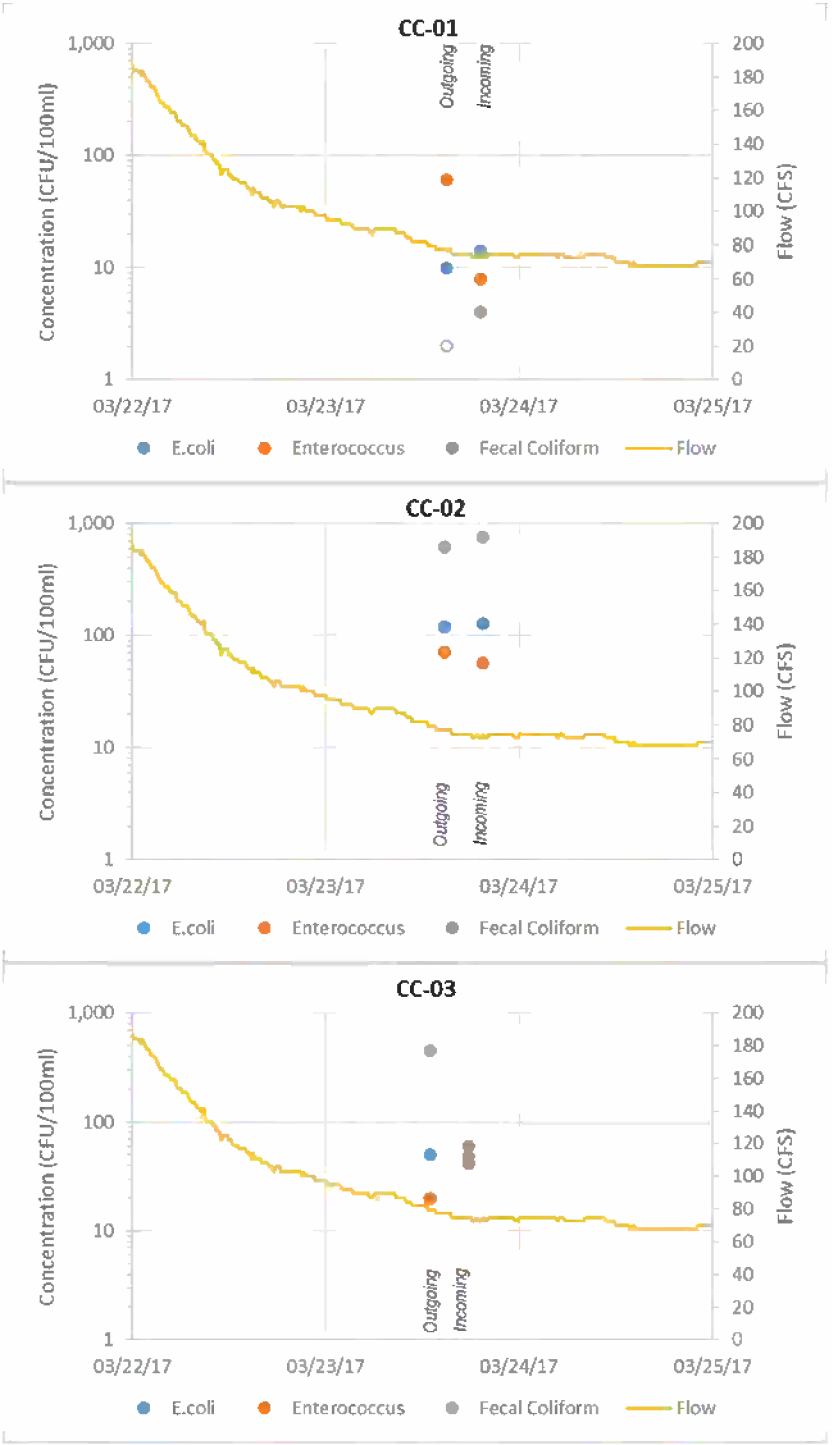
The first dry weather event (Dry 1), on March 23, 2017, had the highest tributary (i.e. Chester Creek, Ridley Creek) flows of all of the dry weather sampling events (as shown in Table 2-7). This was expected as the Spring (mid-March) season tends to have higher base flow due to snow melt infiltration and higher frequency of rainfall that typically occurs. Laboratory results are presented by waterbody below.

4.1.1 Chester Creek Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant and the majority of concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-1 shows the concentrations at each station. Note that in this figure, solid dots are measured results while open dots are non-detect results plotted at the detection limit. Additional plots are provided in Appendix H.

Fecal coliform levels tended to have the highest concentrations of the three pollutants of concern (POC) while enterococcus tended to have the lowest concentrations. However, the fecal coliform results at CC-01 appear to be anomalous, as they are the lowest concentrations of the POCs and lower than corresponding E. coli levels, which is physically impossible because E. coli is a subgroup within the fecal coliform group. These anomalies are likely mostly due to the difficulty in measuring low levels of bacteria concentrations (see Section 5 for additional discussion). These figures also illustrate an increase in each POC levels from the upstream location (CC-01) to the downstream locations (CC-02 &CC-03) during both incoming and outgoing tidal conditions. This may be indicative of dry weather sources of bacteria entering Chester Creek, such as illicit discharges and connections or wildlife and pet contributions. Additional analysis and interpretation of the data will be conducted as part of the water quality model development and calibration process.

Figure 4-1: Dry Weather 1 Concentrations in Chester Creek

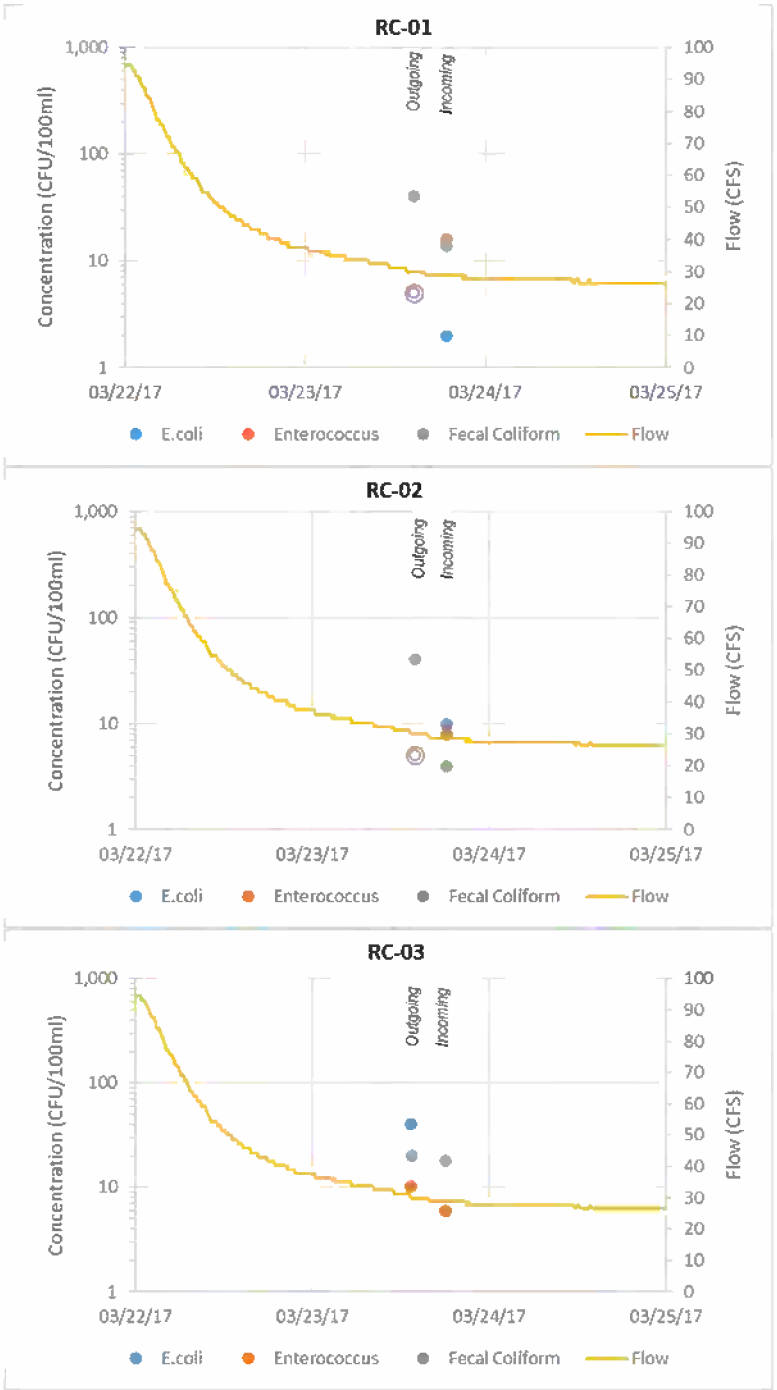


4.1.2 Ridley Creek Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant and the majority of concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-2 shows the concentrations at each station. Note that in this figure, solid dots are measured results while open dots are non-detect results plotted at the detection limit. Additional plots are provided in Appendix H.

With few exceptions, fecal coliform tended to have the highest concentrations of the three pollutants of concern (POC) while enterococcus tended to have the lowest concentrations. These figures also illustrate an increase in E. coli levels from the upstream (RC-01) locations to the downstream locations (RC-02 and RC-03). However, the spatial trend for fecal coliform show a decrease in concentrations from upstream to downstream, while enterococcus levels were similar at all locations. Additional analysis and interpretation of the data will be conducted as part of the water quality model development and calibration process.

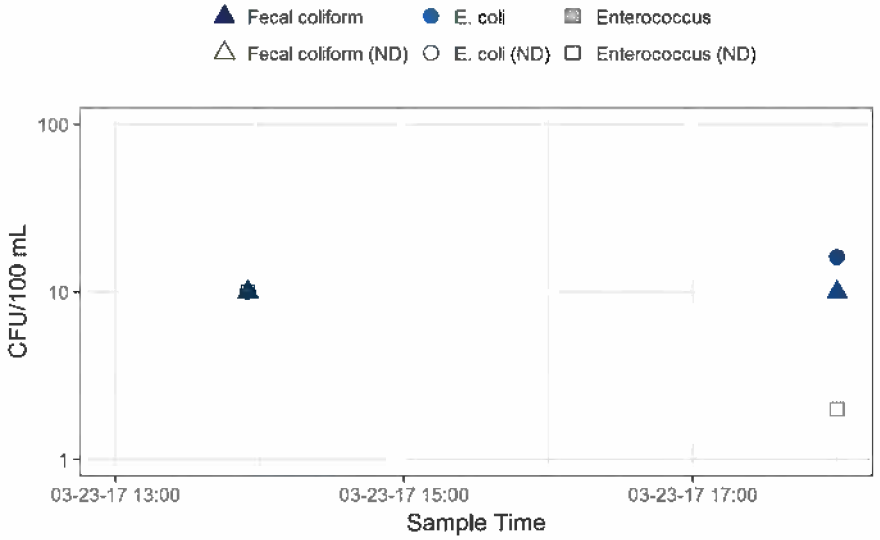
Figure 4-2: Dry Weather 1 Concentrations in Ridley Creek



4.1.3 Delaware River Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant and all of concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-3 shows the concentrations at DR-03, the mid-point station on the river. Additional plots are provided in Appendix H.

Figure 4-3: Dry Weather 1 Concentrations in Delaware River at DR-03



Fecal coliform levels tended to have the highest of the three pollutants of concern (POC) while enterococcus levels tended to be the lowest. Concentrations for all POCs were all fairly low, with twelve (12) of the 33 results reported as less than the reporting limit (shown as open symbols in the Appendix figures). In addition, nineteen (19) of the 33 results were flagged as based on counts outside the ideal counting range, which is often applied when the concentrations are very low. Results are similar to historical data collected previously by the Delaware River Basin Commission (DRBC).

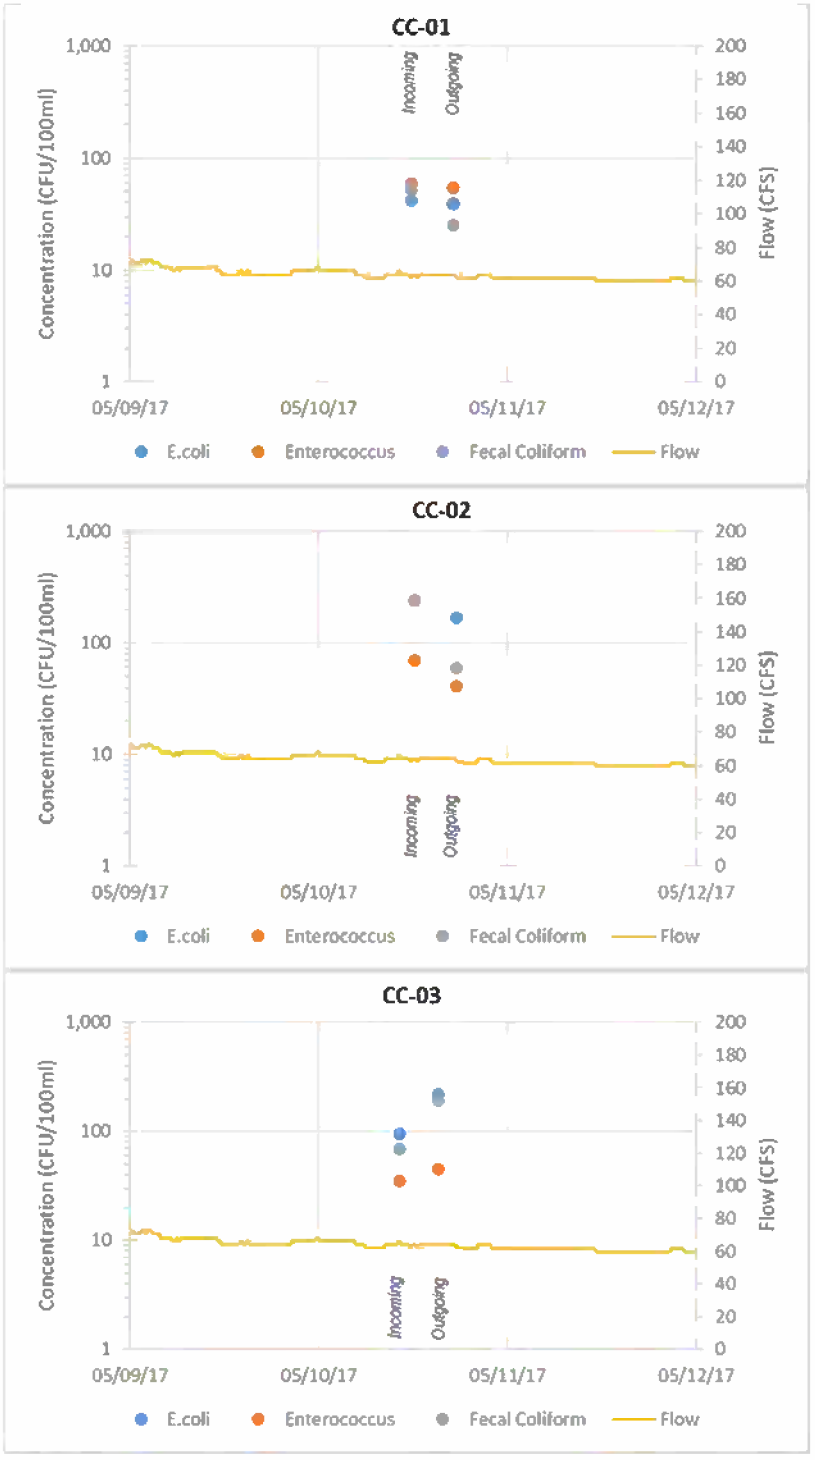
4.2 Dry Weather Sampling – Event 2 Results

The second dry weather event (Dry 2), on May 10, 2017, had fairly typical dry weather flows in each waterbody (as shown in Table 2-7). Laboratory results are presented by waterbody below.

4.2.1 Chester Creek Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant and the majority of concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-4 shows the concentrations at each station. Additional plots are provided in Appendix H.

Figure 4-4: Dry Weather 2 Concentrations in Chester Creek



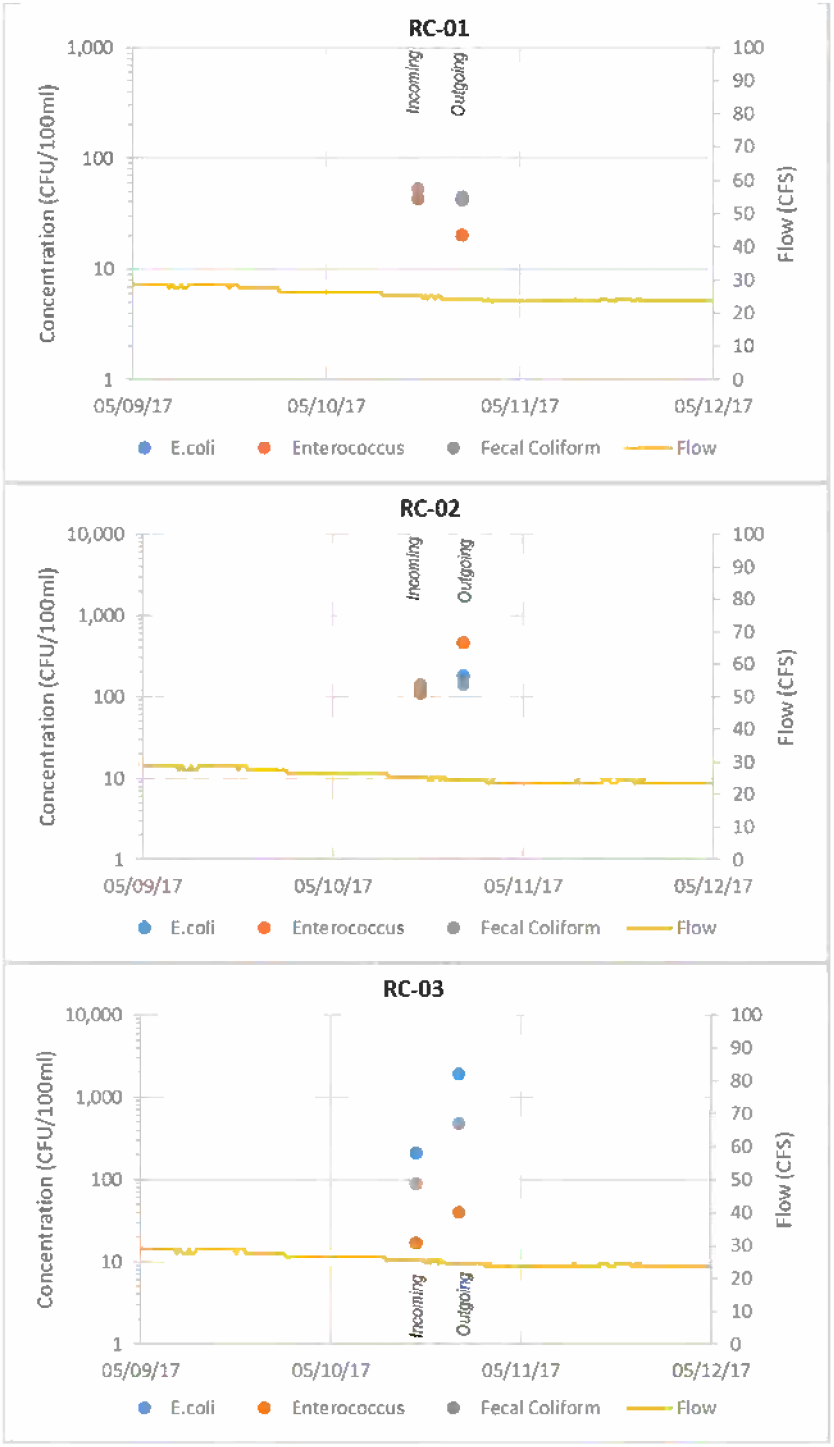
E. coli levels tended to have the highest of the three pollutants of concern (POC) while enterococcus levels tended to be the lowest. As noted in the introduction to Section 4, E. coli is a subgroup of fecal coliform and should have lower concentrations than fecal coliform. It is, however, fairly common for E. coli to be reported with higher concentrations than corresponding fecal coliform results, due to differences in the analytical methodology, the challenge of obtaining a homogenous sample, and the difficulty in measuring low levels of bacteria concentrations (see Section 5 for additional discussion). These figures also illustrate an increase in fecal coliform and E. coli POC levels from upstream (CC-01) to downstream to the mouth (CC-03) during both incoming and outgoing tidal conditions while enterococcus levels tended to be similar from upstream to downstream. Additional analysis and interpretation of the data will be conducted as part of the water quality model development and calibration process.

4.2.2 Ridley Creek Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant and the majority of concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-5 shows the concentrations at each station. Additional plots are provided in Appendix H.

At RC-01 and RC-02, fecal coliform levels tended to have the highest of the three pollutants of concern (POC) while enterococcus levels tended to be the lowest. At RC-03, E. coli concentrations were higher than corresponding fecal coliform concentrations. As noted in the introduction to Section 4, E. coli is a subgroup of fecal coliform and should have lower concentrations than fecal coliform. It is, however, fairly common for E. coli to be reported with higher concentrations than corresponding fecal coliform results, due to differences in the analytical methodology, the challenge of obtaining a homogenous sample, and the difficulty in measuring low levels of bacteria concentrations. These figures also illustrate an increase in fecal coliform and E. coli levels from upstream (RC-01) to downstream to the mouth (RC-03), while enterococcus levels were similar at all locations. Additional analysis and interpretation of the data will be conducted as part of the water quality model development and calibration process.

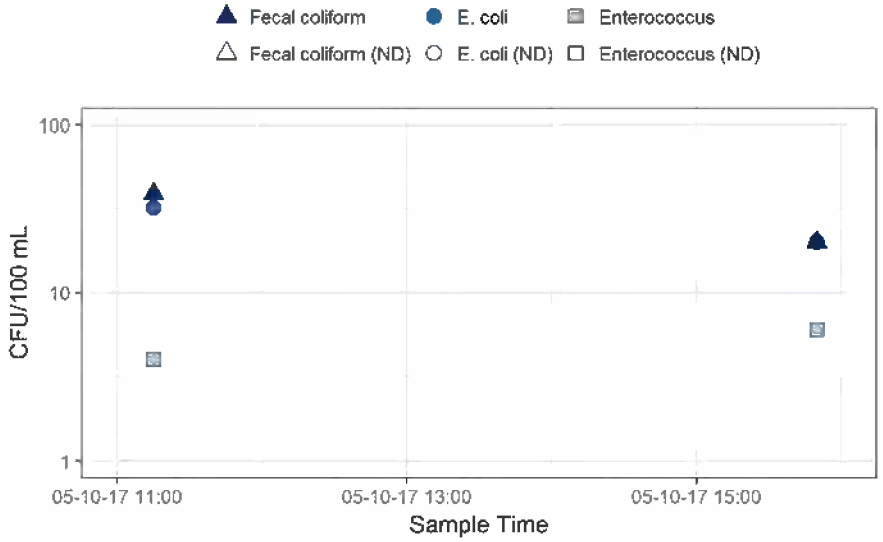
Figure 4-5: Dry Weather 2 Concentrations in Ridley Creek



4.2.3 Delaware River Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant and all of concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-6 shows the concentrations at DR-03, the mid-point station on the river. Additional plots are provided in Appendix H.

Figure 4-6: Dry Weather 2 Concentrations in Delaware River at DR-03



Concentrations for all POCs were higher than Dry 1 but were still fairly low, well below maximum water quality standard criteria. Results were similar to historical data collected previously by the Delaware River Basin Commission (DRBC).

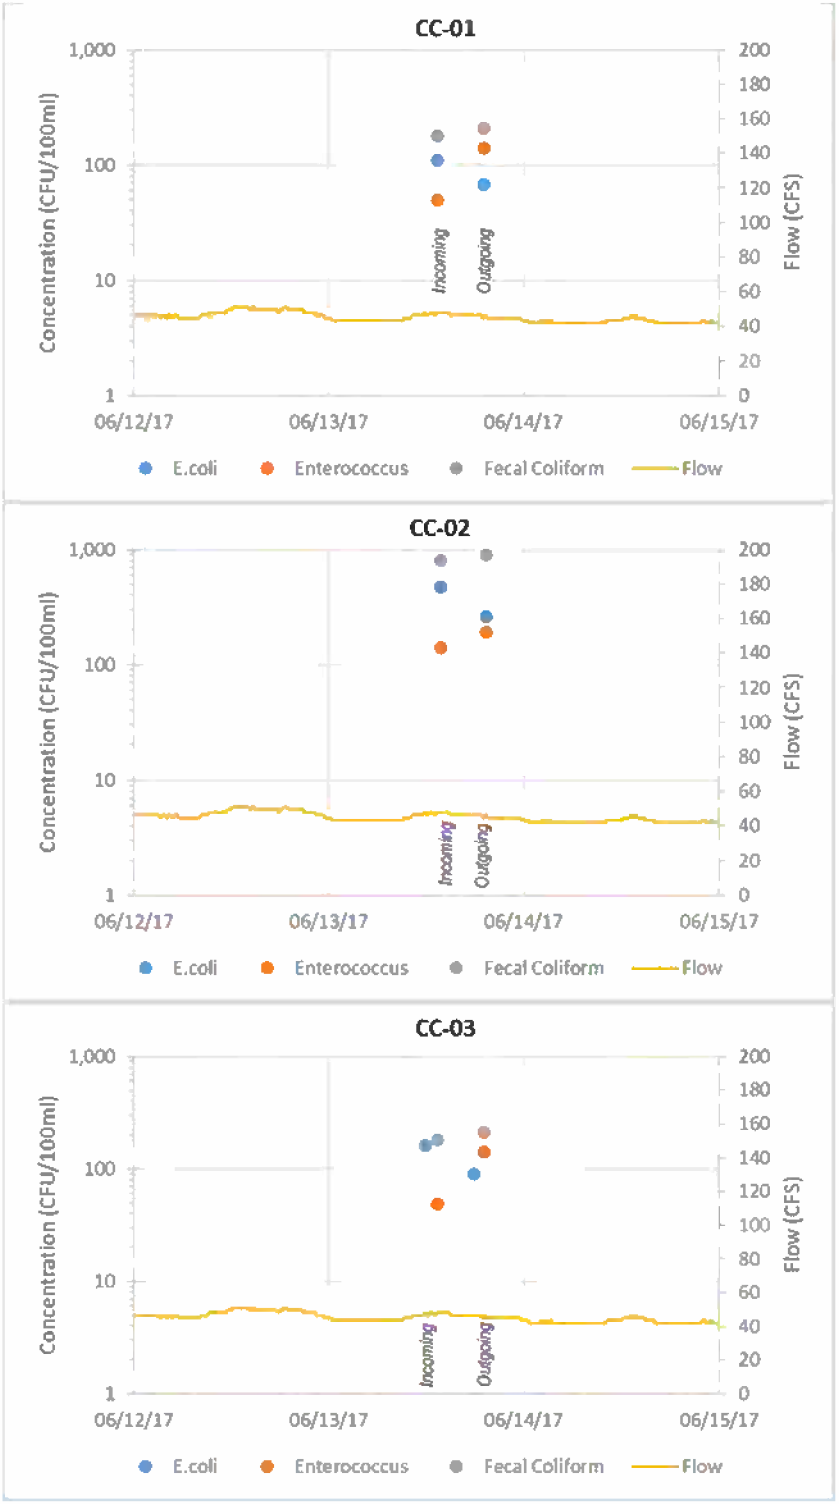
4.3 Dry Weather Sampling – Event 3 Results

The third dry weather event (Dry 3), on June 13, 2017, had the lowest dry weather flows in each waterbody (as shown in Table 2-7), approaching the 25th percentile flow. Laboratory results are presented by waterbody below.

4.3.1 Chester Creek Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant. Enterococcus concentrations at each location tended to be higher on outgoing tide samples than incoming tide samples while the reverse was observed for E. coli. The majority of concentrations were higher than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-7 shows the concentrations at each station. Additional plots are provided in Appendix H.

Figure 4-7: Dry Weather 3 Concentrations in Chester Creek



Fecal coliform levels tended to have the highest of the three pollutants of concern (POC) while enterococcus levels tended to be the lowest. These figures also illustrate an increase in POC levels from upstream (CC-01) to downstream to the mid-point (CC-02) during both incoming and outgoing tidal conditions, followed by a decline in POC levels near the mouth (CC-03). Additional analysis and interpretation of the data will be conducted as part of the water quality model development and calibration process.

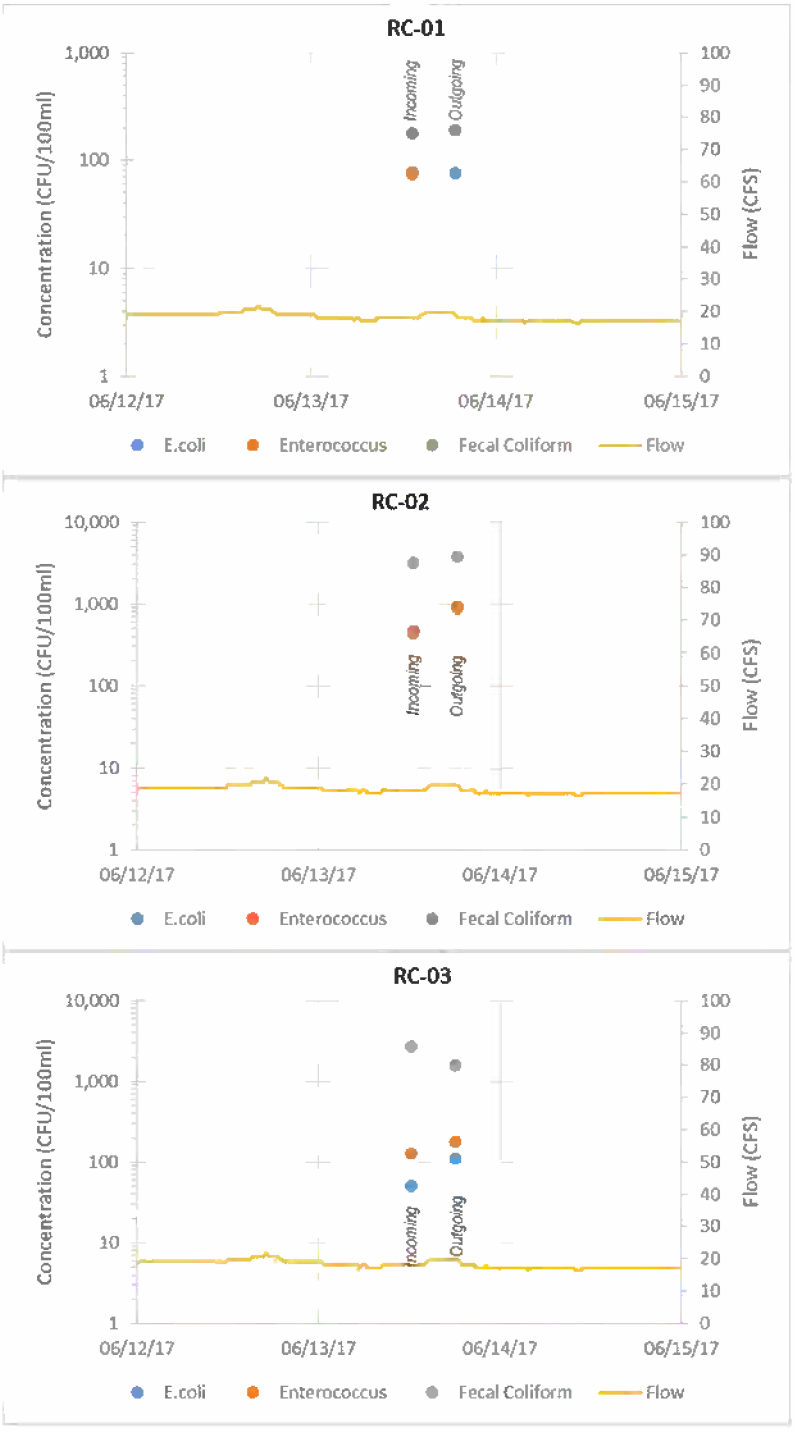
4.3.2 Ridley Creek Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant. However, concentrations of enterococcus tended to be about two times higher in the outgoing samples than incoming sample levels.

Fecal coliform and enterococcus concentrations tended to be higher than the other dry weather events and maximum water quality standard criteria. The majority of E. coli concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-8 shows the concentrations at each station. Additional plots are provided in Appendix H.

Fecal coliform levels tended to have the highest of the three pollutants of concern (POC) while enterococcus levels tended to be the lowest, except at RC-03. As with the other dry weather events, the laboratory encountered difficulties in analyzing the samples at the best dilution and quantifying results for samples with low concentrations. These figures also illustrate an increase in POC levels from upstream (RC-01) to downstream to the mid-point (RC-02) during both incoming and outgoing tidal conditions, followed by a decline in POC levels near the mouth (RC-03).

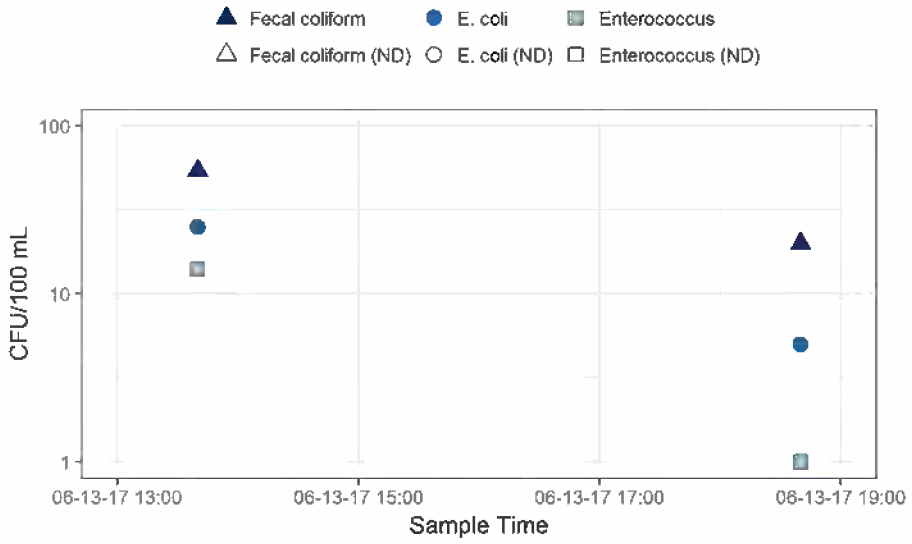
Figure 4-8: Dry Weather 3 Concentrations in Ridley Creek



4.3.3 Delaware River Results

Samples collected on incoming and outgoing tides were fairly similar in concentrations of each pollutant and all of concentrations were within values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-9 shows the concentrations at DR-03, the mid-point station on the river. Additional sampling plots are provided in Appendix H.

Figure 4-9: Dry Weather 3 Concentrations in Delaware River at DR-03



Concentrations for all POCs were fairly low, well below maximum water quality standard criteria. Results were similar to historical data collected previously by the Delaware River Basin Commission (DRBC).

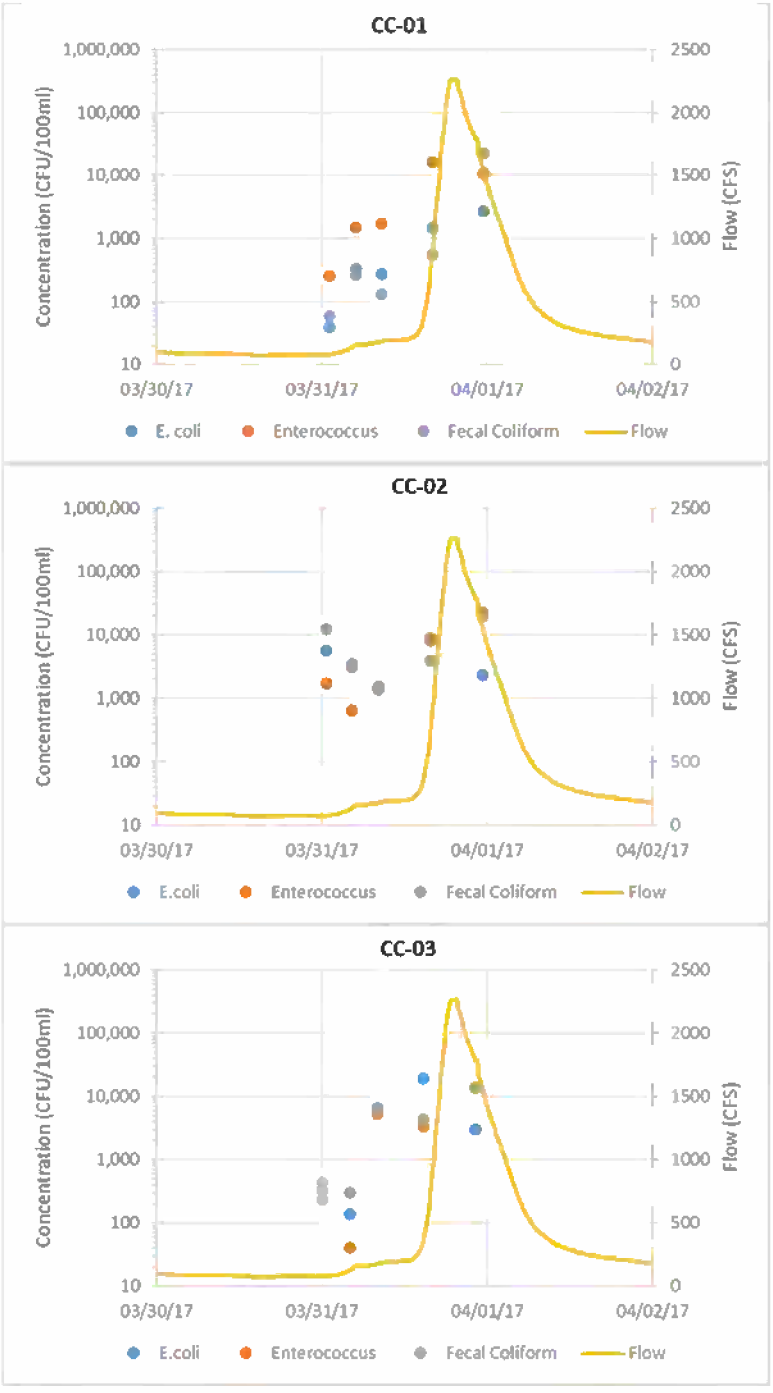
4.4 Wet Weather Sampling – Event 1 Results

Wet weather event 1 (Wet 1), was conducted on March 31-April 1, 2017. This event was the largest of the three events, with just over 1.5" recorded at the Philadelphia Airport. Rainfall was also mostly uniform across the watershed. This event also had the highest flows in the tributaries of the three sampled wet weather events. Laboratory results are presented by waterbody and source type below.

4.4.1 Chester Creek Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. The majority of concentrations for all of the POCs were higher than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-10 shows the concentrations at each station in the creek and the flow measured at the USGS gage just upstream of the DELCORA study area. Additional sampling plots are provided in Appendix H.

Figure 4-10: Wet Weather Event 1 Concentrations in Chester Creek



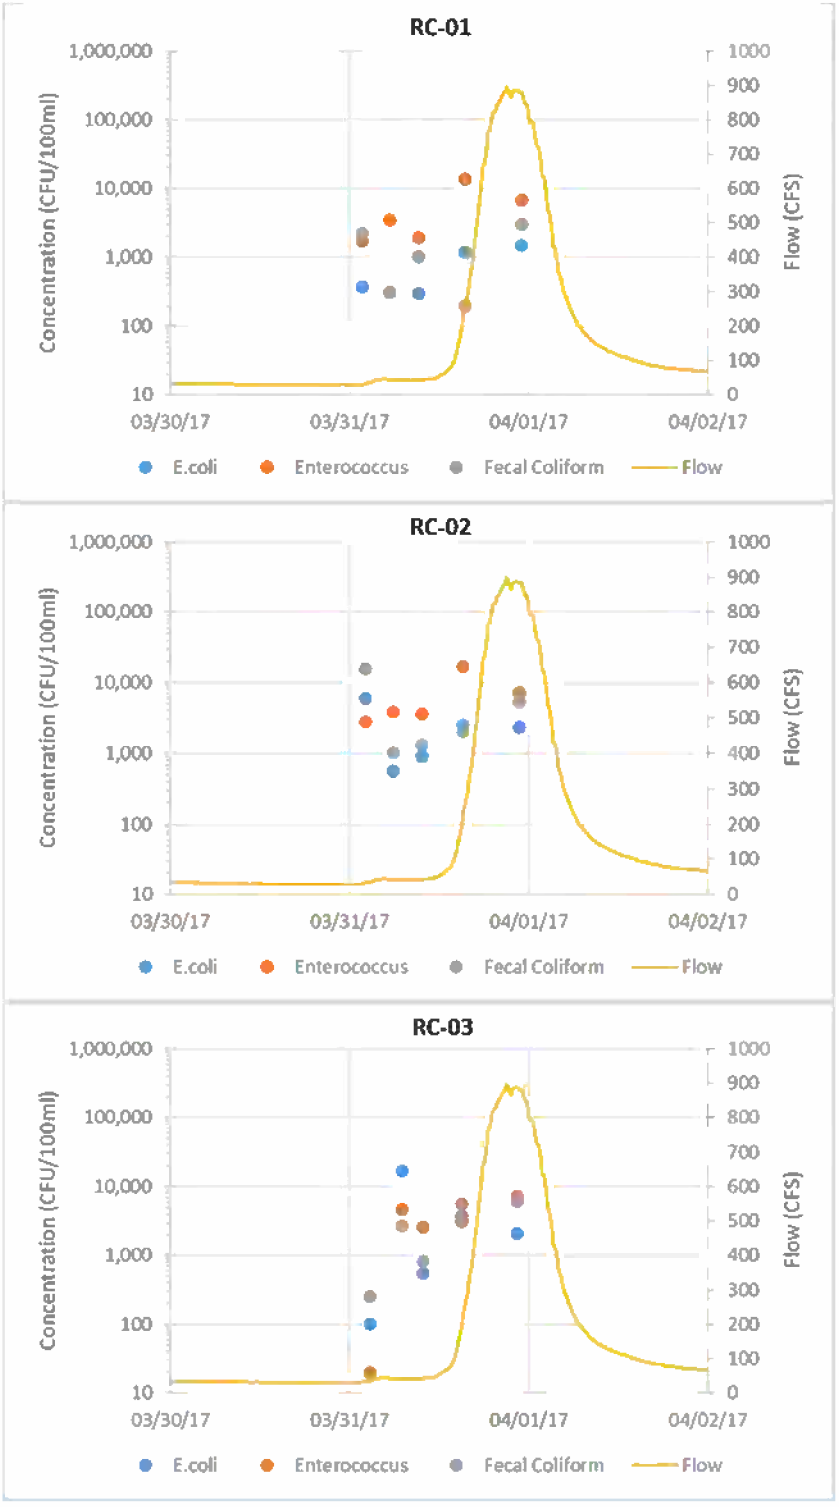
The impact of DELCORA's CSOs and Chester stormwater POC loads are most evident in the data at CC-02 for first two rounds of sampling, which correspond to roughly the first six hours of the event. Similar concentrations were measured further downstream at CC-03 during the third and fourth rounds of sampling, which corresponds to approximately hours 8 through 16 of the event. The data at CC-01 suggest that loads from upstream sources reached the study area in the fourth and fifth rounds of sampling, approximately 16 to 24 hours of the event. POC concentrations peak at 23,000 cfu/100 ml (fecal coliform).

4.4.2 Ridley Creek Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and Section 2.5.2. The majority of concentrations for all of the POCs were higher than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-11 shows the concentrations at each station in the creek and the flow measured at the USGS gage just upstream of the DELCORA study area. Additional sampling plots are provided in Appendix H.

The impact of DELCORA's CSOs and Chester stormwater POC loads are most evident in the data at RC-02 for first two rounds of sampling. Similar concentrations were measured further downstream at RC-03 during the third and fourth rounds of sampling. The data at RC-01 suggest that loads from upstream sources reached the study area in the fourth and fifth rounds of sampling. POC concentrations peak at 17,000 cfu/100 ml (enterococcus).

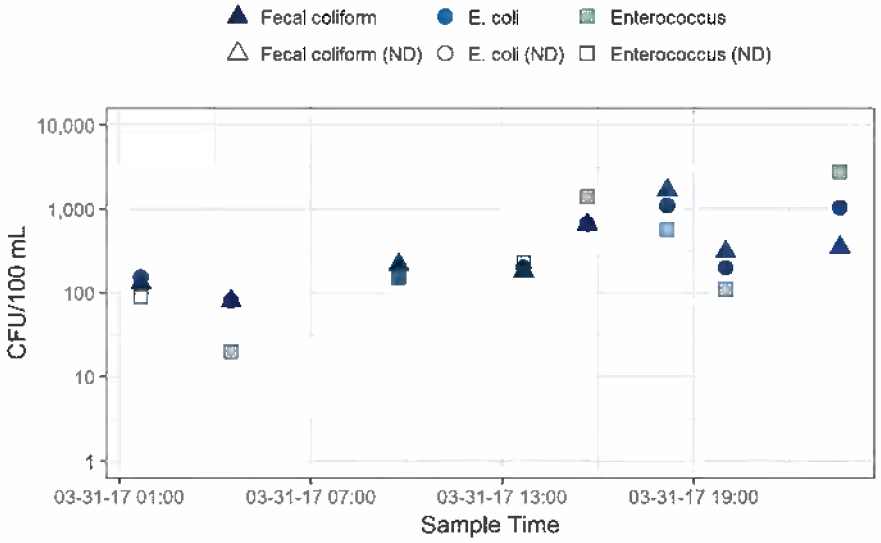
Figure 4-11: Wet Weather Event 1 Concentrations in Ridley Creek



4.4.3 Delaware River Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. Samples were collected more frequently in the Delaware River than in the tributaries to ensure that wet weather impacts were characterized under an entire tidal cycle. Figure 4-12 shows the concentrations at DR-03, the mid-point station on the river. CSOs impacts would be captured at this station under all tidal conditions. Similar levels were observed at the other near shore Delaware River locations. These time series plots are provided in Appendix H.

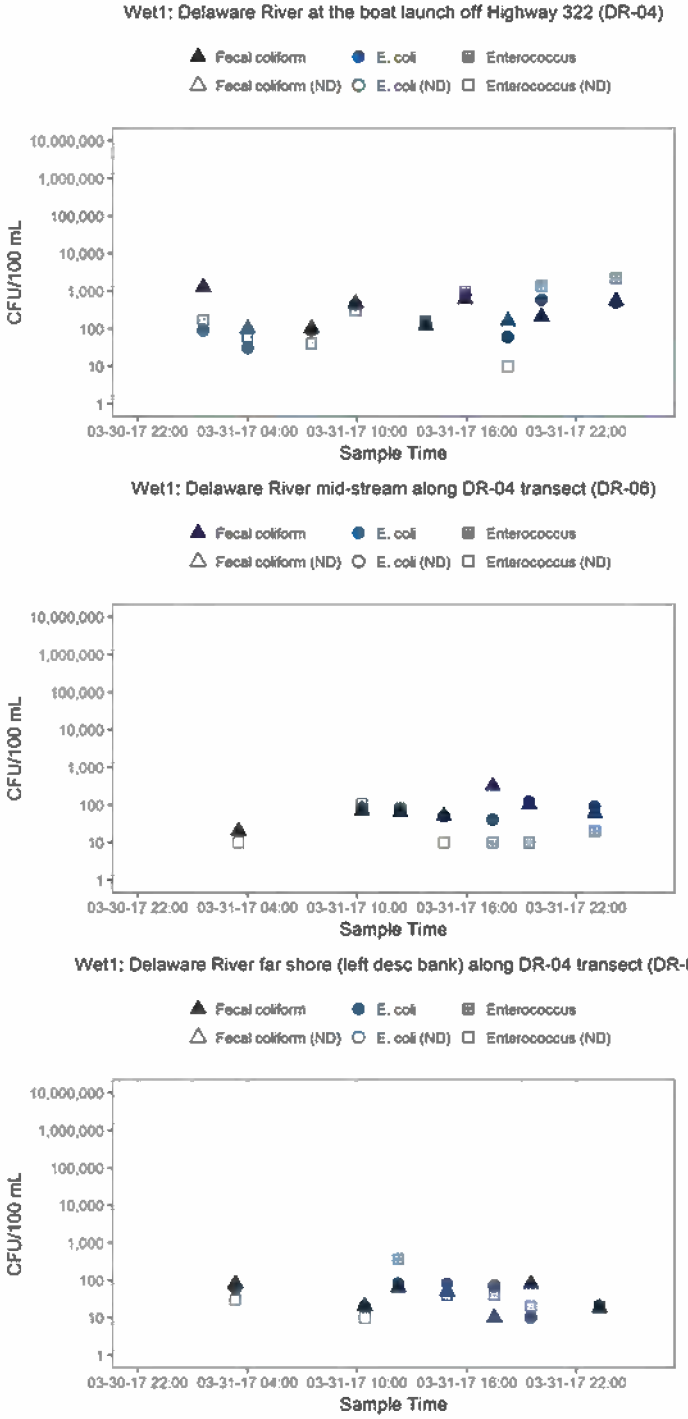
Figure 4-12: Wet Weather Event 1 Concentrations in Delaware River at DR-03



POC concentrations in the Delaware River tend to be approximately an order of magnitude lower than the levels observed in the tributaries, though there are several measurements that are higher than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2.

Near shore impacts of DELCORA's CSOs were assessed by collecting samples across the transect corresponding to near shore station DR-04 (see Figure 2-2). Results are shown for DR-04, DR-06 (mid-stream) and DR-07 (far shore) in Figure 4-13. This figure indicates that there is a small lateral gradient during the period when DELCORA's CSOs were discharging. The near shore concentrations are typically an order of magnitude larger than the mid or far shore concentrations, indicating that the influence of the DELCORA CSOs is limited to the near shore area. A better understanding of lateral mixing will be obtained through the model calibration process.

Figure 4-13: Wet Weather Event 1 Concentrations Across the Delaware River



4.4.4 Combined Sewer Overflow (CSO) Location Results

All of the CSOs were sampled during this event. Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. A full set of samples (i.e. 8 rounds) were collected at each CSO, except CSO-018, which had 7 rounds of sampling conducted before it stopped discharging. Concentrations for each POC for each CSO are presented in Figures 4-14 through 4-16. Concentration time series figures are presented in Appendix H.

Figure 4-14: CSO Fecal coliform Concentrations in Wet 1 Event

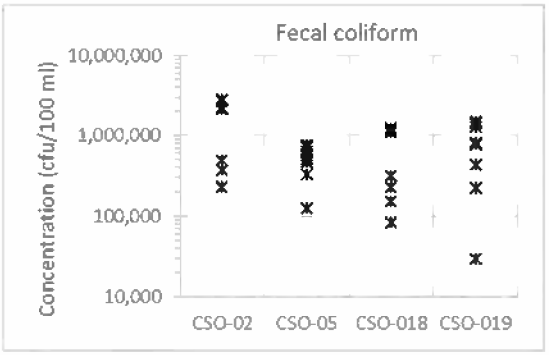


Figure 4-15: CSO E. coli Concentrations in Wet 1 Event

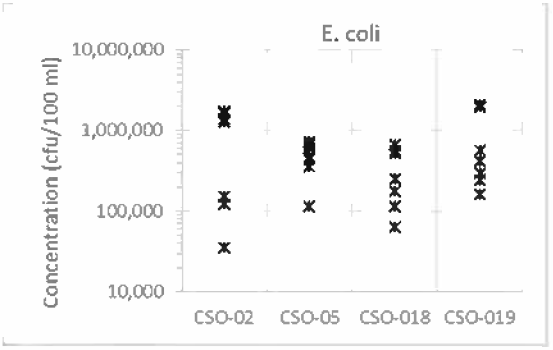

Figure 4-16: CSO Enterococcus Concentrations in Wet 1 Event

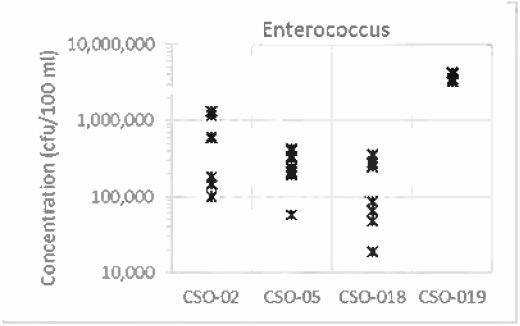


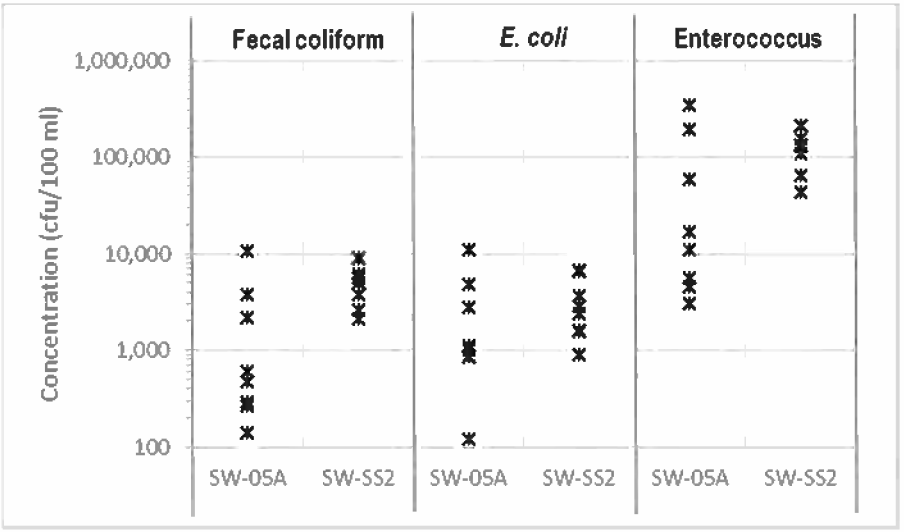
One potential outlier result was identified: the enterococcus result in round 1 at CSO-019 was 3,220,000 cfu/100 ml, and flagged as quantified with a count outside the ideal counting range. The next highest quantified result was 500,000 cfu/100 ml, nearly an order of magnitude lower. However, in round 4 at CSO-019, the result was reported as >600,000 cfu/100 ml (ie. actual concentration is greater than 600,000 cfu/100 ml), which provides some supporting evidence that enterococcus results in CSO-019 were higher than in the other CSOs and the potential outlier may be a legitimate reflection of conditions. The effect of this potential outlier will be further evaluated through the model calibration process.

Measured concentrations were within the range of CSO bacteria concentrations reported in the literature (EPA 2002) but tended to be lower than concentrations measured in other communities. Several potential explanations for this include: 1) the highly industrialized nature of the DELCORA service area may result in a smaller bacteria load to the combined system than communities with less industrial land; 2) DELCORA may have a relatively high percentage of stormwater in the combined system.

4.4.5 Stormwater Location Results

Both stormwater outfalls were sampled during this event. Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. A full set of samples (e.g. 8 rounds) were collected at each stormwater location. Concentrations for each POC are presented in Figure 4-17. Concentration time series figures are provided in Appendix H.

Figure 4-17: Stormwater POC Concentrations in Wet 1 Event



Most of the measured concentrations were within the range of stormwater bacteria concentrations reported in the literature (NSQD, 2015). It was somewhat surprising that the enterococcus results tended to be higher than the fecal coliform and E. coli data at both locations. However, there is very little data in the literature for enterococcus so it is difficult to assess whether these results are unusual. Additional evaluation of POC loads will be conducted as part of the watershed and water quality model calibrations.

4.5 Wet Weather Sampling – Event 2 Results

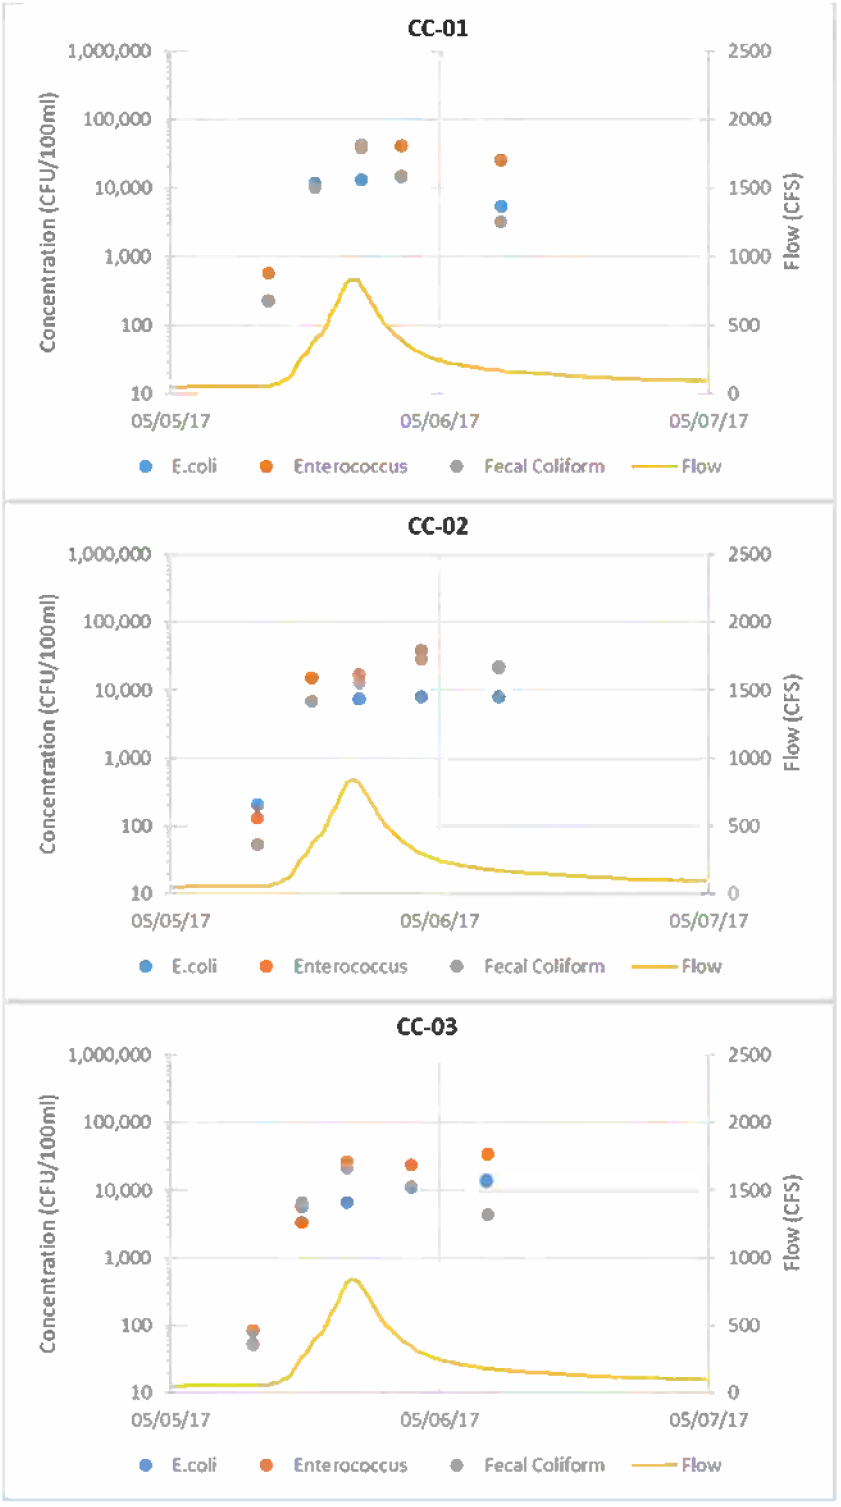
Wet weather event 2 (Wet 2), was conducted on May 5, 2017. This event was slightly smaller than the first wet weather event, with 1.47" recorded at the Philadelphia Airport. Rainfall varied somewhat across the watershed, with less rain falling in the DELCORA area and the upstream Chester and Ridley Creek watersheds, than in the Philadelphia area and areas bordering the Delaware River. Laboratory results are presented by waterbody and source type below.

4.5.1 Chester Creek Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan (SAP). The majority of concentrations for all of the POCs were higher than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-18 shows the concentrations at each station in the creek and the flow measured at the USGS gage just upstream of the DELCORA study area. Additional sampling plots are provided in Appendix H.

The impact of DELCORA's CSOs and Chester stormwater POC loads appear to begin in the second round of sampling. Concentrations remain elevated throughout the rest of the event at all three locations, despite the fact that DELCORA CSOs stopped discharging within 8 hours. This suggests that upstream and/or other bacteria sources are likely also impacting the creek. POC concentrations peak at 44,000 cfu/100 ml (fecal coliform).

Figure 4-18: Wet Weather Event 2 Concentrations in Chester Creek

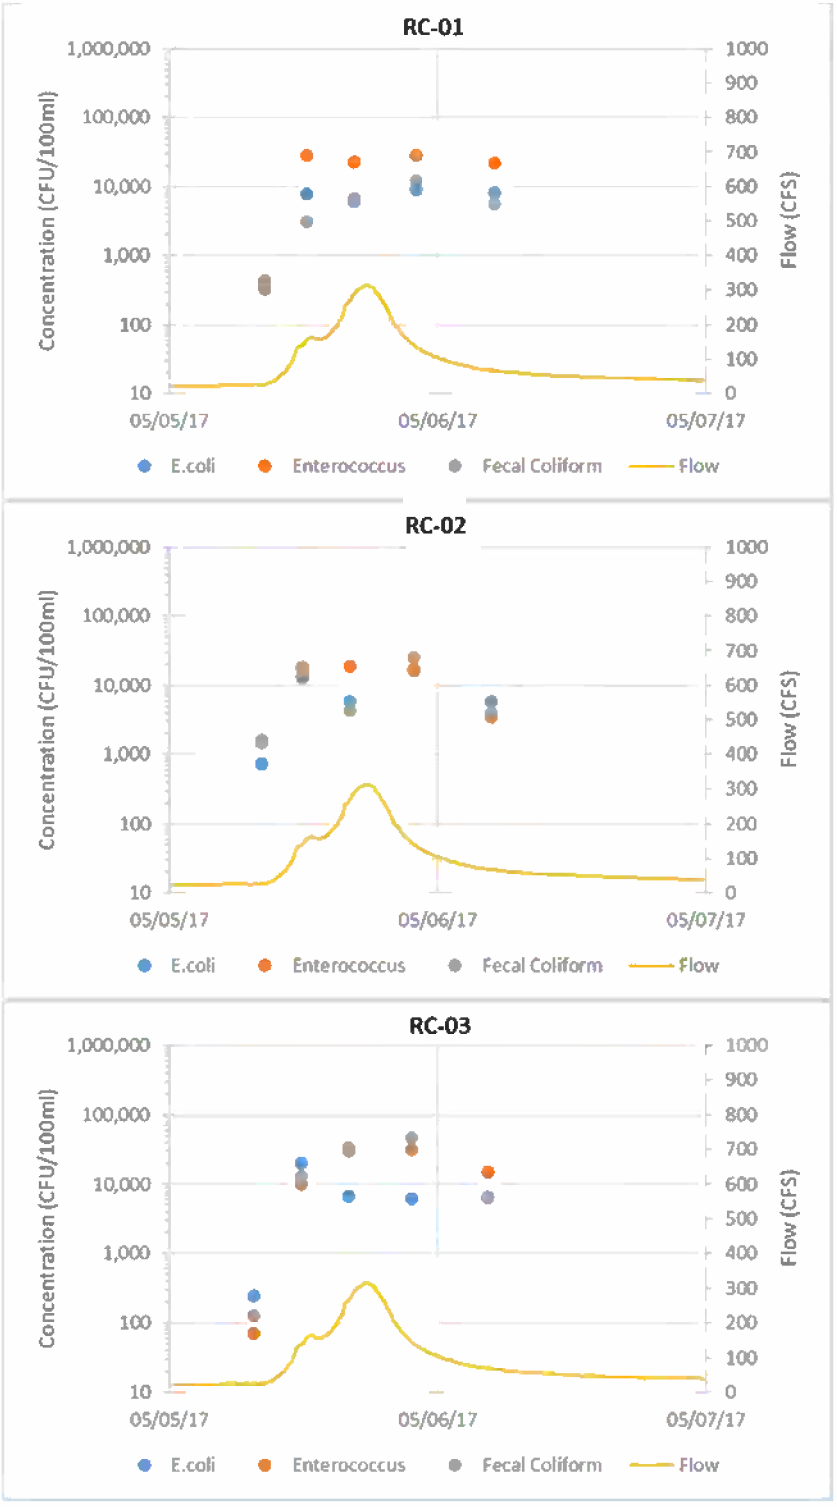


4.5.2 Ridley Creek Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. The majority of concentrations for all of the POCs were higher than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-19 shows the concentrations at each station in the creek and the flow measured at the USGS gage just upstream of the DELCORA study area. Additional sampling plots are provided in Appendix H.

The impact of DELCORA's CSOs and Chester stormwater POC loads appear to begin in the second round of sampling. Concentrations remain elevated throughout the rest of the event at all three locations, despite the fact that DELCORA CSOs stopped discharging within 8 hours (based on sampling intervals where samples could be collected in the CSOs). This suggests that upstream and/or other bacteria sources are likely also impacting the creek. POC concentrations peak at 47,000 cfu/100 ml (fecal coliform).

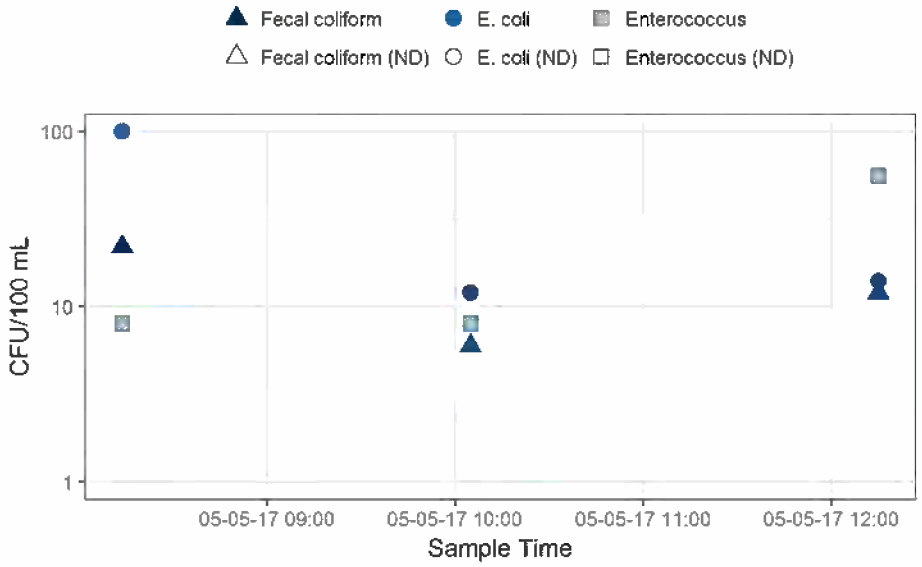
Figure 4-19: Wet Weather Event 2 Concentrations in Ridley Creek



4.5.3 Delaware River Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. Samples were collected more frequently in the Delaware River than in the tributaries to ensure that wet weather impacts were characterized under an entire tidal cycle. Figure 4-20 shows the concentrations at DR-03, the mid-point station on the river. CSOs impacts would be captured at this station under all tidal conditions. Similar levels were observed at the other near shore Delaware River locations. All concentration time series figures are provided in Appendix H.

Figure 4-20: Wet Weather Event 2 Concentrations in Delaware River at DR-03



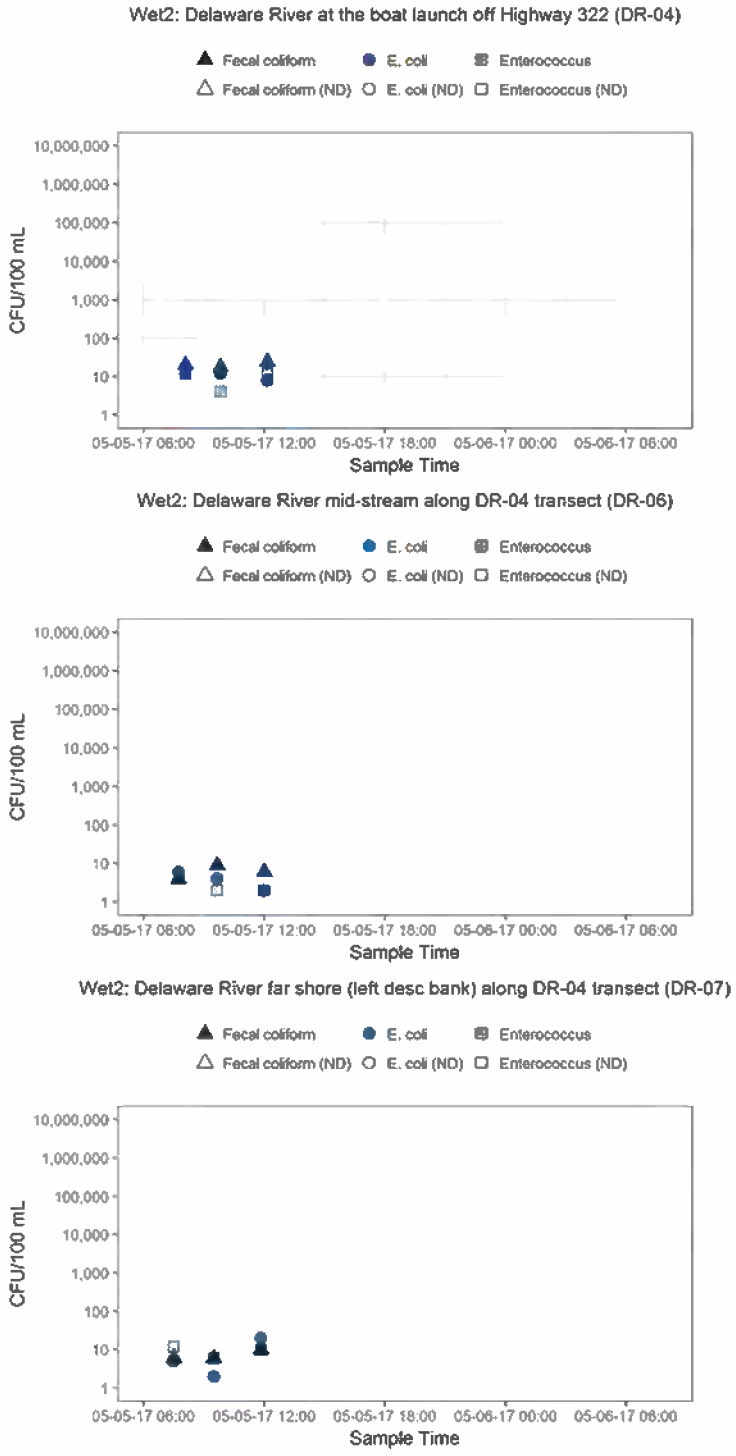
Note that sample collection in the Delaware River had to be stopped midway through the event, as described in Section 3 so the time series includes the three rounds of sampling that were completed as per the Sampling and Analysis Plan. Additional samples were collected from the bank during this event. The data from these locations are higher than the samples collected with the boat and likely reflect localized conditions rather than conditions at the scale of the water quality model.

POC concentrations in the Delaware River tend to be approximately 1-2 orders of magnitude lower than the levels observed in the tributaries. Only the last round of sampling at DR-05 had any POC concentrations greater than 100 cfu/100 ml (the maximum value shown on the y-axis). Because DELCORA's CSOs had stopped discharging well before this round, the concentrations are likely due to loads from other sources. All of the other measurements in the Delaware River are lower than values used as values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2.

Near shore impacts of DELCORA's CSOs were assessed by collecting samples across the transect corresponding to near shore station DR-04. Results are shown for DR-04, DR-06 (mid-stream) and DR-07 (far shore) in Figure 4-21. This figure indicates that a lateral gradient is very slight for the sampling rounds that could be collected. POC concentrations on the near shore and far shore are slightly higher

(~2x) than the mid-stream concentrations. A better understanding of lateral mixing will be obtained through the model calibration process.

Figure 4-21: Wet Weather Event 2 Concentrations Across the Delaware River



4.5.4 Combined Sewer Overflow (CSO) Location Results

All of the CSOs were sampled during this event. Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. Five rounds of samples were collected at each CSO before discharges ended. Concentrations for each POC for each CSO are presented in Figures 4-22 through 4-24. Time series plots are presented in Appendix H.

Figure 4-22: CSO Fecal coliform Concentrations in Wet 2 Event

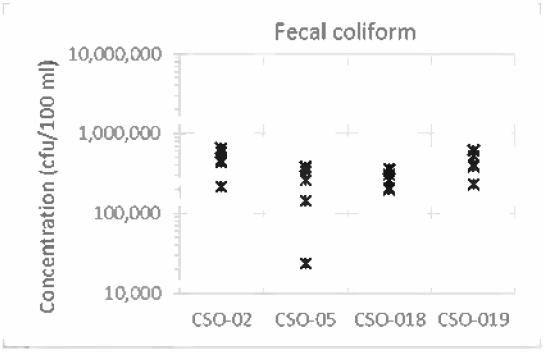


Figure 4-23: CSO E. coli Concentrations in Wet 2 Event

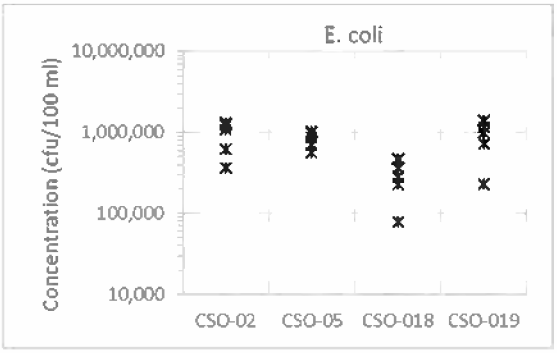

Figure 4-24: CSO Enterococcus Concentrations in Wet 2 Event

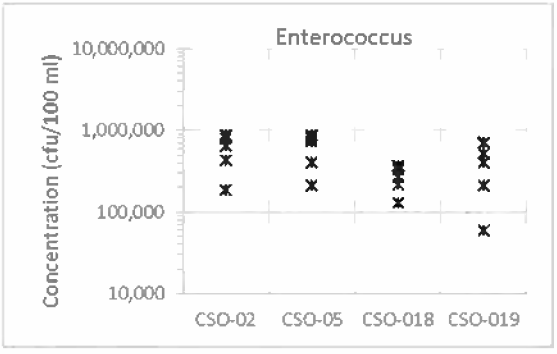
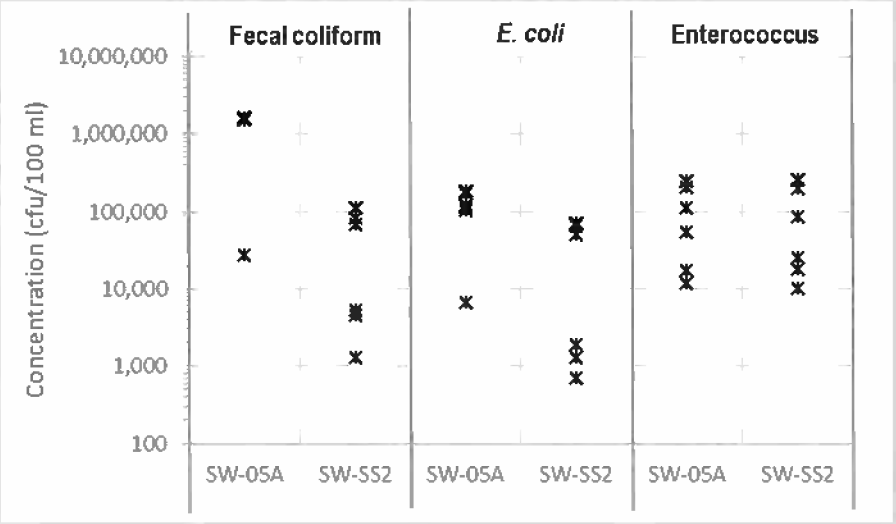


Measured concentrations were within the range of CSO bacteria concentrations reported in the literature (EPA 2002) and were similar to concentrations measured in other communities. Because this event had less rain than Wet Weather Event 1, CSO discharges likely had a smaller fraction of stormwater than in Wet Weather Event 1, resulting in slightly higher concentrations throughout the discharge period.

4.5.5 Stormwater Location Results

Both stormwater outfalls were sampled during this event. Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. Six rounds of samples were collected at each stormwater location before the runoff ended. Concentrations for each POC are presented in Figure 4-25. Time series plots are provided in Appendix H.

Figure 4-25: Stormwater POC Concentrations in Wet 2 Event



Most of the measured concentrations were within the range of stormwater bacteria concentrations reported in the literature. The enterococcus results were similar in magnitude to, though still higher on average than, the fecal coliform and E. coli data. Additional evaluation of POC loads will be conducted as part of the watershed and water quality model calibrations.

4.6 Wet Weather Sampling – Event 3 Results

Wet weather event 3 (Wet 3), was conducted on May 22, 2017. This event was the smallest storm, with 0.51" recorded at the Philadelphia Airport. Rainfall varied across the watershed, with the upper tributary watersheds receiving much less rain than the areas closer to the Delaware River. Less rain fell in the DELCORA area than Philadelphia. Laboratory results are presented by waterbody and source type below.

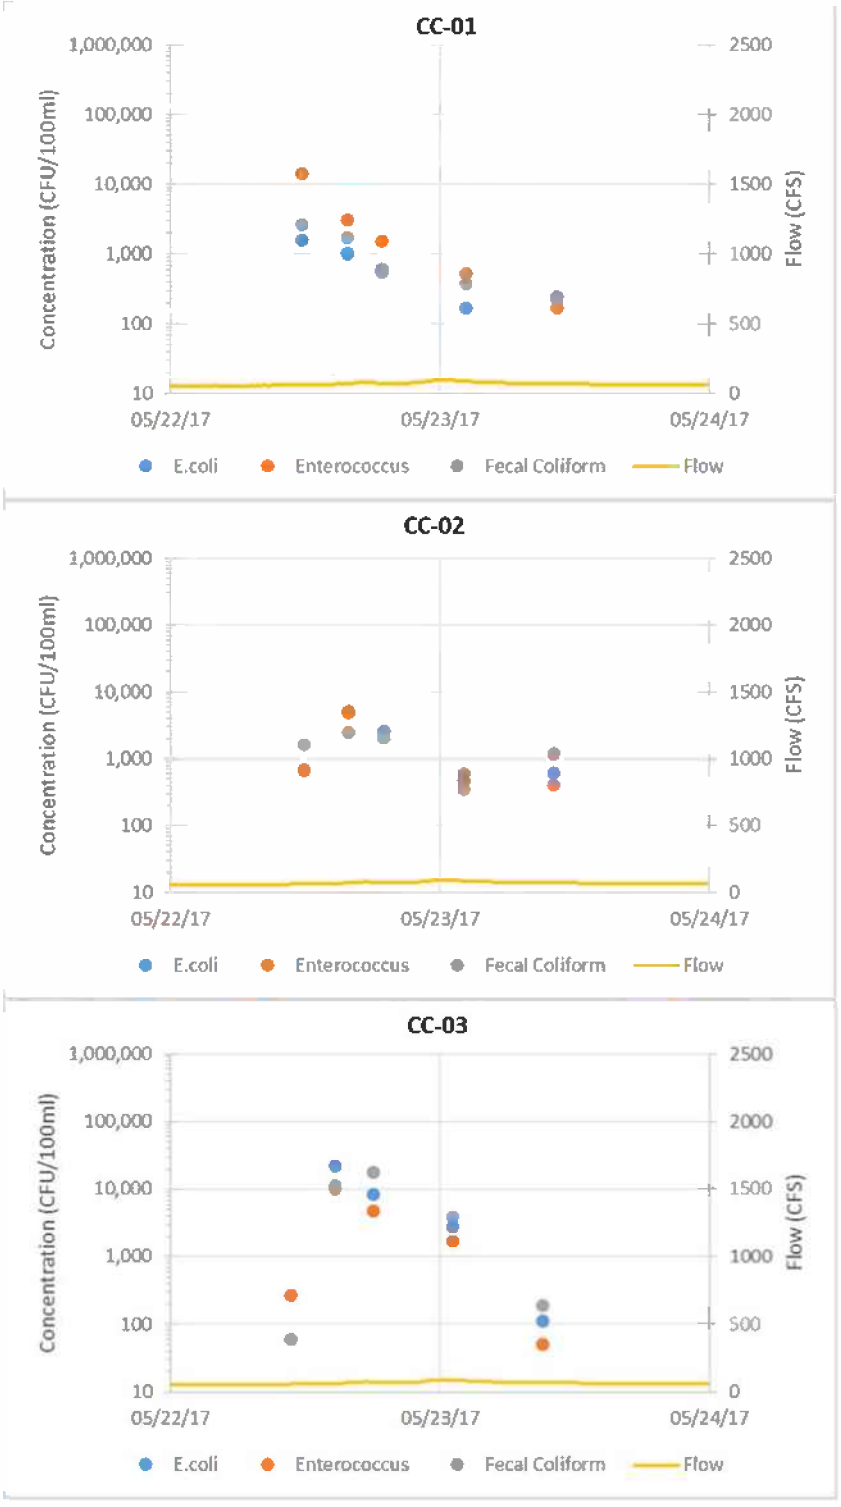
4.6.1 Chester Creek Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. The majority of concentrations for all of the POCs were higher than values used as

maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-26 shows the concentrations at each station in the creek and the flow measured at the USGS gage just upstream of the DELCORA study area. Additional sampling plots are provided in Appendix H.

The impact of DELCORA's CSOs and Chester stormwater POC loads are most evident in the data at CC-03 for second and third rounds of sampling. The data at CC-01 suggest that loads from upstream sources reached the study area at the beginning of the event, which likely reflects the spatial variability in the rainfall. POC concentrations peak at 22,000 cfu/100 ml (E. coli).

Figure 4-26: Wet Weather Event 3 Concentrations in Chester Creek

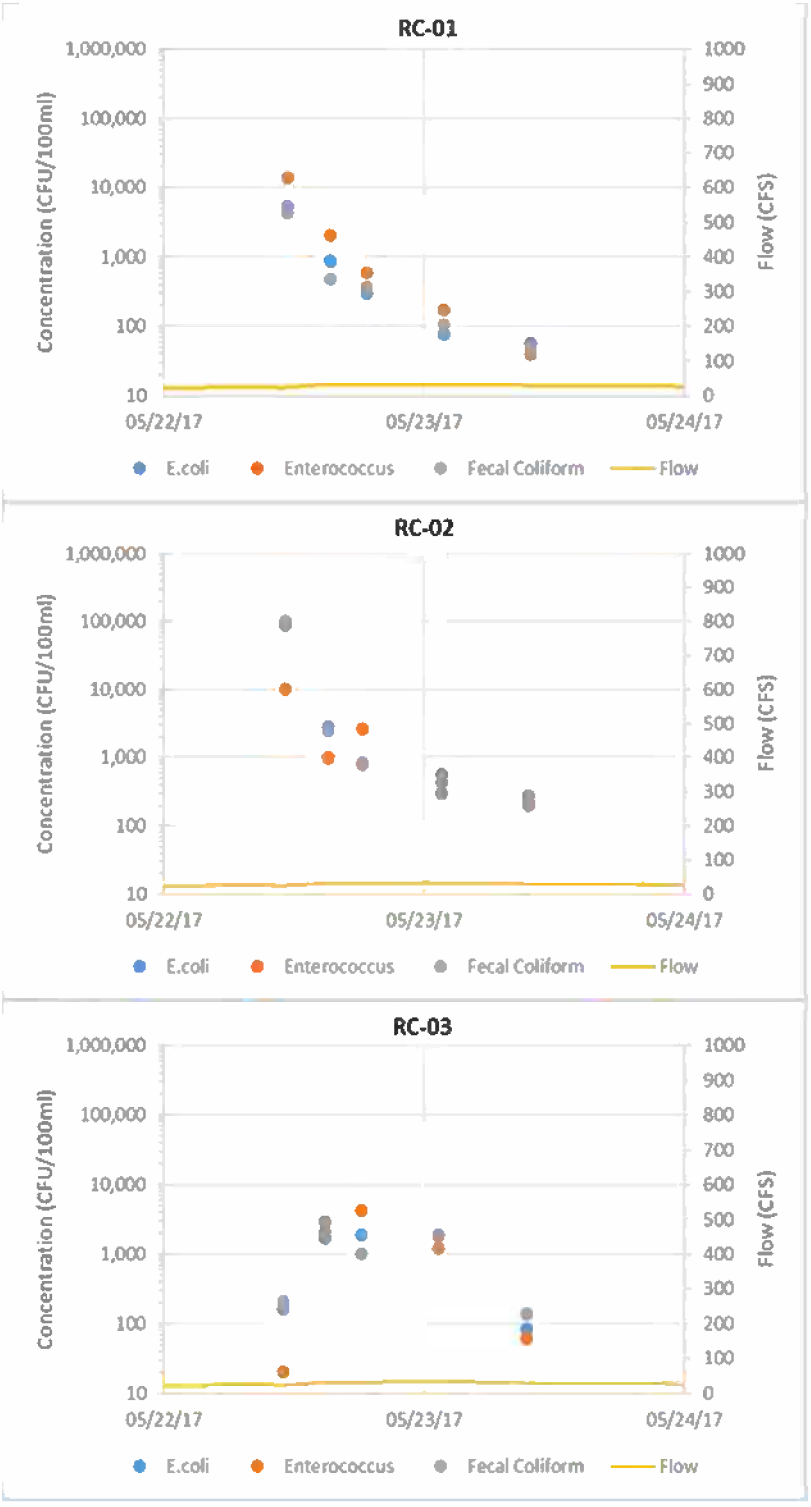


4.6.2 Ridley Creek Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. The majority of concentrations for all of the POCs were higher than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2. Figure 4-27 shows the concentrations at each station in the creek and the flow measured at the USGS gage just upstream of the DELCORA study area. Additional sampling plots are provided in Appendix H.

The impact of DELCORA's CSOs and Chester stormwater POC loads are most evident in the data at RC-02 in the second round and RC-03 in the second and third rounds of sampling. The data at RC-01 suggest that loads from upstream sources reached the study area at the beginning of the event, which likely reflects the spatial variability in the rainfall. POC concentrations peak at 103,000 cfu/100 ml (fecal coliform).

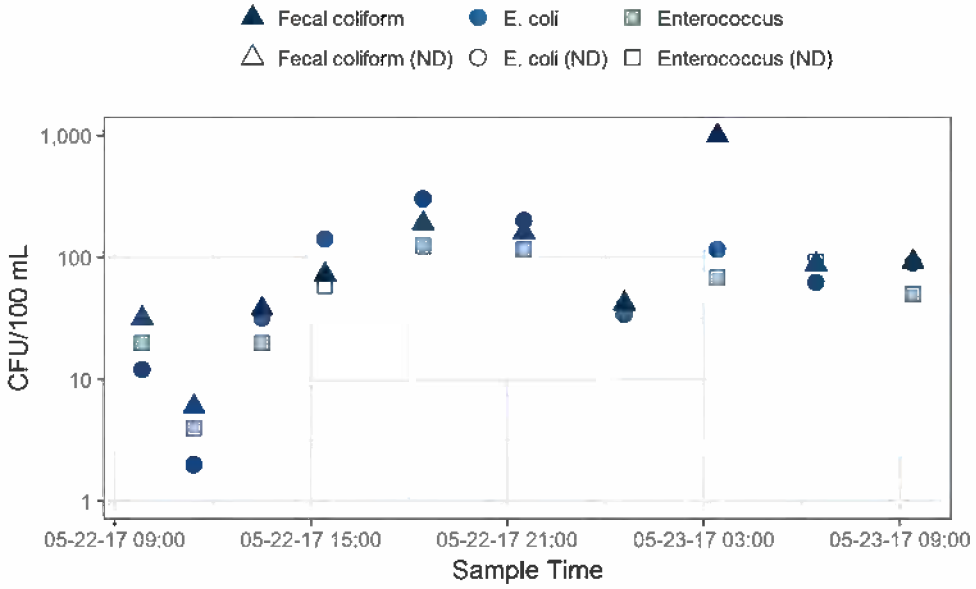
Figure 4-27: Wet Weather Event 3 Concentrations in Ridley Creek



4.6.3 Delaware River Results

Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. Samples were collected more frequently in the Delaware River than in the tributaries to ensure that wet weather impacts were characterized under an entire tidal cycle. Figure 4-28 shows the concentrations at DR-03, the mid-point station on the river. CSOs impacts would be captured at this station under all tidal conditions. Similar levels were observed at the other near shore Delaware River locations. All concentration time series figures are provided in Appendix H.

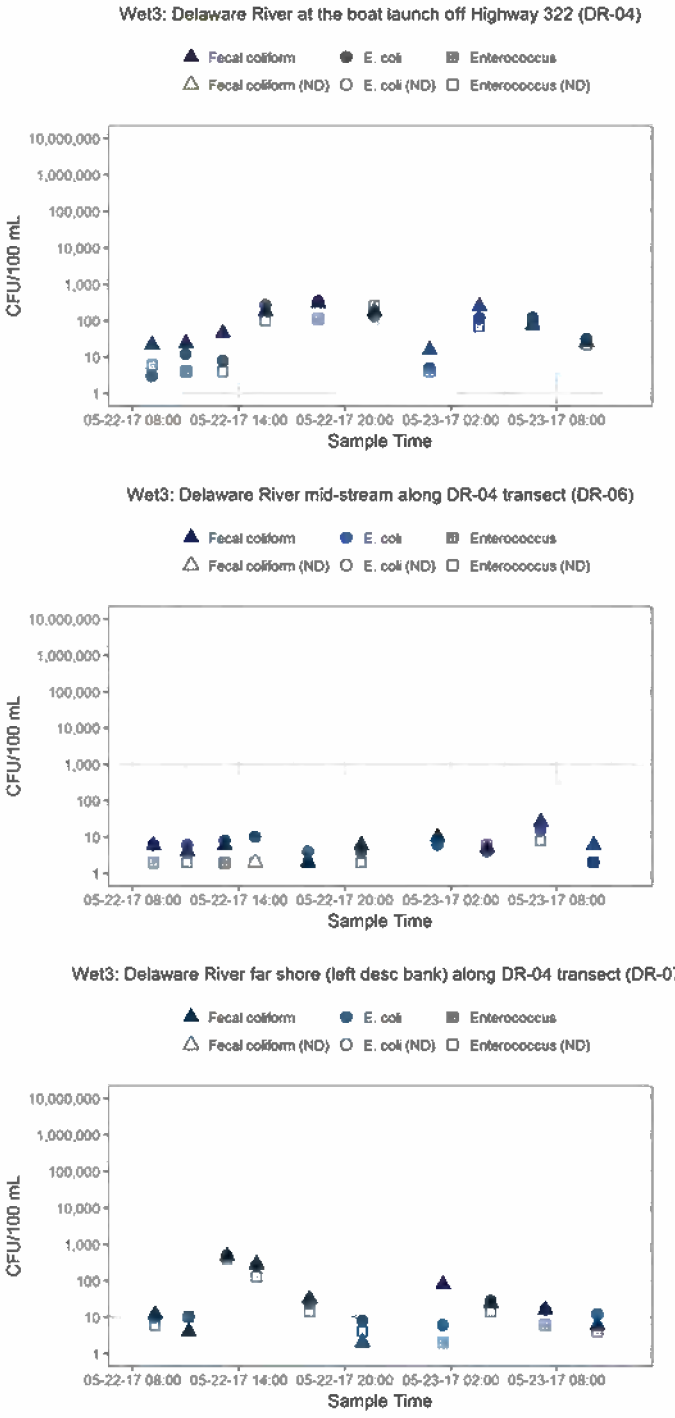
Figure 4-28: Wet Weather Event 3 Concentrations in Delaware River at DR-03



POC concentrations in the Delaware River tend to be approximately 1-2 orders of magnitude lower than the levels observed in the tributaries. The highest concentrations were observed in Rounds 5 and 8 (Hours 9 and 18) at this location. Most of the other measurements in the Delaware River are lower than values used as maximum water quality standard criteria. Maximum water quality standard criteria are shown in Figure 2.1 in Section 2.

Near shore impacts of DELCORA's CSOs were assessed by collecting samples across the transect corresponding to near shore station DR-04. Results are shown for DR-04, DR-06 (mid-stream) and DR-07 (far shore) in Figure 4-29. This figure indicates that a lateral gradient exists with both shores. POC concentrations on the near shore and far shore are approximately 1-2 orders of magnitude higher than the mid-stream concentrations. A better understanding of lateral mixing will be obtained through the model calibration process.

Figure 4-29: Wet Weather Event 3 Concentrations Across the Delaware River



4.6.4 Combined Sewer Overflow (CSO) Location Results

All of the CSOs were sampled during this event. Samples were collected at the intervals specified in the Sampling and Analysis Plan (SAP). Four rounds of samples were collected at each CSO before discharges ended. Concentrations for each POC for each CSO are presented in Figures 4-30 through 4-32. Figures of concentrations over time are presented in Appendix H.

Figure 4-30: CSO Fecal coliform Concentrations in Wet 3 Event

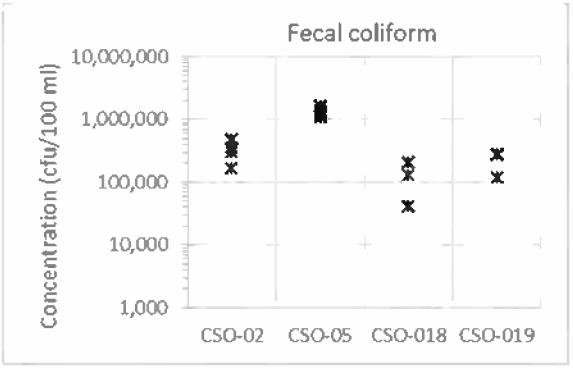


Figure 4-31: CSO E. coli Concentrations in Wet 3 Event

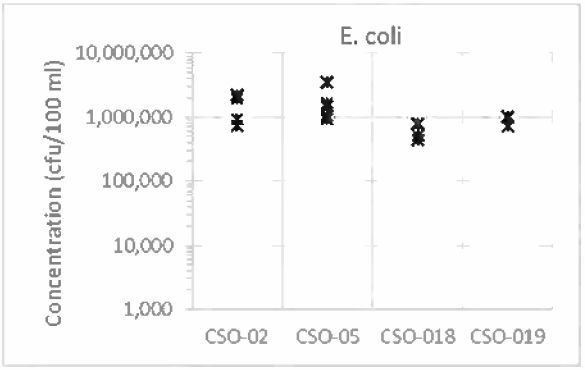

Figure 4-32: CSO Enterococcus Concentrations in Wet 3 Event

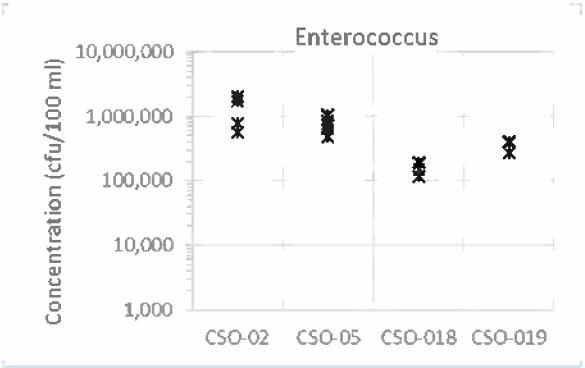
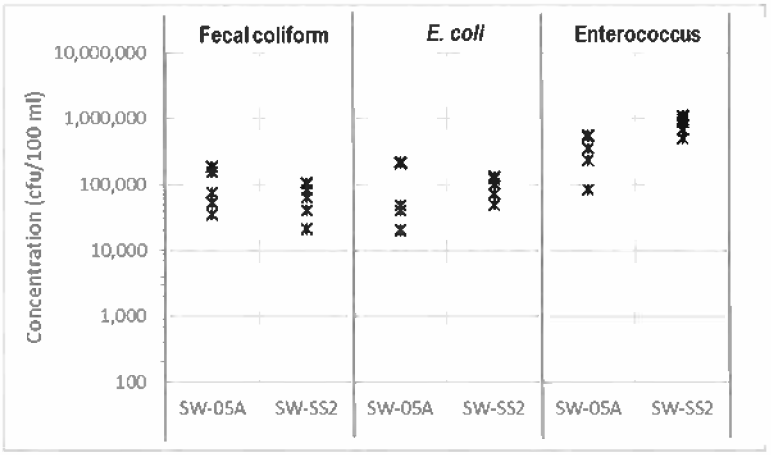


Measured concentrations were within the range of CSO bacteria concentrations reported in the literature (EPA 2002) and tended to be somewhat higher overall than concentrations measured in other communities. Because this event had much less rain than the first two wet weather events, the CSO discharges likely contained a much higher percentage of sanitary sewage than the other events.

4.6.5 Stormwater Location Results

Both stormwater outfalls were sampled during this event. Samples were collected at the intervals specified in the Sampling and Analysis Plan and summarized in Section 2.5.2. Five rounds of samples were collected at each stormwater location before the runoff ended. Concentrations for each POC are presented in Figure 4-33. Figures of concentration over time are provided in Appendix H.

Figure 4-33: Stormwater POC Concentrations in Wet 3 Event



Most of the measured concentrations were within the range of stormwater bacteria concentrations reported in the literature (NSQD 2015). It was somewhat surprising that the enterococcus results tended to be higher than the fecal coliform and E. coli data at both locations. However, there is very little stormwater data in the literature for enterococcus so it is difficult to assess whether these results are unusual. Additional evaluation of POC loads will be conducted as part of the watershed and water quality model calibrations.

Section 5 Comparison of Laboratory Results to QAPP

The Sampling Program execution was consistent with the QAPP objectives. This section presents a summary of the quality of the data relative to the QAPP objectives. Out of a total of 1,195 analysis, 1,104 (92%) did not require data qualifications as a result of poor QA/QC. The remaining 91 analysis were conducted outside the specified 8 hour hold time. However, of these 91 analyses, 84 were completed within 10 hours. These results have been qualified but minimal impact on the use of the data is anticipated due to the similarity in concentrations between results measured within and outside the analytical hold time. Much more uncertainty exists within the analytical methodology and field practices (e.g. obtaining a homogenous, representative sample, etc.). The most common qualifier applied to the data was due to bacteria counts outside ideal ranges. Most of these were the result of low ambient concentrations and the uncertainty associated with their quantification reflects the limitations of the analytical methodology.

Complete Laboratory QA Program Manuals and SOPs for each laboratory procedure are found in Appendix I.

5.1 QAPP Requirements

Section 2.4 of the QAPP provided data quality objectives for the following areas:

- Accuracy
- Precision
- Completeness
- Representativeness
- Comparability
- Required detection limits

Accuracy, precision and detection limits requirements for field and laboratory activities are summarized in Table 5-1. Completeness objectives for the field measurements and sample collection was 90%. The completeness objective was 95% for the laboratory (see Section 2.1.4.3 of the QAPP). Representativeness and comparability objectives were qualitative and will be presented in the context of the sample program comparison in Section 5.2.

Table 5-1: Data Quality Objectives

Parameter	Data Accuracy Objectives (% R)		Data Precision Objectives				Required Detection Limits	
			Field Precision (RPD)		Analytical Precision (RPD)			
	Estimated By	Objective	Estimated By	Objective	Estimated By	Objective	Reference Method	RL*
Fecal coliform	Presence/ Absence Control	P/A	Field Duplicates	50%	Lab Replicates	40%	SM 9222D	10 No./ 100 ml
Escherichia coliform (E. coli)	Presence/ Absence Control	P/A	Field Duplicates	50%	Lab Replicates	40%	EPA 1603	10 No./ 100 ml
Enterococcus	Presence/ Absence Control	P/A	Field Duplicates	50%	Lab Replicates	40%	EPA 1600	10 No./ 100 ml

P/A - method detects presence when bacteria is present in control (P) and method does not detect bacteria when absent in control (A).
RL - Reporting Limit
SM - Standard Methods of the Examination of Water and Wastewater, 22nd Edition

5.2 Comparison of Results to QAPP

This section presents a high level summary of the comparison of the QAPP objectives to the results from the Sampling Program.

5.2.1 Accuracy

Accuracy cannot be directly measured for bacterial samples. Accuracy was assessed by the laboratory through the analysis of positive and negative controls and matrix spikes and with field blanks in the field. Field blanks are used to determine if samples collected were contaminated. Dilution blank samples and method blank samples were generated by the contract laboratory and used to assess contamination resulting from laboratory procedures. Overall, the accuracy of the Sampling Program was excellent.

A total of 21 field blanks were collected during the Sampling Program with at least one field blank collected per sampling event. Each field blank was analyzed for all three POCs, providing up to 63 measures of field accuracy. Only two of the 63 field blank results had a measurement higher than the analytical reporting limit. The field blank concentrations for these two results were inspected for potential evidence of contamination in the associated sample. The comparison indicated that the field blank concentration was much lower than the corresponding sample concentration, so the apparent field contamination impact on the sample result was nominal.

Eurofins, the laboratory that conducted the bacteria analyses for the sampling program, conducted positive/negative controls for E.Coli and Enterococci. Fecal coliform does not require analysis of this QA/QC measure. A positive control is a sample known to have bacteria while a negative control is a

sample known to be bacteria-free. The test is intended to confirm that the laboratory can grow bacteria for the positive controls and does not grow any measurable bacteria for the negative controls. For both E. coli and Enterococcus, six positive and six negative controls were analyzed. All measures met the requirements except one E. coli positive control, which did not have sufficient bacteria growth. Overall, this corresponds to a 96% success rate.

Matrix spikes are analyzed at a frequency of approximately one every 20 samples, depending on available sample volume, sufficient hold time and laboratory capacity. Matrix spikes are prepared by adding a known quantity of bacteria to a sample and measuring the amount recovered. Although this QA/QC measure was not included in the Sample Program QAPP, it provides another measure of laboratory accuracy. Matrix spikes were performed for all three parameters of interest using DELCORA samples.

Results are summarized in the table below. A percent recovery range of 50% - 150% recovery was used for acceptance windows. Note that percent recovery cannot be calculated under the following circumstances:

1. If the unspiked sample has a very high concentration relative to the amount spiked
2. If the matrix spike sample concentration exceeds the quantitation range (e.g. ">")

Both of these situations occurred with each parameter, as shown in the table below.

Table 5-2: Laboratory Matrix Spike Summary

Parameter	Number of MS samples analyzed	Number of MS samples without calculable percent recovery	Number of MS samples with measurable percent recovery	Number of MS samples with acceptable percent recovery
E. coli	13	4	9	6 (67%)
Enterococcus	12	4	8	8 (100%)
Fecal Coliform	10	5	5	3 (60%)

Overall, 77% of the matrix spikes where a percent recovery could be calculated were within the 50% - 150% windows.

5.2.2 Precision

Precision is a measure of agreement between two or more measurements. The precision test objective is shown in Table 5-1. Field duplicates and laboratory replicates samples were taken for a portion of the samples. As noted in the QAPP (Section 2.4.1.2), the precision test (i.e.: comparison between two or more samples) is applied if the average result of the duplicate/replicate samples is greater than five times the analysis detection limit. If the average result of the duplicate/replicate samples is less than five times the analysis detection limit, the precision test was not utilized. Overall, the precision of the Sampling Program was mostly successful at meeting the QAPP objectives. The issues impacting field precision were largely due to factors outside the control of sampling personnel as well as by the well-established difficulty in generating reproducible results analytically for these parameters.

A total of 23 field duplicates were collected during the Sampling Program, with at least one field duplicate collected per sampling event. Each field duplicate was analyzed for all three POCs, providing up to 69 measures of field precision. Table 5-2 provides a summary of the field duplicate precision, calculated as the relative percent difference (% RPD).

Table 5-3: Field Precision % RPD Summary

Event	Location	E. coli % RPD	Fecal % RPD	Entero % RPD
Dry1	CC-01	<5x RL	<5x RL	<5x RL
Dry1	DR-02	<5x RL	<5x RL	<5x RL
Dry1	RC-03	91%	<5x RL	<5x RL
Dry2	CC-02	60%	59%	11%
Dry2	DR-04	80%	7%	<5x RL
Dry2	RC-02	7%	49%	42%
Dry3	CC-03	22%	9%	55%
Dry3	DR-03	18%	5%	<5x RL
Dry3	RC-01	44%	10%	0%
Wet1	CC-03	44%	36%	56%
Wet1	CSO-02	45%	107%	20%
Wet1	DR-02	55%	41%	<5x RL
Wet1	DR-04	133%	0%	52%
Wet1	RC-01	34%	67%	1%
Wet2	CC-01	27%	35%	3%
Wet2	CSO-018	2%	19%	18%
Wet2	DR-03 (LAND)	75%	147%	15%
Wet2	RC-02	34%	6%	18%
Wet3	CC-02	2%	50%	18%
Wet3	CSO-019	22%	1%	36%
Wet3	DR-01	50%	58%	<5x RL
Wet3	DR-02	6%	40%	34%
Wet3	RC-03	41%	21%	26%

Twelve (12) of the 69 RPDs could not be calculated because of the low pollutant concentrations in the samples and the field duplicates. For E. coli, 15 of the 21 calculable field duplicates met the 50% precision objective. For fecal coliform, 15 of the 20 calculable field duplicates met the 50% precision objective. For enterococcus, 13 of the 16 calculable field duplicates met the 50% precision objective.

Laboratory replicates are analyzed at a frequency of approximately one every 20 samples, depending on available sample volume, sufficient hold time and laboratory capacity. Replicates are prepared by analyzing a second aliquot of a sample and measuring the agreement between the two analyses as the

relative % difference (% RPD). Replicates provide an assessment of laboratory precision. Replicates were performed for all three parameters of interest using DELCORA samples.

Results are summarized in the table below. A % RPD target of 40% was specified in the QAPP for acceptance windows. Note that % RPD cannot be calculated under the following circumstances:

1. If the sample or replicate concentration exceeds the quantitation range (e.g. ">")
2. If the sample or replicate concentration is less than the reporting limit (e.g. "<")

Both of these situations occurred with each parameter, as shown in the table below. In addition, the sample id for one of the replicates for each parameter was inadvertently not recorded so it was not possible to compare its concentration to the first aliquot.

Table 5-4: Relative Percent Difference Summary

Parameter	Number of replicate samples analyzed	Number of replicate samples without calculable % RPD	Number of replicate samples with measurable % RPD	Number of replicate samples with acceptable % RPD
E. coli	13	6	7	7 (100%)
Enterococcus	12	7	5	3 (40%)
Fecal Coliform	10	7	3	1 (40%)

Overall, 73% of the replicates where a % RPD could be calculated were within the 40% window.

5.2.3 Completeness

Completeness is a measure of the amount of valid data obtained from the monitoring program compared to the amount of data that were expected. Events that may contribute to reduction in measurement completeness include sample container breakage, inaccessibility to desired sampling locations, automatic sampler failure, and laboratory equipment failures.

Field completeness is determined by the number of measurements collected versus the number of measurements planned for collection. As noted in the QAPP, The completeness criterion for all measurements and sample collection is 90 percent, but will be influenced by environmental situations that may alter monitoring schedules. These environmental situations were presented in Section 3 of this report for each event. Laboratory completeness is a measure of the amount of valid measurements obtained from all samples submitted for each sampling activity. The completeness criterion for all measurements is 95 percent.

All analyses were completed on the samples that were collected so the laboratory completeness measure is 100%. The overall field completeness was 87%. Field completeness was impacted by the sampling challenges described in Section 3, including weather-related safety issues and mechanical problems with the boat that resulted in several rounds of sampling that could not be conducted as planned. These issues only impacted the wet weather sampling in the Delaware River. When possible, samples were collected from the bank but access was limited to only two stations. For the tributaries, CSOs and stormwater

locations, the field completeness was 100%. Depending on the location in the Delaware River, the field completeness ranged from 67% to 78%. Overall, the completeness objective was successfully achieved as most of the problems affecting the ability to collect the planned samples in the Delaware River were unavoidable.

5.2.4 Representativeness

Representativeness is the degree to which data accurately and precisely represents a characteristic of a population, parameter variations at a sampling point, a process condition, or an environmental condition. Representative data of dry weather and wet weather conditions are required to support the evaluation and modeling efforts.

For sample collection, representativeness will be assured by following the Water Quality Monitoring and Modeling Work Plan (Greeley and Hansen / Limnotech, Revised July 2017) and applying proper collection techniques including the proper sample sizes and volumes, sampling times, and sampling locations. The volumes of the samples depend on the analytical methods and should allow for QC sample analysis and reanalysis, if required. In the laboratory, representativeness will be ensured by using the appropriate sample preparation techniques, by following appropriate analytical procedures, and by meeting the recommended sample holding times.

Representativeness was achieved in the Sampling Program by sampling three dry weather events under a range of flow conditions and during both the spring and summer season, and by sampling three wet weather events under a range of environmental conditions, with rainfall ranging from 0.5 inches to more than 1.5 inches. Figures 5-1 and 5-2 shows the sampling intervals in each of the waterways for the three dry weather and three wet weather events, respectively. There were no instances where samples lacked sufficient volume for analysis. In the laboratory, representativeness was generally good.

All samples were analyzed for all POCs using accepted methods. However, of the 459 samples collected in the Sampling Program, 61 had at least one parameter analyzed outside the specified hold time of 8 hours. Most of these samples were associated with the wet weather events, reflecting the logistical challenges associated with this type of sampling. A total of 91 analyses were conducted after the hold time had expired. However, 84 of these analyses were completed within 10 hours, so the hold time was missed by less than 2 hours for the vast majority of samples. These results have been qualified but minimal impact on the use of the data is anticipated due to the similarity in concentrations between results measured within and outside the analytical hold time. Much more uncertainty exists within the analytical methodology and field practices (e.g. obtaining a homogenous, representative sample, etc.).

Overall, the representativeness objectives of the QAPP was achieved through the selection of sampling events that collectively, capture the river and tributary characteristics over a range of environmental conditions.

Figure 5-1: Representativeness of Dry Weather Sampling Events and Sampling Intervals in Each Waterway

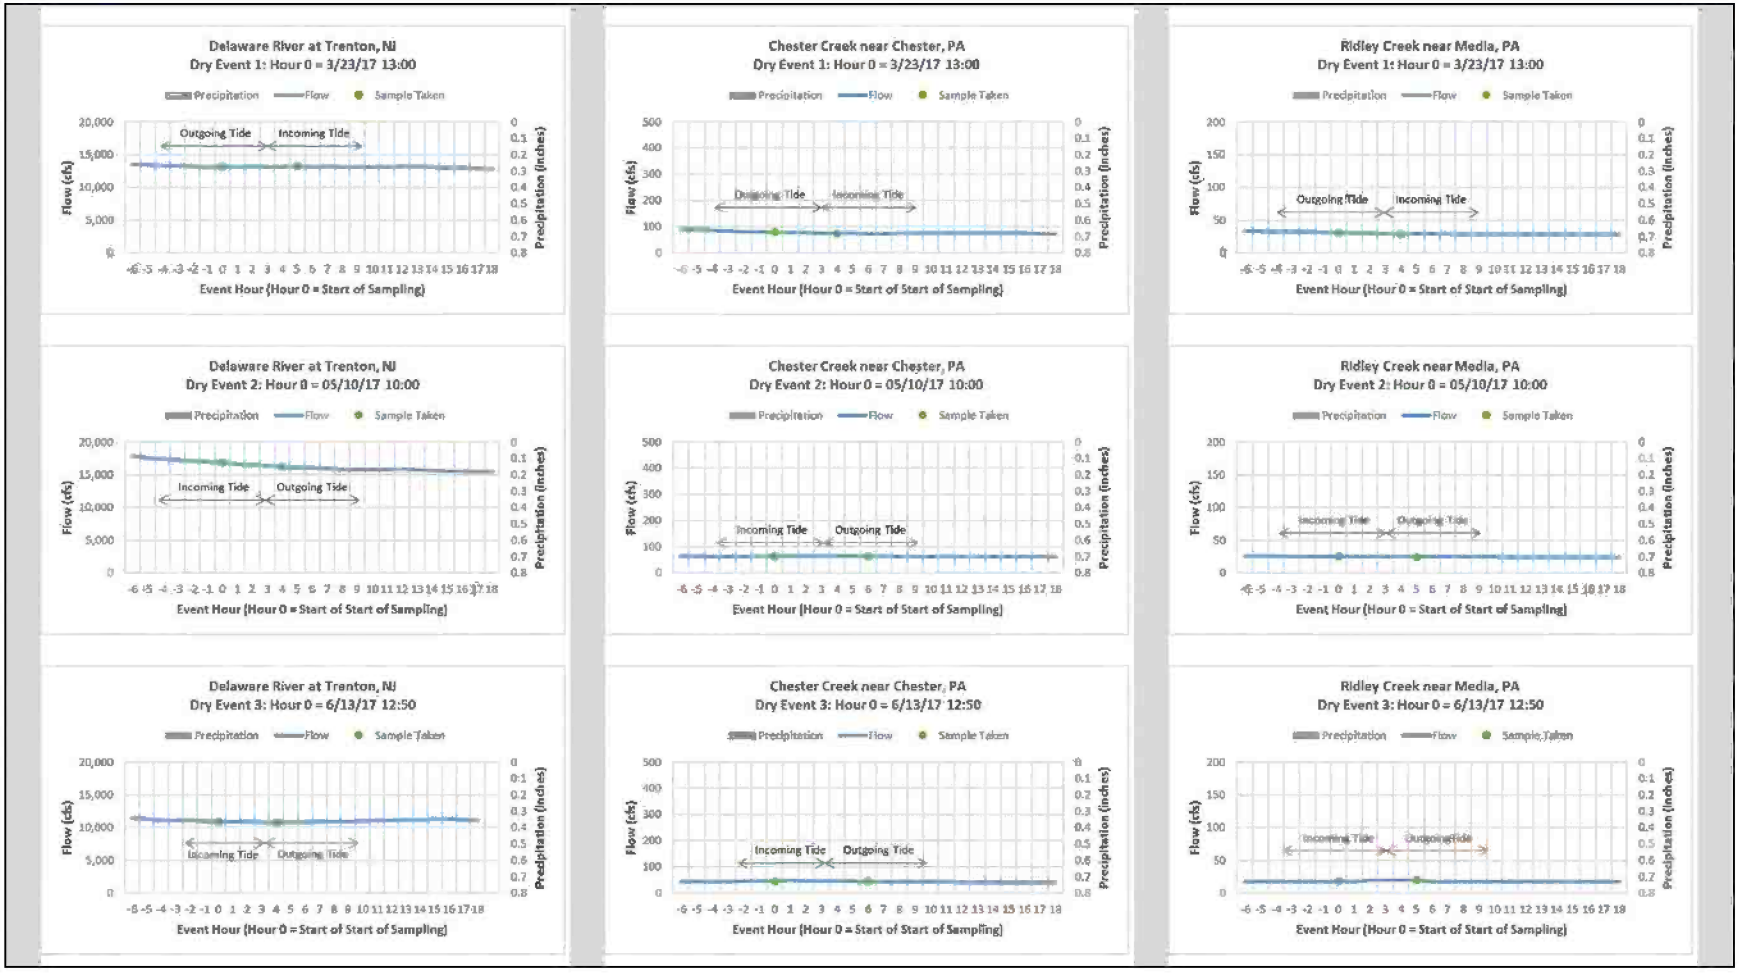


Figure 5-2: Representativeness of Wet Weather Sampling Events and Sampling Intervals in Each Waterway

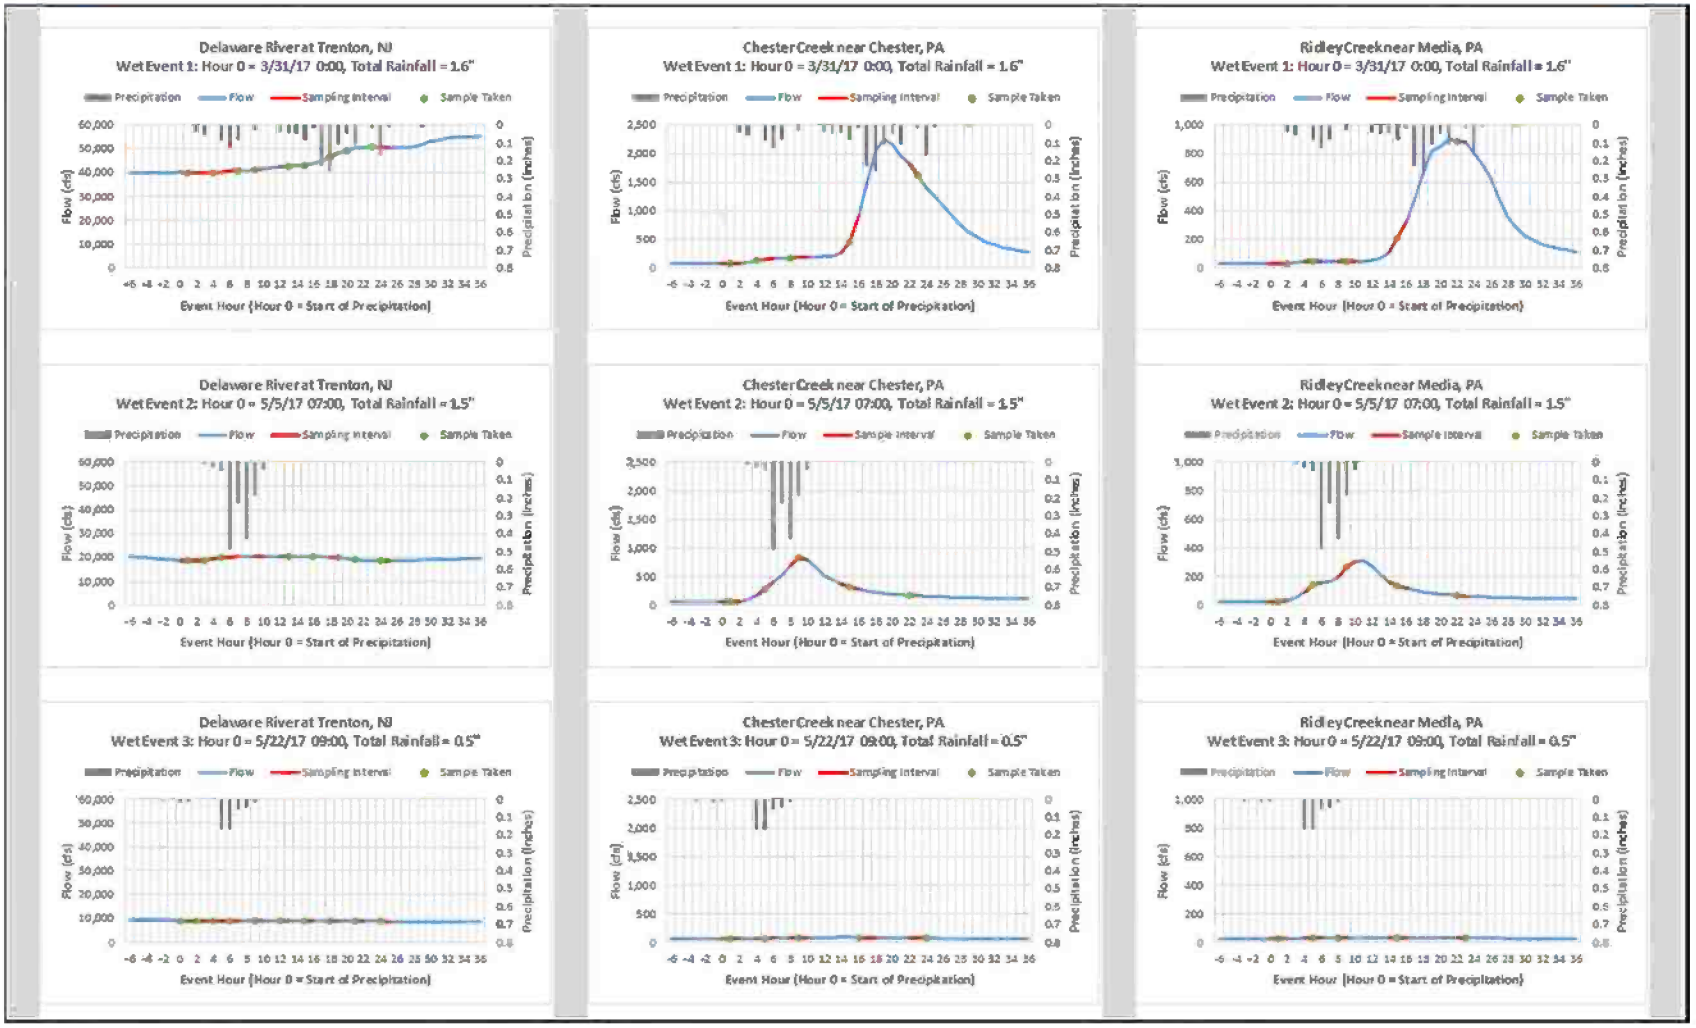

5.2.5 Comparability

The objective for data comparability is to generate data for each parameter that related water quality conditions between sampling locations and over time. Data comparability will be promoted by:

1. Using standard U.S. EPA approved methods, where possible.
2. Consistently following the sampling methods detailed in the SAP.
3. Consistently following the analytical methods detailed in the QAPP.
4. Achieving the required detection limits detailed in the QAPP.

All sample collection and analytical methods will be specified, and any deviations from the methods will be documented. All results will be reported in the standard units as shown in QAPP. All field and laboratory calibrations will be performed using standards traceable to National Institute of Science and Technology (NIST) or other U.S. EPA approved sources.

The field crews and laboratory were consistent in collecting and analyzing the samples from the Sampling Program in a manner that allows the data to be compared between events. In the laboratory, the same EPA-approved analytical method was used for each parameter across all sampling events and samples were consistently analyzed at the dilutions specified in the QAPP and Work Plan. The Sampling Program successfully met this objective of the QAPP.

5.2.6 Required Detection Limits

All required detection limits were met in the Sampling Program.

Section 6 Water Quality Sampling Results Summary

This section presents additional analysis of the water quality sampling program results, particularly with respect to their use in the development and calibration of the water quality model.

6.1 Data Analysis

Section 4 presented an overview of the dry and wet weather datasets by individual event. The following observations were presented with respect to the data:

- Bacteria concentrations tended to be similar in all of the waterbodies during dry weather for both incoming and outgoing tidal conditions;
- Dry weather concentrations in the tributaries were mostly below numeric thresholds used for water quality standard criteria;
- Dry weather concentrations in the Delaware River tended to be well below numeric thresholds used for water quality standard criteria;
- An increase in POC concentration from upstream to downstream was observed in each of the tributaries, suggesting there may be significant bacteria sources impacting these tributaries during dry weather;
- Wet weather concentrations in all of the waterbodies tended to exceed numeric thresholds used for water quality standard criteria;
- Lateral POC gradients in the Delaware River were present but not at a significant level (e.g. orders of magnitude); and,
- The time series profiles in the Chester Creek and Ridley Creek waterbodies suggest that DELCORA's CSO discharges and Chester's stormwater discharges are not the only sources impacting these tributaries during wet weather. Upstream or other wet-weather sources also contribute to high bacteria concentrations during wet weather events.

In addition to the insights gleaned from the time series figures described in Section 4 and presented in Appendix H, this section presents data analyses that considered the results for the events more holistically than the individual event summaries presented in Section 4. Additional data analyses presented in this section include 1) an evaluation of the waterway response to the various environmental conditions during the sampled events and 2) an evaluation of whether a first flush could be discerned for any of the POCs in the source (e.g. CSO and stormwater) data.

6.1.1 Evaluation of Waterway Response to Environmental Conditions

Because multiple storm events were sampled, along with several dry weather events, a comparison of the response at each stream location across the sampling events may yield insight into how sensitive a given stream reach is to the amount and distribution of rainfall. This may be an important factor to consider in developing CSO control strategies. For example, a control strategy may target reductions of CSOs in non-tidal areas if those portions of the streams show a stronger response to rainfall than tidal areas.

Figure 6-1 presents box-and-whisker plots of the tributary sampling locations in Chester Creek and Ridley Creek. The figures are ordered such that the top figure is the most upstream sampling location and the bottom figure is the most downstream sampling location. The boxes in the figure correspond to the 25th and 75th percentiles of the data. The line in the center of the box is the median concentration. The end of the whiskers correspond to the minimum and maximum concentrations. The data for each wet and dry weather events were grouped separately into subsets for the purpose of the plot. Similar figures are presented in Appendix H for the other POCs and sampling locations.

The following insights can be gleaned from these figures:

- Dry weather concentrations of the analyzed bacteria are lower than each of the wet weather event concentrations;
- The stream response was most pronounced for the second wet weather event. This event was slightly less depth than the first wet weather event (1.47 inches vs. 1.5 inches) but the rainfall occurred over a shorter duration and with higher intensity in the second wet weather event, resulting in a stronger in-stream response.
- Downstream locations show more spread in the distribution of concentrations within each event as compared to the most upstream locations. This is likely the result of higher mixing with the Delaware River and the tidal influence on water quality at the more downstream locations.

Figure 6-2 presents box-and-whisker plots of three Delaware River locations: DR-01, which is the most upstream (e.g. least tidally impacted) station, DR-03, which is approximately midway along the reach of the river adjacent to the DELCORA service area, and DR-05, which is the most downstream station.

This figure shows some of the same characteristics as Figure 6-1 as well as some differences. Like the tributaries, the most downstream location shows the largest spread in concentrations, likely the result of higher mixing associated with the tidal influence on water quality at this station compared to the others located further upstream. Unlike the tributaries, which had the largest response to the second wet weather event, the Delaware River had the highest concentrations in the first wet weather event, though at DR-05, the peak concentration occurred during the second wet weather event. Another difference between the characteristics of the Delaware River and the tributaries' water quality is that the dry and wet weather concentrations in the Delaware River tended to be more similar than in the tributaries. Additional analysis and interpretation of the data will be conducted as part of the water quality model development and calibration process.

Figure 6-1: Comparison of Fecal Coliform Concentrations for the Sampling Events in Chester and Ridley Creeks

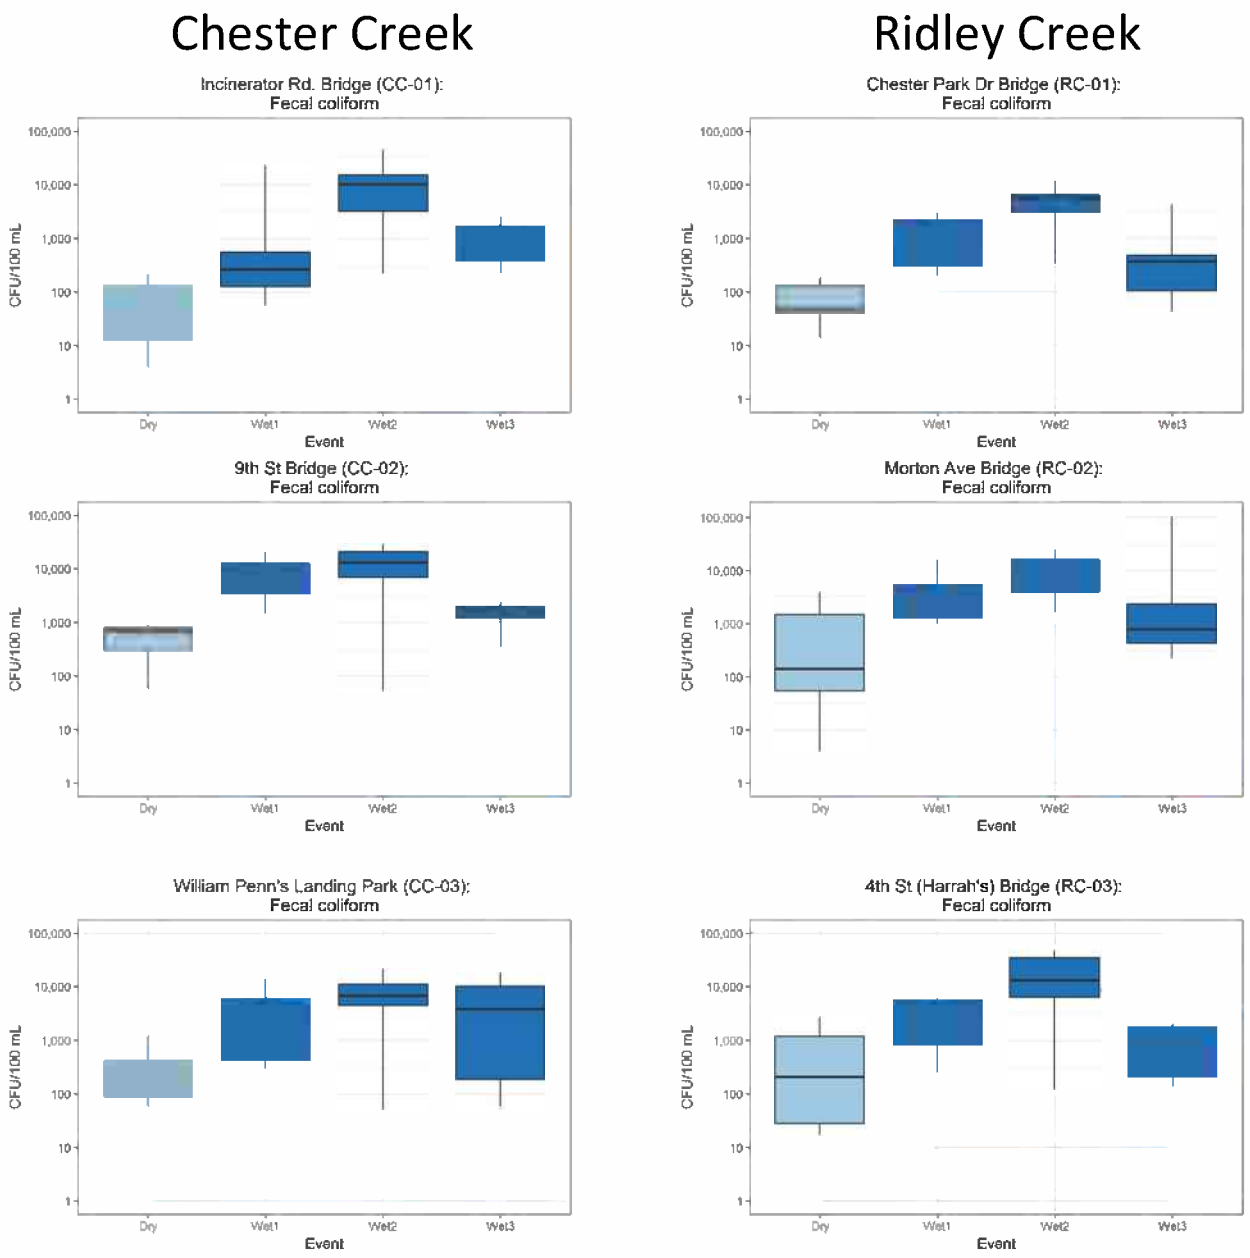

Figure 6-2: Comparison of Fecal Coliform Concentrations for the Sampling Events in the Delaware River

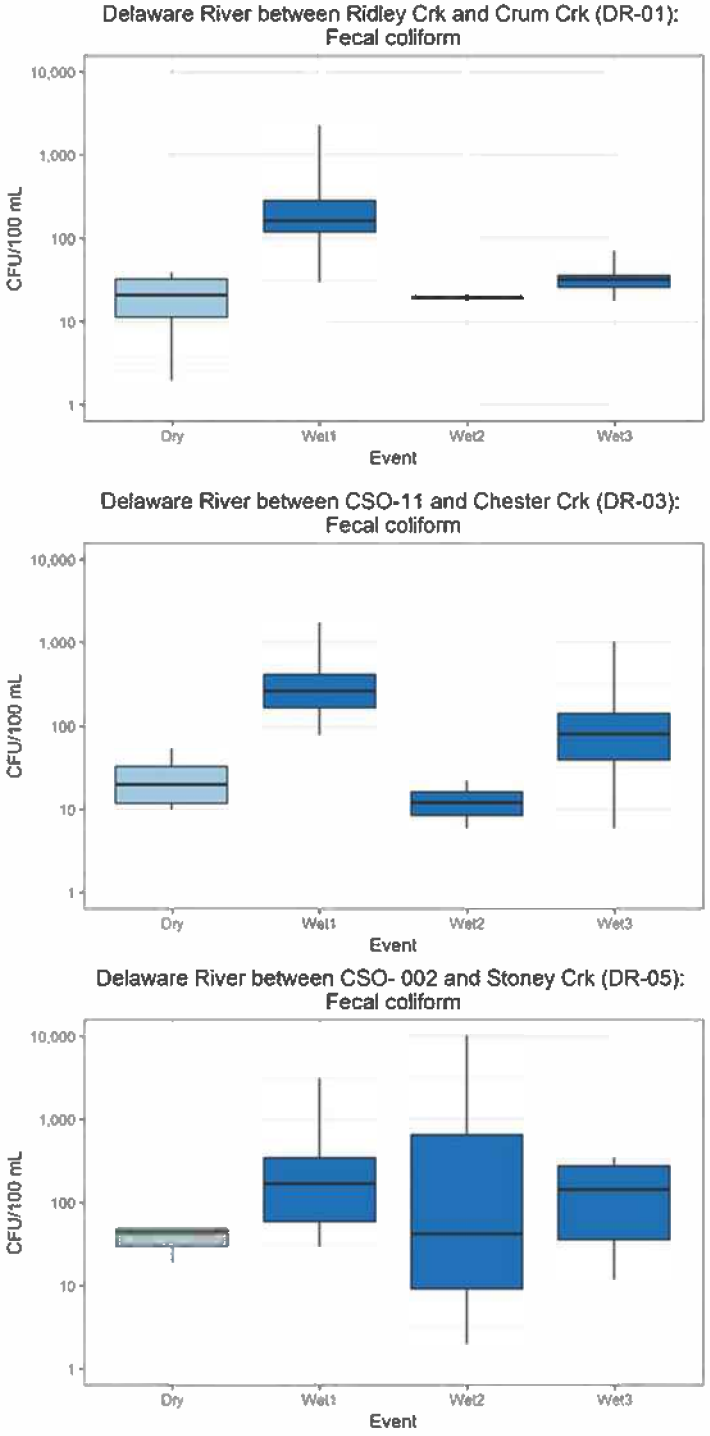

6.1.2 CSO and Stormwater First Flush Effect Analysis

A second analysis that was conducted across all of the event datasets was an evaluation of the CSO and stormwater data for first flush effects. A first flush effect means that pollutant concentrations that build up on the land surface between rainfall events are quickly washed off and flushed through the collection system, resulting in higher pollutant concentrations during the beginning of the discharge period compared to concentrations during the later portion of the discharge event.

Figure 6-3 presents a comparison of fecal coliform data in each of the CSOs for each of the wet weather events by sampling round. Note that the first three rounds are sampled within the first hour of discharge, with the fourth round representing the 2nd hour of discharge. If a first flush effect existed, concentrations during one or more of these rounds of sampling would be consistently higher than the later rounds. As this figure illustrates, there are combinations of events and rounds where the concentration is significantly higher than other events and/or other rounds, but no consistent pattern is discernible. Similar results were obtained for the other POCs (see Appendix H). Bacteria concentrations can be highly variable and it is typically very difficult to identify a consistent first flush for these parameters.

Figure 6-4 presents a similar analysis and result for the two stormwater outfalls for fecal coliform. Plots for the other POCs are presented in Appendix H.

This figure also shows a significant outlier data point during Wet 2 (1,500,000 cfu/100 ml) that is not believed to be representative of the quality of the stormwater runoff. The field notes, chain of custodies and laboratory analytical reports were inspected for potential explanation for the high value but none could be determined from the record set. This data point was not used in any statistical calculations or other data analyses.

6.1.3 CSO and Stormwater Event Mean Concentrations

Based on the first flush effect analysis presented in the previous section, the CSO and stormwater data were further analyzed to develop an initial estimate of representative concentration for each source type to calculate pollutant loads. These representative concentrations are referred to as event mean concentrations (EMCs) and represent the average water quality in the CSO and storm sewer systems.

Figure 6-3: CSO Fecal Coliform Concentrations by Sampling Round

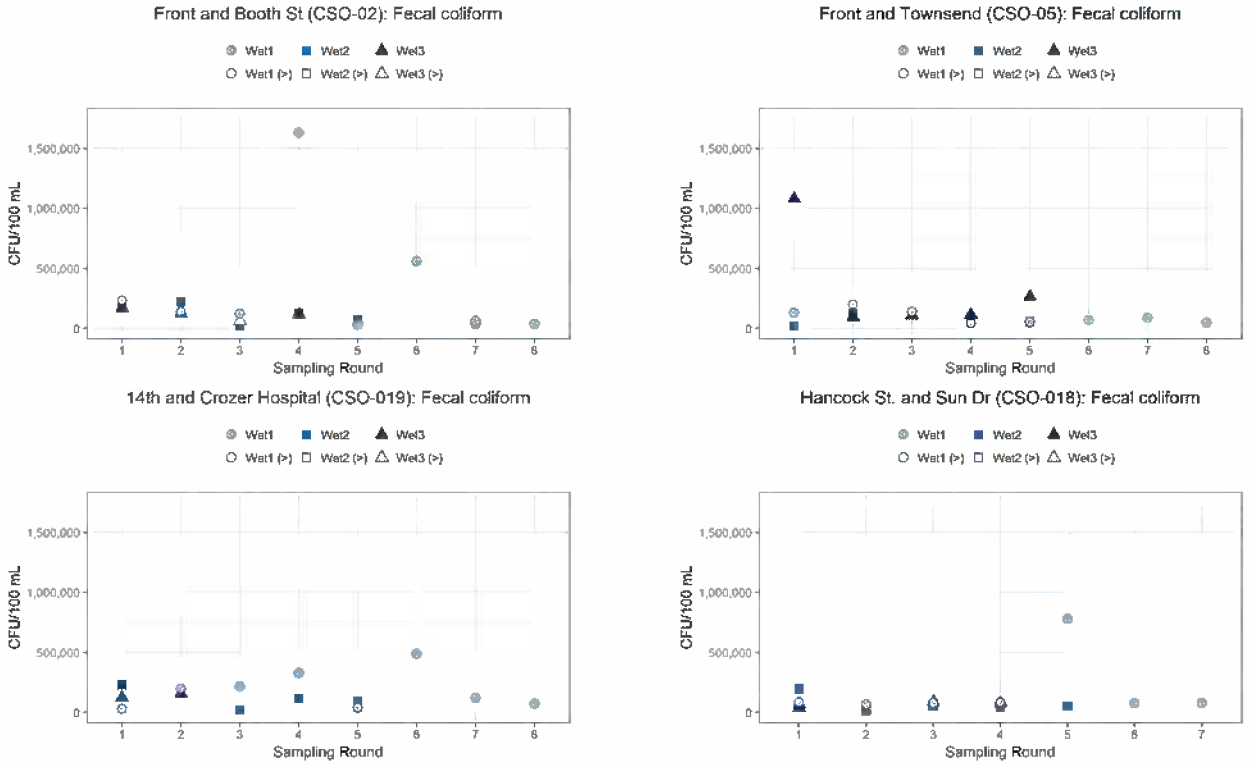

Figure 6-4: Stormwater Fecal Coliform Concentrations by Sampling Round

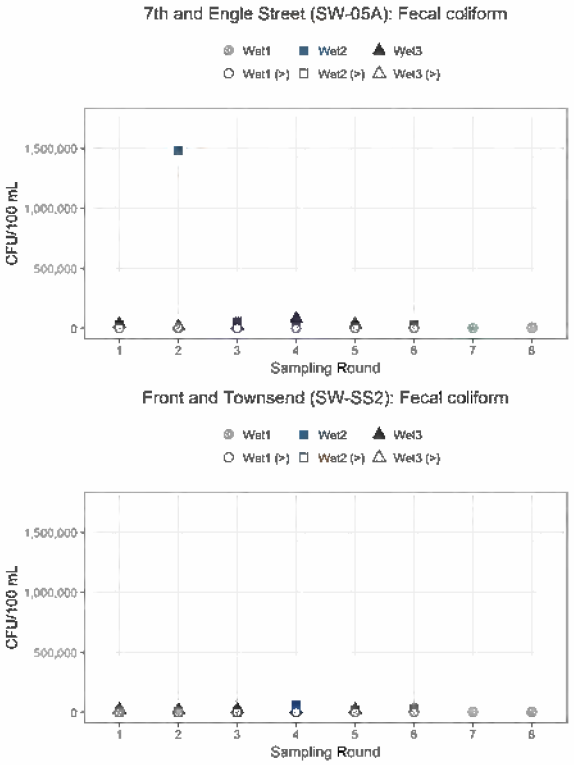

Flow-weighted EMCs were calculated for CSO-02, CSO-05, and CSO-019 using the metered flow data at the CSO diversion structure and the measured concentration data. Since CSO-018 was not metered, this method could not be applied for this CSO. A summary is presented in Table 6-1 for each event and POC.

Table 6-1: Flow-weighted CSO Event Mean Concentrations

	CSO-019	CSO-02	CSO-05
Fecal coliform			
Wet 1	175,264	160,758	75,948
Wet 2	97,421	95,158	72,093
Wet 3	125,183	124,408	126,934
Average	128,814	123,924	88,578
E. coli			
Wet 1	233,830	112,097	42,575
Wet 2	232,809	176,018	107,485
Wet 3	689,748	304,759	370,265
Average	334,860	181,845	119,216
Enterococcus			
Wet 1	167,891	110,237	52,790
Wet 2	149,515	141,616	119,217
Wet 3	254,176	305,311	142,677
Average	185,474	168,291	96,475

It should be noted that these calculations are a starting point for determining EMCs for use in the water quality model. The calculations shown in Table 1 present a challenge in that the E. coli values are higher than the fecal coliform values, which is not physically possible.

A statistical analysis was conducted on the CSO and stormwater data directly with results shown in Table 6-2. This analysis allows the data from locations without flow data, such as CSO-018 and the two stormwater locations, to be included for consideration. All of the data for a given location were evaluated together in developing the statistics presented in Table 6-2.

Table 6-2: Distribution of CSO and Stormwater Pollutant Concentrations

	Sample Count	Geomean	25th Percentile	75th Percentile
Fecal coliform				
CSO-02	18	116,611	60,750	205,250
CSO-05	18	99,861	56,750	126,750
CSO-018	17	74,335	53,000	85,000
CSO-019	15	116,754	83,773	206,000
SW-05A	19	5,522	883	31,000
SW-SS2	19	3,693	913	21,000
E. coli				
CSO-02	18	158,546	60,500	345,500
CSO-05	18	144,369	66,000	231,250
CSO-018	17	95,812	63,000	104,000
CSO-019	15	189,860	100,000	286,000
SW-05A	19	3,843	1,180	16,500
SW-SS2	19	2,407	625	18,000
Enterococcus				
CSO-02	18	123,582	73,250	288,750
CSO-05	18	90,052	61,250	180,000
CSO-018	17	48,669	29,000	83,000
CSO-019	15	131,911	56,500	197,000
SW-05A	19	25,118	5,700	112,000
SW-SS2	19	40,217	19,250	119,250

Results in this table for each location are slightly lower than the results using the flow-weighted method average results presented in Table 6-1. The results also show that the CSO E. coli values are higher than the CSO fecal coliform values, which is not physically possible since E. coli is a subset of fecal coliform. The 25th and 75th percentile values will be used as a basis for adjusting the EMC value used in estimating the loads from each source type. Additional analysis and interpretation of the data will be conducted as part of the water quality model development and calibration process.

6.2 Conclusion

The DELCORA Sampling Program was designed to fill data gaps necessary to characterize sources and surface waters during dry and wet weather events to support the development of water quality models for use in the development of the CSO Long Term Control Plan Update. It provides the first co-located, coordinated sampling of Chester Creek, Ridley Creek and the Delaware River for the three bacteria parameters most often used to protect recreational water quality and identified as Pollutants of Concern. This was also the first Sampling Program to capture both dry and wet weather in-stream conditions, conduct time-intensive wet weather sampling, and concurrently characterize CSO and stormwater

sources. The data are sufficient to characterize DELCORA's CSO and stormwater source loads for the water quality model. The data also span a range of environmental conditions and provide an extensive dataset for demonstrating the robustness of the water quality model. The Sampling Program fully achieved the objectives of collecting comprehensive and complete datasets needed to characterize pollutant sources, produce an appropriately calibrated watershed and water quality model, and successfully meet the quality objectives of the QAPP. No further data collection is required at this time to develop or calibrate the models for use in the development of DELCORA's Long Term Control Plan Update.

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Revised Identification of Sensitive Area Analysis (RISAA) dated May 13, 2016. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). EPA hereby approves the RISAA.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

APPENDIX B

DRY WEATHER EVENT 2 – FIELD LOGS AND LAB RESULTS SUMMARY

(Chain of Custody Forms and Complete Lab Results provided in digital form only on CD attached to this report)

DRY WEATHER EVENT: 2

DATE: 5/10/2017 — **Note Temperature of Receiving Stream if below 10 °C threshhold**

EVENT START TIME: 10:00

Sampling Station	Sampling Round	Target Sample Collection Time (hh:mm)	Actual Sample Collection Time (hh:mm)	Duplicate Sample Collected? [1] (Y/N)	Duplicate Collection Time (hh:mm)	Field Blank Sample Collected? [1] (Y/N)	Field Blank Collection Time (hh:mm)	Chain of Custody Provided & Completed (Y/N)	Time Sample Transferred to Lab Courier (hh:mm)	Water Salinity Reading (%)	Water Temperature Reading (°C)	Conductivity Reading (umhos/cm)	Field Observations[2] (see notes, below)
CC-01	Incoming tide	11:00	11:46	N	N/A	N	N/A	Y	12:07	0.02	11.33	0.330	Clear sky, 61 °F, water very clear, no debris
	Outgoing tide	17:00	17:07	N	N/A	N	N/A	Y	18:00	0.33	12.54	0.511	Clear sky 71 °F, water clear, no debris
CC-02	Incoming tide	12:00	12:07	N	N/A	N	N/A	Y	12:07	0.23	13.86	0.378	Clear sky 61 °F, water mostly clear, minimal debris
	Outgoing tide	17:25	17:30	Y	17:31	N	N/A	Y	18:00	0.30	11.69	0.464	Clear sky 71 °F, water little cloudy, no debris
CC-03	Incoming tide	10:00	10:16	N	N/A	Y	10:09	Y	12:07	0.32	10.56	0.467	Clear sky, 59 °F, water mostly clear, no debris
	Outgoing tide	15:40	15:44	N	N/A	N	N/A	Y	18:00	0.21	14.44	0.339	Clear sky 71 °F, water mostly clear, minimal debris
RC-01	Incoming tide	11:20	11:26	N	N/A	N	N/A	Y	12:07	0.34	16.73	0.590	Clear sky 60 °F, water very clear, small amount of foam
	Outgoing tide	16:40	16:45	N	N/A	N	N/A	Y	18:00	0.35	16.47	0.590	Clear sky 70 °F, water clear, some foam
RC-02	Incoming tide	11:00	11:02	Y	11:02	N	N/A	Y	12:07	0.26	16.00	0.439	Clear sky 60 °F, water clear, small amount of floating debris
	Outgoing tide	16:20	16:21	N	N/A	N	N/A	Y	18:00	0.25	16.69	0.440	Clear sky 70 °F, water clear, some floating debris
RC-03	Incoming tide	10:30	10:43	N	N/A	N	N/A	Y	12:07	0.27	16.49	0.458	Clear sky 59 °F, water mostly clear, no debris
	Outgoing tide	16:00	16:04	N	N/A	N	N/A	Y	18:00	0.22	15.93	0.378	Clear sky 71 °F, water clear, no debris

APPENDIX C

DRY WEATHER EVENT 3 – FIELD LOGS AND LAB RESULTS SUMMARY

(Chain of Custody Forms and Complete Lab Results provided in digital form only on CD attached to this report)

DRY WEATHER EVENT: 3

DATE: 6/13/2017 **Note Temperature of Receiving Stream if below 10 °C threshhold**

EVENT START TIME: 11:40

Sampling Station	Sampling Round	Target Sample Collection Time (hh:mm)	Actual Sample Collection Time (hh:mm)	Duplicate Sample Collected? (Y/N)	Duplicate Collection Time (hh:mm)	Field Blank Sample Collected? (Y/N)	Field Blank Collection Time (hh:mm)	Chain of Custody Provided & Completed (Y/N)	Time Sample Transferred to Lab Courier (hh:mm)	Water Salinity Reading (%)	Water Temperature Reading (°C)	Conductivity Reading (umhos/cm)	Field Observations (see notes, below)
CC-01	Incoming tide	13:19	13:23	N	N/A	N	N/A	Y	14:17	0.38	23.17	748	Clear sky, very little foam, no debris
	Outgoing tide	19:05	19:07	N	N/A	N	N/A	Y	20:06	0.38	25.02	786	Clear sky, little foam, no debris
CC-02	Incoming tide	13:36	13:41	N	N/A	N	N/A	Y	14:17	0.39	21.98	749	Clear sky, some debris, no foam
	Outgoing tide	19:25	19:24	N	N/A	N	N/A	Y	20:06	0.39	23.79	776	Clear sky, little debris, no foam little turbidity
CC-03	Incoming tide	11:57	12:00	Y	12:00	Y	11:59	Y	14:17	0.38	22.30	733	Clear sky, little debris, no foam little turbidity
	Outgoing tide	17:48	17:48	N	N/A	N	N/A	Y	20:06	0.24	21.37	455	Clear sky, 95 F, some floating debris
RC-01	Incoming tide	12:59	13:02	N	N/A	N	N/A	Y	14:17	0.32	22.08	624	Clear sky, little foam, little debris
	Outgoing tide	18:40	18:43	Y	18:43	N	N/A	Y	20:06	0.32	23.38	637	Clear sky, little foam, 94 F
RC-02	Incoming tide	12:34	12:37	N	N/A	N	N/A	Y	14:17	0.33	20.91	617	Clear sky, little debris, very little foam
	Outgoing tide	18:25	18:20	N	N/A	N	N/A	Y	20:06	0.34	23.35	675	Clear sky, 94 F, little debris, no turbidity
RC-03	Incoming tide	12:14	12:20	N	N/A	N	N/A	Y	14:17	0.32	22.08	609	Clear sky, no foam, no debris, little turbidity
	Outgoing tide	18:05	18:04	N	N/A	N	N/A	Y	20:06	0.26	22.86	512	Clear sky, 94 F, debris, little turbidity
DR-01	Incoming tide	13:00	13:00	N	N/A	Y	13:05	Y	14:17	0.14/0.14/0.14	21.82/21.8/21.7	275/274/273	Total Depth = 24 ft

APPENDIX D

WET WEATHER EVENT 1 – FIELD LOGS AND LAB RESULTS SUMMARY

(Chain of Custody Forms and Complete Lab Results provided in digital form only on CD attached to this report)

WET WEATHER EVENT: 1

IN-STREAM TRIBUTARY STATION: CC-01

DATE: *3/31/2017* **Note Temperature of Receiving Stream if below 10 °C threshhold**

START OF RAINFALL TIME: *23:30*

Sampling Round	Sample Interval from Start of Rainfall (Hours)	Target Sample Collection Time (hh:mm)	Actual Sample Collection Time (hh:mm)	Duplicate Sample Collected? (Y/N)	Duplicate Collection Time (hh:mm)	Field Blank Sample Collected? (Y/N)	Field Blank Collection Time (hh:mm)	Chain of Custody Provided & Completed (Y/N)	Time Sample Transferred to Lab Courier (hh:mm)	Water Salinity Reading (%)	Water Temperature Reading (°C)	Conductivity Reading (umhos/cm)	Field Observations (see notes, below)
1	0.5-2.5	1:00	1:03	N	N/A	N	N/A	Y	3:04	0.30	9.00	431.9	Raining
2	4.5-6.5	6:00	4:54	N	N/A	N	N/A	Y	6:55	0.20	8.90	515	Raining

APPENDIX E

WET WEATHER EVENT 2 – FIELD LOGS AND LAB RESULTS SUMMARY

(Chain of Custody Forms and Complete Lab Results provided in digital form only on CD attached to this report)

WET WEATHER EVENT: 2

IN-STREAM TRIBUTARY STATION: CC-01

DATE: *5/5/2017* **Note Temperature of Receiving Stream if below 10 °C threshhold**

START OF RAINFALL TIME: *7:30*

Sampling Round	Sample Interval from Start of Rainfall (Hours)	Target Sample Collection Time (hh:mm)	Actual Sample Collection Time (hh:mm)	Duplicate Sample Collected? (Y/N)	Duplicate Collection Time (hh:mm)	Field Blank Sample Collected? (Y/N)	Field Blank Collection Time (hh:mm)	Chain of Custody Provided & Completed (Y/N)	Time Sample Transferred to Lab Courier (hh:mm)	Water Salinity Reading (%)	Water Temperature Reading (°C)	Conductivity Reading (umhos/cm)	Field Observations (see notes, below)

APPENDIX F

WET WEATHER EVENT 3 – FIELD LOGS AND LAB RESULTS SUMMARY

(Chain of Custody Forms and Complete Lab Results provided in digital form only on CD attached to this report)

WET WEATHER EVENT: 3

Sampling Round	Sample Interval from Start of Rainfall (Hours)	Target Sample Collection Time (hh:mm)	Actual Sample Collection Time (hh:mm)	Duplicate Sample Collected? (Y/N)	Duplicate Collection Time (hh:mm)	Field Blank Sample Collected? (Y/N)	Field Blank Collection Time (hh:mm)	Chain of Custody Provided & Completed (Y/N)	Time Sample Transferred to Lab Courier (hh:mm)	Water Salinity Reading (%)	Water Temperature Reading (°C)	Conductivity Reading (umhos/cm)	Field Observations (see notes, below)
IN-STREAM TRIBUTARY STATION: CC-01													
DATE: *5/22/2017* **Note Temperature of Receiving Stream if below 10 °C threshhold**													
START OF RAINFALL TIME: *10:30*													
1	0.5-2.5	10:30	11:42	N	N/A	N	N/A	Y	12:28	0.27	16.18	465	Raining
2	4.5-6.5	14:30	15:40	N	N/A	N	N/A	Y	17:48	0.26	16.21	439	Raining
3	8.5-10.5	18:30	18:46	N	N/A	N	N/A	Y	19:50	0.27	16.36	462	Raining

Chester Creek	CC-01	5	0.5-2.5, 4.5-6.5, 8.5-10.5, 14.5-16.5, 22-24	5	1	1 See notes column	E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (surface water depth)	x			17		CC-01 HR 8.5-10.5		Prepare field blank at first sampling location for each event, regardless of tide condition.
Chester Creek	CC-02	5	0.5-2.5, 4.5-6.5, 8.5-10.5, 14.5-16.5, 22-24	5			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (surface water depth)	x						CC-02 HR 4.5-6.5	
Chester Creek	CC-03	5	0.5-2.5, 4.5-6.5, 8.5-10.5, 14.5-16.5, 22-24	5			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (surface water depth)	x				CC-03 HR0.5-2.5			
Ridley Creek	RC-01	5	0.5-2.5, 4.5-6.5, 8.5-10.5, 14.5-16.5, 22-24	5	1	1 See notes column	E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (surface water depth)	x			17	RC-01 HR 14.5-16.5			
Ridley Creek	RC-02	5	0.5-2.5, 4.5-6.5, 8.5-10.5, 14.5-16.5, 22-24	5			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (surface water depth)	x					RC-02 HR0.5-2.5		
Ridley Creek	RC-03	5	0.5-2.5, 4.5-6.5, 8.5-10.5, 14.5-16.5, 22-24	5			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (surface water depth)	x						RC-03 HR4.5-6.5	
Delaware River	DR-01	10	0, 2, 4, 6, 9, 12, 15, 18, 21, 24	10	2	1 See notes column	E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (at surface water, mid, near bottom depths)	x	x	x	73		DR-01 HR 9		
Delaware River	DR-02	10	0, 2, 4, 6, 9, 12, 15, 18, 21, 24	10			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (at surface water, mid, near bottom depths)	x	x	x		DR-02 HR 2			
Delaware River	DR-03	10	0, 2, 4, 6, 9, 12, 15, 18, 21, 24	10			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (at surface water, mid, near bottom depths)	x	x	x			DR-03 HR 21	DR-03 HR 4	
Delaware River	DR-04	10	0, 2, 4, 6, 9, 12, 15, 18, 21, 24	10			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (at surface water, mid, near bottom depths)	x	x	x		DR-04 HR 15			
Delaware River	DR-05	10	0, 2, 4, 6, 9, 12, 15, 18, 21, 24	10			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (at surface water, mid, near bottom depths)	x	x	x				DR-05 HR 12	
Delaware River	DR-06	10	0, 2, 4, 6, 9, 12, 15, 18, 21, 24	10			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (at surface water, mid, near bottom depths)	x	x	x					
Delaware River	DR-07	10	0, 2, 4, 6, 9, 12, 15, 18, 21, 24	10			E. coli, Enterococcus, Fecal coliform	Salinity, Temperature, Conductivity (at surface water, mid, near bottom depths)	x	x	x					
Outfall (combined sewer)	CSO-02	8	0, 0.5, 1, 2, 4, 8, 12, 24	8 max	1	1 Same location as field duplicate, See notes column	E. coli, Enterococcus, Fecal coliform	none				34	CSO-02 HR 1			Prepare field blank at same location as field duplicate. Prepare field blank once crew arrives at sampling location.
Outfall (combined sewer)	CSO-05	8	0, 0.5, 1, 2, 4, 8, 12, 24	8 max			E. coli, Enterococcus, Fecal coliform	none								
Outfall (combined sewer)	CSO-18	8	0, 0.5, 1, 2, 4, 8, 12, 24	8 max			E. coli, Enterococcus, Fecal coliform	none						CSO-18 HR 1		
Outfall (combined sewer)	CSO-19	8	0, 0.5, 1, 2, 4, 8, 12, 24	8 max			E. coli, Enterococcus, Fecal coliform	none							CSO-19 HR 1	
Outfall (storm water)	SW-05A	8	0, 0.5, 1, 2, 4, 8, 12, 24	8 max	0	0	E. coli, Enterococcus, Fecal coliform	none				16				
Outfall (storm water)	SW-SS2	8	0, 0.5, 1, 2, 4, 8, 12, 24	8 max	0	0	E. coli, Enterococcus, Fecal coliform	none

BioBall SingleShot

Certificate of Analysis

Lot Number: B3628

Reference Material Data

Organism:	*Escherichia coli*
Designation:	NCTC 9001
Reference:	413832 10 Vials
	56033 20 Vials
BTF Internal Reference:	B-EC9001-30-10
	B-EC9001-30-20
Date of Manufacture:	19 July 2016
Expiry Date:	19 July 2018
Extended Expiry Date*:	N/A

Quantification Data
(Method Ref: BB-001)
cfu Count per BioBall ©

Mean cfu	SD
29.6	2.6

95% Prediction Interval

Lower Limit	Upper Limit
24.3	34.8

For an explanation of the Prediction Interval see the BioBall Instructions For Use on the BioBall website - www.bioball.com

Culture Information

No. of Passages:	4
QC Media:	Nutrient agar
Plate Incubation Time (hrs):	14 - 24
Plate Incubation Temp °C:	37 Aerobic

Note: Number of passages are indicated from the original strain assuming original strain is zero

Strain Confirmation

Bacteria strains are confirmed by genetic typing. Yeast and Mould strains are confirmed by Commonwealth Scientific and Industrial Research Organisation (CSIRO).

Quality Officer:

Frank Pollock

19 August 2016

NATA

Accredited for compliance with ISO Guide 34

Accredited Reference Material Producer
Accreditation Number: 14063
Site Number: 15276

Strain sourced from NCTC (National Collection of Type Cultures)

*BTF occasionally extends the expiry dates on selected BioBall products. Please check the BioBall website http://bioball.com/bioball/certificate-of-analysis/ to determine whether or not the shelf life of your BioBall batch has been extended.

CSO Long Term Control Plan Update
Delaware County Regional Water Quality Control Authority

GREELEY AND HANSEN

LimnoTech

DELAWARE COUNTY REGIONAL WATER QUALITY CONTROL AUTHORITY
P.O. BOX 999 • CHESTER, PA 19016-0999

March 17, 2017

To Whom It May Concern:

The Delaware County Water Quality Control Authority (DELCORA) is a municipal authority located in Chester, PA, established in 1970 with the acquisition and upgrade of the City of Chester's wastewater treatment plant to become DELCORA's Western Regional Treatment Plant (WRTP). DELCORA owns, operates and maintains collection systems that serve approximately a half million people in the Greater Philadelphia area, including 42 municipalities in Delaware and Chester Counties.

DELCORA entered into a Consent Decree (CD) with the United States Government to establish a schedule for implementation of Long Term Control Plan Update (LTCPU) to achieve full compliance with the Clean Water Act and the regulations and Clean Streams Law and regulations. As part of the DELCORA LTCPU, water quality monitoring is required.

Greeley and Hansen LLC currently serves as a consultant to DELCORA for the LTCPU Project in an effort to address combined sewer overflows (CSO) associated with the Consent Decree.

Greeley and Hansen's work incudes conducting receiving stream surveys and collecting samples from manholes, outfalls and surface waters. As such, Greeley and Hansen's employees, as well as employees from Greeley and Hansen's sub-consultants, will be working along shorelines and in boats and will be temporarily stopped in vans on local roadways to access sampling points from the spring of 2017 through the summer of 2017. Representatives of Greeley and Hansen LLC and their sub-consultants who are carrying out these responsibilities should not be deemed as trespassers as they are authorized to conduct these field surveys on behalf of DELCORA.

Should you have any questions, please do not hesitate to contact me by telephone at (610) 876-5523 or (267) 212-4559 or by e-mail at hurstc@delcora.org.

Thank you.

Sincerely,

Charles Hurst, P.E.

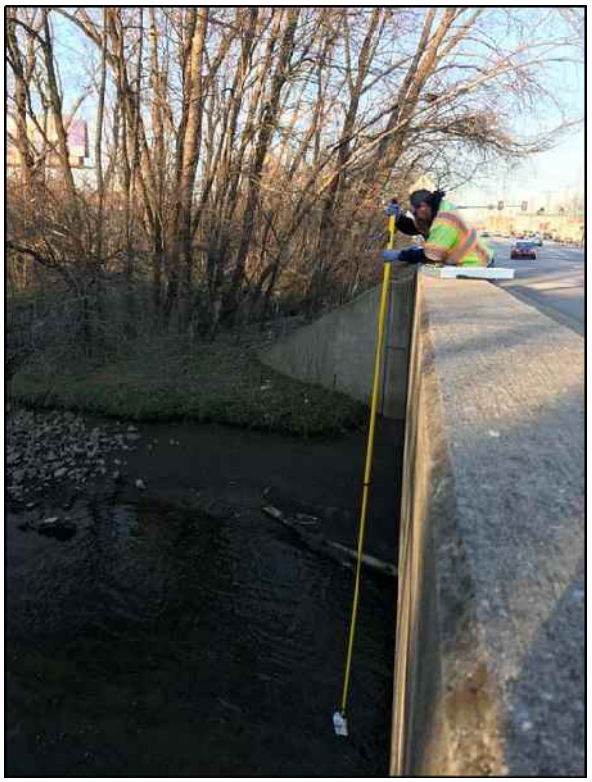
APPENDIX K
SAMPLING PHOTOS

All water quality samples were collected and transeffered into 250 mL bottles provided by Eurofins QC, Inc. The samples were preserved immideatley on ice for transfer to the laboratory for further analysis.

A view of the Delaware River, looking out from the bulkhead wall at the WRTP toward sampling location DR-05.

Sampling off of overpass bridges at Chester Creek (CC-03) and Ridley Creek (RC-03) sampling locations.

Sampling off of the overpass bridge at Ridley Creek (RC-03) sampling location required use of a Bailer Bottle Sampler due to the increased height requirements at the site.



Sampling off of an overpass bridge at Ridley Creek (RC-02) sampling location.

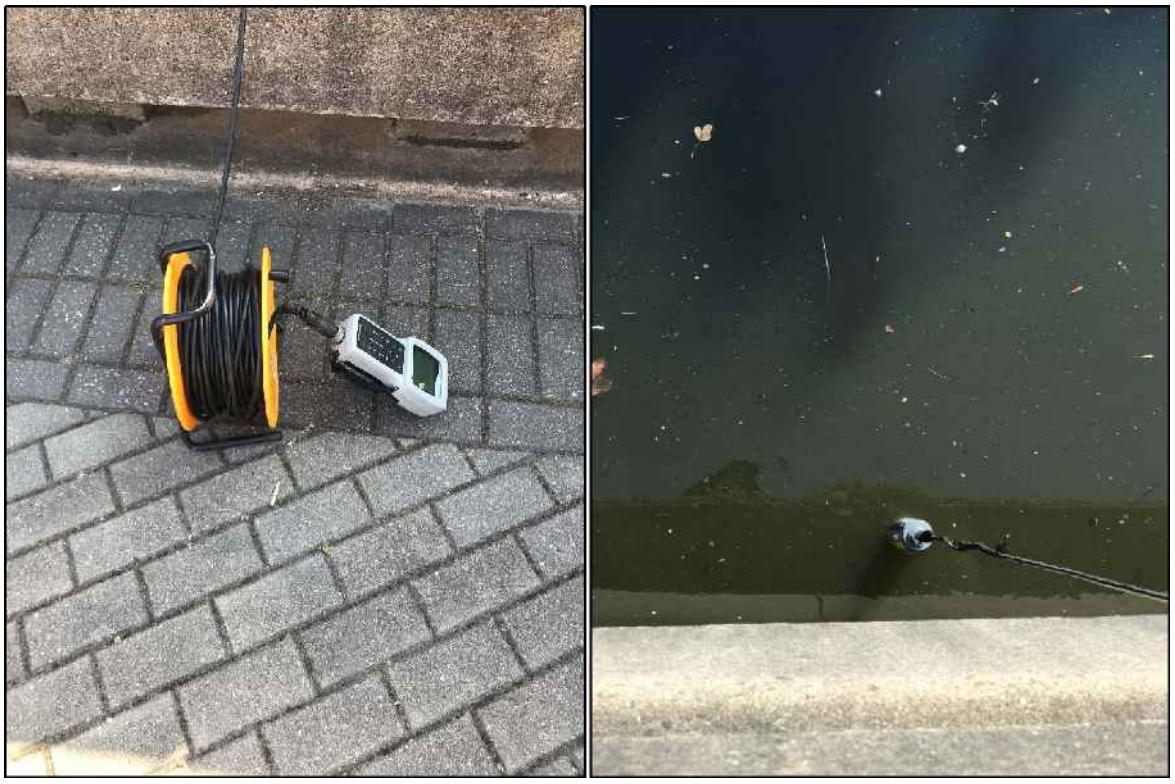
Sampling off of an overpass bridge at Ridley Creek (RC-01) sampling location.

Sampling off of an overpass bridge at Chester Creek (CC-01) sampling location.

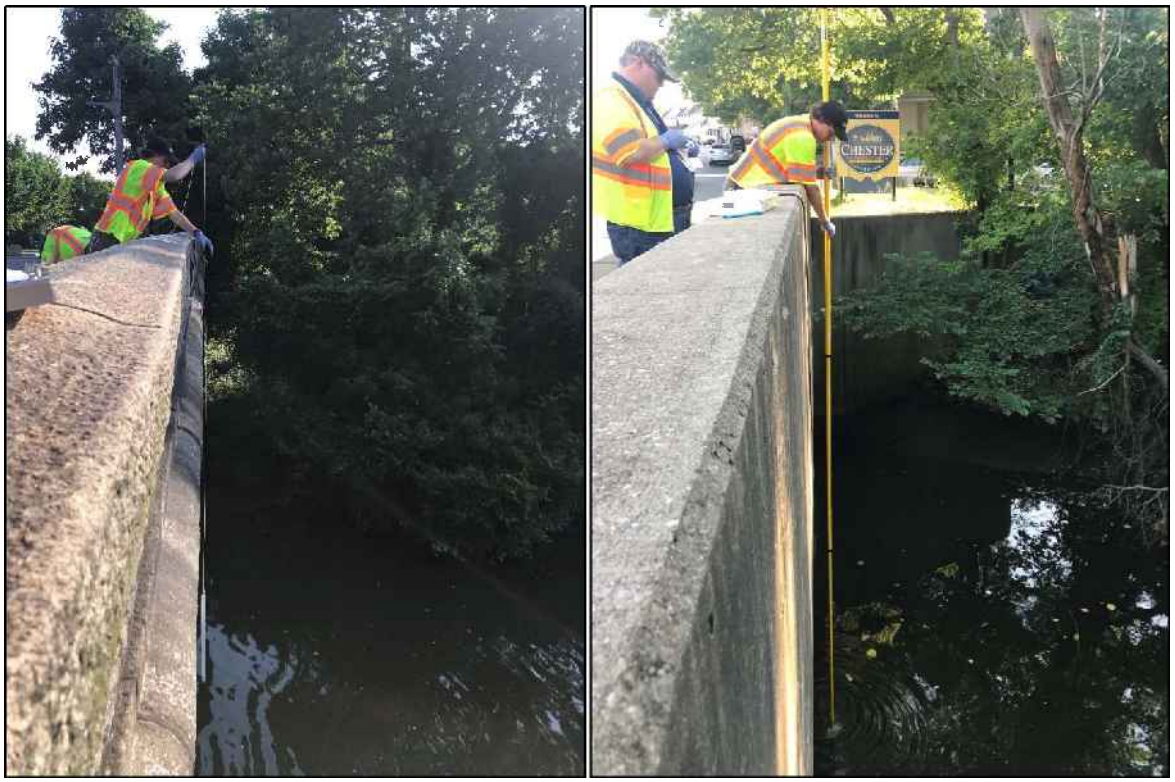
Sampling off of an overpass bridge at Chester Creek (CC-02) sampling location.

During the third wet-weather sampling event, one of the two boats in the Delaware River had to be removed from the river due to punctures in its hull. Grab samples were collected at accessible points along the Delaware shore in proximity to DR-03 and DR-04.

During the second wet-weather sampling event, boat activities were halted in the Delaware due to hazardous conditions (lightning and visibility issues). Conditions eventually improved, allowing for the resumption of boat activities after approximately four hours.



In-situ field measurements were taken using a YSI Model 556 with a 6920 V2 sonde. These measurements included water temperature, salinity, and conductivity in the receiving waters.



Sampling off of an overpass bridges at Ridley Creek (RC-02) sampling location.

APPENDIX C
Water Quality Model Calibration Results

Notes:

1. The 2017 Dry Weather Event in-stream sampling typically has two results per POC, per event, and per location. One sample was taken on the incoming tide and one sample was taken on the outgoing tide. There was no dry weather sampling at DR-05 and DR-06.
2. The 2017 Wet Weather Event in-stream sampling typically has five or more results per POC, per event, and per location. These were taken at t=0 (onset of rain) and then at approximately every 2 hours after that.
3. More information on the 2017 in-stream sampling results can be found in DELCORA's "Water Quality Sampling Report" (DELCORA, 2017).
4. More information on the 2012 DRBC boat run program can be found online at http://www.state.nj.us/drbc/programs/quality/boat-run.html

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. DeSantis:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Regional Water Quality Control Authority (DELCORA) Water Quality Model Report dated February 27, 2018. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). EPA accepts and approves the subject report.

Sincerely,

Andrew F. Seligman, Environmental Scientist

Section 1 Introduction

1.1 Introduction

The Delaware County Regional Water Quality Control Authority (DELCORA) is a municipal wastewater authority that owns, operates and maintains collection systems that serve approximately a half-million people in southeastern Pennsylvania, including 45 municipalities in Delaware and Chester Counties, and is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA operates a Combined Sewer System (CSS) that is comprised of sewer sections that accept both stormwater and sanitary wastewater, which is treated at DELCORA's Western Regional Treatment Plant (WRTP).

Under National Pollutant Discharge Elimination System (NPDES) Permit No. PA0027103, DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall 001), four stormwater outfalls at the WRTP (028-031) and from twenty-six (26) combined sewer overflow (CSO) regulators that discharge to twenty-five (25) CSO outfalls (002-027, 032, 033), and then discharge to the Delaware River, Chester Creek and/or Ridley Creek. CSOs are point source discharges that must be provided control measures in accordance with the Federal Clean Water Act and the 1994 National CSO Policy. CSO are allowed to discharge only when flows in the CSS exceed the conveyance or treatment capacities of the system during wet weather periods, and dry weather overflows are prohibited.

DELCORA is in the process of developing a Long Term Control Plan (LTCP) Update for the Combined Sewer System as part of a Consent Decree entered with the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP). Paragraph V.A.16 of the Consent Decree requires DELCORA to submit an Existing Service Area Characterization Report to the USEPA and PADEP for review and approval.

This Existing Service Area Characterization Report has been prepared to fulfill the requirements of Paragraph V.A.16 of the Consent Decree, and of the federal CSO Control Policy Section II.C.1 – Characterization, Monitoring and Modeling of the Combined Sewer System. This Service Area Characterization Report presents the results to characterize, monitor and model DELCORA's combined sewer system, and incorporates the conclusions about Sensitive Areas that were previously determined in DELCORA's report *Identification of Sensitive Areas and Pollutants of Concerns* (Greeley and Hansen, 2016c).

1.2 Regulatory Requirements

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. Consent Decree Paragraph V.A.16 (Existing Service Area Characterization) requires that within two years after the Date of Lodging of the Consent Decree, DELCORA shall submit to the USEPA and PADEP a System Characterization Report for review and

approval. Details of the Consent Decree requirements and the associated regulatory requirements for the Existing Service Area Characterization are respectively found below in Sections 1.2.1.
Requirements from the Consent Decree

The primary requirements for the Existing Service Area Characterization Report are established in the Consent Decree. Paragraph V.A.16 of the Consent Decree, Existing Service Area Characterization, states that:

> *"Not later than two years (24) months after the Date of Lodging of the Consent Decree, DELCORA shall submit a characterization of the Model Area that includes all of the information required by CSO Control Policy Section II.C.1 and associated guidance to Plaintiffs for review and approval in accordance with the requirements of Section VI (Review and Approval of Submittals). The characterization shall include, but not be limited to, the following:*
>
> *DELCORA shall use the updated, calibrated, and validated H&H Model to characterize the expected volume, frequency, and duration of CSO discharge events from each CSO during the Typical Year, based on an inter-event period of twelve (12) hours;*
>
> *DELCORA shall incorporate the results of its investigation of Sensitive Areas;*
>
> *DELCORA shall provide a characterization of current water quality in its Receiving waters, based upon all available sampling data, and its efforts to identify POCs.*
>
> *The characterization submitted pursuant to this paragraph shall include the entire model Area, including the hydrology (i.e., runoff) from and within the entire Model Area."*

Additionally, the Consent Decree requires Rainfall and Flow Monitoring in Paragraph V.A.14.d. that:

> *"Rainfall and flow monitoring that shall be carried out in accordance with current good industry practice for a period of at least twelve (12) months, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization of dry and wet weather flows for the entire Model Area, and the response of each CSO to wet weather flows."*

1.2.1 Requirements from the USEPA's CSO Control Policy

Additional requirements for the Existing Service Area Characterization Report are established in the USEPA's CSO Control Policy (USEPA, 1994). Section II.C.1 of the CSO Control Policy "Characterization, Monitoring and Modeling of the Combined Sewer System" states:

> *"In order to design a CSO control plan to adequately meet the requirements of the CWA, a permittee should have a thorough understanding of its sewer system, the response of the system to various precipitation events, the characteristics of the overflows, and the water quality impacts that result from CSOs. The permittee should adequately characterize through monitoring,*

modelling, and other means as appropriate, for a range of storm events, the response of its sewer system to wet weather events including the number, location and frequency of CSOs volume, concentration and mass of pollutants discharged and the impacts of the CSOs on the receiving waters and their designated uses."

The CSO Control Policy states that the major elements of a sewer system characterization include:
Rainfall Records

"The permittee should examine the complete rainfall record for the geographic area of its existing CSS using sound statistical procedures and best available data. The permittee should evaluate flow variations in the receiving water body to correlate between CSOs and receiving water conditions."

Combined Sewer System Characterization

"The permittee should evaluate the nature and extent of its sewer system through evaluation of available sewer system records, field inspections and other activities necessary to understand the number, location and frequency of overflows and their location relative to sensitive areas and to pollution sources in the collection system, such as indirect significant industrial users."

CSO Monitoring

"The permittee should develop a comprehensive, representative monitoring program that measures the frequency, duration, flow rate, volume and pollutant concentration of CSO discharges and assesses the impact of the CSOs on the receiving waters."

Modeling

"Modeling of a sewer system is recognized as a valuable tool for predicting sewer system response to various wet weather events and assessing water quality impacts when evaluating different control strategies and alternatives. EPA supports the proper and effective use of models, where appropriate, in the evaluation of the nine minimum controls and the development of the long-term CSO control plan."

1.3 Contents of this Report

To satisfy the requirements of DELCORA's Consent Decree and of the CSO Control Policy, this Existing Service Area Characterization Report provides a comprehensive characterization of DELCORA's combined sewer system and of the CSS monitoring and modeling that DELCORA has completed. In addition to describing the characteristics of the wastewater collection system, this report presents the results of DELCORA's rainfall and flow monitoring programs, its receiving water monitoring program, and the results from the H&H model from the typical year for the Combined Sewer System.

Table 1-1 lists the individual sections of the Report and contents.

Table 1-1 DELCORA Existing Service Area Characterization Report

Section	Description
Section 1 Introduction	This section introduces DELCORA's system, the Consent Decree requirements, requirements from the USEPA's CSO Control Policy, as well as individual sections of the Plan.
Section 2 Overview of DELCORA's Facilities and Service Areas	This section provides an overview of DELCORA's facilities, a description of DELCORA's Service Areas, an overview of DELCORA's treatment facilities, and an overview of DELCORA's combined sewer system within the City of Chester.
Section 3 Characteristics of the Model Area Sewer System	This section describes the details of the combined sewer system and includes the physical characteristics and attributes of DELCORA's Sewer System. These include system configuration, regulator, manhole; pump stations and force main characteristics.
Section 4 Collection of Precipitation and Sewer Flow Data	This section presents the results of DELCORA's efforts to collect precipitation monitoring data for locations throughout the areas served by DELCORA's Sewer System. It also presents the results of DELCORA's efforts to collect flow monitoring data in the combined sewer system and in the receiving waters. It presents the dry weather and wet weather flow data for DELCORA's Sewer System.
Section 5 Characteristics of the Receiving Waters and Watersheds	This section provides an overview of the location, physical characteristics, waterbody classifications and analysis of the current water quality of DELCORA's receiving waters. This section also incorporates the results of DELCORA's investigation of Sensitive Areas, and their relative location to the CSOs.
Section 6 Collection of Water Quality Data	This section presents the results of DELCORA's investigation into the current water quality in the receiving waters. This section also presents the CSO water quality data resulting from DELCORA's CSO Monitoring Program.
Section 7 Typical Hydrologic Period	This section summarizes the typical hydrologic period to be used for modeling based on previously submitted *Typical Hydrologic Period Report*.
Section 8 Hydrologic and Hydraulic Modeling	This section provides an overview of the Hydrologic and Hydraulic Model of the combined sewer system that DELCORA has developed. It also presents the results from the modeling of DELCORA's sewer system and the expected volume, frequency, and duration of CSO discharge events from each CSO during the Typical Hydrologic Period.

Section 2 Overview of DELCORA's Facilities and Service Areas

2.1 Overview of DELCORA's Facilities

DELCORA owns and operates an extensive conveyance system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 2-1. The total service area served by DELCORA, as shown on Figure 2-2, is approximately 82,977 acres and illustrates that DELCORA serves a significant and widespread portion of Delaware County. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers and over 14 miles of large-diameter (>24-inch) force mains. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-six (26) combined sewer regulators that discharge to twenty-five (25) combined sewer outfalls, as CSO Regulators #009 and #010 both discharge to CSO Outfall #009. The combined sewer area simulated in DELCORA's Hydrologic and Hydraulic (H&H) model is located within the City of Chester and consists of a drainage area of approximately 1,506 acres. It comprises approximately half of Chester City's serviced area. The location of Chester City's service area is illustrated on Figure 2-2.

DELCORA has characterized its service areas as "Eastern" and "Western." Historically, the Eastern service area discharged to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PSWPCP) while the Western Service Area discharged to DELCORA's Western Regional Treatment Plant (WRTP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority in the Eastern Service Area now discharges to the WRTP while only those CDPS flows above 20 MGD are to be directed to the PWD-SWPCP. Figure 2-1 shows the interconnections in DELCORA's system. The left side of the figure indicates the Western Service Area and the right side indicates the Eastern Service Area. This interconnectivity coupled with the legal agreements DELCORA maintains with the municipalities and conveyance authorities in Delaware County creates the complicated legal/financial framework under which DELCORA operates.

Under its National Pollutant Discharge Elimination System (NPDES) Permit No. PA0027103, issued and administered by the PADEP, DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four storm water outfalls at the WRTP (028-031) and from the 26 CSO regulators (#002-#005, #007-#026, #032 and #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek. There are a total of 26 combined sewer overflow (CSO) regulators listed with 25 discharge points (Regulators 009 and 010 both discharge at Outfall 009) in DELCORA's existing NPDES Permit.

Figure 2-1: DELCORA Conveyance System

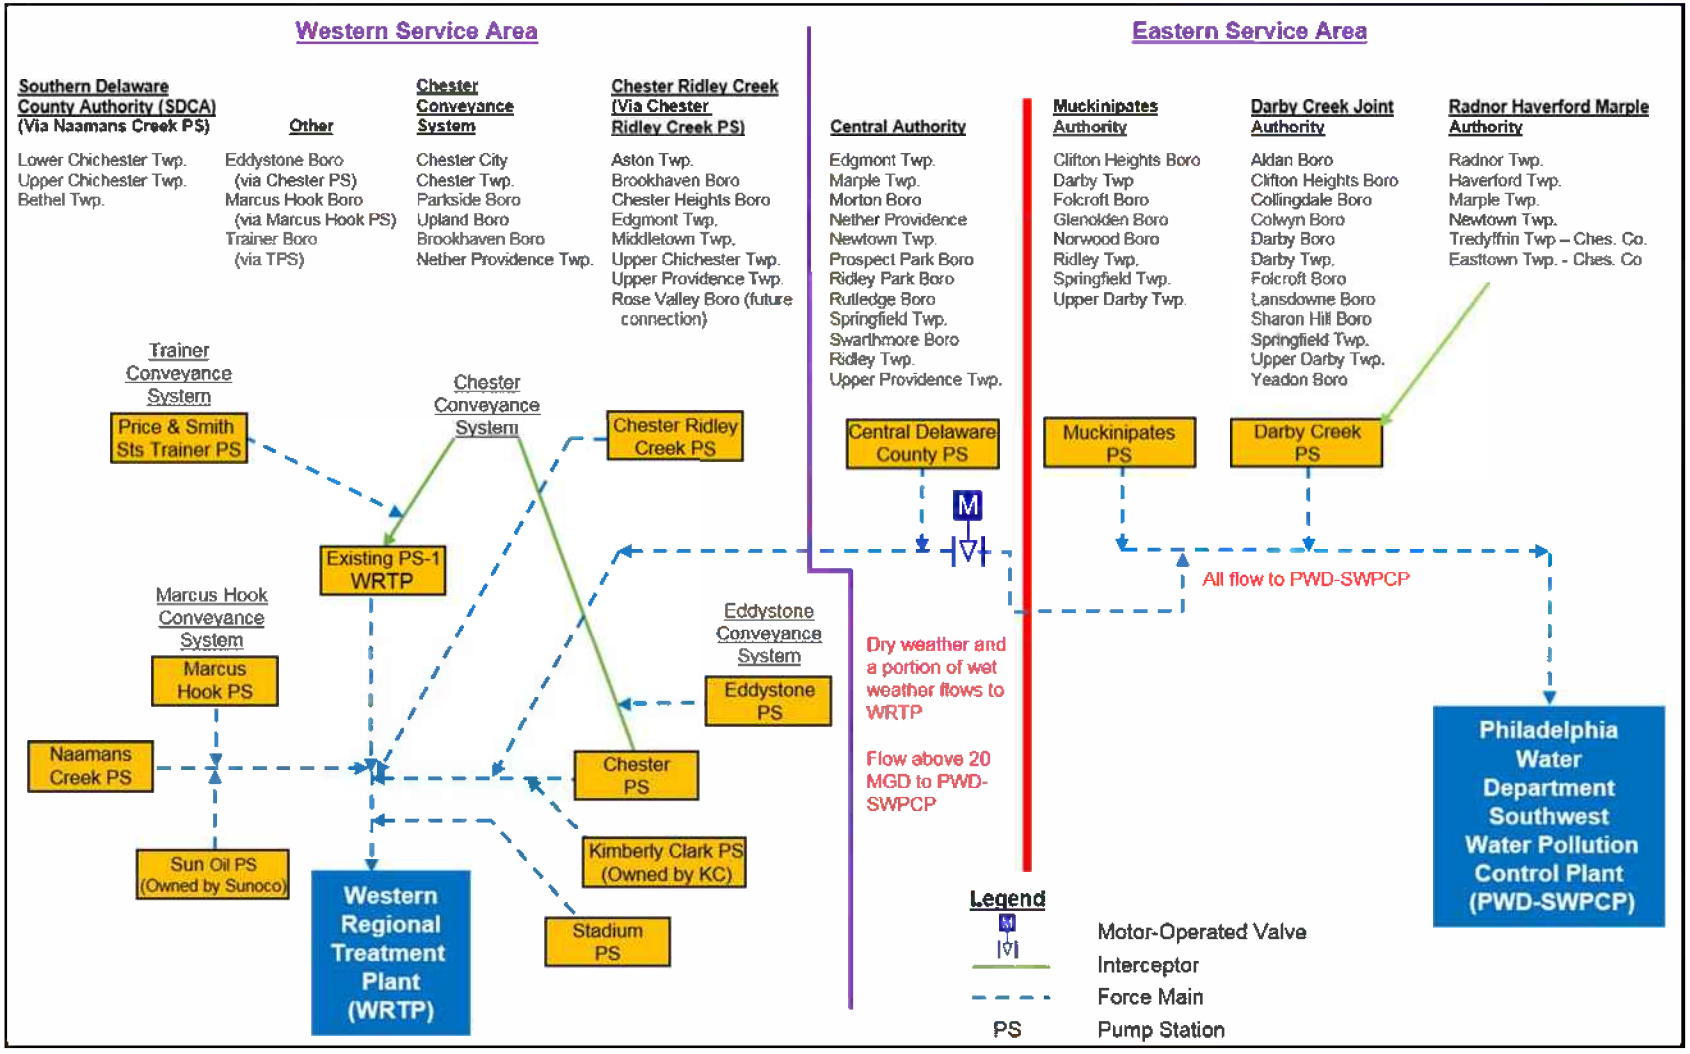

Figure 2-2: DELCORA Service Area

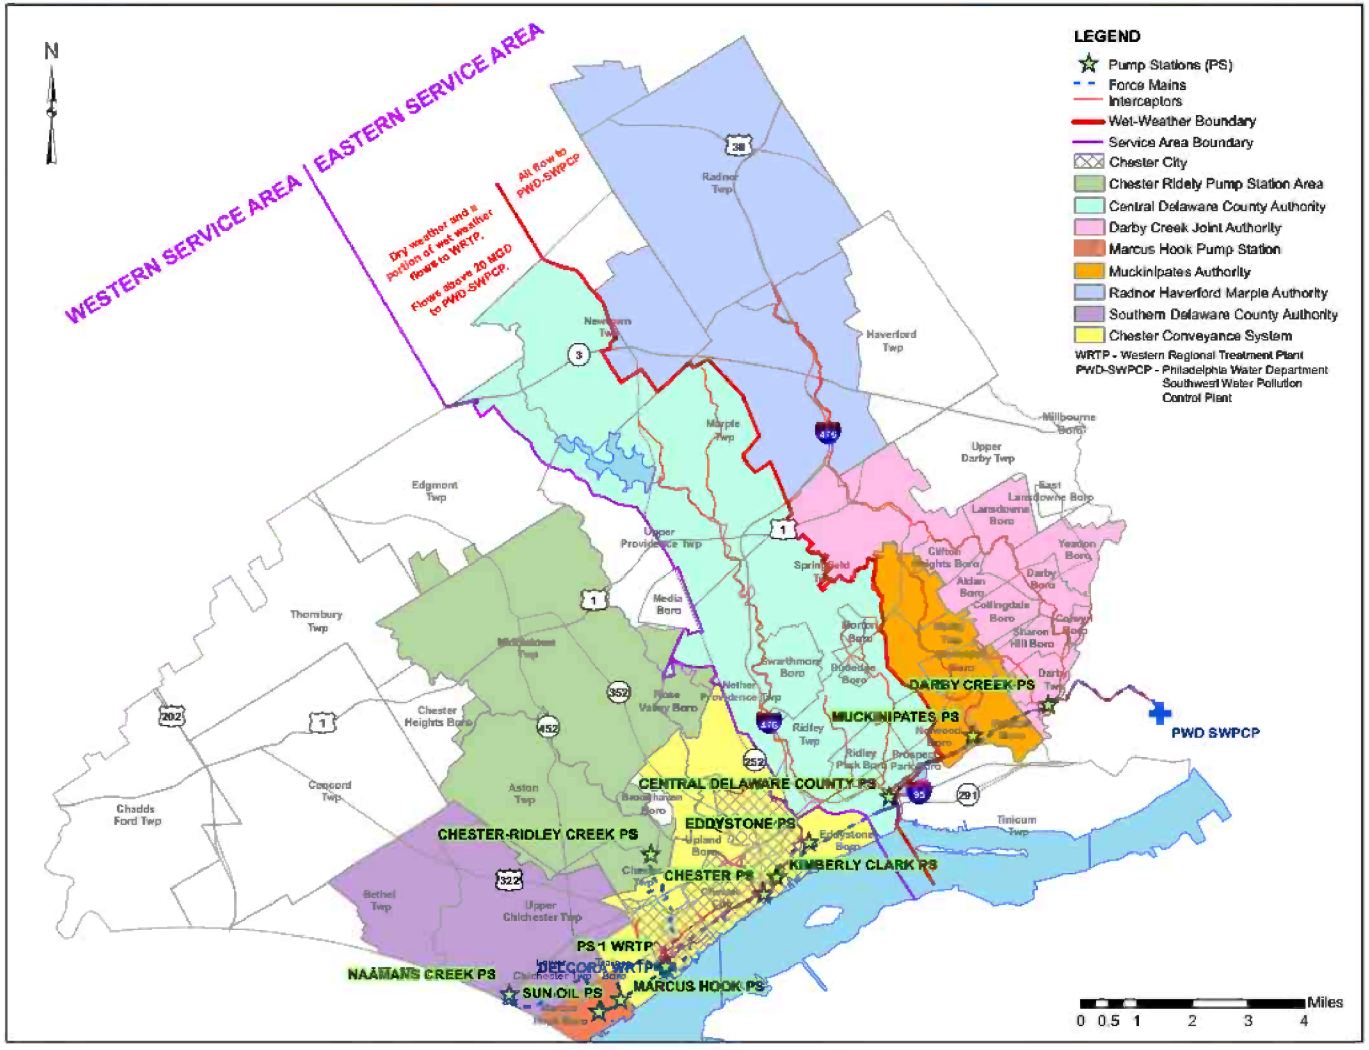

2.2 DELCORA's Service Areas

As mentioned previously and depicted in Figure 2-2, DELCORA serves a significant and widespread portion of Delaware County. To support this service area, DELCORA owns and operates over 137 miles of gravity sewers and over 14 miles of large-diameter (>24-inch) force mains. Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western Service Area discharges to the Western Regional Treatment Plant. The Eastern Service Area discharges to the Philadelphia Southwest Water Pollution Control Plant (PSWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are to be directed to the PWD-SWPCP. As such, dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

2.2.1 Eastern Service Area

The Eastern Service Area is composed of four subareas that are served by conveyance authorities. These areas are the Radnor Haverford Marple (RHM) Authority, Darby Creek Joint Authority (DCJA), Muckinipates Authority (MA), and Central Delaware County Authority (CDCA) and are delineated in Figure 2-2. Each of these authorities has a legal agreement with their member municipalities to dispose of their wastewater. In turn, DELCORA has legal agreements with each of the authorities, except RHM, to receive and dispose of the collected wastewater. RHM discharges to the DCJA.

DELCORA owns and operates three large pump stations that serve DELCORA's Eastern Service Area; they are the Central Delaware County Pump Station, the Muckinipates Pump Station, and the Darby Creek Pump Station. These pump stations are designed to pump the wastewater from DELCORA's Eastern Service Area to the Philadelphia Southwest Water Pollution Control Plant for treatment. Originally constructed in the 1970s, the Central Delaware Pump Station (serving CDCA) is rated for 40 MGD. As originally designed, the Central Delaware pump station discharges though a 1.9-mile, 36-inch-diameter prestressed concrete cylinder pipe (PCCP) force main that runs northeast toward the Muckinipates Pump Station. The next pump station is the 24-MGD Muckinipates Pump Station (serving MA). Here the force main increases to 48 inches in diameter and continues approximately 1.65 miles northeast to the Darby Creek Pump Station. Upon reaching the 60-MGD Darby Creek Pump Station (serving DCJA and RHM), the force main increases in diameter to 66 inches and continues approximately 2.5 miles on to PSWPCP.

The operation of the Central Delaware Pump Station (CDPS) had been modified in 2002 to allow for flow from the CDPS to be discharged to the WRTP. Currently, wastewater flows up to 20 MGD are discharged to WRTP and the wastewater flows in excess of 20 MGD are conveyed to PWD-SWPCP.

2.2.2 Western Service Area

DELCORA's Western Service Area is also shown in Figure 2-2. DELCORA owns and operates the collection system in the following communities in the Western service area:

Chester City
Chester Township[1]
Marcus Hook Borough
Parkside Borough
Rose Valley Borough[2]
Upland Borough
Trainer Borough

DELCORA does not own or operate the collection system in the following communities in the Western Service Area:

Brookhaven Borough
Lower Chichester Township
Nether Providence Township
Eddystone Borough

2.3 Model Area

As described in the Consent Decree, the characterization report will evaluate the Model Area comprising those areas hydraulically connected to the WRTP. Section V.A.14.b of the Consent Decree describes the Model Area as follows:

> *"… all areas tributary to the entire Collection System, as well as all areas tributary to all municipal wastewater collection and transmission systems that are, as of the date the LTCP is submitted, hydraulically connected to, or that directly or indirectly influence flow to, the CSOs and/or the WRTP, regardless of who owns or operates the system(s), including but not limited to the entire "Western Service Area" and "Eastern Service Area" depicted on Figure 1-2 of the Long-Term Control Plan submitted by DELCORA in April 2012, and attached as Appendix A hereto (collectively, the "Model Area")."*

As shown in the schematic of DELCORA's conveyance system (see Figure 2-1), the conveyance system is divided into the Western Service Area and the Eastern Service Area. The Western Service Area discharges to DELCORA's WRTP and is therefore included in the Model Area. The Eastern Service Area is served by three pumps stations: the Central Delaware Pump Station, the Muckinipates Pump Station and the Darby Creek Pump Station. Up to 20 MGD (which includes both dry and wet weather flows) from the Central Delaware Pump Station can be pumped to, and thus is hydraulically connected to, DELCORA's WRTP. Therefore, municipalities connected to the Central Delaware Pump Station are

[1] DELCORA owns only a portion of the collection system in Chester Township.
[2] Rose Valley Borough collection system discharges to its own treatment plant and a portion is discharged to the WRTP via Nether Providence's collection system.

considered part of the Model Area. Sewage from the Muckinipates Pump Station and the Darby Creek Pump Station flows to the PWD-SWPCP rather than to the WRTP. Therefore, municipalities connected to these pump stations are not hydraulically connected to the WRTP and do not directly or indirectly influence CSOs or flow to the WRTP, and, therefore, are not considered part of the Model Area. In summary, the Model Area includes the municipalities in the Western Service Area plus those municipalities in the Eastern Service Area that are connected to the Central Delaware Pump Station, as described in Table 2-1. The Model Area is illustrated in Figure 2-3.

Table 2-1: Model Area

Municipality	Service Area
Aston Township	Western

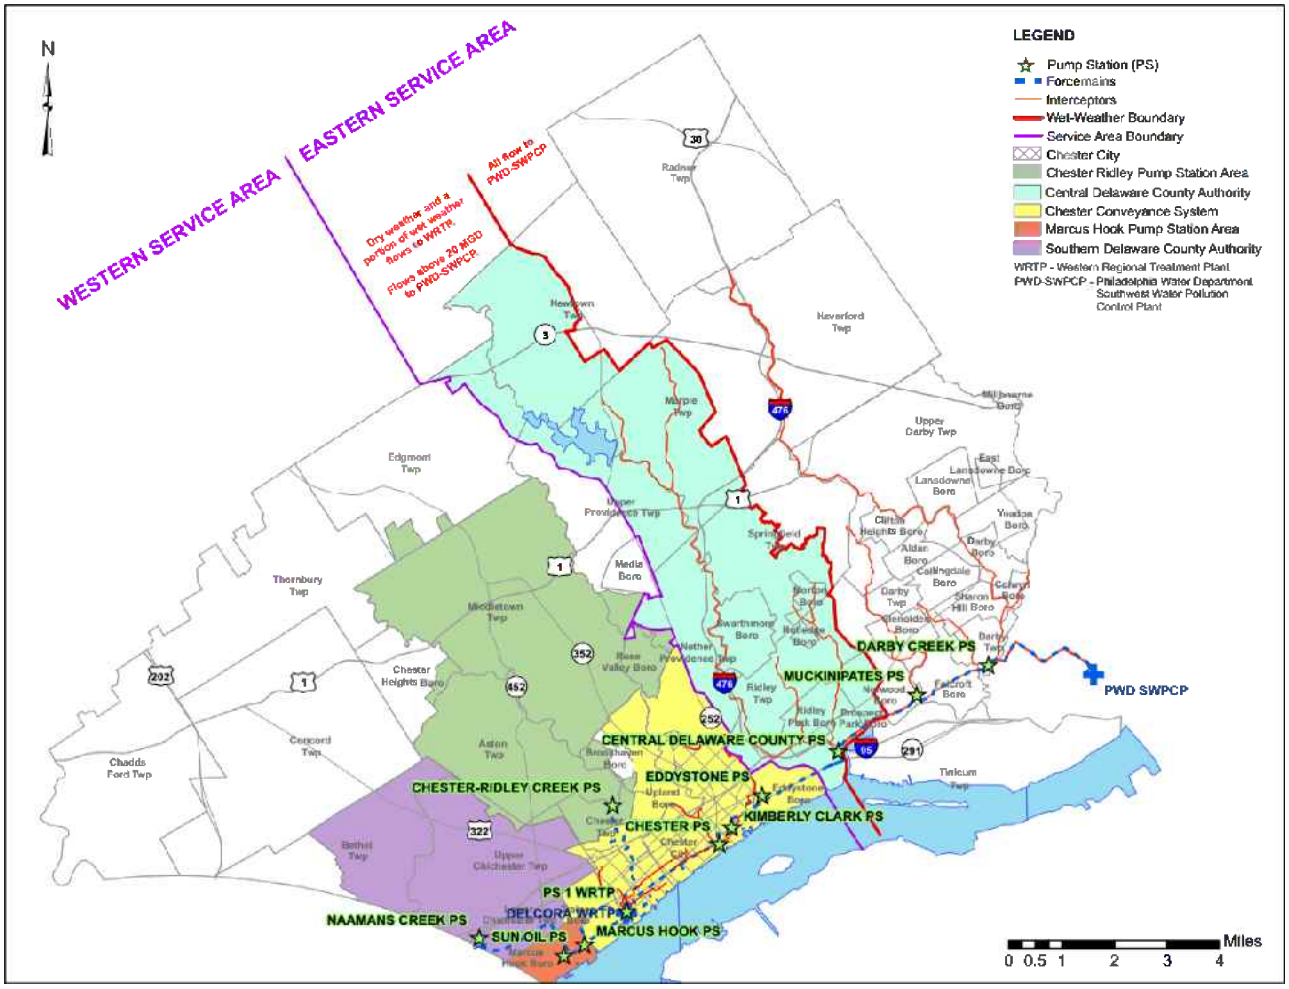
Figure 2-3: DELCORA LTCP Model Area



2.4 Watersheds

The watersheds of concern for the Model Area include portions of the Delaware River, Chester Creek and Ridley Creek watersheds. Figure 2-4 illustrates the watershed boundaries along with the boundaries of the Model Area.

2.5 DELCORA's Treatment Facilities

DELCORA's primary treatment facility is the WRTP located at 3201 W. front Street in Chester, PA. The WRTP is a permitted 44 MGD activated sludge treatment plant, shown schematically in Figure 2-5. The PADEP and the Delaware River Basin Commission (DRBC) have approved the re-rate of the WRTP to 50 MGD. DELCORA will need to extend the WRTP discharge outfall approximately 455 feet into the Delaware River to meet DRBC regulatory requirements for a re-rate to 50 MGD. Peak capacity at the WRTP is approximately 110 MGD. Based on data obtained for the period 18 March 2016 to 1 May 2017, the annual average dry weather flow to the WRTP is approximately 28 MGD. This facility treats all wastewater from the Model Area, including all flows from the Western Service Area as well as up to 20 MGD from the Central Delaware County Authority.

All wastewater from the Muckinipates Authority, Darby Creek Joint Authority, and the Radnor Haverford Marple Authority are transported to the PSWPCP for treatment and disposal. The Central Delaware Pump Station can direct flow to the WRTP via the Central Diversion Force Main or to the PSWPCP. DELCORA has an agreement with the City of Philadelphia for the disposal of wastewater. This agreement specifies DELCORA's flow thresholds to the PSWPCP to be an annual average of 50 MGD, a daily maximum of 75 MGD, and an instantaneous peak flow of 100 MGD. Flows above these thresholds are subject to exceedance charges.

DELCORA also purchased the Rose Valley Treatment Plant in 2009. The Rose Valley Treatment Plant is permitted at 0.13 MGD and is located in Delaware County. On March 1, 2010, DELCORA purchased the Riverside Treatment Plant in Pocopson Township, Chester County. It is permitted at 0.045 MGD.

Section 3 Characteristics of the Model Area Sewer System

3.1 Introduction

This section presents an investigation of the collection system to meet the requirements of Section II.C.1.b, Combined Sewer System Characterization, of the USEPA's CSO Control Policy. Section II.C.1.b requires DELCORA to evaluate the nature and extent of the sewer system through evaluation of available sewer records and inspections necessary to understand the number, location and frequency of overflows, and their locations relative to Sensitive Areas and to pollution sources in the collection system.

3.2 Sources of Collection System Data

The characteristics and attributes of DELCORA's collection system were determined through the collection, assessment, and evaluation of existing data and information, as part of the implementation of the *Hydrologic and Hydraulic Model Update and Calibration Plan* (Greeley and Hansen, 2015).

Data and information on the collection system were obtained from several sources including DELCORA's input, DELCORA's Geographic Information System (GIS), as-built record drawings, design drawings and field surveys.

3.3 Overview of Sewer System Characteristics

The wastewater collection system within the Model Area consists of separated storm and sanitary sewer piping in some areas and combined sewer system piping in other areas. The Model Area covers approximately 50,000 acres, with approximately 48,540 acres served by separated storm and sanitary systems while only 1,463 acres are served by a combined sewer system. The combined sewer system is located entirely within the City of Chester. However, the City of Chester also has areas that are served by separated storm and sanitary piping or are direct drainage. The remaining areas of the Model Area outside of the City of Chester are all served by separated storm and sanitary sewer piping.

In separated areas, the sanitary sewers convey wastewater to the WRTP for treatment and stormwater runoff is collected through storm sewers and discharged directly to the receiving waters.

Within the City of Chester's combined sewer areas, however, sanitary and storm sewers are combined into the same pipe. During dry weather, the sanitary wastewater is conveyed to the WRTP. During large storms, the stormwater runoff causes the carrying capacity of these combined sewers to be exceeded, and part of this combined flow may discharge directly to the receiving waters without undergoing any treatment.

Sewersheds (subcatchments) are delineated based on the drainage network and area characteristics. Each sewershed has a dry weather and a wet weather flow input to the model network. The model network comprises 114 sewersheds (subcatchments), including 53 combined and 61 separated subcatchments.

3.4 Characteristics of Separated Sewer Areas

Sanitary sewers within the separated areas deliver flow to the WRTP through connections to DELCORA's sewers and through connections to DELCORA's pump station. In many cases, DELCORA does not own or operate the sanitary sewers in separated areas. Consequently, detailed information regarding the characteristics of sanitary sewers from the separated areas is not included in this Report. For modeling purposes, the separated areas will be treated as node inputs to the H&H Model. Flow inputs at the nodes will be derived as described in Sections 4 and 8. Key characteristics necessary for developing flow inputs include delineation of subcatchment boundaries (see Figures 3-1 and 3-2) and areas (see Table 3-1).

3.5 Characteristics of Combined Sewer System

As noted in Section 2.1, the combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's serviced area. The combined wastewater/stormwater system in the City is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, and CSO regulators and CSO outfalls. The City owns, operates and maintains the inlets, stormwater-only sewers that connect to the combined sewer system and any stormwater-only outfalls. The City is also responsible for the maintenance and cleaning of the streets, planning, zoning, and development controls.

The CSS system in the City of Chester has several key components that all impact how the system operates. These key components are the local street sewers, combined collector sewers, CSO regulators, interceptors, and outfalls. The system starts with local street sewers that take flow from houses and businesses as well as the stormwater inlets that drain the streets. These local street sewers typically range in size from 12" to 24" in diameter. The local street sewers discharge to combined collector sewers (shown in Figure 2-1) which flow to the CSO regulators. The combined collector sewers are larger pipes typically range in size from 18" to 72" in diameter and connect directly to the CSO regulator.

Generally, in the CSO drainage areas, flows from the separate sanitary sewers flow into the combined sewers. Flows from the combined sewers in the collection system flow to the regulator structures where dry weather flow and a portion of wet weather flow are diverted into the interceptors. The remainder of the wet weather flow that exceeds the capacity of the interceptors is discharged directly to the closest receiving water (Delaware River, Chester Creek or Ridley Creek) through the CSO outfalls.

3.5.1 Overall Configuration

A schematic of the CSS was developed to facilitate the development, calibration, and validation of the H&H Model. The schematic illustrates the relationship between all major regulators, interceptors, outfalls, pump stations, force mains and other major appurtenances. The schematic also includes the location of the flow meters, and provides and good understanding of the relationship between the flow meters. The schematic of the collection system components is shown on Figure 3-3.

Figure 3-1: DELCORA Model Area Subcatchments

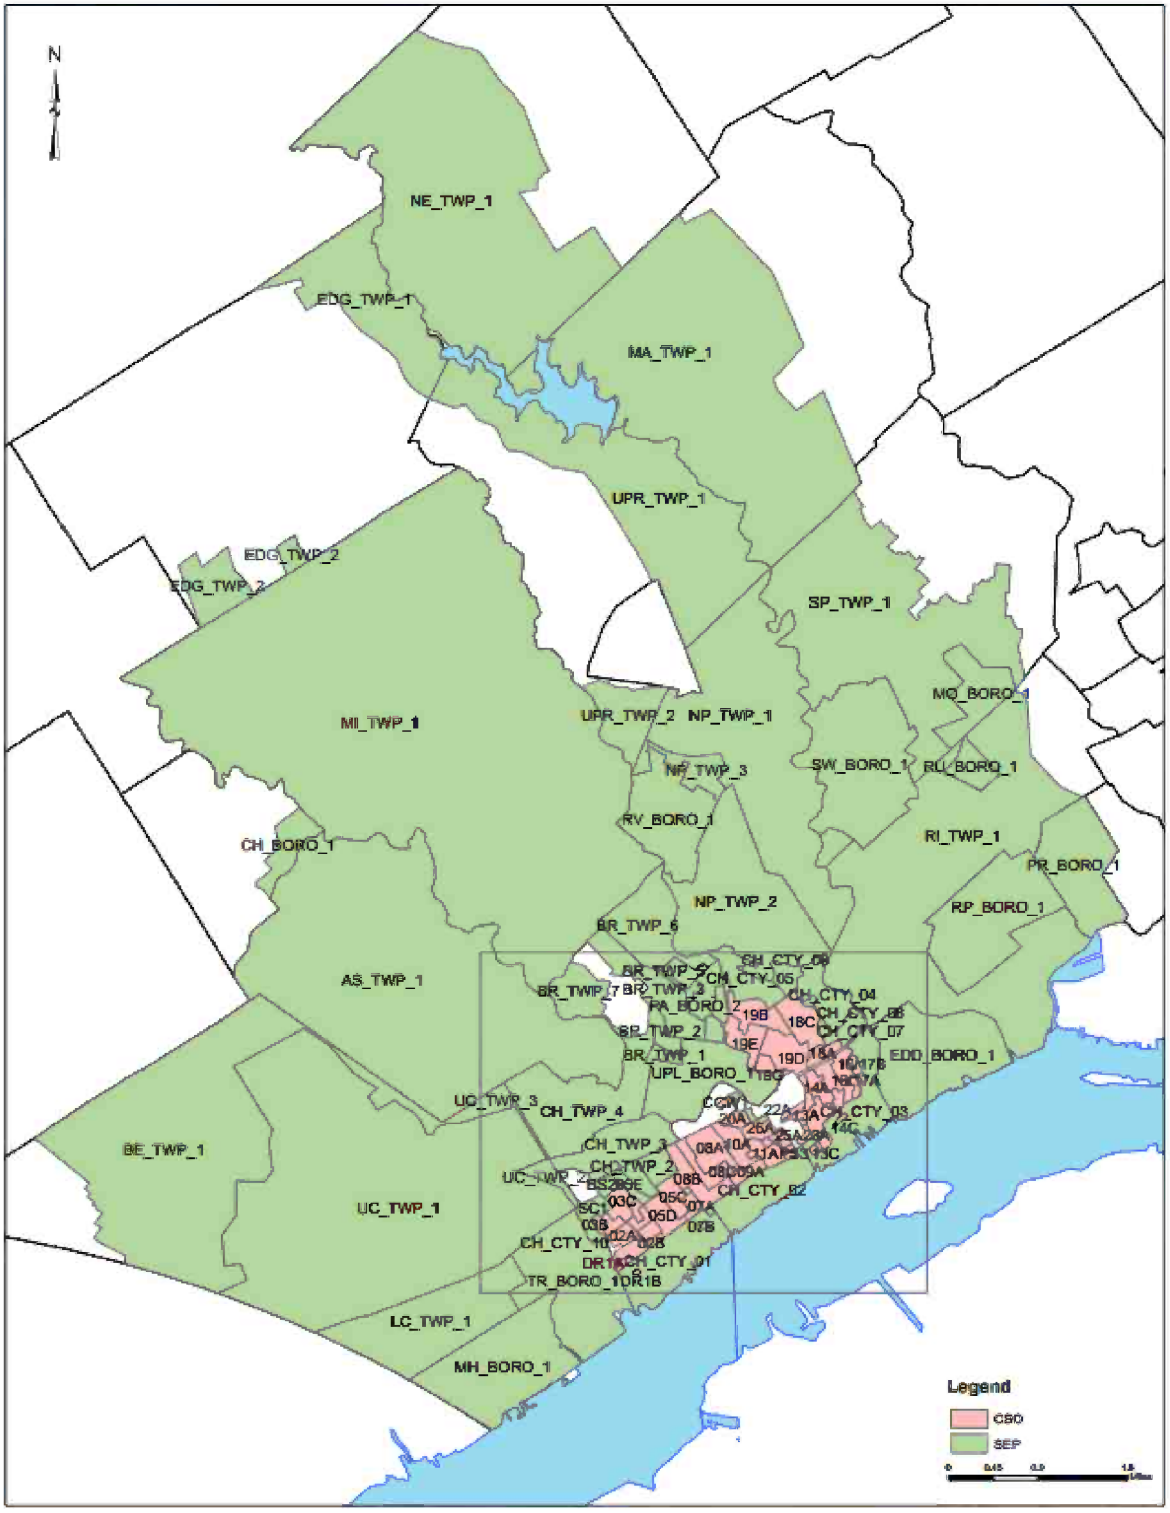

Figure 3-2: DELCORA CSS Area Subcatchments (Enlarged)

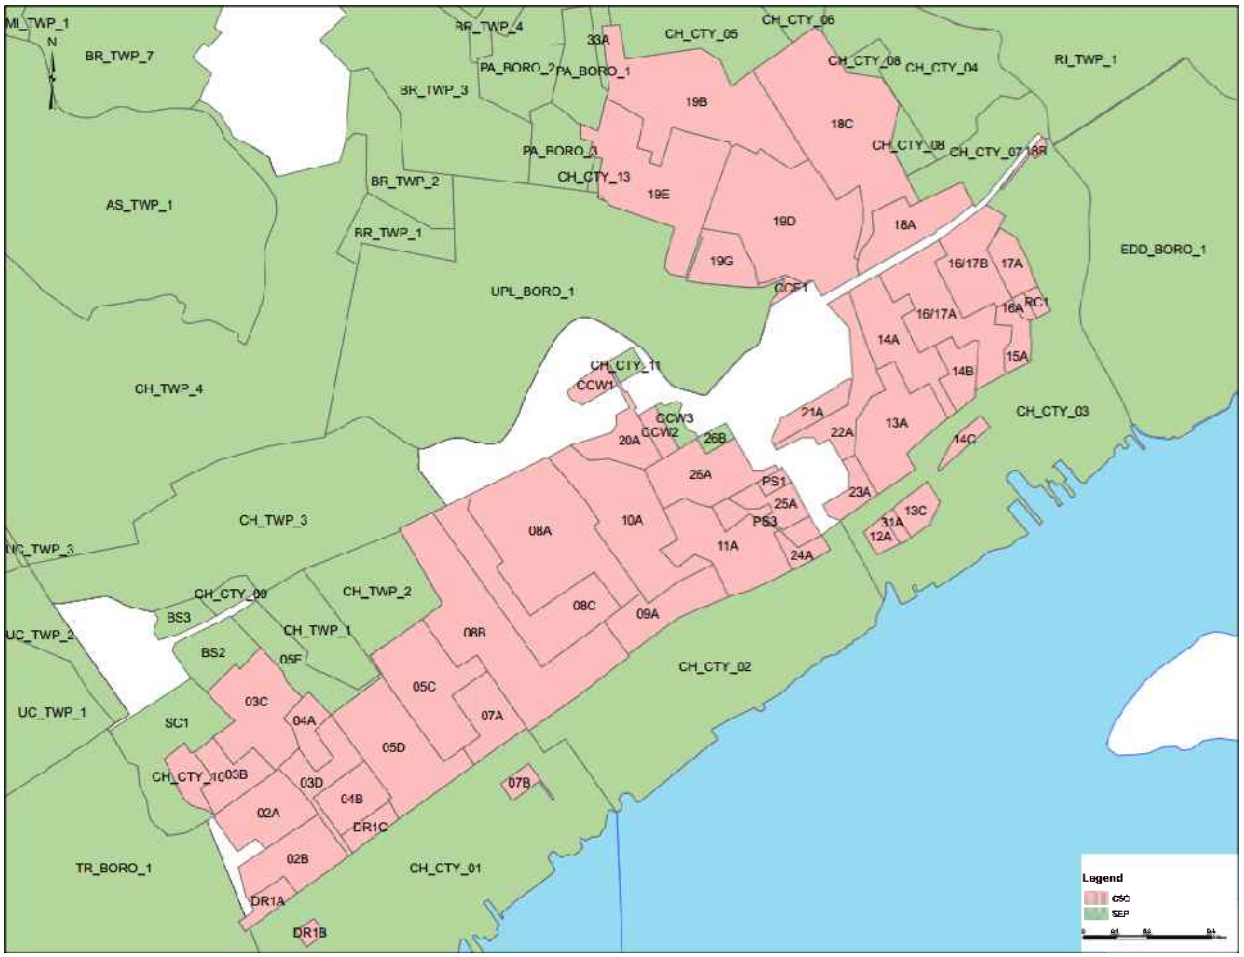

Figure 3-3: Schematic of Chester CSO System

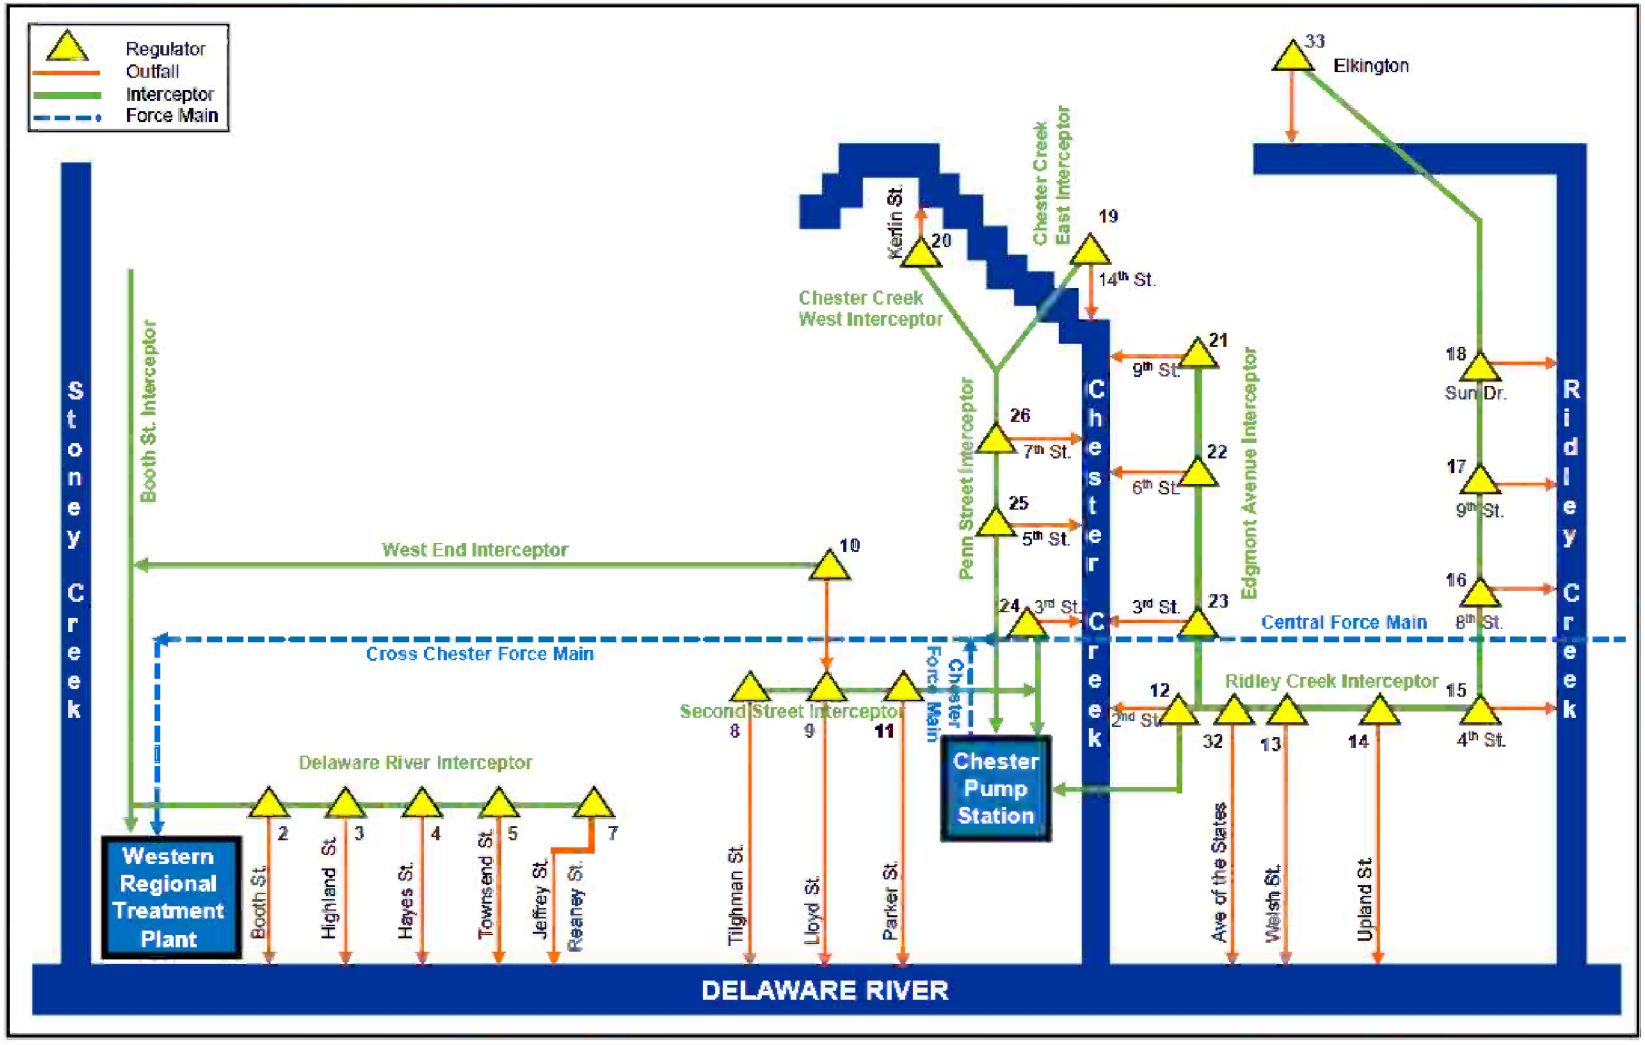

Figure 3-4 depicts the locations of DELCORA's CSO regulators and outfalls. Figure 3-4 also depicts the various drainage subcatchments that flow to each of the CSO regulators. Information about the 26 CSO drainage areas including their subcatchments, total acreage and combined sewer acreage are shown depicted in Table 3-1. Together Figure 3-4 and Table 3-1 also provide a sewer system characterization and illustrate the breakdown of each outfall and how each drainage area has combined sewers and separate sewers.

3.5.2 Sewer Mains

Sewer data was collected from DELCORA's GIS in support of the work to develop and update and calibrate the H&H model. Most of the pipe input characteristics, including upstream and downstream nodes, dimension, shape, number of barrels, and flap gate information, were found or estimated from record drawings, design drawings and sewer gravity main GIS shapefiles. If sewer main information was not available, sewer length was estimated in GIS geometry measurement; sewer size were assumed based on upstream and downstream sewers; sewer upstream and downstream offsets were estimated based on sewer connectivity assuming constant slope. Conduit ID was inherited from the 2012 H&H Model and new IDs were provided for the pipes not in the 2012 H&H Model.

Manhole information, including invert and rim elevations, were found or estimated from record drawings, design drawings, and the sewer manhole shape file. For water tight manholes or manholes with bolted down covers, a surcharge depth of 50-ft will be applied. Manhole ID was inherited from the name of the manhole in the sewer GIS. The naming convention is "MH_XXXX". Manhole input information was updated based on the latest available GIS information.

3.5.3 Flow Diversion Structures and CSO Regulators

The Chester CSO system contains 26 permitted CSO regulators as listed in Table 3-2. The CSO regulators and outfalls serve as combined sewer reliefs necessitated by stormwater entering the sewer system and exceeding the hydraulic capacity of the sewers and/or treatment plant. Wet weather flows in excess of the collection system's capacity are discharged to the Delaware River, Chester Creek or Ridley Creek. Although there are 26 regulators, there are only 25 CSO discharge locations, as CSO #010 discharges to the Delaware River through CSO #009. Table 3-2 shows that eleven of the outfalls, CSO Outfalls #002, 003, 004, 005, 007, 008, 009, 011, 013, 014, and 032, discharge excess wet weather flows into the Delaware River. Nine of the outfalls, CSO Outfalls #012, 019, 020, 021, 022, 023, 024, 025 and 026, discharge excess wet weather flows into the Chester Creek. The remaining five designated outfalls, Outfall #015, 016, 017, 018 and 033[3] , discharge excess wet weather flows into the Ridley Creek.

Since the approval of the first LTCP in 1999, DELCORA has under-taken a program to replace and/or rehabilitate CSO regulators and tide gates in the City of Chester CSO system. In some cases, regulators have been eliminated. The modifications DELCORA committed to in the 1999 LTCP include a complete

[3] DELCORA's NPDES permit includes 26 regulators. After the NPDES permit was issued, CSO regulator 033 was disconnected from the CSS.

Notes: - CSO Regulator 010 discharges at Outfall 009. - CSO Regulators 006 ad 007 have been disconnected from CSS and removed from NPDES permit - CSO Regulator 033 has been disconnected from the CSS but had not been removed from NPDES permit at the date of this Report						

replacement of the mechanism, installation of a monitoring system to determine if flow is passing over the CSO regulator diversion weir to the outfall, and conversion of the CSO regulators to Type A. After installation of the first CSO regulator monitoring systems, DELCORA determined that the monitoring system improves system operation and significantly reduces dry-weather overflows by notifying operators at the WRTP that flow is passing over the diversion weir. (If it is not raining, this notification is indication of a dry-weather overflow and DELCORA dispatches a maintenance crew to correct the situation.) After this determination, DELCORA installed the monitoring system on all CSO regulators even though it was not required until the CSO regulator was replaced. DELCORA continues to use this system and it provides critical information to maintain proper operation of the CSO regulators.

As indicated in Table 3-2, the majority of the City's CSO regulators are Brown & Brown type regulators. The original CSO regulators were Type B regulators in which the regulator gate position is controlled by the level in the trunk sewer entering the CSO regulator chamber. As part of its regulator replacement program DELCORA is replacing the regulators with Type A regulators in which the gate position is controlled by the level in the interceptor. This allows for the interceptor to operate at full capacity thus maximizing amount of flow being sent to the WRTP for treatment. Flow that cannot enter the interceptor because it is at capacity, passes over the CSO regulator diversion weir and into the outfall for release to the receiving water.

The updated model includes twenty-five[1] (25) CSO regulators, which were modeled as weirs and orifices. The configuration of CSO regulators was obtained from both record drawings and field surveys.

3.5.3.1 Flow Diversion Structure Components

The key components required for modeling these structures include float-operated gates, orifice plates and diversion weirs. Schematic representations of the flow diversion structures are shown in Figure 3-5. Table 3-2 lists basic information for each of DELCORA's 26 CSO regulators. Appendix A contains the data collected for each CSO regulator structure in the collection system that was utilized in the updated H&H Model. Appendix A, Table A-1, shows the invert elevation of the outfall pipe at the regulator and the invert elevation of the outfall pipe at the receiving stream.

Regulator Gates

Characteristics of the regulator gates were obtained from as-built drawings and field surveys. The gates are rectangular, covering rectangular openings except at Regulator #004, which is circular. The gates open and close based on their associated floats. Settings for opening and closing of the gates based on levels in the float chamber and regulator limit settings were obtained as part of the characterization survey. All regulator gates are modeled as side-type orifices and have been assigned a discharge coefficient of 0.65. For cases where the regulator float and gate have been removed, dry weather flow and some portion of the wet weather flow will pass through the opening previously covered by the now removed gate. Flow through this opening will be modeled as an orifice. When weather flow exceeds the capacity of the orifice, the level in the sewer will continue to rise until it is high enough for a portion of the flow to pass over the weir and discharge through the associated outfall. Regulator gate ID is named according to the CSO regulator points. For example, the regulator gate for CSO regulator 003 is named "REG_003_Gate." A summary of regulator gate characteristics is shown in Appendix A, Table A-2.

Orifices

Most of the regulators include an orifice between the regulator gate and the downstream interceptor. All orifices in the collection system are side orifice type, rectangular in shape and were assigned a discharge coefficient of 0.65. The dimensions are based on record drawings.

A summary of the orifice data used in the model is contained in Appendix A, Table A-3. The updated H&H model has 20 orifices. All orifices are side type and are rectangular in shape. Regulators 004, 015, 017 018 and 032 do not have an orifice plate. Regulators 006, 027 and 033 are no longer connected to the CSS and therefore do not have any orifices, weirs or outfalls included in the H&H model. The orifice ID used in the H&H model is named according to the CSO overflow points. For example, the orifice for CSO 03 is named "REG_03_Orifplate".

Weirs

Characteristics for the diversion weirs were obtained from record drawings and were field verified as necessary. All weirs were found to be of the transverse type with no end contractions. All weirs are assigned a discharge coefficient of 3.33. Weir ID will be named according to the CSO overflow points. For example, the weir for CSO 03 will be named "Weir_03". A summary of the weir data used in the model is contained in Appendix A, Table A-4.

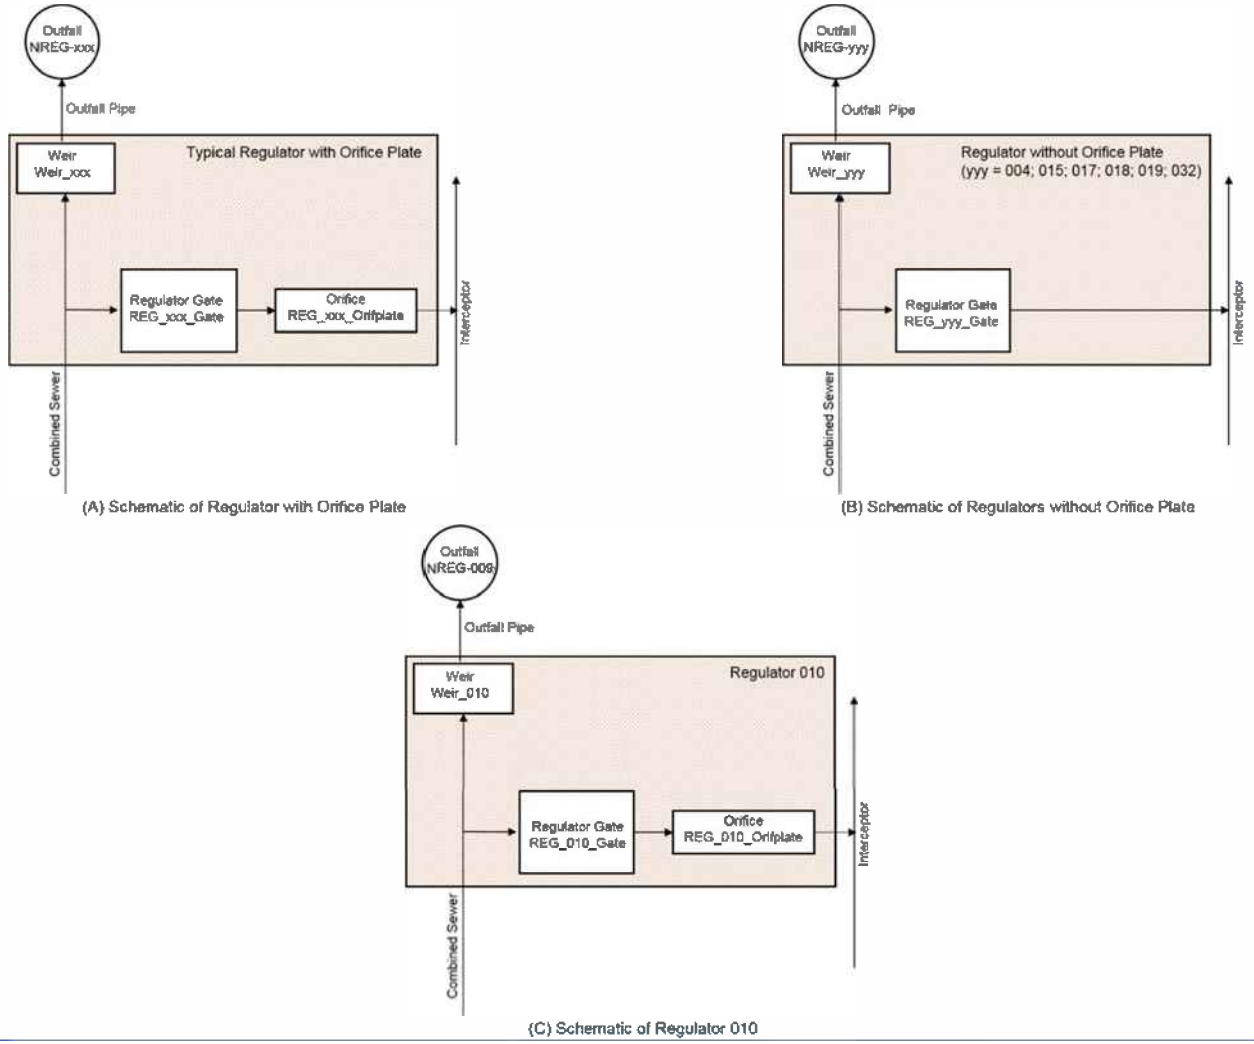
3.5.4 Interceptors

The interceptors convey flow from the CSO regulators to the WRTP or to the Chester Pump Station, which discharges directly to the WRTP. The interceptors shown on Figure 2-3 vary in size from 24" to 72" in diameter. Any flow entering the interceptor system will eventually reach the WRTP for treatment.

Figure 3-3 is a schematic of the Chester CSO system and shows the outfalls and the interceptors that are connected to each CSO. Specifically as diagrammed in Figure 3-3, the relationship between DELCORA's interceptors and outfalls are as follows:

- The Delaware River Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 002, 003, 004, 005 and 007 into the Booth Street Interceptor that then leads to the WRTP.
- The Second Street Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 008, 009, 011 and 024 to the Chester Pump Station, which is then pumped to the WRTP.
- The West End Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Area 010 into the Booth Street Interceptor and then to the WRTP.
- The Ridley Creek Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 012, 013, 014, 015, 016, 017, 018 and 032 to the Chester Pump Station, which pumps the flow to the WRTP.

Figure 3-5: Flow Diversion Structure Schematic



- The Edgmont Avenue Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 021, 022 and 023 into the Ridley Creek Interceptor and from there to the Chester Pump Station and then to the WRTP.
- The Chester Creek East Interceptor and the Chester Creek West Interceptor respectively convey the dry weather flow and a portion of the wet weather flow from CSO Service Areas 019 and 020. These two interceptors then both flow into the Penn Street Interceptor that also conveys the dry weather flow and a portion of wet weather flow from CSO Service Areas 025 and 026 to the Chester Pump Station, which pumps the flow to the WRTP.

3.5.5 CSO Outfalls

Outfalls are the discharge points at the receiving streams. The outfalls can either be free outfalls without any boundary conditions or the outfalls can have a boundary condition that the head needs to overcome for outflow to occur. The outfalls in the DELCORA's collection system are mostly in the tidal river reach. Therefore, appropriate tidal stages from NOAA data were used to set boundary conditions. Outfalls can have a flap gate or other backflow device at the end to prevent backflow.

CSO outfalls will be simulated as outfall nodes in the model. Outfall ID will be named according to the CSO regulator overflow points. For example, the outfall for CSO regulator 002 will be named "NREG-002". The inverts of outfalls were estimated based on record drawings and design drawings.

A summary of the outfall data used in the model is contained in Appendix A, Table A-5. One regulator (Regulator 010) does not have its own outfall, but rather discharges through the same outfall (Outfall 009) as Regulator 009. Also, Regulator 033 has been disconnected from the CSS and, therefore, its outfall is not included in the updated H&H model. As a result, there are a total of 25 CSO outfalls in the updated H&H model.

3.5.6 Drainage Areas and Subcatchments

Each of the 25 CSO regulators has a unique drainage area associated with it. A CSO drainage area is defined as the entire surface area contributing overland wet weather flow to a specific CSO. Subcatchments are smaller drainage basins located within the overall CSO drainage area. Subcatchments are more useful when developing a model, because the area is smaller and it becomes more site-specific. Subcatchment boundaries were determined from sewer system maps and local topography. GIS software was then used to estimate the acreage within a subcatchment boundary. There are a total of 53 subcatchments within DELCORA's 25 drainage areas of the CSS. An overall configuration of the CSS drainage areas is presented in Figure 3-4. This figure shows the boundaries of each of the 25 CSO regulator drainage areas (subcatchments), as well the combined and separated portions of these service areas. Table 3-1 presented a listing of the subcatchment areas associated with each CSO regulator, and the type of collection system (CSS or separated) within the subcatchment.

3.5.7 Percent Imperviousness

Areas that are impervious to rainfall infiltration, like pavement and rooftops, generate the most runoff in urban settings. Percent imperviousness is the fraction or percentage of a particular subcatchment that is covered by impervious materials like parking lots, streets, and rooftops. The percent of directly

connected impervious area is the ratio of hydraulically connected impervious areas (parking lots, streets, etc.) to the total subcatchment area. Directly connected impervious areas are effectively connected to the sewer collection system. As a result, runoff from these areas is completely captured by the collection system. Runoff from the rest of the impervious area is deemed not to be captured by the system due to various potential reasons including, but not limited to, drains to pervious areas/creeks/streams, limited number and capacity of stormwater inlets, and bypassing. For model construction, the percent imperviousness was calculated using the high resolution land cover raster published by the Chesapeake Conservancy (Chesapeake Conservancy, 2017) as well as the land use shapefile published in 2015 by the Delaware Valley Regional Planning Commission as the initial inputs. Then, the impervious percentage values were adjusted during the model calibration process (see Section 7) to best simulate the observed hydrologic response over the selection of precipitation events.

For the separated areas within the City of Chester, the initial percent imperviousness was set at 0% because the impervious area in the separated area is not contributing runoff to the CSS, therefore it is not effectively connected. Subcatchment parameters mentioned hereafter were set at default values for the separated subcatchments.

3.5.8 Depression Storage

Depression storage is the rainfall abstraction volume that must be filled prior to the occurrence of runoff. It represents the loss (initial abstraction) caused by surface ponding, surface wetting, etc. The initial values of depression storage were set to 0.05 for impervious surfaces and 0.15 for pervious surfaces. Typical depression storage values are 0.05-0.10 for impervious surfaces and 0.10-0.30 for pervious surfaces. Depression storage is an empirical value and may be treated as a calibration parameter, especially to adjust runoff volumes.

In the model, the subcatchment was divided into three subareas: pervious area with depression storage, impervious area with depression storage, and impervious area without depression storage. The initial percent of the impervious area without depression storage was set to 0.10.

3.5.9 Soil Infiltration Parameters

Soil information is needed to estimate infiltration in the pervious areas of the CSS. The rate of infiltration is a function of soil properties and antecedent soil conditions. Infiltration parameters influence the runoff hydrograph from the combined sewer system subcatchments by absorbing rainfall into the soil. The infiltration capacity of the soil is exceeded when the soil becomes saturated during continuous simulation and heavy precipitation. When soil saturation is reached, most of the subsequent rainfall becomes runoff making the pervious areas behave as impervious areas.

Three infiltration methods are available in the software: the Horton method, Green-Ampt method, or Natural Resources Conservation Service (NRCS) Curve Number method. The Horton method has been extensively used for similar type of modeling work and it was used in this modeling effort to estimate infiltration. The required soil parameters for Horton method include:

- Maximum Infiltration rate (in/hr)
- Minimum Infiltration Rate (in/hr)

- Decay Constant (/hr)
- Drying time (d)
- Maximum Infiltration Volume Possible (inch)

To determine the Horton infiltration parameters, a soil map was first obtained from the NRCS (USDA, 2017). The soil types were then correlated to standard hydrologic soil groups.[4] A map of the hydrologic soil groups found in the CSS is presented in Figure 3-6. Hydrologic soil groups found in DELCORA's CSS are groups A, B, C, B/D and C/D. Horton's infiltration parameters for these soil groups were estimated based on typical values from literature and are shown in Table 3-3.

Table 3-3: Horton Infiltration Parameters

Horton Infiltration Parameter	Soil A	Soil B	Soil C	Soil B/D	Soil C/D
Max Infiltration Rate (in/hr)	5	3	2	2	1.5
Min Infiltration Rate (in/hr)	1.18	0.43	0.2	0.22	0.06
Decay Constant (1/hr)	4	4	4	4	4
Drying Time (d)	2	3	8	8	10.5
Max Volume (in)	14	13.2	12.5	9.8	7.0

3.6 Collection System Pump Stations and Force Mains

Major pump stations in the Western Service Area and the Central Delaware Pump Station in the Eastern Service Area were added to the updated model, as well as force mains connecting the pump stations to the WRTP. The list of the pump stations included in the H&H Model is as follows:

- Chester PS (CPS)
- Existing PS-1 (EPS-1)
- Marcus Hook PS (MHPS)
- Naamans Creek PS (NCPS)
- Eddystone PS (EDPS)
- Central Delaware PS (CDPS)
- Chester Ridley Creek PS (CRPS)
- Sun Oil PS (Owned by Sunoco) (SPS)
- Kimberly Clark PS (Owned by KC) (KCPS)

[4] Soil types can be categorized into standard hydrologic soil groups A, B, C and D, with group A having the lowest runoff potential and group D having the highest runoff potential. Dual rated groups are group D in their natural state, but can behave according to the first letter if the area is drained. Additional information regarding hydrologic soil group descriptions can be found in the Appendix.

The following pump stations were excluded from the H&H Model:

- Price & Smith Street Trainer PS
- Stadium PS

Flow from the Price & Smith Street Trainer PS discharges to the downstream existing PS-1 Pump Station (EPS-1) where it is re-pumped. The updated H&H model assumes that all flow from subcatchments associated with the Price and Smith Street Trainer PS can be treated as an input to EPS-1.
Flow from the Stadium PS is sanitary sewage with no wet weather flow. The Stadium PS discharges flow only during events held at the stadium. Due to the limited flow, its sporadic nature and the lack of wet weather flow, the Stadium PS is expected to have negligible effect on the wet weather capacity of the CSS. Therefore, the Stadium PS was not included in the H&H Model.

DELCORA owns or operates a number of lift stations that contribute to the Western Service Area and whose flows are handled by the above list of pumps stations. It was determined that the behavior of these lift stations would not require modeling and that inflow can be assumed to equal outflow to the downstream conduit.

Figure 3-7 presents a map of the pump stations that are included within the updated H&H model.

3.6.1 Force Mains

DELCORA's Model Area include several force mains to convey flow from various pump stations to the WRTP.

- Chester Force Main
- Central Force Main
- Chester-Ridley Creek Force Main
- Naaman's Creek Force Main
- Marcus Hook/Sun Oil Force Main
- Eddystone Force Main
- Kimberly Clark Force Main.
- Existing Pump Station Force Main

The 40-MGD Chester Pump Station discharges to the Chester Force Main which then runs to the WRTP as a 54-inch diameter ductile iron force main.

The Central Delaware Pump Station (CDPS) discharges through two force mains, one of which connects to the Model Area and the WRTP while the other delivers flow to PSWPCP. The force main to the Model Area is referred to as the Central Force Main and is a 3.4-mile, 24-inch ductile iron force main which subsequently connects to the Chester Force Main. This connection allows DELCORA to send up to 27 MGD of flow from the CDPS to the WRTP, however, DELCORA's operating policy limits this flow to 20 MGD, with flows above this point to be directed to PSWPCP. Only the force main connecting to the Model Area is included in the updated H&H model.

A schematic representation showing the force mains can be found in Figure 3-3. A map showing the location of the force mains is depicted in Figure 3-8.

Section 4 Collection of Precipitation and Sewer Flow Data

4.1 Introduction

This section presents information on the collection of precipitation and sewer flow data to meet the requirements of Section V.A.14.d of the Consent Decree, and Paragraphs II.A.C.1.a and b of the USEPA's CSO Control Policy. Section V.A.14.d of the Consent Decree requires DELCORA to conduct rainfall monitoring in accordance with current good industry practice for a period of at least (12) months.

The rainfall and flow monitoring program was developed to provide adequate data for the development, calibration and validation of the H&H Model. The goals of this program were met by collecting rainfall and flow monitoring data for just over 12 months, from March 18, 2016 to April 4, 2017. Rainfall and flow monitoring data were collected on a monthly basis with quarterly reports were submitted to US EPA on August 28, 2016; November 1, 2016; February 1, 2017; and May 1, 2017. DELCORA considers Consent Decree requirements to be met due to no comments from US EPA and PA DEP.

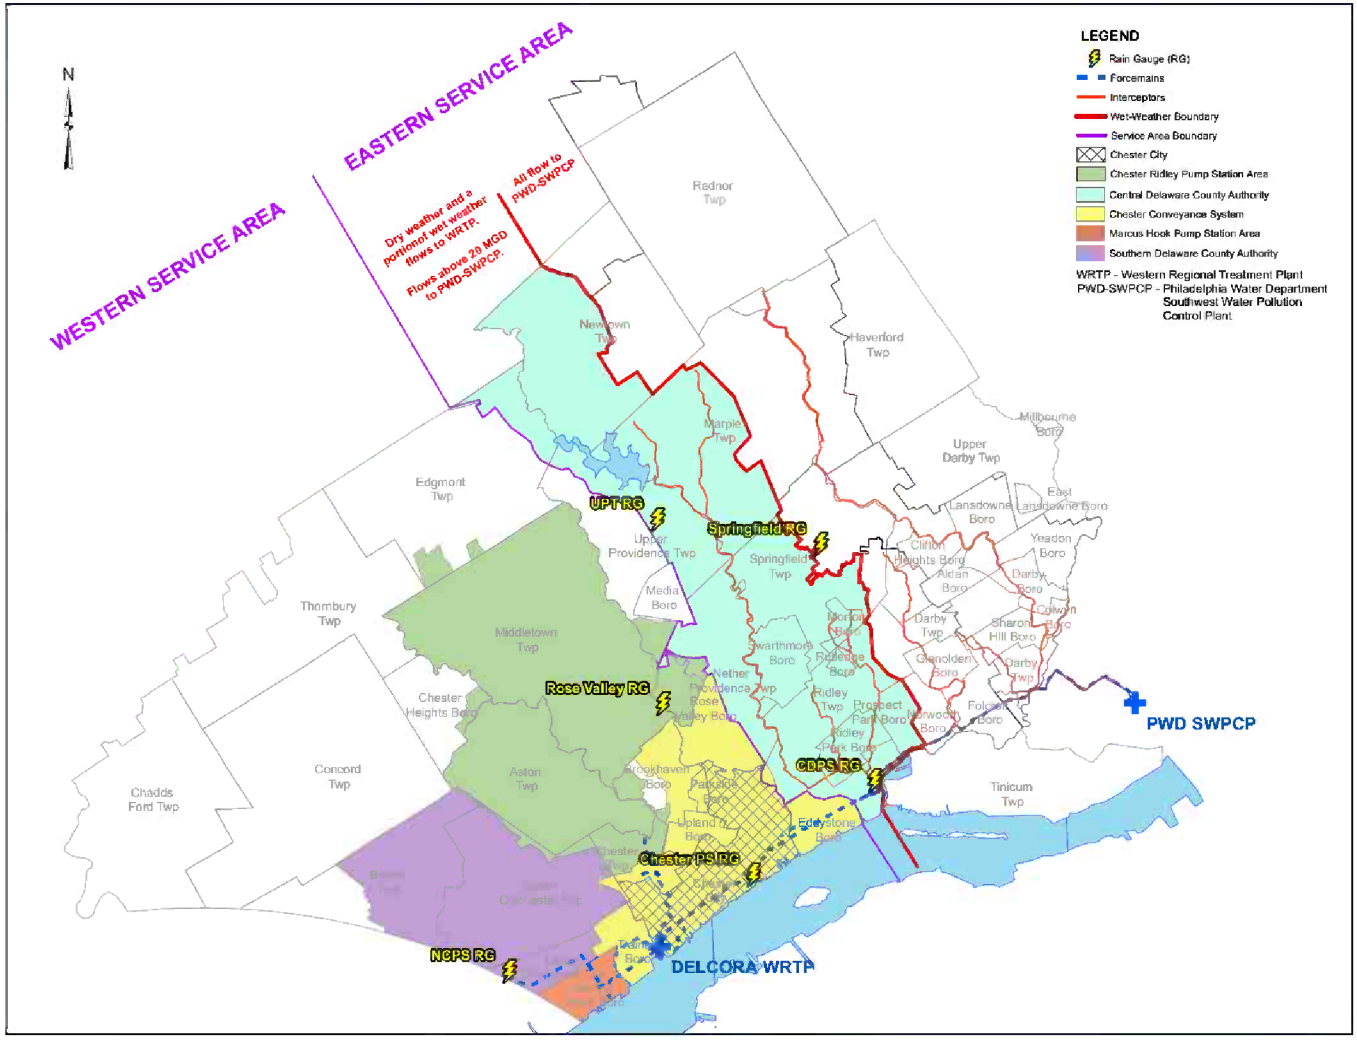
After it was carefully reviewed and analyzed, the data was deemed adequate to facilitate the development, calibration and validation of the H&H Model. This section contains a summary of the rainfall and flow monitoring program and discusses the network of rainfall and flow monitoring instrumentation, outlines the monitoring program, and describes how the data collected for the rainfall and flow monitoring program was analyzed for use in the H&H Model calibration and validation. Additional details can be found in the rainfall and flow monitoring quarterly reports, in the *Hydrologic and Hydraulic Model Update and Calibration Plan* (Greeley and Hansen, 2015), and in the *Sewer System Hydrologic and Hydraulic Model Report* (Greeley and Hansen, 2017c).

4.2 Rainfall Monitoring and Analysis

A total of six (6) rain gauges were used for the monitoring program. As depicted in Figure 4-1, the gauges are stationed at the following locations:

- Rose Valley
- Chester Pump Station (CPS)
- Naaman's Creek Pump Station (NCPS)
- Springfield
- Upper Providence Township (UPT)
- Central Delaware County Pump Station (CDPS)

Figure 4-1: Rain Gauge Locations



Five out of six of the gauges provided data at 5 minute intervals. One rain gauge provided data on 15-minute intervals. The gauge rainfall data from the six rain gauges installed throughout the DELCORA service area was analyzed and used to:

- Document rainfall and flow monitoring locations,
- Overview flow monitoring data quality,
- Analyze rainfall data to identify dry weather and wet weather conditions and to characterize individual rainfall event for precipitation depth, duration, maximum intensity, and return frequency,
- Analyze flow data to determine dry weather flow and diurnal pattern, wet weather flow and peak factor, and system response to wet weather events, and
- Determine the wet weather events for H&H Model calibration and validation.

An inter-event time of 48 hours was used to identify individual rainfall events. The inter-event time specifies the minimum duration in which precipitation does not occur. Based on this criterion, a dry weather time period and the number of total rainfall events were identified. The rainfall events during the flow monitoring periods had a wide variation in terms of total depth, intensity, duration, and antecedent conditions to provide a large dataset for balanced model calibration and validation.

4.3 Rain Event Summary

The rainfall events were characterized by event start time, event end time, rainfall depth, duration, maximum intensity, and return frequency. As an initial screening criterion, rainfall events with a minimum of 0.9 inches of rainfall were identified. Further screening based on requiring at least two dry days prior to the event resulted in an initial list of ten (10) candidate events for calibration and validation as listed in Table 4-1 below.

Table 4-1: Top 10 Rainfall Events

Event	Event Start	Event End	Chester-PS Rainfall (in)	Duration (hr)	Max Intensity (in/hr)
E1	5/29/16 19:00	5/30/16 5:00	1.82	11.00	0.78
E2	9/28/16 12:00	9/30/16 10:00	2.36	47.00	0.37
E3	11/29/16 7:00	11/29/16 20:00	1.08	14.00	0.21
E4	3/30/17 21:00	4/1/17 3:00	1.83	31.00	0.25
E5	5/21/16 11:00	5/22/16 21:00	1.71	35.00	0.33
E6	7/28/16 15:00	7/29/16 9:00	1.26	19.00	0.74
E7	9/19/16 8:00	9/19/16 16:00	0.96	9.00	0.42
E8	3/13/16 18:00	3/14/16 14:00	1.08	21.00	0.25
E9	5/6/16 4:00	5/7/16 11:00	1.18	32.00	0.24
E10	10/8/16 14:00	10/9/16 11:00	1.00	22.00	0.15

4.4 Gauge-Adjusted, Radar Estimated Precipitation

According to the Consent Decree, rainfall data to be used for calibration and validation of the model *"…shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per kilometer"*. In order to achieve this density, Gauge-Adjusted Radar Rainfall (GARR) was employed. The rain gauges used to complete the flow monitoring program and choose the wet weather events used in calibration and validation were also used in the GARR analysis which provided effective spatial coverage of the entire Model Area. GARR data was provided for each of the subbasins in the Model Area. This rainfall data was input as a time series into the H&H Model for calibration and validation. An in-depth explanation of the use of GARR data in both the H&H Model and the Water Quality Model can be found in the *Sewer System Hydraulic and Hydrologic Report* and the *Water Quality Monitoring and Modeling Quality Assurance Project Plan*, respectively (Greeley and Hansen, 2017c), (Greeley and Hansen, 2017b).

4.5 Flow Monitoring

DELCORA owns and operates a flow monitoring network across the DELCORA Service Area. The monitoring network includes various types of flow meters located throughout DELCORA's Eastern Service Area and Western Service Area, at the WRTP, in each of the Pump Stations, and at the tie-in points where other municipal collection systems tie-into the collection system. Seven existing flow meters in the separated area (outside the CSO area), eight existing flow meters at pump stations and one existing flow meter at WRTP were used for the calibration and validation of the H&H Model. In addition, temporary flow meters were installed at 38 new locations to characterize surface runoff from the combined area and CSO discharges. The locations of flow meters installed specifically for the flow monitoring program and the H&H Model calibration and validation can be categorized into the following five categories:

1. Located on the influent pipe to CSO regulators, this is to measure the influent flow to CSO regulators and for combined area runoff calibration. Sixteen (16) meters were installed for this category.
2. Located on the effluent pipe and overflow pipe of CSO regulators, this is to measure the CSO overflows and calibrate CSO regulator parameters. Twelve (12) meters were installed for this category. They are on the effluent and overflow pipe of CSOs 02, 03, 05, 08, 14, & 19.
3. Located on the side-line from the combined areas (flows from the combined area tie into interceptor instead of CSO regulator). This is to measure flows from the combined area and to calibrate combined area runoff parameters. Two (2) meters were installed for this category.
4. Located upstream of the combined area, this is to measure flows from the upstream separated area for RDII characterization. Three (3) meters were installed for this category.
5. Located in the main interceptors to measure level and flows in the major interceptors. Five (5) meters were installed for this category.

Table 4-2 lists the flow meter locations and location categories of the meters. Figures 4-2 and 4-3 show the locations of the flow meters that were used for H&H Model calibration and validation. After initial installation of the new temporary flow meters, difficulties were encountered at Manhole MH3029. The site was severely surcharged during field investigation. Meanwhile it was found that at Manhole MH3002 (four manholes upstream of MH3029, approximately 800 feet upstream) another existing flow meter (Ridley Creek MH-28) was already installed for DELCORA. Instead of installing a new temporary flow meter around the site, the existing meter Ridley Creek MH-28 was used for the flow monitoring program.

Data was gathered from a total of 55 flow meters, 38 of which were newly installed as part of the flow monitoring program.

Figure 4-2: DELCORA Flow Meters

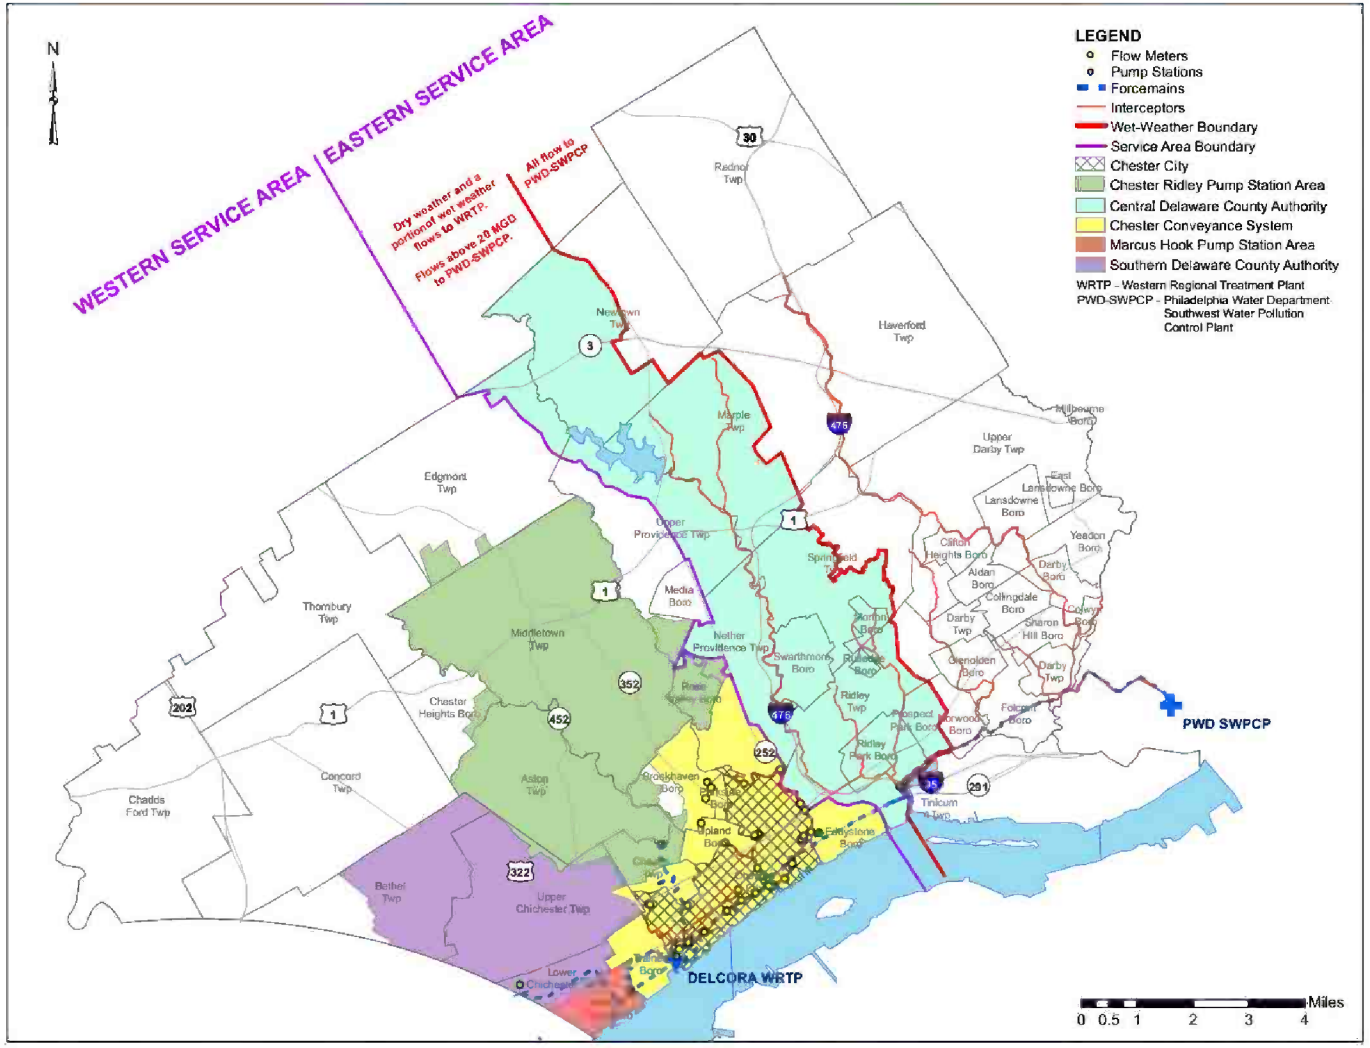

Figure 4-3: Enlarged Map of Flow Meters

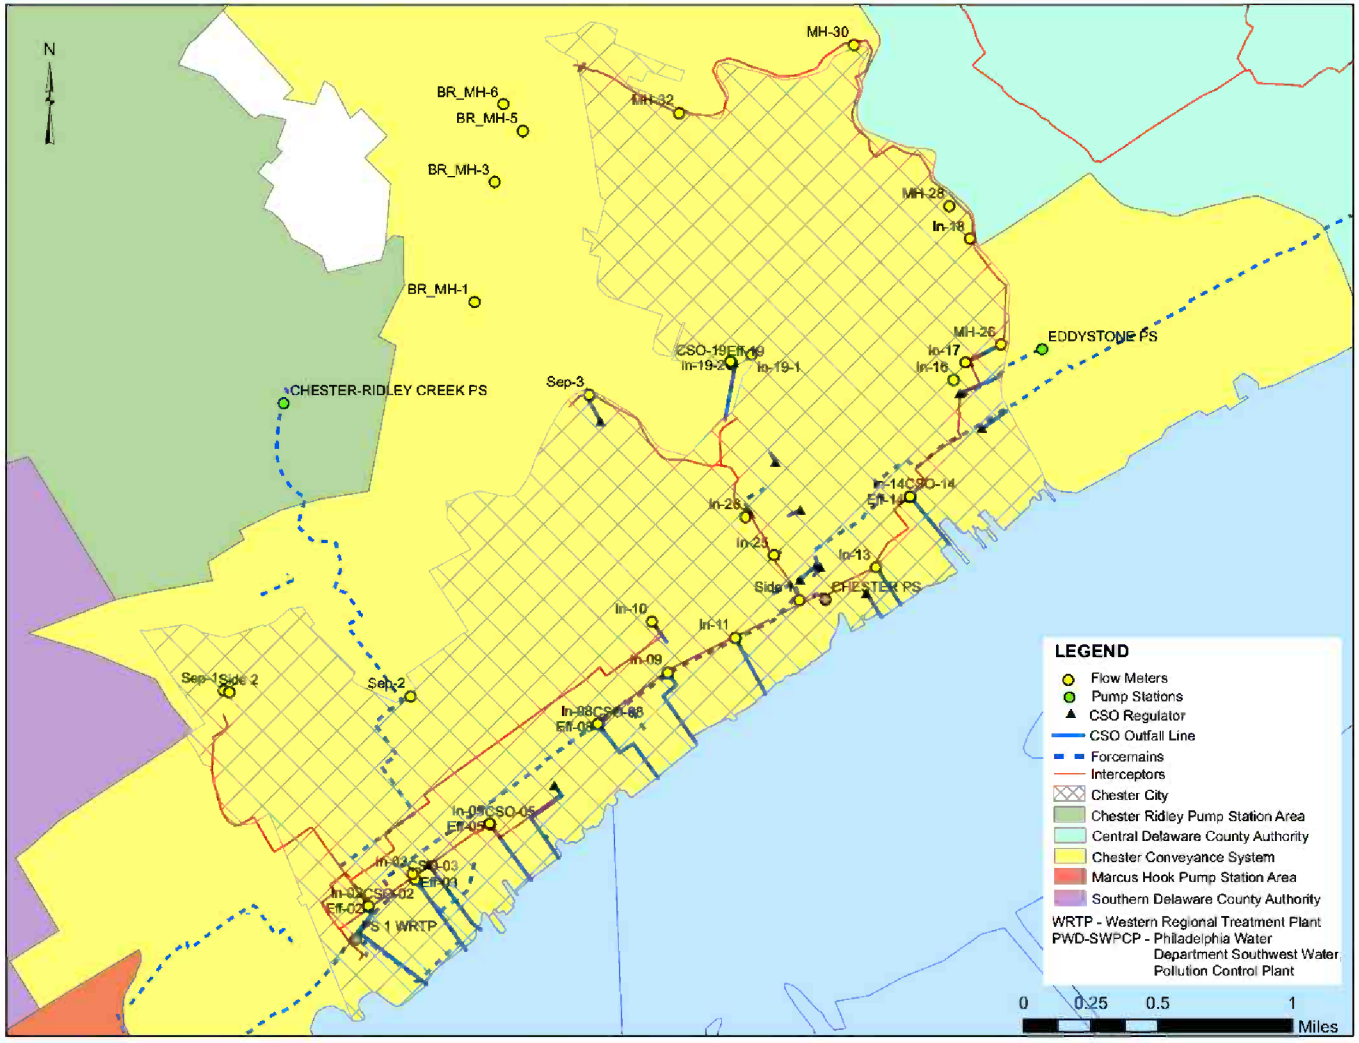

The network of flow meters can be grouped to define metersheds where flow from a given area discharges through a common flowmeter. Subcatchments associated with each metershed are shown in Table 4-3 along with the associated metershed acreage. Rainfall and flow data gathered for each metershed will be used to calibrate the associated subcatchments in the H&H Model.

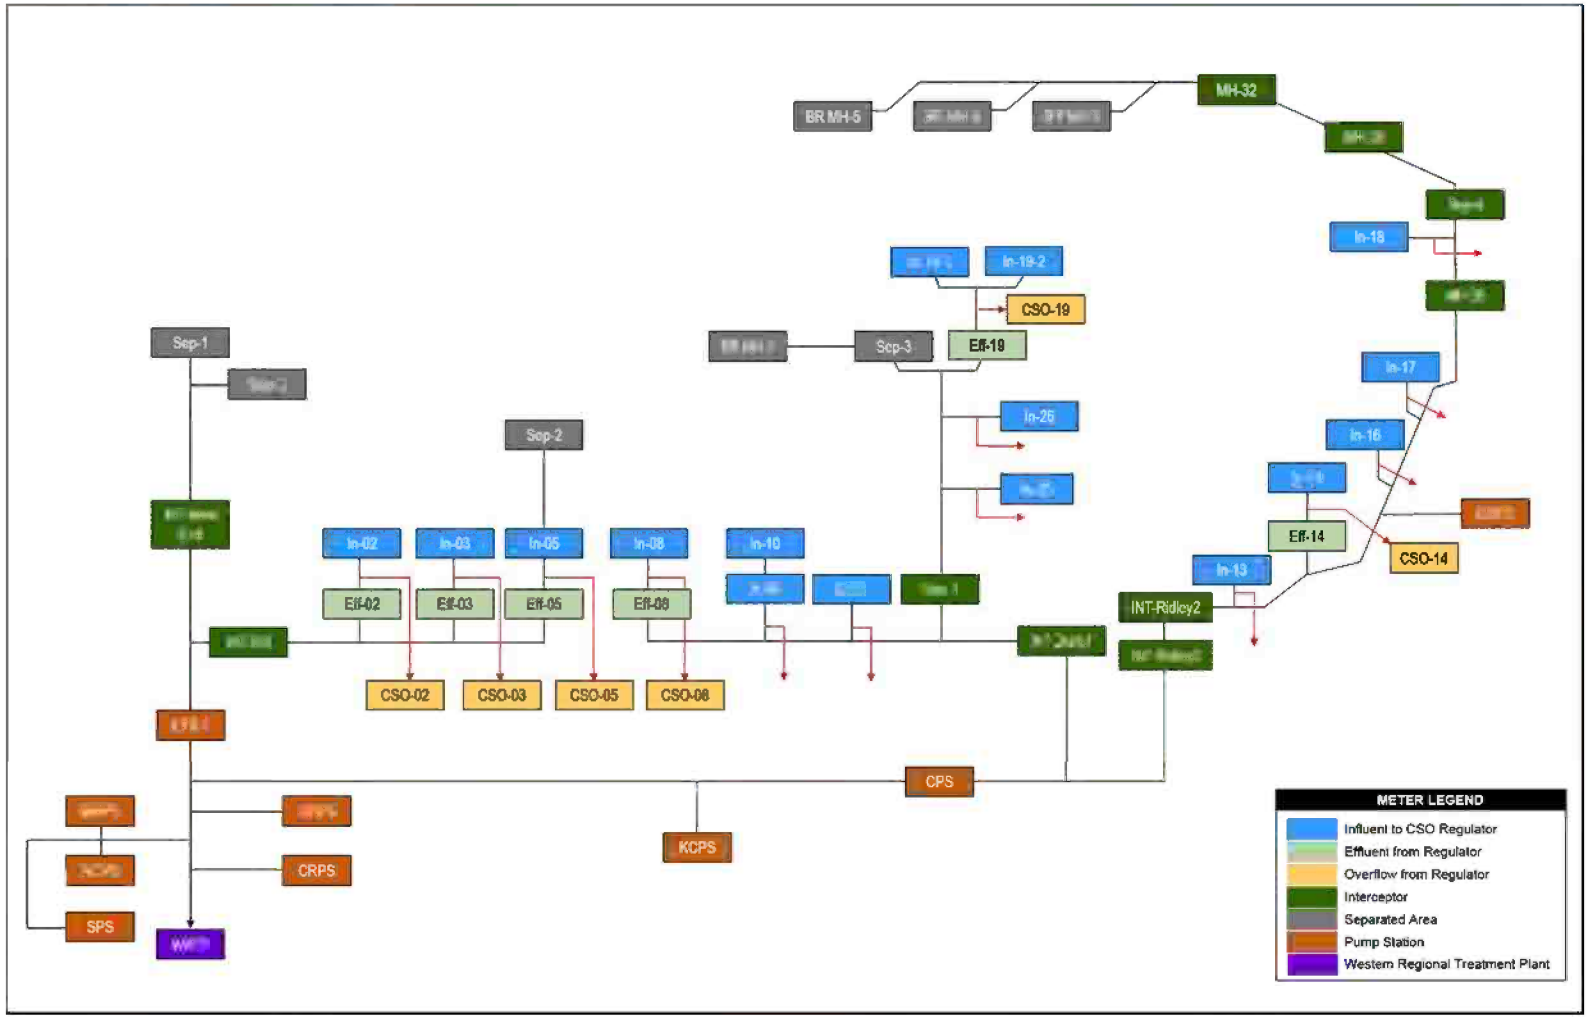
A schematic of the collection system was created to facilitate the development, calibration and validation of the H&H Model and is shown below as Figure 4-4. The schematic illustrates the relationship between all major trunk sewers, force mains, interceptors, pump stations, and other major appurtenances. The schematic also includes the location of the flow meters, and provides and good understanding of the relationship between them. Figures of the diversion structure configurations were also developed to help give a better understanding of the collection system.

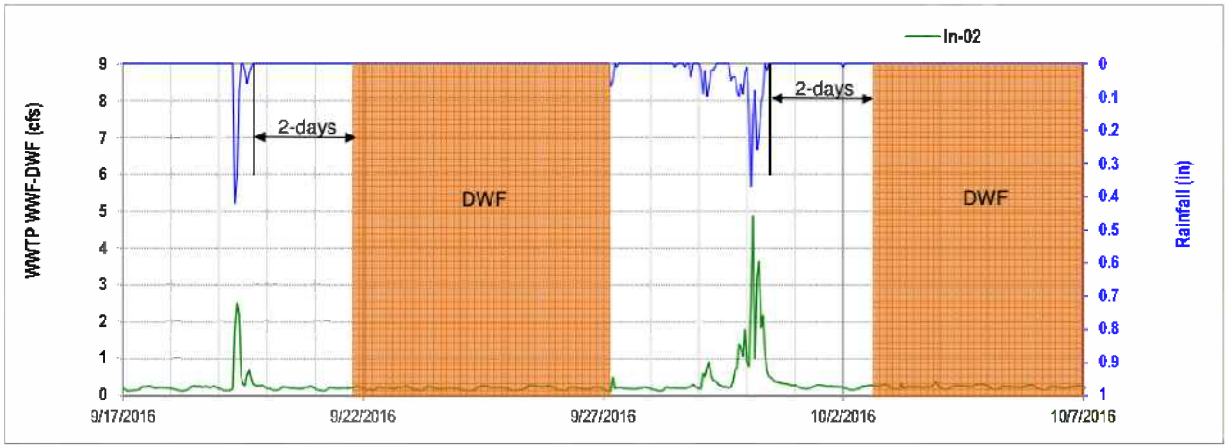
Figure 4-4: Flow Monitoring Schematic



4.6 Dry Weather Flow (DWF) Analysis

A "dry weather" condition was defined as a period with no precipitation that begins 48 hours after the last wet weather event ends and lasts until the beginning of the next precipitation event (i.e. the rain gauge read a 0.01 inch value). Dry weather flow (DWF) periods based on this definition are illustrated in the hydrograph shown in Figure 5-4.

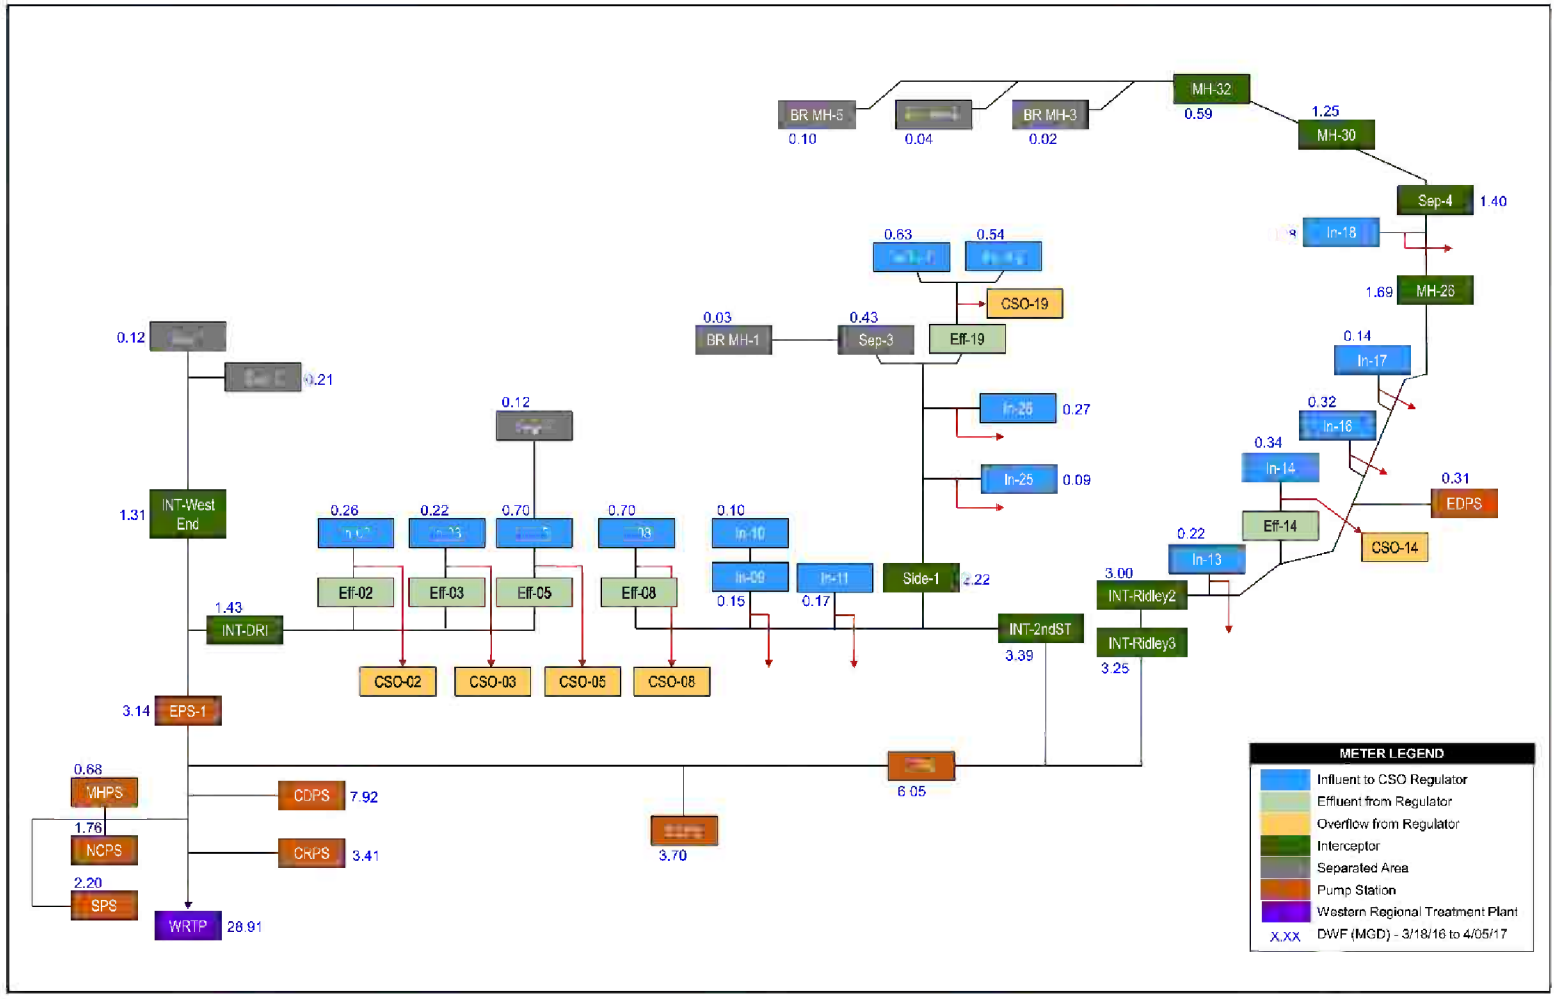
Figure 4-5: Hydrograph to Show Dry Weather Flow



Overall hourly average DWF was calculated by taking the average of the monitored DWF for each hour during the flow monitoring period. Monthly DWF was calculated by averaging the DWF for each month during the flow monitoring period. The overall hourly and monthly DWFs for all monitoring sites were analyzed and used as inputs in the H&H Model.

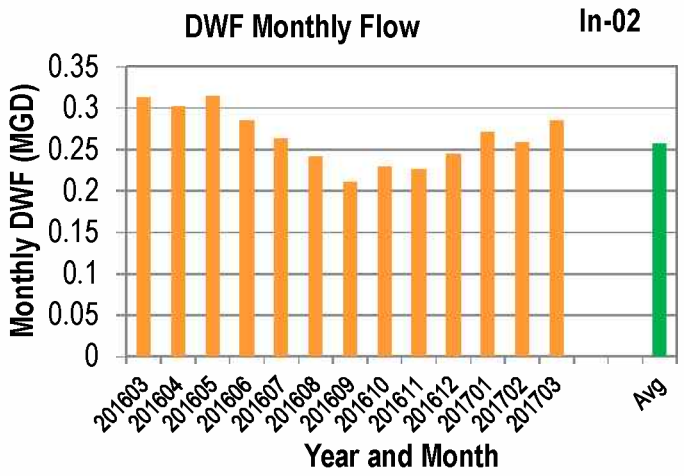
The DWFs for the one year monitoring period are also shown in the schematic in Figure 4-6. Each value displayed next to each flow meter represents the DWF overall average (in MGD) for one quarter. These values were ultimately averaged and input into the model as the overall annual average DWF. Generally the downstream dry weather flow is greater than the upstream locations for all of the meters. For meters immediately upstream and downstream of CSO regulators, the upstream and downstream dry weather flows should be similar.

Figure 4-6: Dry Weather Flow Balance Schematic



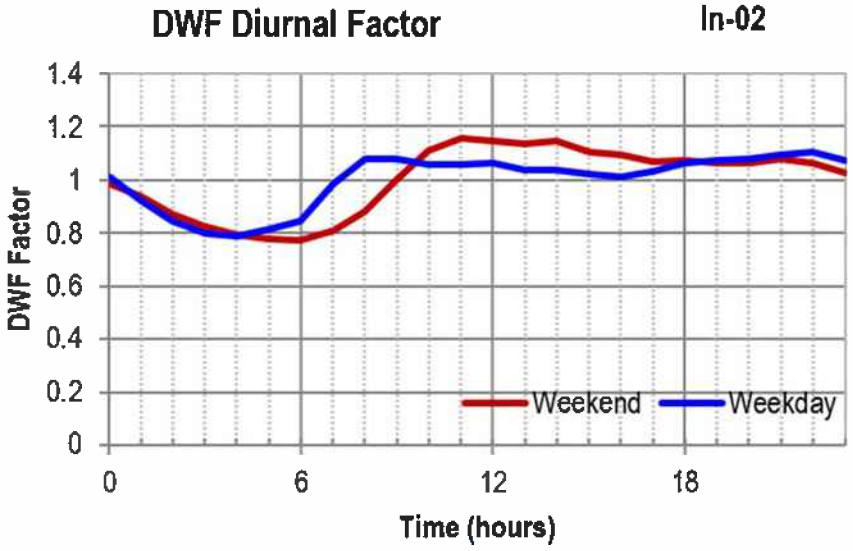
Monthly DWFs were calculated during the DWF analysis by averaging the overall DWF during each month. Average monthly DWFs were input into the model along with the overall annual averages for each flow meter. Figure 4-7 below shows the monthly DWFs input into the model for meter In-02.

Figure 4-7: Average Monthly DWF



The DWFs vary throughout the day, with the highest flows normally occurring around noon and the lowest rates between midnight and early morning. Flow data from the dry weather periods were used to develop a diurnal pattern for each flow meter. Diurnal patterns were analyzed for both weekdays and weekends. In the plot shown on Figure 4-8, the weekend DWF peak and valley have a 3-hour lag compared to the weekday pattern. The weekday and weekend diurnal patterns were input into the model along with the overall annual average values discussed above.

Figure 4-8: Weekday and Weekend Dry Weather Flow Diurnal Pattern

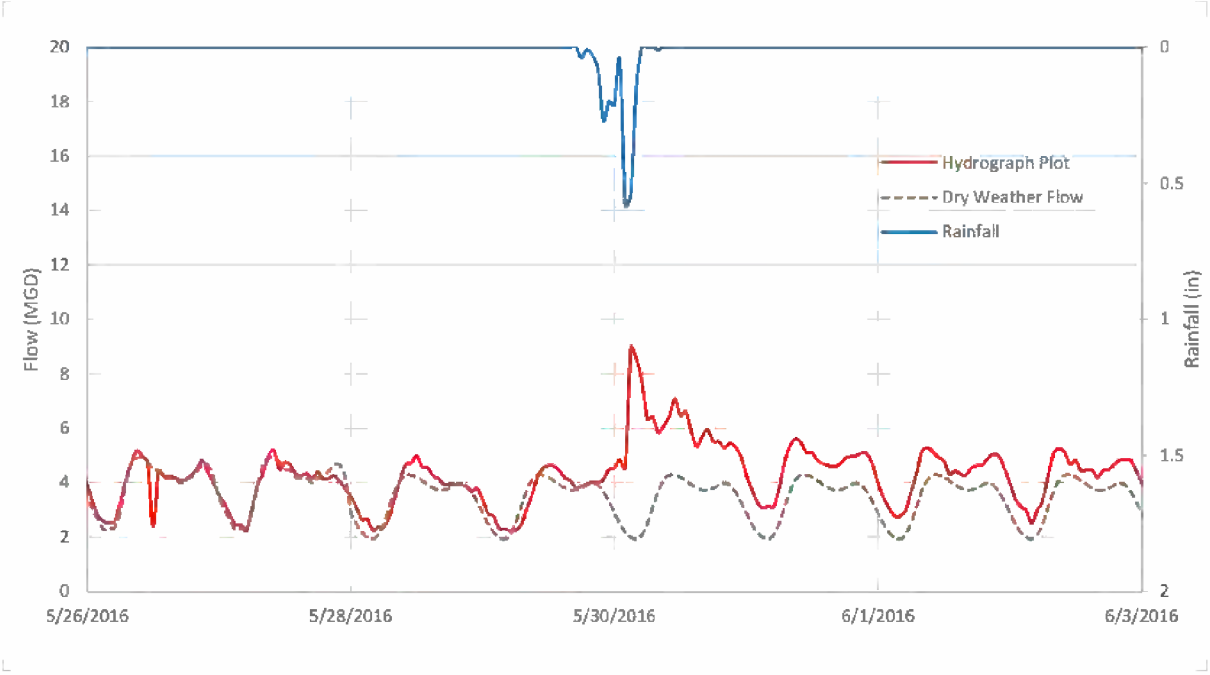


4.7 Wet Weather Flow Analysis

Wet weather flows are the combination of dry weather flows and additional flows that enter the system during wet weather conditions. The additional flows are from combined area surface runoff and RDII. Inflow normally occurs when rainfall enters the system through direct connections such as roof leaders, yard drains, catch basins, sump pumps, manhole covers and frame seals or indirect connections with storm sewers. Inflow is usually recognized graphically by large magnitude, short duration spikes immediately following a rain event. Infiltration occurs during wet weather conditions when water enters a sewer system from the ground through means which include, but not limited to, deteriorated pipes, pipe joints, connections, or manholes. It is significantly influenced by the size and duration of the rainfall event. Infiltration is often recognized graphically by a gradual increase in flow after a wet weather event. The increased flow typically sustains for a short period after rainfall has stopped and then gradually drops off.

The peaking factor represents the ratio of the peak wet weather flow to the average dry weather flow. Usually, an hourly peaking factor is used to represent the wet weather peaking factor. Peaking factors were analyzed for each flow monitoring site. The peaking factors in the separated area can be used to determine the extent of the RDII within a particular basin. Figure 4-9 is a flow hydrograph plot showing an hourly peaking factor of approximately 4.5 for the monitoring site. This high peaking factor indicates that a significant amount of RDII enters the collection system. The immediate flow increase shortly after the rainfall indicates significant inflow into the collection pipes, and the long tail back to the base flow indicates infiltration occurrence at the site as well.

Figure 4-9: Hydrographs of Flow Meters in Separated Area (Example Plot)



4.8 Wet Weather Event Selection for Model Calibration and Validation Flow Analysis

Based on the rainfall and flow monitoring data analysis, the rainfall events shown in Table 4-4 were selected for model calibration and validation. The events were selected from the top ten rain events that are shown in Table 4-1. The calibration and validation events cover variations in terms of rainfall depth, intensity, duration and antecedent conditions.

Table 4-4: Calibration and Validation Rainfall Events

Event	Start	End	Chester-PS Rainfall (in)	Duration (hr)	Max Intensity (in/hr)
E1	5/29/16 19:00	5/30/16 5:00	1.82	11.00	0.78
E2	9/28/16 12:00	9/30/16 10:00	2.36	47.00	0.37
E3	11/29/16 7:00	11/29/16 20:00	1.08	14.00	0.21
E4	3/30/2017 21:00	4/1/20170 3:00	1.83	31.00	0.25
E5	5/21/16 11:00	5/22/16 21:00	1.71	35.00	0.33
E6	7/28/16 15:00	7/29/16 9:00	1.26	19.00	0.74

Storms were chosen from the top ten rain events based first on their accumulation, with larger depths being preferred. But, if a rain event had a preceding storm, it was lowered in rank. Events with varying durations were chosen so that variations in length of time of a storm could be calibrated in the model. Higher intensity storms were chosen over lower intensity storms. But, again, if an event had a preceding storm, it was lowered in rank.

The amount of rainfall that accumulated at the Chester Pump Station rain gauge during event 2 was the largest at 2.36 inches. Event 2 also had the longest duration at 47 hours. However, event 1 had the highest intensity at 0.78 inches per hour.

4.9 Flow Monitoring Data Summary

The majority of the flow meters measured flow, level and velocity data for each flow monitoring site at 5-minute intervals, other flow meters measured the same parameters in 15 minute intervals. Metering data was analyzed for dry weather flows (DWF) and wet weather flows (WWF) for each monitoring site.

The DWF was ultimately used as inputs into the model. Overall annual average DWFs, average monthly DWFs, and weekday and weekend diurnal patterns were input into the model for each flow meter in the combined area. The WWF were used to calibrate the model output. Model data was compared side by side with metered data for each wet weather event for each flow meter.

4.10 Collection of WRTP Operational Data

In addition to flow data collected from the flow meters located in the collection system, flow data from DELCORA's WRTP influent flow meter was obtained for the same time period. A summary of the plant flow data is shown in Figures 4-10-through 4-13.

Figure 4-10: DELCORA WRTP Influent Flow

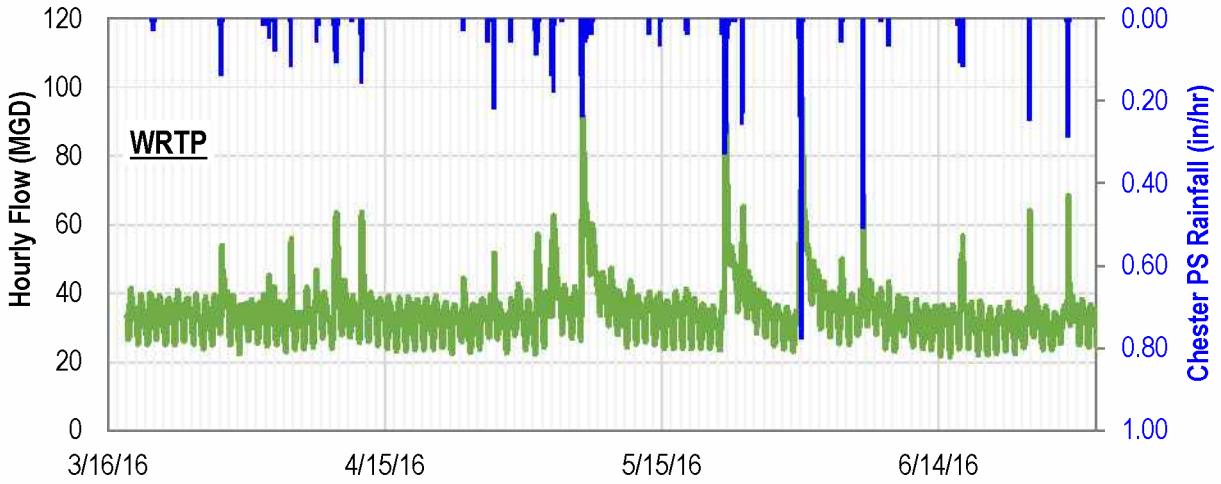


Figure 4-11: DELCORA WRTP Influent Flow

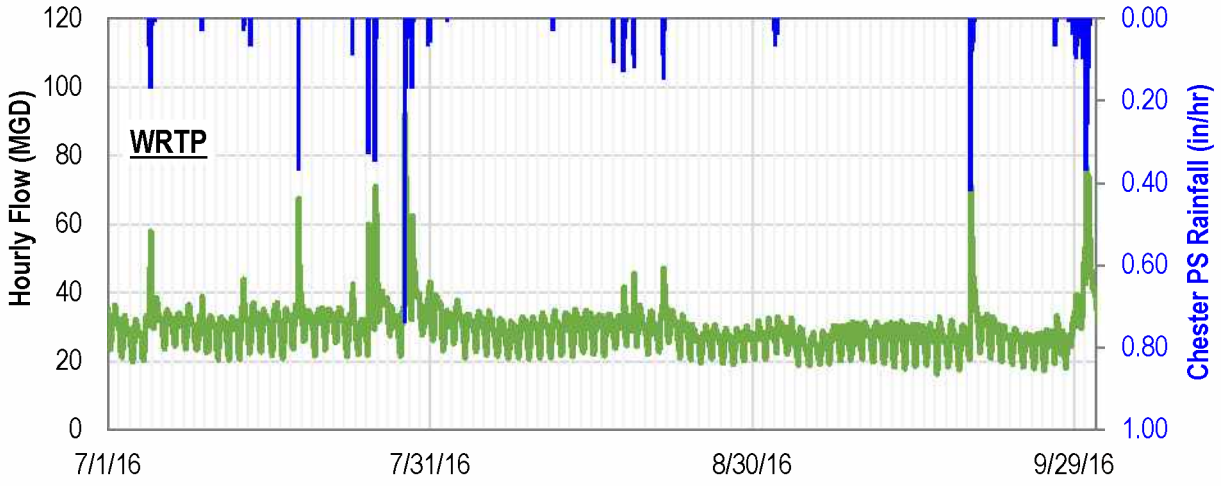

Figure 4-12: DELCORA WRTP Influent Flow

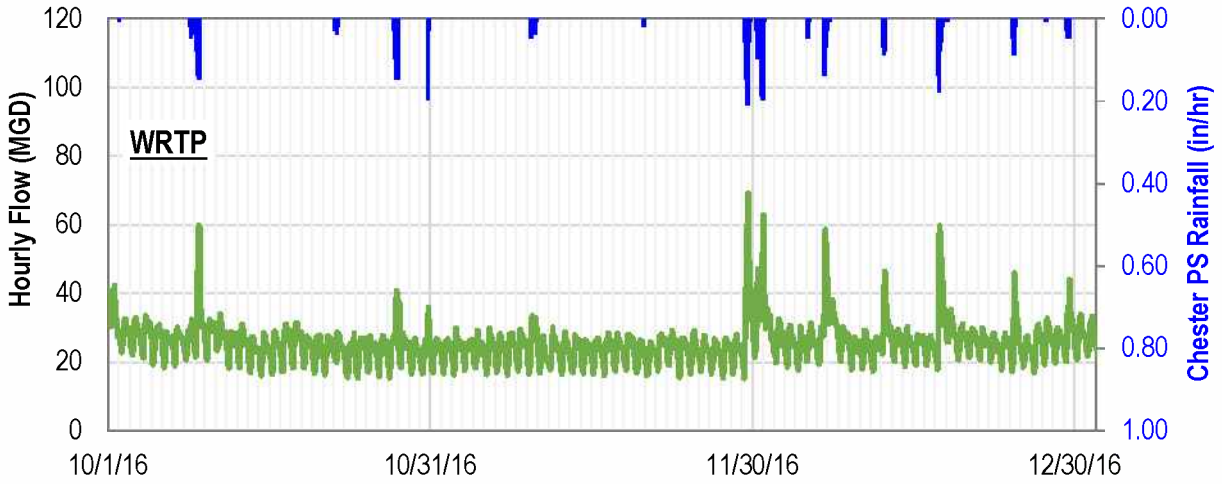

Figure 4-13: DELCORA WRTP Influent Flow

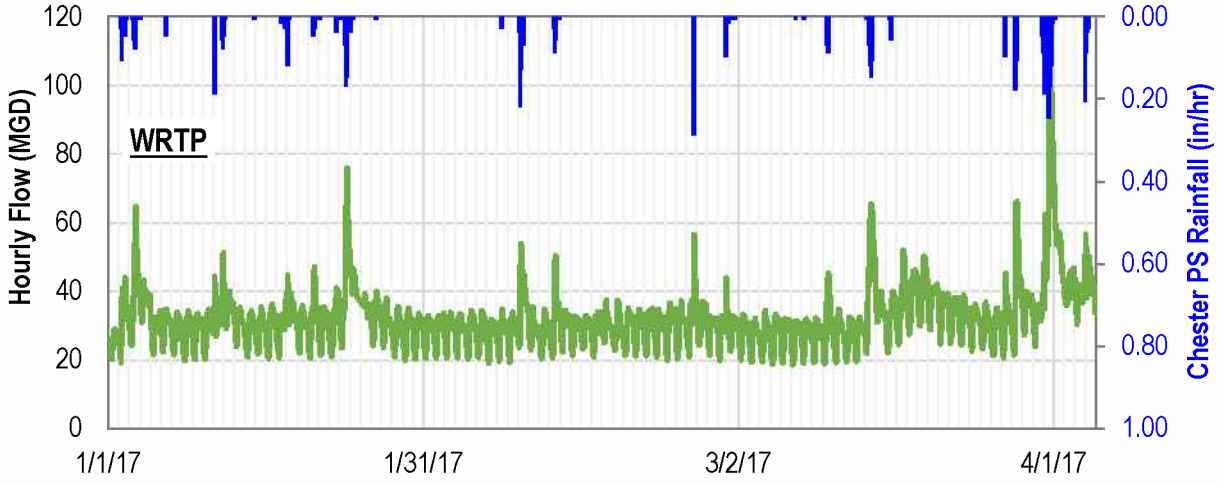

4.11 Summary

The rainfall and flow monitoring program was developed to provide adequate data for the development, calibration and validation of the H&H and Water Quality Models. The goals of this program were met with the collection of the flow monitoring and rainfall data for more than 12 months.

Rainfall data was collected for five rain gauges throughout the Model Area. The Chester rain gauge was analyzed to determine which wet weather events would be used for model calibration. All rain gauge data was ultimately compared with GARR data as a quality check. The GARR data was input into the model as rainfall data.

The flow meter data was analyzed based on the rainfall patterns and then input into the model as overall annual average DWF, average monthly DWFs, and weekday and weekend diurnal curves for each meter in the combined area. To calibrate the model, model-generated data was compared to the metered-data hydrographs for each wet weather event for each flow meter.

Section 5 Characteristics of the Receiving Waters

5.1 Physical Characteristics

The CSS discharges to portions of the Delaware River and two of its tributaries, Chester Creek and Ridley Creek. These receiving waters are located in the tidal portion of the Delaware River Basin, which stretches from the mouth of the Delaware Bay (River Mile 0) to Trenton (River Mile 133.4). The segment of the Delaware River directly impacted by DELCORA's CSO discharges is Zone 4, which extends from River Mile 78.8 to River Mile 95.0 (see Figure 5-1). Chester Creek is located at River Mile 82.93 and Ridley Creek at River Mile 83.8. These creeks are tidally influenced tributaries to the Delaware River. For Chester Creek, the tidal portion extends from the mouth of the tributary at Delaware River upstream to Kerlin Street in Chester City while for Ridley Creek, the tidal portion extends from the mouth of the tributary at the Delaware River upstream to MacDade Boulevard in Chester City (PAFBC, 2017).

In March 2017, an elevation (bathymetric) survey was conducted by LimnoTech for the lower portions of Chester and Ridley Creeks. Figure 5-2 shows the transect locations where elevation measurements were collected. Reaches surveyed included the lower 2.75 miles of Chester Creek and 3.25 miles of Ridley Creek to their discharge into the Delaware River. Transects were collected on ¼-mile interval spacing. Access to the creeks on the upper portions, generally greater than 1 mile upstream, was by wading where the bottom was shallow and firm. The portions below 1 mile were too deep and soft to be accessed on foot and a john boat with tagline was utilized.

Each creek cross section was surveyed at approximately five locations across the bed, water surface, bank toe, and bank top. Access to the entire upland bank at transect locations was not always possible; so the closest points safely accessed to the bank toe were surveyed.

Elevation measurements from this survey were compared with similar elevation data from a 1977 Federal Emergency Management Agency (FEMA) Flood Insurance Study (FIS) of the creeks (FEMA, 2015). Though the FEMA study was completed several decades ago, it serves as a useful check on the accuracy and sufficiency of the bathymetric survey data. Figures 5-3 and 5-4 compare the LimnoTech survey data with the FEMA data.

In Chester Creek, the LimnoTech bed elevations are substantially higher (about five to ten feet) than FEMA elevations. Higher contemporary creek elevations influence both the degree of tidal exchange in the lower reaches of the creeks, and travel times of upland runoff and base flow to the Delaware River. To check for potential bias in the LimnoTech measurements, the LimnoTech measurements of water surface elevation were compared to similar data maintained by NOAA at a nearby tide gage (Philadelphia gage, #8545240). These measurements of water surface elevation agreed well (within two inches) which is a strong indication that the LimnoTech creek bed elevations are not biased high.

Figure 5-1: Zones of the Delaware River and Bay

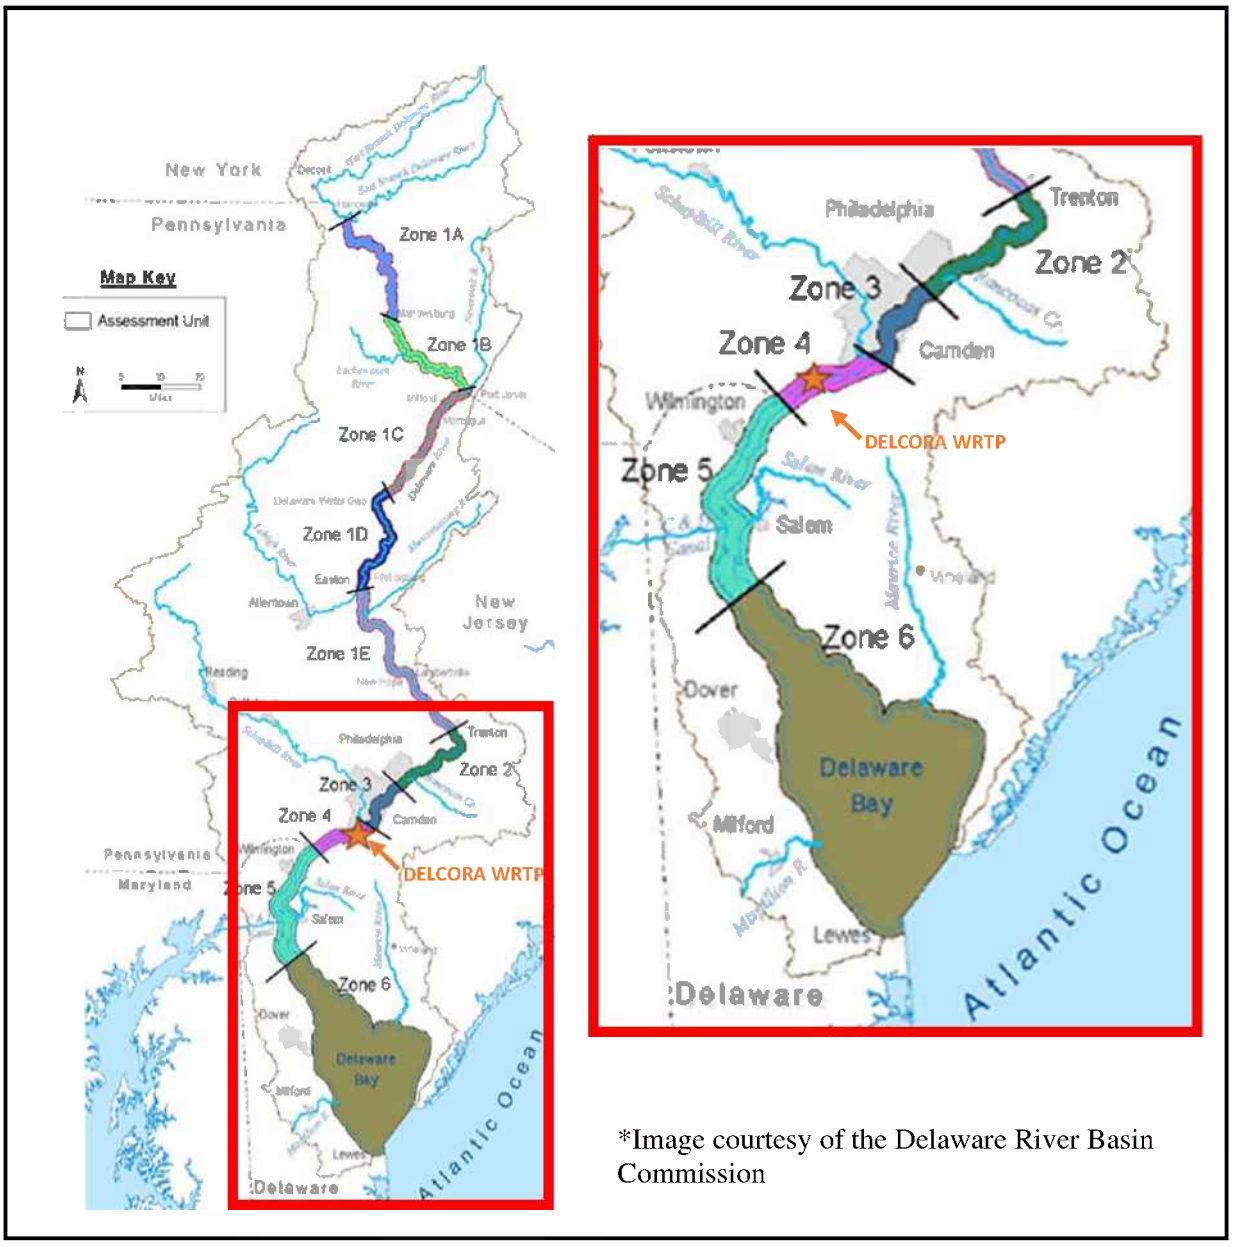

*Image courtesy of the Delaware River Basin Commission

Figure 5-2: Locations of Creek Elevation Measurements in Chester and Ridley Creeks

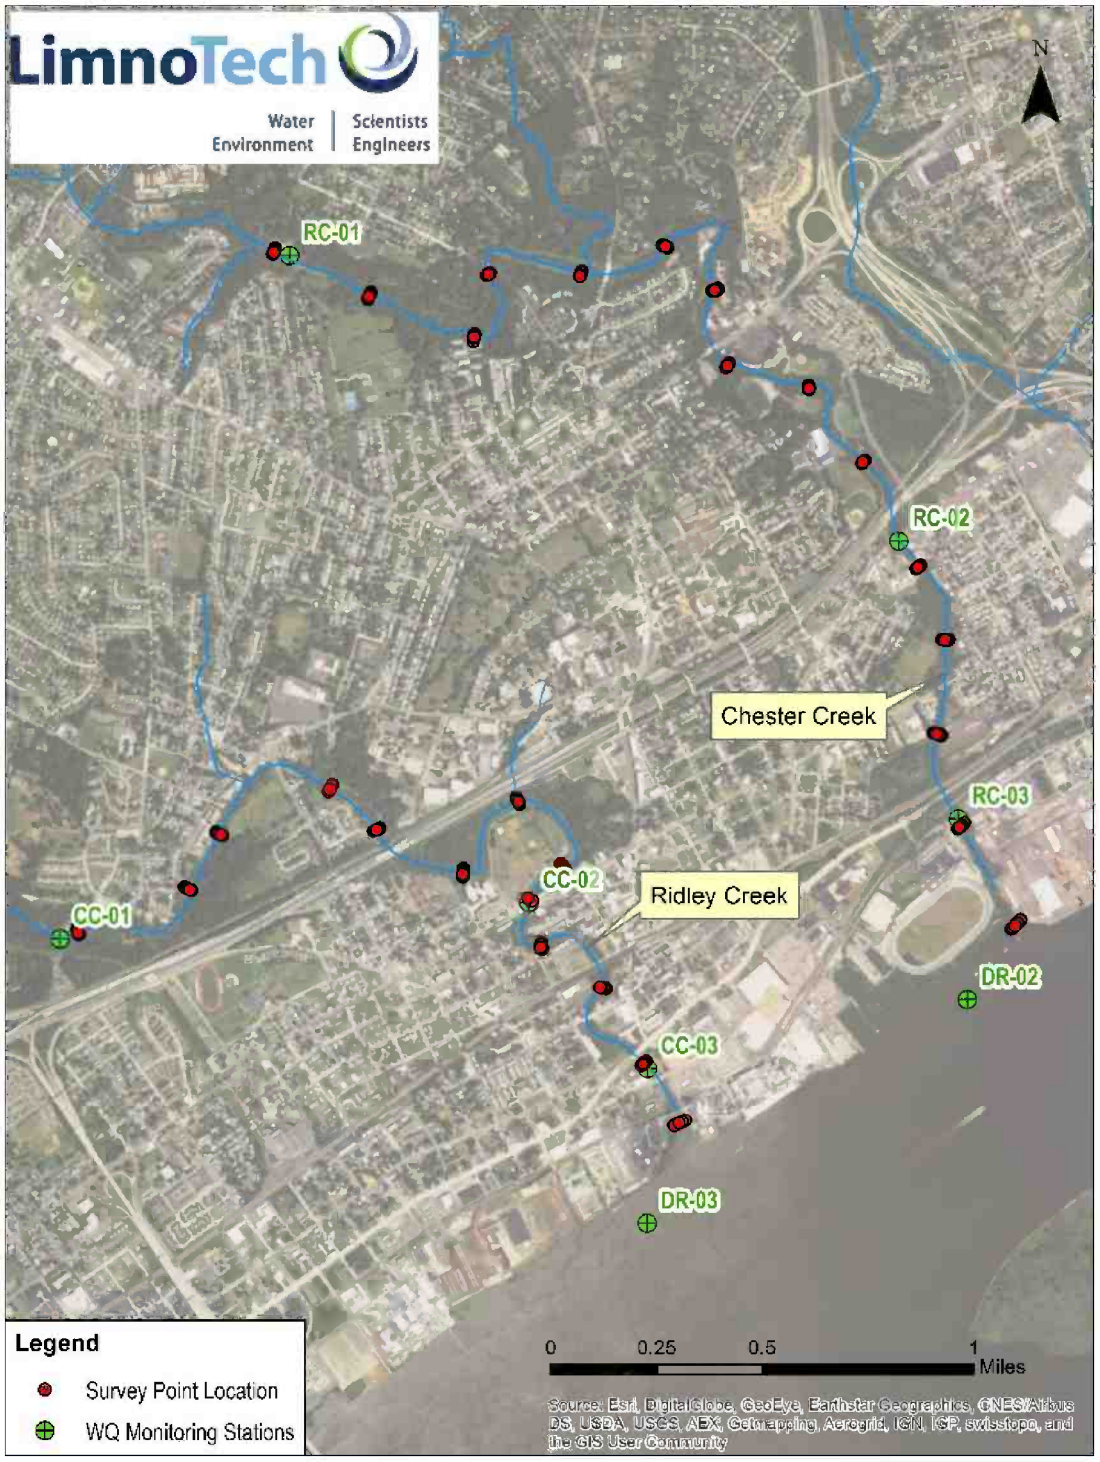

Figure 5-3: Comparison of Chester Creek bed elevation measurements

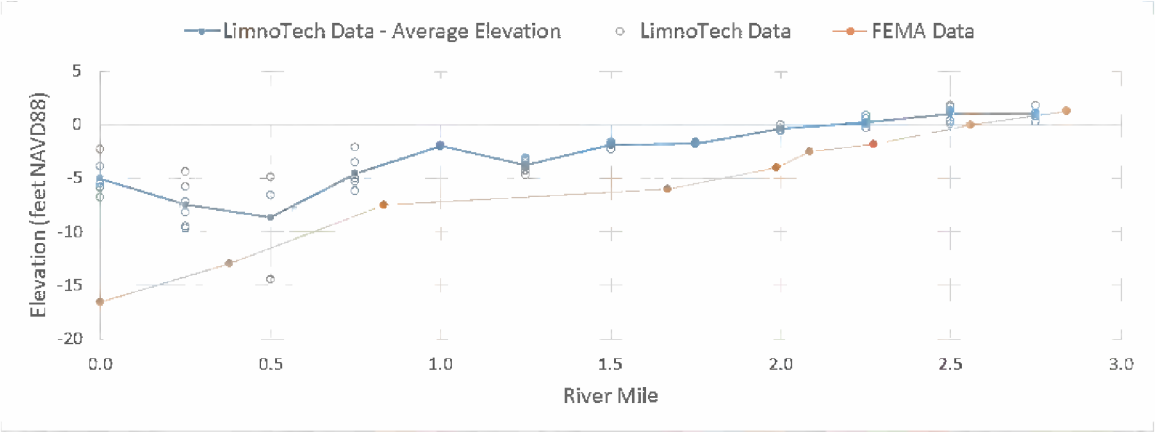

Figure 5-4: Comparison of Ridley Creek Bed Elevation Measurements

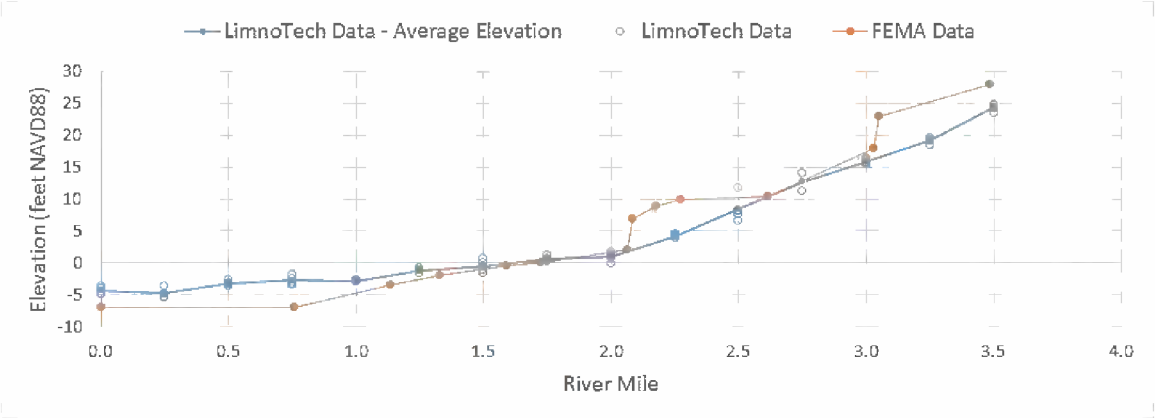


Higher creek bed elevations near the Chester Creek mouth are an indication that soft sediments have accumulated there since the 1970s. The highest observed peak flow in Chester Creek occurred a few years before the FEMA survey (in 1971, peak flow of 21,000 cfs) while recent peak flows have been significantly lower (average peak flow of 4,000 cfs in the last ten years) (USGS, 2017). Lower contemporary peak flows may have allowed for the accumulation of soft sediments in the lower reaches of Chester Creek.

Another significant observation from the LimnoTech data is that a pipe crossing near river mile 1.0 in Chester Creek created a high point in the creek bed profile. This high point acts to slightly reduce upstream water currents during lower flow conditions. This would tend to lengthen travel times of bacteria.

In Ridley Creek the LimnoTech data show a more constant bed slope between river miles 2.0 and 3.5 than the FEMA data. This is because low head dams existed in the 1970s near river miles 2.0 and 3.0, but are no longer in place. These dams previously acted to accumulate sediments in their shallow upstream pools, but when the dams were no longer present these accumulated sediments were likely washed away downstream.

These comparisons between the LimnoTech survey data, the historical FEMA data, and the NOAA tide gage, show consistency and provide confidence in the data collected. These comparison also help to identify locations where the creek bed has changed in the last several decades in ways that would influence creek hydraulics and pollutant transport.

The Delaware River bathymetric survey information was obtained online from National Oceanic and Atmospheric Administration (NOAA) website.

- NOAA, 2009. Hydrographic Survey H12149. Pennsylvania and New Jersey. Delaware River. Data obtained online at: https://www.ngdc.noaa.gov/nos/H12001-H14000/H12149.html
- NOAA, 2009. Hydrographic Survey H12150. Pennsylvania and New Jersey. Delaware River. Data obtained online at: https://www.ngdc.noaa.gov/nos/H12001-H14000/H12150.html

The survey was conducted in 2009, although other surveys conducted by NOAA over time (going back several decades) will also be used to construct the bathymetry datasets for the Water Quality Model. This information will serve to assist in determining tidal currents and mixing within the Delaware River Estuary as part of the Water Quality Modeling.

5.2 Watershed Drainage Basins

The Chester Creek and Ridley Creek watersheds extend from the mouth of the tributaries upstream through Delaware County and into Chester County, well beyond the boundaries of DELCORA's Model Area. The extent of the watersheds within Delaware County is illustrated in Figure 2-4, along with the boundaries of DELCORA's Model Area.

5.3 Pollutants of Concern

This section provides a summary of the current water quality in DELCORA's receiving waters based on DELCORA's efforts to identify Pollutants of Concerns, in order to meet the requirements of Section V.A.16.c of the Consent Decree. To satisfy this Consent Decree requirement, DELCORA submitted the *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016c), which was approved by PA DEP and US EPA on October 13, 2016. The remainder of Section 5 is based on this approved report.

DELCORA's CSOs discharge to three receiving waters - the Delaware River, the Chester Creek and the Ridley Creek – all of which are within the Delaware Estuary portion of the Delaware River Basin. As part of the *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016c), DELCORA conducted a literature review to determine the applicable water quality standards (WQS) for each of the three receiving water bodies, the designated uses for the water bodies, the primary causes of impairment, and the Total Maximum Daily Load (TMDL) status of the water bodies (if any).

Requirements of the USEPA's CSO Guidance Document

Section 2.5.3.3 of the USEPA's CSO Guidance document states that to assess the impacts of wet weather runoff, the water quality of the receiving waters should be understood for normal dry weather periods. The water quality data that is collected during dry weather conditions provides a basis for comparing the data collected during wet weather conditions. The CSO Guidance Document says:

> *"Receiving water monitoring should include identified parameters of concern. These parameters typically include those previously identified for combined sewage and CSO monitoring.*
>
> - *pH*
> - *BOD*
> - *TDS*
> - *TSS*
> - *Nutrients*
> - *Metals*
> - *Indicator bacteria*
>
> *Knowledge of the site-specific water quality concerns could expand the list to include dissolved oxygen, toxics, biological assessment, and sediment."*

5.4 Receiving Water Use Designations and Applicable Water Quality Standards

Information about the applicable water quality standards (WQS), the designated uses and the impairment status for the three receiving water bodies impacted by DELCORA's CSOs were obtained from the PADEP's 2014 Integrated Water Quality Monitoring and Assessment Report (or "303(d) list"), the Pennsylvania Code, the Delaware River Basin Commission's (DRBC's) Water Quality Regulations (WQRs) and from the DRBC's 2014 Delaware River and Bay Water Quality Assessment (DRBC, 2014).

5.4.1 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) list)

The primary source of information about the causes of impairment, and the Total Maximum Daily Load (TMDL) status of the water bodies (if any) is the 2014 PA Integrated Water Quality Monitoring and Assessment Report (PA Integrated Report), which satisfies Pennsylvania's requirement of both Section 303(d) and 305(b) of the Clean Water Act (CWA). The PA Integrated Report lists all impaired surface waters within Pennsylvania that are not attaining designated and existing uses, even after appropriate and required pollution control technologies have been applied. A TMDL is designed to reduce pollutant loads to impaired waters and enable these waters to meet water quality standards.

The Integrated Report uses a five-part categorization (lists) of water according to their use attainment status. The categories represent varying levels of use attainment, ranging from Category 1, where all designated water uses are met to Category 5, where impairment by pollutants required the development of a TMDL to correct. Each segment of the waterbody is placed into one of these five categories. "Impairment" of a receiving water body is indicated to exist for a particular parameter if the parameter appears in Categories 4A and 5, as they indicate the need for a TMDL in the receiving water body and the limiting of additional loadings for those parameters.

The PADEP's website explains the categories as follows:

- *Category 1:* *Waters attaining all designated uses.*
- *Category 2:* *Waters where some, but not all, designated uses are met. Attainment status of the remaining designated uses maybe unknown because data are insufficient to categorize a water body consistent with the states' listing methodology or may be impaired.*
- *Category 3:* *Waters for which there are insufficient or no data and information to determine, consistent with the state's listing methodology, if designated uses are met.*
- *Category 4:* *Waters impaired for one or more designated use but not needing a TMDL. States may place these waters in one of the following three subcategories:*
  - *Category 4A: TMDL is approved.*
  - *Category 4B: Expected to meet all designated uses within a reasonable timeframe (three years).*
  - *Category 4C: Not impaired by a pollutant.*
- *Category 5:* *Waters impaired for one or more designated uses by any pollutant and requiring the development of a TMDL. Category five includes waters shown to be impaired as the result of biological assessment used to evaluate aquatic life even if the specific pollutant is not known unless the state can demonstrate that non-pollutant stressors cause impairment or that no pollutant(s) causes or contribute to the impairment.*"

The Category 5 list constitutes the Section 303(d) list that the USEPA will approve or disapprove under the CWA. For the purposes of the determination of Pollutants of Concern, Categories 4A and 5 are the relevant categories as they indicate the need for a TMDL in the receiving water body and the limiting of additional loadings for those parameters. All of the lists are sorted by an 8-digit Hydrologic Unit Code (HUC) that is particular for the water body of interest. For DELCORA's drainage area, the HUC for the

Lower Delaware River (02040202) was used for searching the data in the PA Integrated Report for all three of DELCORA's receiving water bodies.

5.4.2 PA Code Title 25 §93.9g

The primary source of information for the Critical Use Designation for each section of the three receiving water bodies is 25 Pa. Code §93.9g – Drainage List. The relevant Critical Use Designations for DELCORA's receiving water bodies include Warm Water Fishes (WWF), Migratory Fishes (MF), Trout Stocking (TSF), and Water Contact Sports/Recreation (WC).

- The "WWF" designation indicates the maintenance and propagation of fish species and additional flora and fauna which are indigenous to a warm water habitat.
- The "MF" designation indicates the passage, maintenance and propagation of anadromous and catadromous fishes and other fishes which move to or from flowing waters to complete their life cycle in other waters.
- The "TSF" designation indicates maintenance of stocked trout from February 15 to July 31 and maintenance and propagation of fish species and additional flora and fauna which are indigenous to a warm water habitat.
- The "WC" designation indicates the use of the water for swimming and related activities.

5.4.3 DRBC's Water Quality Regulations and PA Code Title 25 §93.7

The applicable water quality standards for the three receiving water bodies are found in the Delaware River Basin Commission's Water Quality Regulations, and in Water Quality Criteria lists found in 25 Pa. Code §93.7 and §93.8c. For the Delaware River, the water quality standards are dictated by the DRBC's WQRs that have primacy over the standards in the PA Code. The water quality standards in the PA Code apply to the non-tidal portions of the Chester Creek and Ridley Creek, and to the Delaware River if there is no standard listed for a particular parameter in the DRBC's WQRs.

5.4.4 DRBC's 2014 Delaware River and Bay Water Quality Assessment

The DRBC's 2014 Delaware River and Bay Water Quality Assessment (DRBC, 2014) reports the extent to which waters of the Delaware River and Bay are attaining designated uses in accordance with Delaware River Basin Commissions' Water Quality Regulations for the period October 1, 2008 through September 30, 2013. The 2014 Assessment involves the comparison of key water quality parameters with the applicable DRBC water quality regulations. The states of Pennsylvania, New Jersey, Delaware and New York consider the DRBC's Assessment report as part of their determinations as to whether sections of the Delaware River should be listed on the state 303(d) list for a certain pollutant.

5.5 Delaware River

5.5.1 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) list)

The 2014 PA Integrated Water Quality and Assessment Report ("the 303(d) List") lists a 61.02 mile segment of the Lower Delaware River in Category 4A as having an approved TMDL for polychlorinated biphenyls (PCBs) from an unknown source related to its fish consumption use. The USEPA approved a

TMDL for PCBs for Zone 2 through Zones 5 in 2003, and a second PCB TMDL was approved for Zone 6 in 2006. The TMDLs for PCBs encompass the Delaware River Estuary and stretch from the mouth of the Delaware River upstream to the Trenton, NJ /Morrisville, PA Bridge. The segment of the Delaware River having an approved TMDL for PCBs is shown in yellow in the map in Figure 5-5, which was derived from the PADEP's eMapPA website.

While the Delaware River is impaired from PCBs, the PCBs are not normally associated with CSOs. Given this reason, and the fact that the PCB impairment begins well upstream of DELCORA's service area – PCBs were screened as not being a Pollutant of Concern (POC). Furthermore, the additional CSO sampling results from November/December 2015 showed that PCBs were found to be at a lower concentration than the Reporting Detection Limit (RDL). For this additional reason it was determined that PCBs are not associated with DELCORA's CSO discharges.

5.5.2 Designated Critical Uses and Specific Water Quality Criteria from PA Code

The Critical Uses for the Delaware River in the area of DELCORA's CSO discharges are designated in Pa. Code §93.9. All stretches of the Delaware River in this area are designated as Warm Water Fishes (WWF) (maintenance only) and Migratory Fishes (MF) (passage only). Additionally the Delaware River has a Water Contact (WC) designation downstream of River Mile 81.8, which is located directly adjacent to the City of Chester between CSO #009 and #011.

For WC-designated waters, 25 Pa. Code §93.7 establishes the following as the water quality criterion for fecal coliform bacteria:

- Fecal Coliform – A geometric mean of 200 colonies per 100 mL during the swimming season (May 1 through September 30) based on a minimum of five samples collected during a 30-day period. For the remainder of the year, the maximum fecal coliform level shall be a geometric mean of 2,000 colonies/100 mL based on a minimum of five samples collected during a 30-day period. There are no fecal coliform bacteria criteria for the Delaware River or tributaries that are not designated as WC waters or for Potable Water Supply (PWS).

For WWF and MF waters the WWF designation is the more restrictive of the two, and 25 Pa. Code §93.7 establishes the following additional standards for WWF waters:

- Dissolved Oxygen – The minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 5.5 mg/L
- Alkalinity – A minimum of 20 mg/L as CaCO3, except where naturally occurring conditions are less
- Ammonia Nitrogen – the maximum total ammonia nitrogen concentration (in mg/L) at all times shall be the numerical value given by un-ionized ammonia nitrogen (NH3-N) x (log-1[pKT-pH] + 1)
- Iron – 30-day average 1.5 mg/L as total recoverable
- pH – From 6.0 to 9.0 inclusive

Figure 5-5: Non-Attaining Streams and TMDL Streams within DELCORA's Service Area

- Temperature – A table is included within 25 Pa. Code §93.7 for maximum water temperatures in the receiving water body at various times of the year
- Total Residual Chlorine – Four-day average 0.011 mg/L; 1-hour average 0.019 mg/L

5.5.3 Designated Zone and Water Quality Regulations from the DRBC

25 Pa. Code §93.9 lists the DRBC regulations for Water Quality Zone 4 as exceptions to PA Code's specific water quality criteria. The DRBC's water quality regulations have primacy over the standards in the PA Code for the Delaware River.

The DRBC defines Zone 4 as that part of the Delaware River extending from R.M. 78.8 to R.M. 95.0, the Pennsylvania-Delaware state boundary line to the upstream side of the Philadelphia Navy Yard, including the tidal portions of the tributaries thereof. The DRBC states that the quality of Zone 4 waters shall be maintained in a safe and satisfactory condition for the following uses:

- Industrial water supplies after reasonable treatment
- Maintenance of resident fish and other aquatic life
- Passage of anadromous fish
- Wildlife
- Recreation - secondary contact above R.M. 81.8
- Recreation (all water-contact sports) below R.M. 81.8
- Navigation

The DRBC's Stream Quality Objectives for Zone 4 are as follows:

1. Dissolved Oxygen
   - 24-hour average concentration shall not be less than 3.5 mg/L.
   - During the periods from April 1 to June 15, and September 16 to December 31, the DO shall not have a seasonal average less than 6.5 mg/L.

2. Temperature shall not exceed:
   - 5°F (2.8°C) above the average 24-hour temperature gradient displayed during the 1961-66 period, or
   - A maximum of 86°F (30.0°C), whichever is less.

   (NOTE: The DRBC's 2014 Delaware River and Bay Water Quality Assessment states that *"atmospheric temperatures and meteorological conditions are strong drivers of water temperature. DRBC previously demonstrated that water temperatures are strongly liked to air temperatures, and that a notable increase in air temperatures is observable between the temperature gradient period (1961-1966) and the current period. At present, we [i.e., DRBC] lack the tools to determine which portion of the exceedance is attributable to potentially controllable anthropogenic thermal inputs, and which portion is due to metrological drivers beyond our control"*.

3. pH between 6.5 and 8.5 inclusive, unless outside this range due to natural conditions.

4. Phenols maximum 0.02 mg/l, unless exceeded due to natural conditions.

5. Threshold Odor Number not to exceed 24 at 60°C.

6. Synthetic Detergents. (M.B.A.S.). Maximum 30- day average 1.0 mg/L.

7. Radioactivity
   - Alpha emitters - maximum 3 pc/L (picocuries per liter);
   - Beta emitters - maximum 1,000 pc/L.

8. Bacteria
   - Fecal Coliform
     - Above R.M. 81.8: maximum geometric average 770 per 100 milliliters
     - Below R.M. 81.8: maximum geometric average 200 per 100 milliliters
   - Enterococcus
     - Above R.M. 81.8: maximum geometric average 88 per 100 milliliters
     - Below R.M. 81.8: maximum geometric average 33 per 100 milliliters

9. Total Dissolved Solids not to exceed 133% of background.
   (NOTE: The background TDS concentration is at present undefined, according to the DRBC's 2014 Delaware River and Bay Water Quality Assessment.)

10. Turbidity unless exceeded due to natural conditions.
    - Maximum 30-day average 40 units (NTU)
    - Maximum 150 NTU

11. Alkalinity between 20 and 120 mg/L.

12. Toxic Pollutants
    - Applicable criteria to protect the taste and odor of ingested water and fish are presented in the DRBC's WQRs Table 4.
    - Applicable freshwater stream quality objectives for the protection of aquatic life are presented in the DRBC's WQRs Table 5.
    - Applicable freshwater stream quality objectives for the protection of human health are presented in the DRBC's WQRs Tables 6 and 7.

5.5.4 DRBC Evaluation of Use Attainment Status

Table 5-1 presents a summary of Table 23 from the DRBC's 2014 Delaware River and Bay Water Quality Assessment for Zone 4 of the Delaware River. Zone 4 is the portion of the Delaware River directly impacted by DELCORA's CSO discharges and it extends from R.M. 95.0 to R.M. 78.8, the

Pennsylvania-Delaware state line including the tidal portions of the tributaries thereof. The extent of Zone 4 can be seen in Figure 5-1.

Table 5-1: Summary of the 2014 DRBC Integrated Assessment for Zone 4 of the Delaware River

Zone	Designated Use			
	Aquatic Life	Drinking Water	Recreation	Fish Consumption
4	NS	N/A	S	NS

Notes:
N/A - Not applicable
NS - The Designated Use is not supported
S - The Designated Use is supported

5.5.4.1 Water Contact Recreation

Table 5-1 shows that the designated use for Water Contact Recreation is being attained for the Delaware River below R.M. 81.8.

5.5.4.2 Aquatic Life

Table 5-1 shows that the designated use for Aquatic Life is not being attained. According to the DRBC's Assessment report (DRBC, 2014), *"the composite aquatic life assessment for 2014 yields a result of "Not Supporting" for all assessment units* (or zones). *It is important to note, however, that this result is largely driven by the requirement to categorize as not meeting criteria any assessment unit* (or zone) *with 1 exceedance plus 1 confirmatory exceedance."*

The DRBC's Assessment Report also states: *"Data showed multiple exceedances of aluminum acute and chronic freshwater objectives for the support of aquatic life in Zone 4. Of 35 surface water samples tested for aluminum in Zone 4 during the assessment period, 34 exceeded the chronic criterion and 8 exceeded the acute criterion at 21PA_WQX-WQN0182 near Marcus Hook, PA. No exceedances of aluminum were reported in Zones 2, 3, 5 and 6."* As part of the Recommendations for Future Action at the end of the report, the DRBC states that the *"exceedances of aluminum criteria in Zone 4 warrant further attention"*.

5.5.4.3 Fish Consumption

Table 5-2 shows that the designated use for Fish Consumption is not being attained. The DRBC's 2014 Delaware River and Bay Water Quality Assessment report states that their assessment criterion for fish consumption is based on the presence of fish consumption advisories from the four Basin states for the mainstem of the Delaware River. If a fish consumption advisory is present, this resulted in the DRBC making an assessment of "not supporting the designated use".

The Assessment report states that the violation criteria for PCBs is also supported by the presence of measureable concentrations of PCBs in the river that exceeded the surface water quality standard.

Twenty-two mainstem channel sites were sampled for PCBs in 2012, from Biles Channel near Trenton, NJ to the ocean boundary between Cape May and Lewis. It was found that all of the samples exceeded the current PCB water quality criteria of 16 µg/L for the protection of human health from carcinogenic effects.

The 2016 Commonwealth of Pennsylvania Fish Consumption Advisories for Zones 2, 3, and 4 of the Delaware River (Trenton, NJ/Morrisville, PA Bridge to PA/DE border) are as shown below in Table 5-2. These advisories identify PCBs as a pollutant of concern in fish tissue.

Table 5-2: PA Fish Consumption Advisory Summary for PCBs in the Delaware River

Fish Species	Meal Frequency	Contaminant
White Perch	1 meal/month	PCB
Flathead Catfish	1 meal/month	PCB
Channel Catfish	1 meal/month	PCB
Striped Bass: over 28 inches in length	1 meal/month	PCB
Carp	6 meals/year	PCB
American Eel	Do Not Eat	PCB

5.6 Chester Creek

5.6.1 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) list)

Chester Creek is listed in Category 5 of the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report as not meeting its recreational use due to pathogens, and for not meeting its aquatic life use due to siltation. "Pathogens" were listed in 2006 for three segments totaling 0.94 miles, and a TMDL is anticipated in 2019. The source for the pathogens is listed as "unknown", and these three stream segments are all well upstream of DELCORA's service area. Therefore it appears that the noted impairment of the Chester Creek due to pathogens is not related to DELCORA's CSO discharges.

"Siltation" was listed in 2014 for four segments of the creek totaling 18.41 miles, and a TMDL is anticipated in 2027. The source for the siltation was identified as "urban runoff/storm sewers". The majority of Chester Creek is not attaining its designated use for aquatic life due to siltation, and the vast majority of these impaired segments are located upstream of DELCORA's service area and are shown in red in the map in Figure 5-5. However, one of DELCORA's CSO outfalls does discharge to the furthest downstream segment of the Chester Creek that is impaired by siltation, which is Outfall #020 near Kerlin Street and Finland Drive. Siltation is measured by the water quality parameter Turbidity with units of Nephelometric Turbidity Units (NTU). The impacts of DELCORA's CSO discharges on the levels of Turbidity within the impaired sections of the Chester Creek have been evaluated further and are discussed herein.

For the Chester Creek, the 2014 PA Integrated Water Quality & Assessment Report shows the creek to be impaired for Aquatic Life from siltation, with Urban Runoff/Storm Sewers identified as the source. The impairment of the Chester Creek by siltation primarily occurs upstream of DELCORA's service area as shown in Figure 5-5. The term "Siltation" is not defined in the 2014 PA Integrated Water Quality & Assessment Report, but through various sources could be defined as:

> *"the pollution of water by fine particulate terrestrial clastic material, with a particle size dominated by silt or clay. It refers both to the increased concentration of suspended sediments, and to the increased accumulation (temporary or permanent) of fine sediments on bottoms where they are undesirable. Siltation is most often caused by soil erosion or sediment spill."*

There is not a water quality standard for "siltation", however, siltation can be considered as closely related to the widely used water quality parameter of "Turbidity", which is associated with CSO discharges. For this reason "Turbidity" was reviewed further as a surrogate for siltation to determine if it might be considered as a POC. Per available USEPA STORET data, the Turbidity concentrations on the Chester Creek was found to be below the WQS and therefore siltation was screened-out as not being a POC.

Category 4A lists a 0.81-mile segment of Chester Creek at its mouth that does not meet its designated use for fish consumption due to PCBs from an unknown source, and for which a TMDL for PCBs was issued in 2006. This is shown in yellow in the map in Figure 5-5 and is related to the TMDL for PCBs in the Delaware River Estuary.

5.6.2 Designated Critical Uses and Specific Water Quality Criteria from PA Code

The Critical Uses for the Chester Creek in the area of DELCORA's CSO discharges are designated in 25 Pa. Code §93.9. All stretches of the Chester Creek in this area are designated as Warm Water Fishes (WWF) (maintenance only) and Migratory Fishes (MF) (passage only). The same specific water quality criteria apply to the WWF and MF Critical Use designations for Chester Creek as apply for the Delaware River.

5.7 Ridley Creek

5.7.1 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) list)

Ridley Creek is listed in Category 5 of the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report as not meeting its aquatic life use due to siltation. The "Siltation" was listed in 2012 for five segments totaling 26.76 miles, and a TMDL is anticipated in 2025. The source for the siltation was identified as "unknown" or from "urban runoff/storm sewers".

In actuality, it appears that the majority of Ridley Creek is not attaining its designated use for aquatic life due to siltation, and the vast majority of these impaired segments are located well upstream of DELCORA's service area and are shown in red in the map in Figure 5-5. However, all of Ridley Creek within DELCORA's service area is shown as impaired for aquatic life due to siltation. As with the

Chester Creek, the Ridley Creek is listed in the 2014 PA Integrated Water Quality & Assessment Report as impaired for Aquatic Life from siltation, with Urban Runoff/Storm Sewers identified as the source.

However as noted for the Chester Creek, there is not a water quality standard for "siltation" but it can be considered as closely related to the widely used water quality parameter of "Turbidity", which is associated with CSO discharges. Per available USEPA STORET data, the Turbidity concentration for the Ridley Creek was found to be below the WQS and therefore siltation was screened-out as not being a POC.

5.7.2 Designated Critical Uses and Specific Water Quality Criteria from PA Code:

The Critical Uses for the Ridley Creek in the area of DELCORA's CSO discharges are designated in 25 Pa. Code §93.9. All stretches of the Ridley Creek in this area are designated as Warm Water Fishes (WWF) (maintenance only), Migratory Fishes (MF) (passage only), or Trout Stocking (TSF). The TSF stretch only applies in the sections of the Ridley Creek upstream of the Chestnut Street bridge crossing.

The same specific water quality criteria apply to the WWF and MF Critical Use designations for Ridley Creek as apply to the Chester Creek and Delaware River, except for the parameters of Dissolved Oxygen and Temperature – which are more stringent in the TSF stretch because of the high oxygen needs of trout.

Specifically, for TSF waters 25 Pa. Code §93.7 establishes the following additional standards:

- Dissolved Oxygen – For the period February 15 to July 31 of any year, the minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 6.0 mg/L. For the remainder of the year, the minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 5.5 mg/L.
- Temperature – A separate table is included within 25 Pa. Code §93.7 for maximum water temperatures in the receiving water body at various times of the year for TSF waters.

5.8 Pollutants of Concern in the Receiving Waters

As part of the requirements of the Consent Decree, DELCORA was tasked to identify the Pollutants of Concern associated with it CSOs into the Delaware River, Chester Creek and Ridley Creek. The result of these investigations were documented in DELCORA's *Identification of Sensitive Areas and Pollutants of Concern* Report. This section summarizes the Pollutant of Concerns that were determined for each of DELCORA's receiving waters.

5.8.1 Consent Decree Requirements for the Determination of POCs

For the Identification of Pollutants of Concern, Section V.A.11 of the Consent Decree specifically states:

> *"For each of its Receiving Waters, DELCORA shall review existing water quality data and recent PADEP CWA § 303(d) listings to identify POCs. Even if a water body has not been formally listed as out of compliance with its water quality standards and designated uses, if available data indicate such impairment exists and such impairment involves pollutants associated with CSOs, DELCORA shall consider the related pollutants to be POCs."*

5.8.2 Methodology for Determination of the POCs

In the effort to identify the Pollutants of Concerns related to its CSO discharges, DELCORA reviewed the 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) List), the historic sampling data for the influent to the Western Regional Treatment Plant, the USEPA's Storage and Retrieval (STORET) Data repository, historic water quality sampling data from the Chester and Ridley Creeks, and additional sampling results from the CSOs that were taken in November and December of 2015.

For the identification of the POCs, DELCORA took an inclusive approach to determine that all relevant water quality parameters were appropriately considered and evaluated. The first step was to develop a comprehensive list of the overall "Parameters Considered", which was then further evaluated and refined to determine the list of the applicable POCs. Development of the list of Parameters Considered was meant to cast a wide net as the first step towards identifying any parameters that might possibly be of concern.

The initial list of the Parameters Considered was compiled from six (6) primary reference sources from the USEPA, PADEP and the DRBC. The Parameters Considered list initially consisted of those specific parameters listed in the USEPA's CSO Guidance Document. Additional parameters were added from the parameters requiring sampling per DELCORA's NPDES permit, from the PA Code's specific water quality criteria for DELCORA's three receiving water bodies, from the DRBC's Water Quality Regulations for Zone 4 of the Delaware River, from the 2014 PA Integrated Water Quality Monitoring and Assessment Report (a.k.a. "303(d) List"), and from the DRBC's 2014 Delaware River and Bay Water Quality Assessment report (DRBC, 2014). Once the initial list of Parameters Considered was developed, additional parameters were added onto the list if they had been detected during the historical sampling data of the influent to the WRTP, and in the existing CSO monitoring data (as required by the NPDES permit). One year's worth of DELCORA's plant influent historical sampling data from September 1, 2014 through September 1, 2015 was collected and analyzed to identify additional Parameters Considered.

To help narrow the list of the Parameters Considered additional wet weather sampling at the CSOs was required. The additional sampling occurred on November 19th and December 1st, 2015 at the three CSO locations DELCORA is required to regularly monitor; the Chester Pump Station wet well, CSO #018 at Sun Drive and Hancock Street, and at CSO #019 at 14th Street and Crozer Hospital. The CSO sampling results were used to confirm if the Parameters Considered were actually prevalent in DELCORA's CSO discharges. If a parameter on the Parameters Considered list was not detected in the November and December 2015 wet weather sampling of the CSOs, those parameters were not considered further as POCs.

For each of the remaining Parameters Considered, the receiving stream water quality data from the USEPA STORET data warehouse for the years 2010 through 2015 was compared to the applicable WQS to check for exceedances. Both the acute and chronic conditions for the Parameters Considered were reviewed, where applicable, to determine if there had been exceedances of the applicable water quality standards. The segments of the Delaware River, Chester Creek and Ridley Creek have unique water quality standards that apply to them depending on the regulating authority, their designated uses, and the specific location within the waterbody. The Delaware River was broken down into two sections for the evaluation; one for the Delaware River upstream of R.M 81.8 ("upper Delaware") and the second for the Delaware River downstream of R.M 81.8 ("lower Delaware") based on the Water Contact Recreation

designated use for the Delaware River below R.M. 81.8 and the more stringent requirements associated with primary contact.

Once the Parameters Considered list was narrowed using the November/December 2015 additional sampling results at the CSOs, the parameters remaining on the narrowed list of Parameters Considered were further evaluated to determine if they are Pollutants of Concern. A parameter was considered to be a "Pollutant of Concern" for a water body if more than 10% of the samples taken exceeded the applicable water quality standard. This criteria was based on guidance provided by the USEPA, which recommends a "greater than 10% exceedance percentage" for determining that waters only partially meet their designated use for aquatic life support. If a parameter was determined to be a POC, it is to be further investigated through additional receiving water quality monitoring and modeling. A parameter was considered to be only a "Parameter of Potential Concern" (POPC) if 2 – 10% of the samples taken exceeded the applicable water quality standard, and any identified POPCs are to continue to be monitored and re-evaluated should the monitoring show their concentrations to increase over time.

5.8.3 Summary of the Identified POCs for each Receiving Water

Three (3) POCs were determined and these include Fecal Coliform bacteria, Enterococcus bacteria and E. coli bacteria. These three POCs apply to each of DELCORA's three receiving waters; the Delaware River, Chester Creek and Ridley Creek. These three POCs are parameters typically associated with CSO discharges, and the list of the POCs is summarized below. The concentrations of these identified POCs in the Delaware River, Chester Creek and Ridley Creek have been further investigated through the receiving water quality monitoring and modeling, subsequently described in Section 6 of this report.

The identified POCs for each of the receiving water bodies are listed below.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria
- For the upper Delaware River (Upstream of R.M. 81.8)
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria
- For the Chester Creek
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria
- For the Ridley Creek
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria

No Parameters of Potential Concern were identified.

5.9 Identification of Sensitive Areas

This section presents information on the identification of Sensitive Areas to meet the requirements of Section V.A.16.b of the Consent Decree, and Paragraph II.A.C.1.b of the USEPA's CSO Control Policy. The information in this section is summarized from the Sensitive Areas investigation originally presented in DELCORA's report *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016c).

5.9.1 Regulatory Requirements

5.9.1.1 Consent Decree Requirements

For the Identification of Sensitive Areas, Section V.A.11 of the Consent Decree states:

> *"For each of its Receiving Waters, DELCORA shall contact appropriate agencies, access available data sources, and collect additional data as necessary to identify Sensitive Areas. DELCORA shall fully document all such contacts and the associated responses, and all additional investigations carried out to identify Sensitive Areas. DELCORA shall also identify any additional areas that, while not Sensitive Areas, have been identified by DELCORA as being appropriate for prioritization ("Priority Areas")."*
>
> *Additionally, "For each of its Receiving Waters, DELCORA shall conduct community outreach and appropriate studies to determine whether and to what extent primary contact recreation is occurring in each Receiving Water, and shall fully document its outreach and study methods, and its findings."*

5.9.1.2 Requirements of the USEPA's CSO Control Policy and Sensitive Areas Definition

The USEPA's CSO Control Policy (59 Fed Reg 75 [April 19, 1994]: 18688-18698) "expects a permittee's long-term CSO control plan to give the highest priority to controlling overflows to sensitive areas" (Section II.C.3). The CSO Control Policy states the six (6) criteria for defining an area as a "Sensitive Area" include:

1. Designated Outstanding National Resource Waters
2. National Marine Sanctuaries
3. Waters with threatened or endangered species and their habitat
4. Waters with primary contact recreation
5. Public drinking water intakes or their designated protected areas
6. Shellfish beds

The CSO Control Policy states that if Sensitive Areas are present and impacted, the LTCP should include provisions to:

- Prohibit new or significantly increased overflows
- Eliminate or relocate overflows wherever physically possible and economically achievable
- Treat overflows where necessary
- Where elimination or treatment is not achievable, reassess impacts each permit cycle

Sensitive Areas should be considered prior to the evaluation of CSO control alternatives. This allows a CSO community to identify and estimate costs for controls that could eliminate or relocate CSOs from Sensitive Areas where pollutant loadings pose a high environmental or public health risk and where control efforts should be focused.

5.9.1.3 Priority Areas Definition

The term "Priority Areas" is not specifically defined by the USEPA in the Consent Decree nor in the CSO Control Policy or Guidance Document. For the purposes of this report, the term "Priority Areas" is defined as follows:

> *"Areas having some environmental significance but not to the level of "sensitive areas" as defined in the federal CSO Control Policy. These priority areas may include: public access areas (i.e., near marinas, schools, playgrounds, parks, or athletic fields); or use of shallow streams for recreational activity, with something less than full contact (i.e., wading)".*

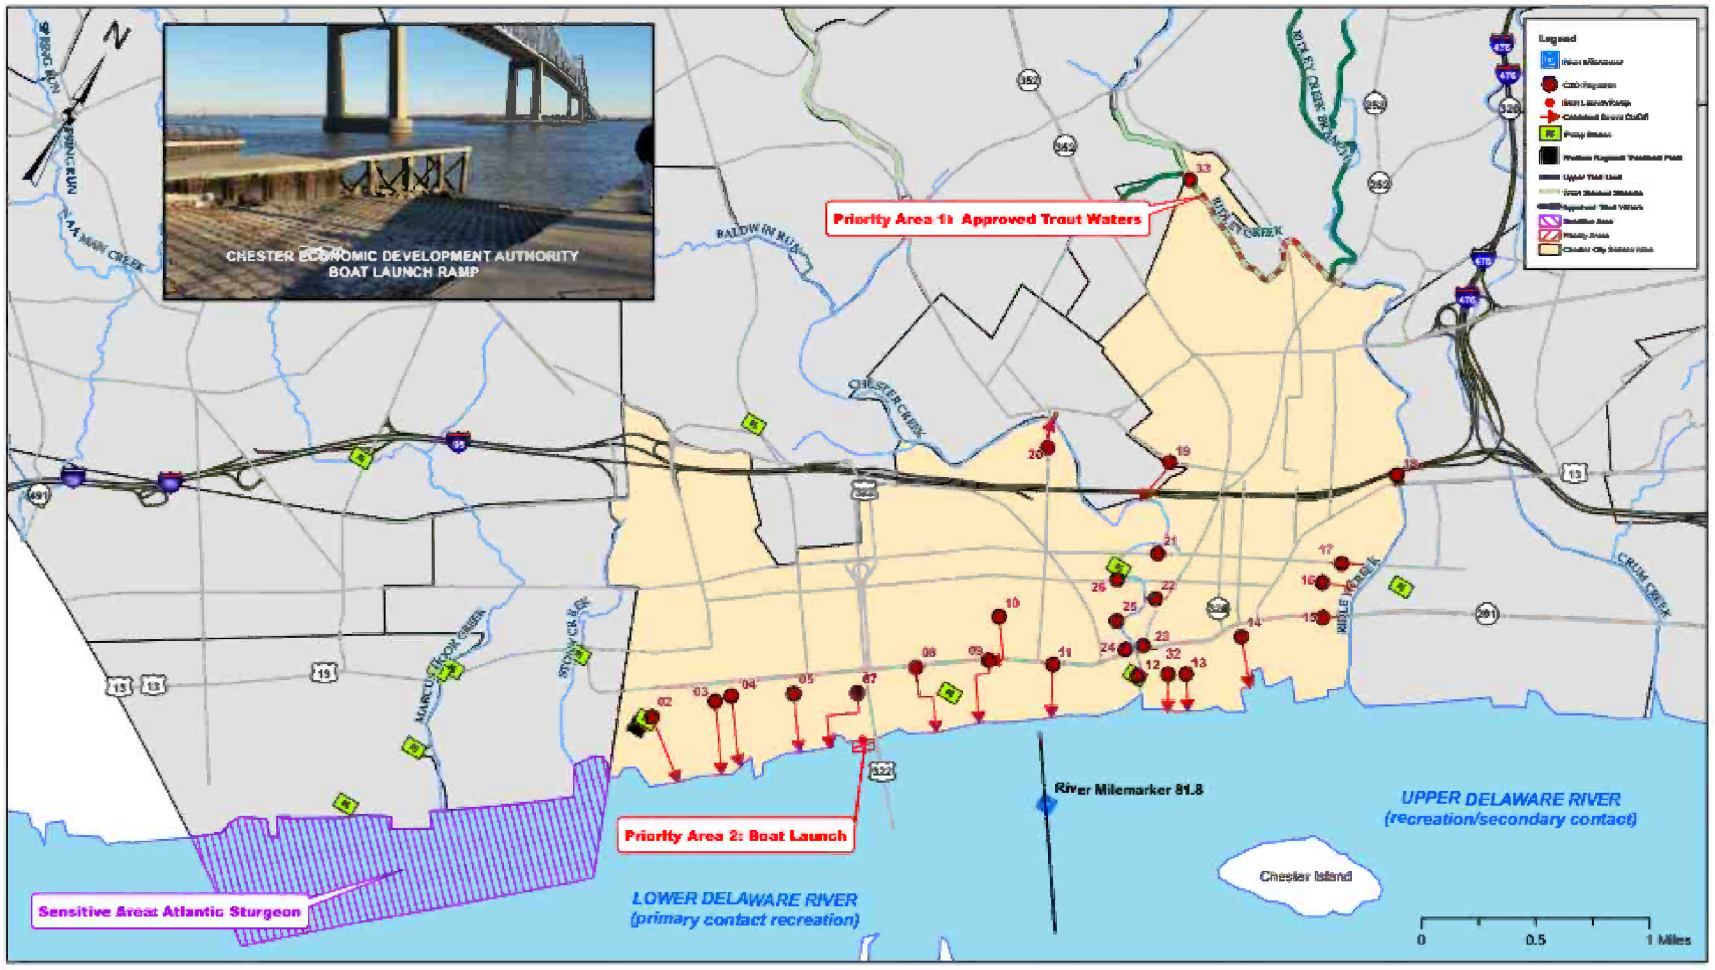
5.9.2 Summary of Sensitive and Priority Areas

The six criteria for Sensitive Areas identified in the CSO policy were evaluated for the Delaware River, Chester Creek and Ridley Creek within DELCORA's service area including reaches upstream of the CSOs. Special consideration was given to areas downstream and within the tidal influence of DELCORA's CSOs as any potential Sensitive Areas within hydraulic proximity to outfalls that may be impacted by their discharge. A comprehensive review of online databases, correspondence with regulatory agencies and local environmental organizations, and responses to the public survey was conducted to identify potential Sensitive Areas and Priority Areas within the CSS portion of the collection system. A summary of the findings for areas within the project boundary is presented below. A map of the sensitive and priority areas is shown in Figure 5-6. Additional details can be found in the report *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016c).

5.9.2.1 Summary of Sensitive Areas

The habitat for year-of-young Atlantic Sturgeon downstream of CSO #002 in the Delaware River meets the Sensitive Area criteria for Endangered or Threatened species. The Atlantic Sturgeon is listed as a threatened species by the US Fish and Wildlife Service with documented habitat in the Delaware River downstream approximately one-half mile downstream of DELCORA's most southern outfall.

Figure 5-6: Sensitive and Priority Areas



There are no Outstanding National Resource Waters nor National Marine Sanctuaries within the project area. Shellfish beds are located well downstream of the CSO locations and are outside the project boundaries. There are numerous drinking water intakes in the geographical area but none are located in close proximity downstream of DELCORA's CSOs on the Delaware River. No drinking water intake locations were found that meet the criteria of a Sensitive Area.

5.9.2.2 Summary of Priority Areas

Priority Areas include areas having some environmental significance but not to the level of "Sensitive Areas" as defined in the federal CSO Control Policy. Two Priority Areas were identified:

- Approved trout waters in Ridley Creek
- Chester Economic Development Authority's boat launch in Chester City

The northern reaches of Ridley Creek within DELCORA's service area are designated as Approved Trout Waters and Trout Stocked Streams. The portion of the approved trout waters from CSO #033 downstream to Chestnut Street (see Figure 5-6) is considered a Priority Area because of this special environmental use.

The boat launch located between CSO #007 and #008 along the Delaware River is located within the portion of the waterbody rated for primary contact. The boat launch is considered a Priority Area due to its location to CSO #007 and #008.

5.9.2.3 Other Considerations

Bald eagles are known to nest in the vicinity of the project area. While the Bald Eagle has been removed from the Federal list of threatened and endangered species, the Bald Eagle along with the Golden Eagle continues to be protected under the Bald and Golden Eagle Protection Act (BGEPA) and the Migratory Bird Treaty Act (MBTA). These Acts prohibit anyone to "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, destroy, molest, disturb, or otherwise harm eagles, their nests, or their eggs". Under the BGEPA, "disturb" means to agitate or bother a Bald or Golden Eagle to a degree that causes, or is likely to cause, based on the best scientific information available: (1) injury to an eagle; (2) decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior; or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior. Since the Bald Eagle has been removed from the Federal list of threatened and endangered species, the Sensitive Area criteria for Threatened or Endangered Species does not apply to the project study area. However, it is acknowledged that these species require special consideration. During the development of CSO abatement alternatives, the project will be evaluated for project size, location and layout in order to comply with the BGEPA and MBTA.

Section 6 Collection of Water Quality Data

6.1 Background

The USEPA CSO Control Policy Section II.C.4 states that the long term CSO control plan should adopt one of the two approaches, Presumptive or Demonstration Approach, for CSO controls sufficient to meet CWA requirements. The DELCORA *Alternatives Evaluation Approach Report* (Greeley and Hansen, 2016b) was submitted to the USEPA and the PADEP in April 2016 proposing to utilize the Demonstration Approach for the DELCORA receiving streams. The USEPA approved this report thereby approving the demonstration approach for each receiving stream in October 2016.

Consent Decree requires that if DELCORA utilizes the Demonstration Approach in one or more of its Receiving Waters, then it is to establish a Monitoring Program to collect any additional data needed to facilitate the development, calibration, and validation of the Receiving Stream Water Quality Modeling Program, once the existing data have been assessed. The calibrated and validated Water Quality Model will be used to evaluate Typical Hydrologic Period in-stream conditions for each identified Pollutant of Concern, previously identified in DELCORA's *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016c).

This section presents the results of the Water Quality Monitoring Program and includes water quality data collected from CSO discharges, storm water discharges, and from the three receiving waters. The Water Quality Monitoring Program was run concurrently with the Rain fall and Flow Monitoring Program in the spring of 2017. The goal of this program was to collect water quality data for the calibration and validation of the Water Quality receiving stream model. The final sampling results analysis is being conducted at this time and will be included in the final Water Quality Sampling Report and the final Water Quality Modeling Report to be issued August 2017 and February 2018 respectively. This Section also includes summary information previously presented in DELCORA's *Water Quality Monitoring and Modeling Work Plan* (Greeley and Hansen, 2017a) and *Water Quality Monitoring and Modeling Quality Assurance Project Plan* (Greeley and Hansen, 2017).

6.2 Regulatory Requirements

6.2.1 Consent Decree Requirements

Paragraphs V.A.10.e and V.A.10.f of the Consent Decree require that the development of the LTCP include:

V.A.10.e.	*Develop and implementation of a Water Quality Model*
V.A.10.f	*Characterization of the service area and the Receiving Waters as required by CSO Control Policy Paragraph II.C.1 and associated guidance.*

Consent Decree Paragraph V.A.15.a.(iv) specifically requires that:

> *"For each water body in which the Demonstration Approach is to be used, the Water Quality Model Plan shall address:*
> *i. Background, Scope and Purpose, Description of System;*
> *ii. Water quality modeling software to be employed;*
> *iii. Model configuration and development, including reaches to be modeled, and segmentation and boundary conditions;*
> *iv. Calibration and validation (dry weather and wet weather, including events and data to be employed, detailed information regarding all additional data collection activities (if needed), quantitative and qualitative calibration criteria, and utilization of H&H Model outputs;*
> *v. Use of the Water Quality Model to evaluate Typical Year instream conditions for each identified pollutant of concern;*
> *vi. Schedule for model development and implementation, including integration into LTCP development consistent with other dates required pursuant to the Consent Decree."*

The Consent Decree further specifies that within sixty (60) days after the approved Water Quality Model Plan is fully implemented according to the schedule included therein, DELCORA shall submit to EPA and PADEP a Water Quality Model Report for review and approval which shall specifically address each item set forth in Paragraph 15(a)(i)-(vi). Per the Water Quality Model Work Plan schedule, the Water Quality Model Report will be submitted February 2018 and will address the items mentioned above including Water Quality Modeling sampling results and assessment.

6.3 Overview of Historical Water Quality Monitoring

The Water Quality Monitoring Program (WQMP) was designed to collect data that will be used to assess water quality concerns identified in the Delaware River watershed and its tributaries, Chester Creek and Ridley Creek, in the vicinity of Chester, PA. Pollutants of concern (POCs) are identified in the *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016c) which was approved by US EPA on October 13, 2016. Table 6-1 below lists the POCs that were identified for the receiving streams and were approved for further investigation through water quality monitoring and modeling. The POCs are *Fecal coliform, Escherichia coli (E. coli)*, and *Enterococcus* and are the primary focus of the WQMP.

Table 6-1: List of Pollutants of Concern (POC)

No.	Upper Delaware River		Lower Delaware River		Chester Creek		Ridley Creek	
Pollutants of Concern (>10% of observed samples exceed WQS)								
1	Fecal Coliform[b]	100%	Fecal Coliform[b]	100%	Fecal Coliform[a],[b]	100%	Fecal Coliform[a],[b]	100%
2	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%
3	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%

[a] Based on historical sampling conducted in 2010 upstream and downstream of CSO outfalls only on Chester and Ridley Creeks.

[b] Fecal Coliform and Enterococcus are listed as POCs due to both being parameters typically associated with CSOs.

[c] DRBC regulations are available for Enterococcus and it is typically associated with CSOs and therefore it is included as a POC. However, in consultation with PADEP Enterococcus could be replaced with E. coli bacteria in the future (based on the anticipation that national standards on E. coli will be adopted in Pennsylvania) and therefore E.coli is also included as a POC.

In completing the initial step of characterizing the watershed, historical data was compiled, reviewed and assessed to determine the need to augment existing data to address the watershed issues identified. This review indicated that one of the POCs, *E. coli*, has not been sampled in all the receiving waters and the data that have been collected for the remaining POCs were of insufficient frequency and spatial density to be useful in the modeling process.

6.3.1 Historic Water Quality Sampling

The Water Quality Model requires robust flow and water quality datasets to build confidence in its use as a tool for CSO planning. Data are needed in the modeled receiving waters for use in model calibration and validation as well as for the predominant wet weather sources, such as DELCORA's CSOs and the City of Chester's MS4 runoff to estimate pollutant loadings to the model. The existing water quality data were reviewed for their adequacy in meeting the data needs of the water quality model for the POCs (fecal coliform, *E. coli*, and *Enterococcus*). The review indicated that Chester Creek and Ridley Creek have limited POC data. Although the Delaware River has more extensive POC data, it lacks the temporal frequency needed to characterize wet weather impacts from DELCORA's CSOs.

It would have been difficult to constrain the Water Quality Model's representation of DELCORA's sources on the receiving waters without additional monitoring data designed specifically for calibrating and validating a robust water quality model. Existing flow data were also reviewed for adequacy; reports of mean daily stream discharge are available from several stream gages along the Delaware River and in tributaries near the DELCORA service area, ranging from as early as 1912 to the present. The existing flow and water quality data are described in this section.

Flow data for the Delaware River and tributaries in the DELCORA service area were obtained from the USGS National Water Information System. Reports of mean daily stream discharge were

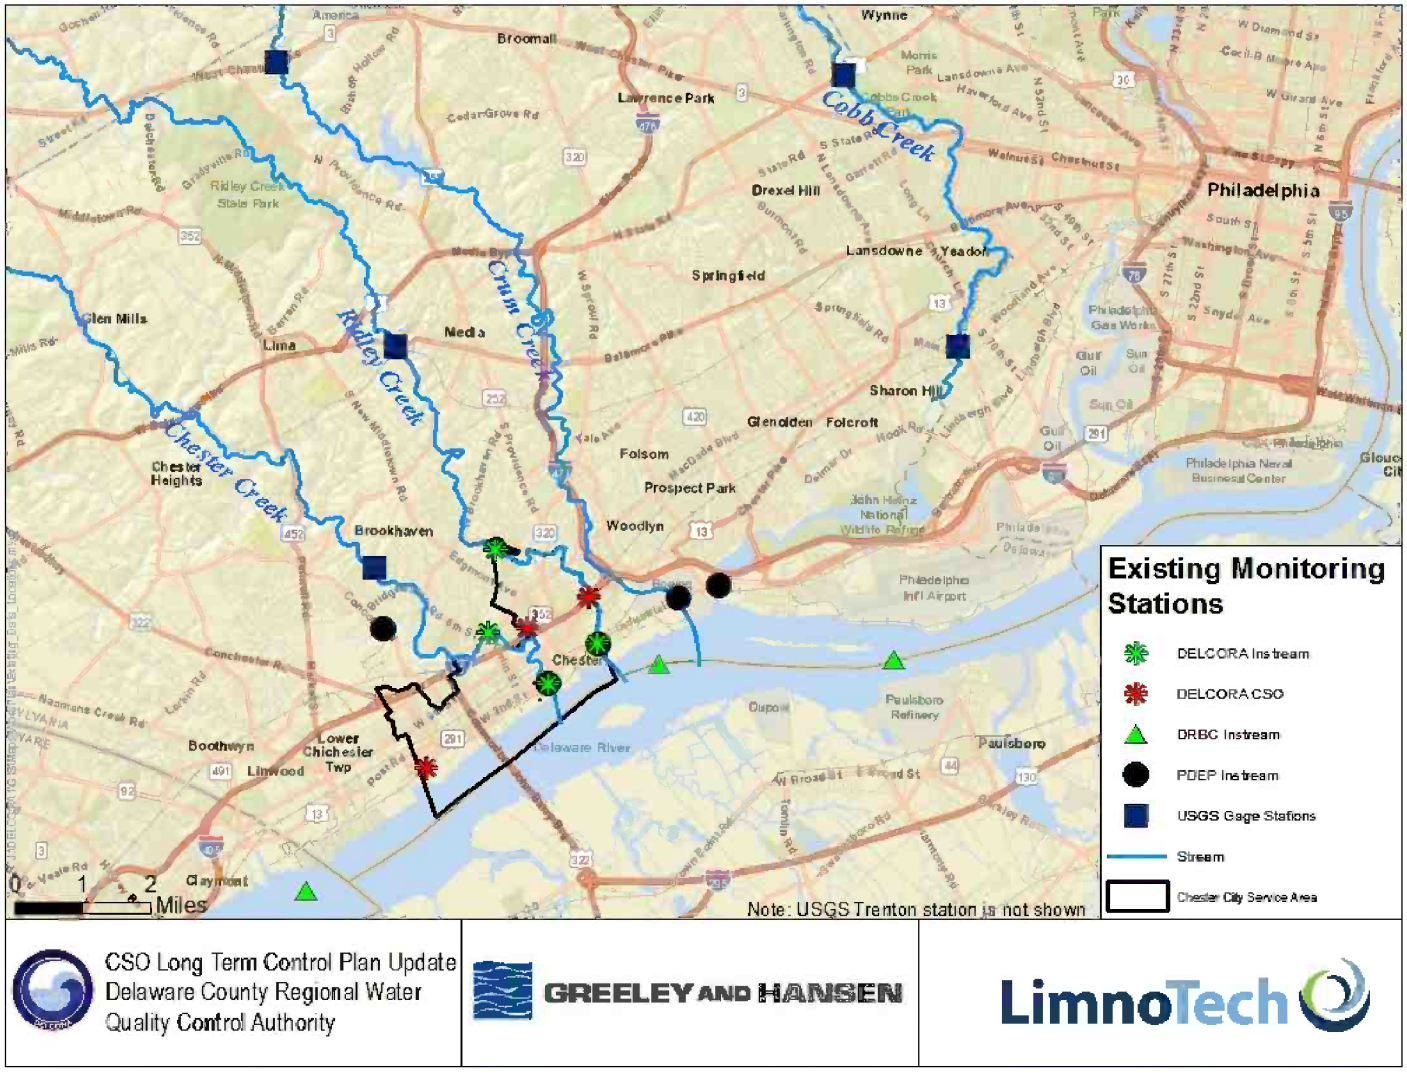
available from five stream gages in DELCORA service area measuring daily mean discharge: Crum Creek near Newtown Square, PA (1980-2016); Chester Creek near Chester, PA (1931-2016); Ridley Creek near Media, PA (1986-2016); Cobbs Creek at U.S. Highway No. 1 at Philadelphia, PA (1964-2016); and Cobbs Creek at Mt. Moriah Cemetery, Philadelphia, PA (2005-2016). Though not in service area, mean daily discharge data were also obtained from the gage at the Delaware River at Trenton, NJ (1912-2016) because it is expected that these data will be used to inform the upstream boundary for the hydraulic portion of the water quality model. The USGS Pennsylvania Water Science Center has conducted water quality sampling at various points in the state. However, none of their sampling locations are near to the DELCORA service area or local waterways.

Monthly effluent data from DELCORA's WWTP are available from the Pennsylvania Department of Environmental Protection's (PADEP) eDMR website (*www.dep.pa.gov/edmr*). Reported data include monthly geometric mean and instantaneous maximum values for fecal coliform from 2009 through 2016. PADEP also monitors water quality of tidal streams that empty into the Delaware River, through the Pennsylvania Water Quality Tributary Project funded by the Delaware River Basin Commission (DRBC). This program monitored for fecal coliform levels in Chester Creek, Ridley Creek, Darby Creek, Crum Creek, and others twice annually from 2007-2010. PADEP also operates the PA Surface Water Quality Monitoring Network, through which Baldwin Run (a tributary to Chester Creek) was sampled monthly for fecal coliform from 1998-1999.

The Delaware River Basin Commission operates its Boat Run program to monitor ambient, sampling for *E. coli*, *Enterococcus*, and fecal coliform at various sites along the Delaware River (Figure 6-1). Samples were collected from each station between one and three times each month from March through November every year since 1999. Through this program, data are available at three sites near DELCORA: Eddystone (2005-2016), Paulsboro (1999-2016), and Marcus Hook (1999-2016).

Since 2009, DELCORA has also done their own sampling at CSO outfall sites and in receiving waters. In 2010, a survey was conducted to measure fecal coliform levels in Ridley and Chester Creeks during wet and dry weather. There were two sample sites in each creek, and over the course of the study, six surveys were conducted. Four surveys occurred during dry weather, one during a wet event, and one during a wet event after a storm. During each survey, one sample was collected at each site. In 2009, DELCORA began sampling in the CSO system as required by their NPDES permit. Four outfalls and pump stations were sampled once annually for fecal coliform from 2009-2011, and three outfalls were sampled once annually for fecal coliform from 2012-2014. In 2015, four outfalls and pump stations were sampled for fecal coliform and *Enterococcus*, on three separate occasions. *E. coli* was not measured in any of these surveys.

Figure 6-1: Historical Flow and Water Quality Sampling Locations Near DELCORA Service Area



CSO Long Term Control Plan Update
Delaware County Regional Water Quality Control Authority

GREELEY AND HANSEN

LimnoTech

The extent of the historical water quality data and its adequacy to support the Water Quality Model development and calibration can be summarized as follows:

- Some CSO water quality data had been collected but mostly for fecal coliform. There were no CSO data for *E. coli*. Another limitation in the CSO data is that the CSO samples did not coincide with in-stream sampling, making it difficult to directly link CSO loads to in-stream impacts.
- No water quality sampling for the POCs had been done of the stormwater runoff in the separated areas of the DELCORA service area.
- The Delaware River had the most data of the receiving waters and it had data for all three POCs. However, the data were collected at regular intervals, independent of weather condition, and typically only one sample per location per survey was collected. These periodic sampling events do not provide enough data to characterize DELCORA loads on the river.
- The tributaries (Chester Creek and Ridley Creek) have been sampled sporadically and rarely within the tidal zone adjacent to DELCORA's service area. Wet weather data collected by DELCORA, consisting of only one sample per event, were not sufficient to characterize the magnitude and duration of the POCs' pollutographs over a storm event. Data are most robust for fecal coliform. There was less data for *Enterococcus* and none for *E. coli*. In addition, no sampling had been conducted in these tributaries since 2010.

DELCORA's Water Quality Monitoring Program conducted during Spring 2017 builds on the water quality sampling that had already been done while addressing the limitations identified in the historical data. The WQMP included a comprehensive monitoring assessment of all of the POCs to characterize loads and in-stream conditions, and these data were used to inform the Water Quality Model development, calibration and validation.

There has not been routine, on-going monitoring for the pollutants of concern in the tributary waterways adjacent to the DELCORA service area. The Delaware River Basin Commission samples the Delaware River near Chester approximately once a month between April and October. The analysis of these samples includes fecal coliform, *E. coli*, and *Enterococcus*, which are the pollutants of concern (POCs).

6.4 Overview of the Water Quality Monitoring Program

6.4.1 Water Quality Monitoring Objectives

The Water Quality Monitoring Program (WQMP) is designed to collect data that will be used to develop and calibrate watershed and receiving water quality models that will be used to assess water quality concerns for the POCs identified in the *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016c). The report identified three indicator bacteria (fecal coliform, *Escherichia coliform* (*E. coli*), and enterococcus) as pollutants of concern (POC) that are potentially impacting receiving water quality during CSO discharges in all three of the receiving waters (Delaware River, Chester Creek and Ridley Creek).

Existing water quality data provides insight into the conditions in the river and streams in the project area but are of insufficient frequency and spatial density to fully support the modeling process. In addition, *E. coli*, one of the identified POCs, was not monitored in the available data. The water quality monitoring objectives are to collect water quality data for the POCs during dry and wet weather event periods that can be used to characterize the bacteria sources in the Delaware River watershed in the vicinity of the City of Chester, PA, and to calibrate and validate the Water Quality Model, consistent with the Consent Decree requirements in Paragraph V.A.15.a. Additional in situ parameters that included salinity, temperature and conductivity were collected to inform the development of the Water Quality Model.

The collection of new water quality data was required to address the shortcomings of the historical water quality data by:

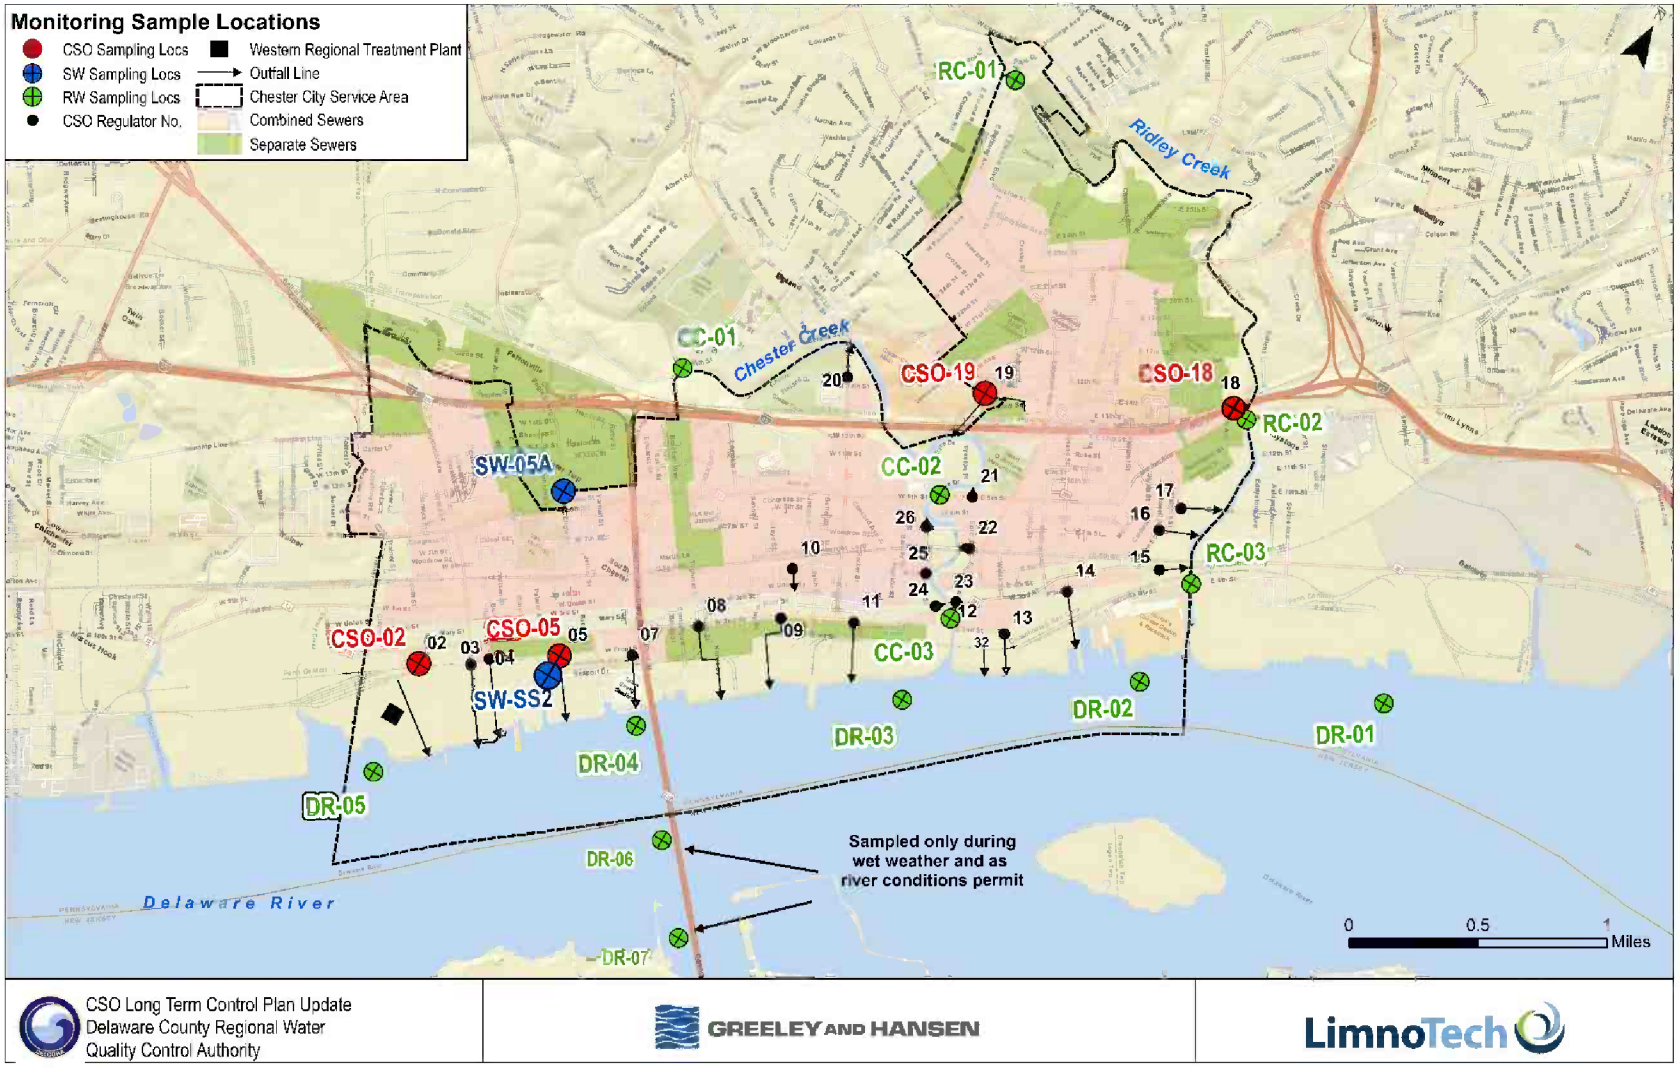
- Providing the frequency needed for in-stream concentrations (multiple samples spaced over several days) during wet weather to calibrate fecal coliform, *E. coli* and *Enterococcus* concentrations in the Receiving Water Quality Model;
- Providing wet weather event data for a range of storm conditions to calibrate and validate the Receiving Water Quality Model;
- Capturing the effects of the wet weather event throughout the CSO model area;
- Providing better constraints on calculated loads from storm water, tributary, and CSO sources than when using historical data

6.4.2 Water Quality Sampling Locations

Water quality monitoring was undertaken at thirteen (13) in-stream locations (seven of which are Delaware River sampling locations), four (4) CSO locations in the DELCORA combined sewer system area, and two (2) stormwater locations in the City of Chester municipal separate storm sewer system, as shown in Figure 6-2. Water quality monitoring and sampling was conducted as follows:

- Eleven (11) in-stream locations in the vicinity of the DELCORA CSO area were sampled for water quality for (3) dry weather events; one of which was targeted for collection during a tributary low-flow period (less than 25th percentile flow). The mid-stream and far-shore Delaware River locations were not sampled during the dry weather surveys because it was expected that water quality in the river is relatively uniform laterally due to

Figure 6-2: Receiving Water (RW), Combined Sewer (CSO) and Stormwater (SW) Monitoring Locations



the lack of active sources during dry weather. Grab samples and *in situ* measurements were collected at each location during each event.

- All thirteen (13) in-stream locations were sampled for water quality using grab samples and in situ monitoring for three (3) discrete wet weather events, according to the surface water quality monitoring program protocols described in the Monitoring Work Plan;
- Up to four (4) CSO and two (2) stormwater outfall locations were sampled for water quality for the same three (3) discrete wet weather events according to the outfall monitoring program protocols described in the Monitoring Work Plan. Samples for all outfalls were collected as grab samples.

The sampling events were planned to be distributed across the sampling season, which is assumed to be March through June 2017. Additionally, bathymetry surveys in the lower portion of the Chester and Ridley Creek were conducted to inform the development of the Water Quality Model.

Monitoring locations were selected to characterize the watershed at a sub-watershed level, recognizing various political and hydrologic features, land uses and potential pollutant sources. Site selection and analytical parameters were designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. The sampling locations are shown in Figure 6-2 and listed in Tables 6-2, 6-3 and 6-4.

Tables 2-1, 2-2 and 2-3 include summaries of the rationales for each sampling location selected. The Chester Creek and Ridley Creek locations were selected to distinguish, to the extent possible, between upstream, stormwater and Chester CSO pollutant loads. The Delaware River sampling locations provided a characterization of water quality entering the Chester CSO area from either tidal direction as well as water quality within the CSO discharge area. During wet weather, three samples were collected across the transect corresponding to the DR-03 sampling location during each sampling round, when sampling across the river was feasible, to characterize lateral variability in the Delaware River during storm events.

The CSO sampling locations were selected based on their outfall discharge location, relatively high frequency of overflow, their overflow volume, and their accessibility. The stormwater sampling locations were selected to characterize the water quality associated with the predominant land uses (residential and commercial/industrial) in the study area. Each stormwater sampling location is in an area that is representative of the land use elsewhere in the City's stormwater area.

Table 6-2: Tributary Receiving Water Sampling Locations

Station ID	Easting[1]	Northing[1]	Receiving Water	Type	Description	Rationale
CC-01	243291.419	371541.259	Chester Creek	Tributary	Chester Creek at Upland-Incinerator Rd.	Upstream of all City sources and upstream of tidal influence
CC-02	248598.992	372750.444	Chester Creek	Tributary	Chester Creek at North Eyre Rd[2]	Characterize impacts from non-CSO urban runoff sources
CC-03	250712.383	369489.807	Chester Creek	Tributary	Chester Creek at E 2nd St.	Characterize impacts from all CSOs discharging to Chester Creek
RC-01	243755.086	380967.554	Ridley Creek	Tributary	Ridley Creek at East Brookhaven Road	Upstream of all City sources and upstream of tidal influence
RC-02	253932.835	376122.878	Ridley Creek	Tributary	Ridley Creek at Chester Pike	Characterize impacts from non-CSO urban runoff sources
RC-03	254545.954	372628.232	Ridley Creek	Tributary	Ridley Creek at East 4th St.	Characterize impacts from all CSOs discharging to Ridley Creek

Notes:
[1] Northing/Easting are referenced to NAD 1983 State Plane New Jersey FIPS 2900 Feet
[2] 9th Street may be used as sampling location if conditions for sampling from the bank at North Eyre St. are deemed unsafe.

Table 6-3: Main Stem Receiving Water Sampling Locations

Station ID	Easting[1]	Northing[1]	Receiving Water	Type	Description	Rationale
DR-01	259153.030	372425.510	Delaware River	Main stem	Delaware River between Ridley Creek and Crum Creek	"Upstream" of DELCORA's CSO discharges[2]
DR-02	250456.388	367784.535	Delaware River	Main stem	Delaware River between CSO-14 and Ridley Creek	Characterize Ridley Creek impacts on Delaware River, in the upper Delaware River (Secondary contact area)
DR-03	245922.404	364715.470	Delaware River	Main stem	Delaware River between CSO-11 and Chester Creek	Characterize Chester Creek impacts on Delaware River, in the upper Delaware River (Secondary contact area)
DR-03-MID[3]	252036.389	365265.510	Delaware River	Main stem	Delaware River mid-stream along the transect of DR-03	Characterize lateral variability in the Delaware River during storm events
DR-03-LDB[3]	253703.965	362951.038	Delaware River	Main stem	Delaware River far shore (left descending bank) along the transect of DR-03	Characterize lateral variability in the Delaware River during storm events
DR-04	241663.723	361297.935	Delaware River	Main stem	Delaware River at the boat launch off Highway 322	Priority area, in the lower Delaware River (Primary contact area)
DR-05	254551.896	370426.118	Delaware River	Main stem	Delaware River between CSO-002 and Stony Creek	"Downstream" of DELCORA's CSO discharges[2], in the Atlantic sturgeon sensitive area

Notes:

[1] Northing/Easting are referenced to NAD 1983 State Plane New Jersey FIPS 2900 Feet

[2] "Upstream" and "downstream" subject to tidal conditions at time of sampling

[3] These locations will be sampled during the wet weather events only, when river conditions permit. POC concentrations are assumed to be laterally well-mixed during dry weather due to the absence of significant pollutant sources.

Table 6-4: CSO and Stormwater Sampling Locations

Station ID	Easting	Northing	Receiving Water	Type	Description	Rationale
CSO-19	248984.7240	374039.747	Chester Creek	CSO	14th and Crozer Hospital	Discharges to Chester Creek, one of the largest volume CSOs in DELCORA system
CSO-05	243892.0527	365166.574	Delaware River	CSO	Front and Townsend	Discharges to Delaware River, one of the largest volume CSOs in DELCORA system
CSO-02	241439.9527	363646.588	Delaware River	CSO	Front and Booth	Aggregates cumulative effect of CS conditions, one of the volume CSOs in DELCORA system
CSO-18	253767.9703	376303.599	Ridley Creek	CSO	Sun Drive and Hancock St.	Discharges to Ridley Creek
SW-05A	242360.2937	368165.917	Chester Creek	SW		Characterize runoff quality from predominantly residential area representative of the residential portion of the study area
SW-SS2	248649.2079	368230.704	Delaware River	SW		Characterize runoff quality from predominantly commercial/industrial area representative of the commercial/industrial portion of the study area

Note: The sampling locations will be finalized once a sampling contractor has been selected and potential sampling locations are assessed with respect to accessibility, feasibility, safety, and representativeness. The northing/eastings information will likely be updated prior to the initiation of the Sampling Program. Northing/Easting are referenced to NAD 1983 State Plane New Jersey FIPS 2900 Feet

6.4.3 Analytical Parameters

All of the in-stream dry and wet weather samples were analyzed for the parameters shown in Table 6-5: Analytical and Field Parameters. The outfall samples were analyzed for only *E. coli*, *Enterococcus* and fecal coliform.

Table 6-5: Analytical and Field Parameters

Parameter	Description	Sampling Program	Type of Measurement
E. coli	Escherichia coli	Dry, Wet	Grab
Enterococcus	Enterococcus sp.	Dry, Wet	Grab
Fecal Coliform	Fecal coliform	Dry, Wet	Grab
wTemp	Water temperature	Dry, Wet, Receiving Water Only	In-situ
Cond	Conductivity	Dry, Wet, Receiving Water Only	In-situ
Salinity	Salinity	Dry, Wet, Receiving Water Only	In-situ

6.4.4 Sampling Schedule and Dates

6.4.4.1 Dry Weather Sampling

The collection of water quality samples was performed for three (3) dry weather (DW) events; with one dry weather sampling event occurring during a low-flow period (less than 25th percentile flow) in Chester Creek and Ridley Creek. Below are the River and Creeks flows for during each of the dry weather sampling events. Table 6-6 below presents the Delaware River, Chester Creek and Ridley Creek flow during each dry weather sampling event. Dry Weather Sampling Event 3 is closest to the 25th percentile river flow.

Table 6-6: Observed River and Creek Flow Statistics

Water Body	Gage Identification	Gage Description	25th Percentile Flow	Dry Weather Event 1		Dry Weather Event 2		Dry Weather Event 3	
			(cfs)	(cfs)	Percentile	(cfs)	Percentile	(cfs)	Percentile
Delaware River	USGS 01463500	Delaware River at Trenton, NJ	4,600	13,323	70.1	16,306	78.1	10,862	62.1
Chester Creek	USGS 01477000	Chester Creek near Chester, PA	41	75.7	60.5	63.9	50.7	46.8	32.2
Ridley Creek	USGS 01476480	Ridley Creek at Media, PA	18	29.4	49	25.0	41.7	19.0	27.5

Source:
- 25th percentile flow (cfs) and percentile for each water body is courtesy of the U.S. Geological Survey (USGS) StreamStats (https://streamstats.usgs.gov/ss/)
- Observed flow data (cfs) for each Dry Weather Event is courtesy of the following current/historical observations link on the National Water Information System (NWIS) webpage:
  Delaware River: https://nwis.waterdata.usgs.gov/nwis/inventory/?site_no=01463500
  Chester Creek: https://nwis.waterdata.usgs.gov/nwis/inventory/?site_no=01477000
  Ridley Creek: https://nwis.waterdata.usgs.gov/nwis/inventory/?site_no=01476480

Two rounds of sampling were conducted for each dry weather survey: one round was completed during ebb (outgoing) tide and the second round was completed during flood (incoming) tide. The following table summarizes the dates of the DW events.

DW Sampling Event	Event Date
DW-1	3/23/2017
DW-2	5/10/2017
DW-3	6/13/2017

These events were distributed across the sampling season, of March through June 2017. The criteria used to define a dry weather event are as follows:

- No precipitation within the upstream watershed at least 48 hours before the event
- No precipitation forecasted for a minimum of three days; and

Dry weather event samples were taken at eleven (11) locations:

- **Three (3) locations on Chester Creek** intended to characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay River, the downstream sampling locations were intended to also reflect these tidal influences on water quality.

- **Three (3) locations on Ridley Creek** intended to characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations were intended to also reflect these tidal influences on water quality
- **Five (5) locations on the Delaware River** intended to characterize water quality in the vicinity of DELCORA's CSO discharges. Sampling locations were selected to separate to the extent possible the effect of DELCORA's CSOs on water quality from other sources contributing pollutants to the waterways. Sampling was conducted near the shoreline adjacent to the City of Chester.

The locations of these sample stations are shown in Figure 6-2, and details for these stations are provided in Tables 6-2, 6-3 and 6-4. The set of parameters for which the samples were analyzed is provided in Table 6-5. In-situ measurements of physical parameters, such as salinity, temperature, and conductivity were collected at each sampling location with a YSI sonde. .In the Delaware River, *in situ* measurements were made at three depths at each sampling location during each round of sampling.

6.4.4.2 Wet Weather Sampling

The collection of water quality samples was performed for three (3) wet weather events. The purpose of the wet weather sampling was to characterize the impact of CSO discharges and non-CSO source runoff on in-stream water quality. The wet weather events spanned a range of precipitation, flow and seasonal conditions. One of the wet weather sampling events was also chosen as a calibration event for the H&H Model and the Water Quality Model.

The goal was to sample storms of at least 0.5 inches of precipitation. The criteria used to define a wet weather event included:

- No precipitation within the upstream watershed 48 hours before the event;
- Forecasts for a 60% (or greater) chance of rain over the entire DELCORA project area; and,
- Approximately 0.50 inches of rainfall forecasted over a six-hour period.

The following table lists the dates that each wet weather sampling event occurred:

WW Sampling Event	Event Date
WW-1	3/31/2017
WW-2	5/5/2017
WW-3	5/22/2017

Wet weather event samples were taken at all 13 in-stream locations as well as at six source locations in the intervals described below:

- **Six (6) In-Stream Tributary Sampling Locations:** Three (3) locations were on the Chester Creek and three (3) locations were on the Ridley Creek. The locations were the same locations

used for the dry weather surveys. Tributary locations were sampled up to five times per event at the following approximate intervals: Hour 0.5-2.5, Hour 4.5-6.5, Hour 8.5-10.5, Hour 14.5-16.5, and Hour 22-24. Sampling intervals were defined by the start of rainfall rather than CSO or SSO activation. A total of 30 samples was collected during each wet weather sampling event from in-stream locations. One field blank and one field duplicate was collected during each event to be used as field quality control (QC).

- **Seven (7) In-Stream Delaware River Locations:** Seven locations were on the Delaware River and were sampled up to ten times per event at the following approximate intervals: Hour 0, Hour 2, Hour 4, Hour 6, Hour 9, Hour 12, Hour 15, Hour 18, Hour 21, and Hour 24 intervals were defined by the start of rainfall rather than CSO or SSO activation. The frequency of sampling was intended to capture in-stream impacts in the vicinity of DELCORA's service area from both DELCORA's CSOs as well as upstream sources. Two additional locations on the Delaware River, one at mid-stream and one near the far shore, were added to characterize lateral variability in water quality during storm event conditions, when sampling across the river was feasible. The sampling regimen was also designed to allow a semi-quantitative mass balance to be computed over a complete tidal cycle. A total of 70 samples were collected during each wet weather sampling event. If river conditions were unsafe for sampling (e.g. small craft advisories, heavy barge traffic, etc.), sampling was suspended for one or more locations and/or sampling rounds. One field blank and one field duplicate was collected during each event to be used for field QC. Final selection of sampling locations and sampling intervals was determined prior to the start of the sampling program and based on logistic considerations (e.g. can seven locations be sampled and dropped off to a courier within the 3 hour sampling window), safety and accessibility to the Delaware River, and available resources. For some of the sampling events some of the planned intervals samples were not obtained if the storm event stopped before the designated sample time or if the boat could not reach the location due to restrictions on the Delaware River.
- **Six (6) Outfall Locations:** Sampling was conducted at two (2) stormwater outfalls and four (4) combined sewer overflow outfalls. The CSO and stormwater sampling locations were finalized prior to the initiation of the sampling program based on accessibility of sampling, safety of sampling personnel, equipment risk, and available resources. Each of the outfall locations had eight sets of samples collected for each event at the following intervals: 1st flush, 30 minutes, and 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, 24 hours. Samples were collected from CSO-05, CSO -02 and CSO-18 and during each wet weather sampling event, and if all monitored outfalls discharge for 24 hours. If a location was not flowing, no sample was collected. However, the actual number of samples was less than the amount indicated since not all the monitored outfalls discharged for the full 24 hour monitoring period. One field blank and one field duplicate were collected during each event to be used as field QC.

The locations of these stations are shown in Figure 6-2. Details for these stations are provided in Tables 6-2, 6-3 and 6-4. The set of parameters for which the samples were analyzed are summarized in Table 6-5. *In-situ* measurements were not collected at the outfall locations.

Sampling crews conducted all wet weather event sampling using the protocols described in the DELCORA's *Water Quality Monitoring and Modeling Quality Assurance Project Plan* (Greeley and Hansen, 2017b). Samples were delivered to the laboratory and analyzed for the parameters shown in Table 6-5: Analytical and Field Parameters.

Determination to mobilize for a Wet Weather Event was a collaborative effort between Greeley and Hansen, LimnoTech, Eurofin (Lab) and DELCORA field sampling team. The intent was to identify a storm that was at least ½ inch rainfall and a 4 to 6 hour window in which a wet weather event may commence 24 hours in advance to assist in mobilization of the sampling crews meeting the requirements stated above for a WW event.

6.4.4.3 In situ Measurements (Receiving Water Only)

Instantaneous water quality measurements (such as salinity, temperature, and conductivity) using field instruments was also collected at the receiving water locations as specified in the *Water Quality Monitoring and Modeling Work Plan* (Greeley and Hansen, 2017a). These measurements, along with calibration and maintenance, were conducted following the SOPs for Water Quality Field Measurements in the Work Plan. Field instruments were calibrated before initiating monitoring activities for each event and a post-monitoring calibration check was conducted at the end of the event.

Salinity, temperature, and conductivity were measured at all in-stream sampling locations using a YSI 6920 sonde during both wet and dry sampling events, prior to sample collection. Whenever possible in the Chester Creek and Ridley Creek, measurements were made mid-channel at mid-depth. Whenever possible in the Delaware River, measurements were made at the surface, mid-depth and near the bottom.

6.4.5 QAPP Overview

Prior to the start of the spring 2017 water quality sampling activities, DELCORA submitted to the EPA and PADEP its *Water Quality Monitoring and Modeling Quality Assurance Project Plan* (Greeley and Hansen, 2017b). This Quality Assurance Project Plan (QAPP) was developed to meet the requirements of the DELCORA Consent Decree Paragraph Section V.A.15.a.(iv) requiring detailed information regarding all additional data collection and water quality modeling activities. The purpose of the QAPP was to document the necessary procedures required to assure that the project is executed in a manner consistent with applicable USEPA guidance documents and with generally accepted and approved quality assurance objectives. The QAPP was organized in accordance with the basic groups and subgroup elements discussed in the USEPA guidance for QAPPs. The four basic groups include project management (Group A); data generation and acquisition (Group B); assessment and oversight (Group C); and data validation and usability activities (Group D). The groups are subdivided into elements covering specific topics related to each group. The Section and Subsection headings of this QAPP include references to the USEPA QAPP Guidance group letters and element numbers to facilitate cross-reference with the Guidance.

The QAPP integrates quality control policies and project-specific work tasks to successfully conduct water quality monitoring and modeling to support the CSO Long Term Control Plan update. Greeley & Hansen served as the contracting authority for the project and provided overall project management. LimnoTech served as the technical advisor for the sampling program and provided the data integration and interaction role. The field contractor, Weston conducted the actual sampling program, and the laboratory contractor, Eurofins, performed laboratory analysis for the project.

The QAPP was designed and organized in terms of compliance with USEPA requirements. It was the overall intent of the QAPP to provide professional guidelines for activities by all personnel on the project and to ensure that quality assurance/quality control QA/QC procedures are followed.

6.5 Receiving Water Quality Results

The identified pollutant of concerns for the Delaware River, Chester Creek and Ridley Creek are the same three indicator bacteria; fecal coliform, *Escherichia coliform* (*E. coli*), and enterococcus. Consequently, the Water Quality Monitoring Program primarily focused on the concentrations of these three parameters.

Water Quality Sampling has been completed; however, the results are currently being reviewed for quality assurance and analyzed. A summary of the sampling results are presented in Appendix D of this report; however, the analysis and conclusions are currently being conducted and will be presented in the final Water Quality Sampling Report and the final Water Quality Modeling Report.

Section 7 Typical Hydrologic Period

7.1 Introduction

7.1.1 DELCORA's Consent Decree

According to the Consent Decree between the USEPA, PADEP, and DELCORA, DELCORA shall submit to Plaintiffs a report or technical memorandum describing DELCORA's statistical evaluation of long-term local rainfall patterns and the identification of an appropriate typical period for LTCP development purposes. To satisfy this Consent Decree requirement, DELCORA submitted the *Typical Hydrologic Period Report* (Greeley and Hansen, 2016a), which was approved by PADEP and USEPA on May 23, 2016. The remainder of Section 7 is based on this approved report.

The statistical evaluation in the *Typical Hydrologic Period Report* (Greeley and Hansen, 2016a) utilizes local long-term rainfall record from the Philadelphia International Airport. It considers various appropriate rain year characteristics, including distributions of event rainfall totals, event durations, and peak and average rainfall intensities.

7.1.2 Typical Year for CSO LTCP Development

Precipitation generates urban storm water, combined sewer overflows (CSOs), and increased wet weather flows to the wastewater treatment plant. These will contribute bacteria and pollutants to the Delaware River and its tributaries. The effect of these contributors on the Delaware River mainly depends on the magnitude and duration of rainfall events and on the prevailing ambient river conditions controlling dilution and transport of the pollutants. This variability and complexity poses a significant challenge for assessing the performance of wet weather and CSO control alternatives.

In accordance with the USEPA CSO Control Policy (CSO Policy), dated April 19, 1994, the CSO control alternatives should be assessed on a "system-wide, annual average basis". This is accomplished by continuous simulation using a typical hydrologic period for the combined sewer system (CSS) and receiving water quality modeling applications. The CSO Policy supports continuous simulation modeling, i.e., using long-term rainfall records rather than records for individual storms. Long-term continuous rainfall records enable simulations to be based on a sequence of storms so that the additive effect of storms occurring close together can be examined. They also enable storms with a range of characteristics to be included.

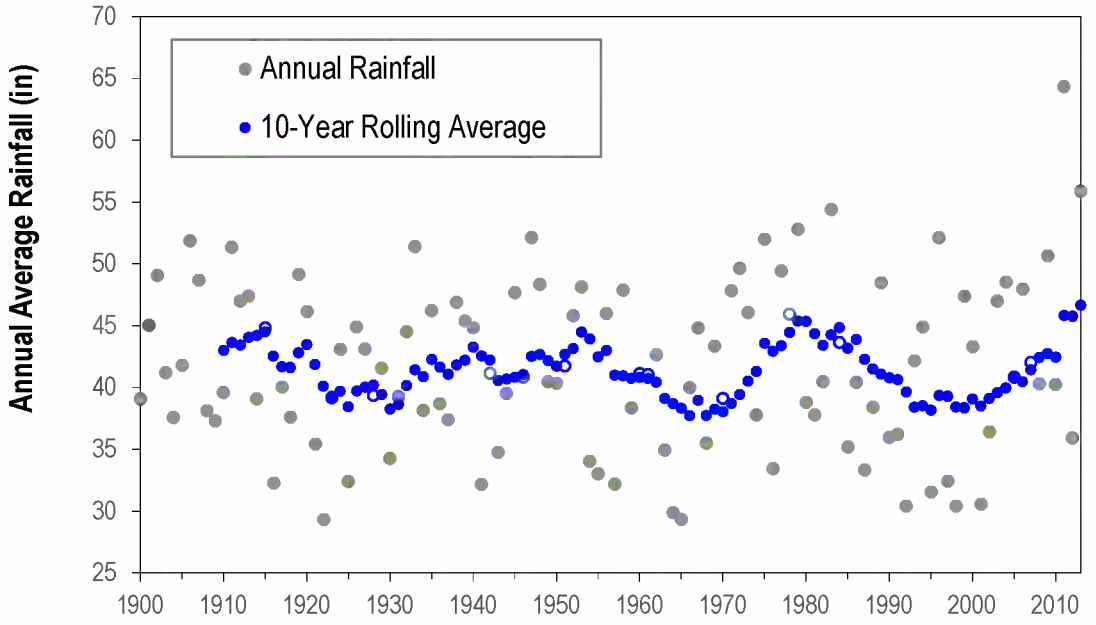
Typically, a 3- to 5-year period is evaluated to balance between manageable model simulation time and representation of various rainfall/river conditions. In this study, a 3-year period is deemed most appropriate considering the modeling complexity. The representative three-year period is intended to contain a relatively wet year, a dry year and an average year. Average year conditions are defined as the arithmetic average of the predictions for the selected period.

7.1.3 Climate Change Considerations

Average U.S. precipitation has increased since 1900, but there are regional differences, with some areas having larger increases, and others, decreases. Local climate change should be considered when selecting appropriate data records for the typical period analysis.
Rainfall data from the Philadelphia International Airport were obtained from the National Oceanic and Atmospheric Administration (NOAA). Hourly rainfall data is available from 1900 through 2013. This provides sufficient data to evaluate climate change in the area. Figure 7-1 shows annual rainfall from 1900 to 2013. A 10-year rolling average trend line is also shown in the figure for characterizing long-term precipitation pattern. In the past 114 years, annual rainfall ranges from 29.3 to 64.33 inches, with the wettest year in 2011. The 10-year rolling average rainfall indicates that precipitation in the area runs through various dry and wet cycles, however with more extreme conditions (dry and wet) in recent years.

Considering the climate change, it is determined that the typical period for the LTCPU be selected based on statistical analysis of rainfall records in recent 30 years (i.e., 1984-2013).

Figure 7-1: Historical Annual Rainfall at Philadelphia International Airport



7.1.4 Methodology of Typical Year Selection

The typical hydrologic period is selected to provide representative and unbiased approximations of expected future conditions in terms of both averages and historical variability. Representativeness is assessed using objective criteria for each of the ambient factors (i.e., river flow and rainfall). As indicated in the previous section, the selection of the typical hydrologic period is based on the historical records in the past 30 years from 1984 through 2013.

The following datasets are used for the analysis of the typical hydrologic period:

- Hourly precipitation data for the National Climate Data Center gauge at Philadelphia International Airport for 1984 - 2013.
- Daily Delaware River stream flow data from the U.S. Geological Survey gauge at Trenton, NJ (USGS 01463500) for 1984 - 2013. This is the closest USGS gauge that with daily river flow available.

Key criteria parameters used in the evaluation are listed in Table 7-1. Each parameter is given a weighting factor to describe the individual importance on the averageness of the analyzed time period. The parameters that are given the highest impact weighting include the following:

- The total annual rainfall depth, which drives the total runoff volume.
- The maximum peak intensity, which usually defines the biggest overflow event.
- The median Delaware River flow; the impact of sewer overflows on the water quality of the receiving water is dependent on the magnitude of the flows in river, and in the project area, intense local rainfall events are typically independent from watershed wide high flow events.

Table 7-1: Hydrologic Period Ranking Parameters

Key Parameter	Weighting Factor	Comments
Annual rainfall depth	25.0%	Important for evaluating annual overflow volume
Number of events > 0.1" rainfall depth	2.5%	Typically storms over 0.1" would start to cause surface runoff
Number of events > 0.25" rainfall depth	2.5%	Previous model indicates system overflows at storms over 0.25"
Number of events > 1.5" rainfall depth	7.5%	Storms to be controlled to meet potential presumption approach
Number of back-to-back events	5.0%	Important for evaluating the antecedent conditions
Maximum peak intensity	20.0%	Storms with high intensity causes overflows
Average rainfall duration	2.5%	Important for evaluating wet weather durations
Average rainfall intensity	5.0%	Important for evaluating overall rainfall intensity
Delaware River flow - 25th percentile	2.5%	Important for evaluating dilution power of the Delaware River flow for water quality
Delaware River flow - 50th percentile	25.0%	
Delaware River flow - 75th percentile	2.5%	

7.2 Typical Year Selection for DELCORA

7.2.1 Annual Rainfall and River Flow Statistics

30-year hourly precipitation data (1984 - 2013) from the Philadelphia International Airport was analyzed to evaluate all individual rainfall events in the period. An inter-event time (IET) of 6 hours (i.e. minimum dry time of 6 hours between rainfall events was used to differentiate between individual events. Precipitation periods with a total rainfall volume of greater than 0.1 inch were counted as rainfall events. If the next rainfall event's starting time is within one day of the previous rainfall event's ending time, these two rainfall events are considered as back-to-back rainfall events. All rainfall events for the data period were analyzed for duration, inter-event duration, total rainfall amount, as well as maximum and average rainfall intensities. A total of 1,934 rainfall events were counted for the period of 1984 - 2013.

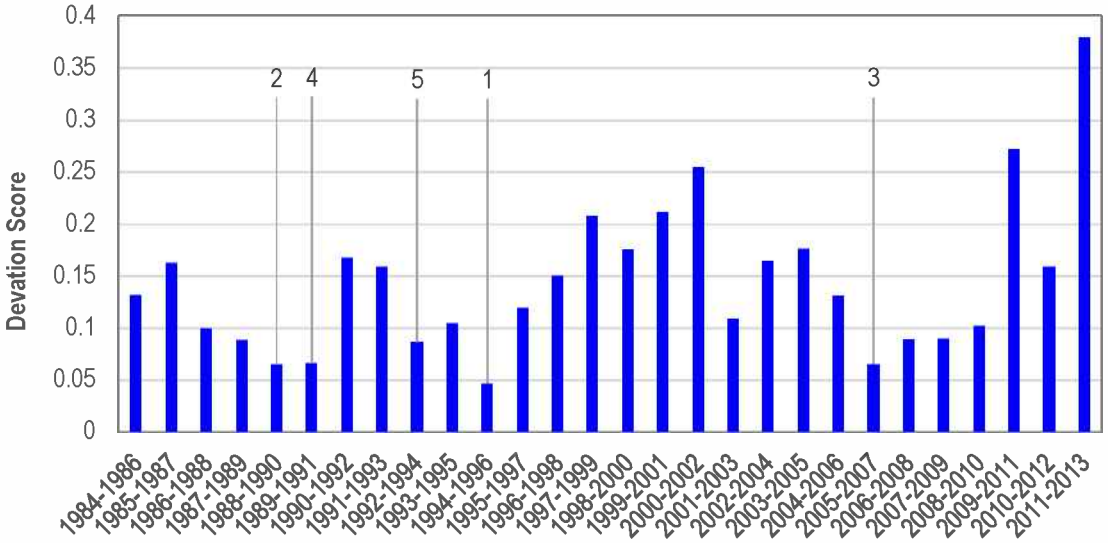
7.2.2 Three-year Rainfall and River Flow Analysis

Once annual rainfall and river flow statistic were determined for the 30 year period, three-year rainfall and river flow characteristics were developed based on an annual average of the three consecutive years. The goal of using a three-year analysis period was to find a period that had a relatively dry year, a relatively wet year, and a relatively average year. That way, any evaluations done using the typical hydrologic period have a more diverse spectrum of wet weather events and dry weather periods.

7.2.3 Ranking Analysis

With the weighting factors listed in Table 7-1, a deviation score was developed for each individual period. The 3-year periods were then ranked based on the deviation score. The lower the deviation score (Figure 7-2 Y-axis), the higher the rank for the hydrologic period (i.e., the closer it is to the average condition). Figure 7-2 shows the ranking results of the 28 hydrologic periods, with a ranking of 1 being the highest and a ranking of 28 being the lowest ranked hydrologic period. Hydrologic period 1994-1996 is ranked No.1 because it has the lowest deviation score of 0.047.

Figure 7-2: Ranking Score of 3-year Period, 1984-2013



7.2.4 Top 5 Ranked 3-year Hydrologic Periods

Based on the ranking analysis, the top 5 ranked hydrologic periods are:

- Rank 1: 1994-1996
- Rank 2: 1988-1990
- Rank 3: 2005-2007
- Rank 4: 1989-1991
- Rank 5: 1992-1994

Table 7-2 shows rainfall and river flow statistics for these top ranked hydrologic periods.

Table 7-2: Top 5 Ranked Hydrologic Periods

Rank	Year	Rainfall								Delaware River Flow (cfs)		
		Annual Rainfall (in)	Max Rainfall Intensity (in/hr)	Average Rainfall Intensity (in/hr)	Average Rainfall Duration (hr)	Events ≥0.10 in.	Events ≥0.25 in.	Events ≥1.5 in.	Back-to-Back Event	25th Percentile	50th Percentile	75th Percentile
1	1994-1996	42.9	1.50	0.08	10.1	65	47	5	7	5,611	9,710	16,775
2	1988-1990	41.0	1.69	0.08	10.5	63	44	5	10	5,598	8,338	13,925
3	2005-2007	43.6	1.55	0.09	10.6	61	45	6	10	6,030	10,450	17,533
4	1989-1991	40.2	1.50	0.08	10.8	63	45	5	10	5,187	8,043	14,467
5	1992-1994	39.2	1.50	0.08	10.6	64	41	5	8	5,070	7,760	13,167
Average 1984-2013		**41.3**	**1.53**	**0.08**	**10.7**	**62**	**44**	**5**	**9**	**5,540**	**9,325**	**15,770**

Rainfall return frequency during 1988 through 2013 was analyzed to understand the distribution of the large rainfall events with return frequencies above 1-year. Table 7-3 summarizes quantity of large rainfall events with return frequencies for the top 5 ranked hydrologic periods.

- All of the top 5 hydrologic periods have a 25-yr storm.
- Hydrologic period 1994-1996 (Rank 1) contains one 25-yr storm, one 10-yr storm and three 1-year storm. Hydrologic period 1988-1990 (Rank 2) contains one 25-yr storm, one 10-yr storm, three 2-year storm and one 1-year storm.
- Hydrologic period 1994-1996 (Rank 1) is more conservative because its annual average rainfall amount of 42.9" is slightly greater than the 30-yr average. It is considered a better option than hydrologic period 1988-1990 (Rank 2), which has a slightly less annual rainfall than the average.

Table 7-3: Rainfall Return Frequency Summary for the Top 5 Ranked Hydrologic Periods

Rank	Year	Quantity of Rainfall Events with Return Frequency above				
		25-yr	10-yr	5-yr	2-yr	1-yr
1	1994-1996	1	1			3
2	1988-1990	1	1		3	1
3	2005-2007	1	1		2	4
4	1989-1991	1			2	3
5	1992-1994	1	1			3

The analysis was also conducted with an IET of 12 hours, and the top five ranked hydrologic periods. The top four hydrologic periods based on the IET of 12 hours are the same as the analysis based on the IET of 6 hours, which include the 3-year period 1994 - 1996 remaining as Rank 1.

7.2.5 Selected Hydrologic Period

The 3-year period 1994-1996 (Rank 1) will be used as the typical hydrologic period for the CSO LTCPU. This period contains a wide range of storms and antecedent conditions. The hydrologic period of 1994-1996 is also evaluated for longer historical rainfall records up to 100 years. It is ranked No. 1 for the 50-years record and No. 2 for the 100-year records (Table 7-4).

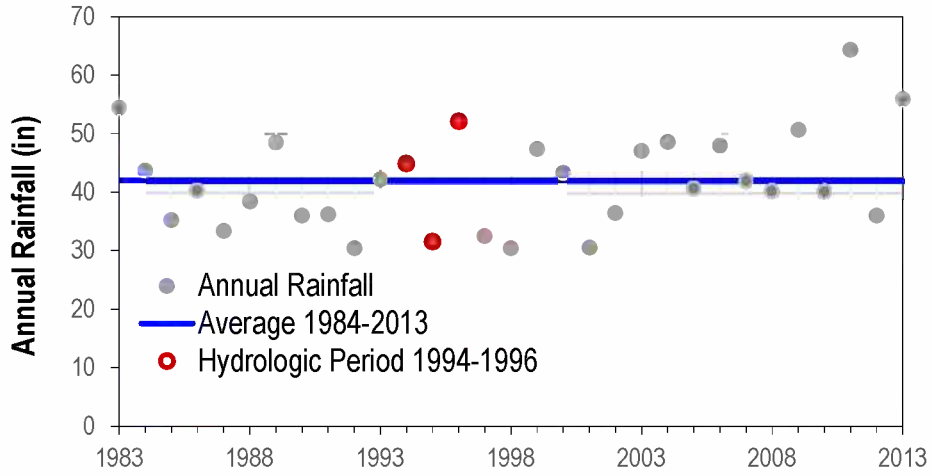
Table 7-4: Rank of Hydrologic Period 1994-1996 from Various Rainfall Data Set

	30-year Rainfall Records, 1984-2013	50-year Rainfall Records, 1964-2013	100-year Rainfall Records, 1914-2013
Rank of 1994-1996	1	1	2 (1925-1927 as Rank 1)

7.2.6 Additional Information on Statistical Analysis of Rainfall Data

Figure 7-3 shows annual rainfall and average annual rainfall for years 1983-2013. The hydrologic period 1994-1996 contains a relatively wet year (1996 with 52.1 inches), a dry year (1995 with 31.6 inches) and a year close to average conditions (1994 with 44.9 inches).

Figure 7-3: Annual Rainfall 1983 - 2013



Characteristics of the top 10 storms (by rainfall depth) in each year of the hydrologic period 1994-1996 are shown in Tables 7-5, 7-6 and 7-7.

Table 7-5: Ten Largest Storms and Return Frequencies in 1994

Top 10 Rainfall Event	Rainfall Start Date and Time	Rainfall Volume (in)	Rainfall Duration (hr)	Max Rainfall Intensity (in/hr)	Rainfall Return Period
1	7/18/1994 7:00	3.45	4	1.5	25-yr
2	7/14/1994 15:00	2.89	7	1.41	10-yr
3	3/9/1994 11:00	2.00	27	0.37	< 1 year

Section 8 Hydrologic and Hydraulic Modeling

This section describes the development and application of the Hydrologic and Hydraulic Model for DELCORA's combined sewer system. This model will aid in the identification and evaluation of a range of potential water pollution treatment/control alternatives for use as part of DELCORA's Combined Sewer Overflow Long-Term Control Plan Update (CSO LTCPU).

8.1 Background

Since 1997, DELCORA has conducted annual modeling of the CSS using the USEPA's Storm Water Management Model (SWMM) to estimate overflows to its receiving waters. SWMM is a dynamic rainfall-runoff simulation model that can simulate single-event or continuous runoff quantity and quality from primarily urban areas. The model simulates the time-varying process of rainfall onto land surfaces, the conversion of rainfall to infiltration, evaporation, or surface runoff, and the routing of mixed stormwater runoff and sanitary sewage through the collection system. This model is also referred to as DELCORA's Hydrologic and Hydraulic (H&H) model.

The original DELCORA H&H model was developed and calibrated for the 1999 LTCP, but it did not include the entirety of DELCORA's service areas. The original model included one (1) rain gage located at the WRTP, 67 subcatchment areas, 29 outfall nodes (CSO outfalls), 736 storage nodes (sewer manholes), 735 conduit links (sewer mains) and 34 orifice links (CSO regulators), but no pump stations and force mains were included.

The model was set up to simulate monthly CSO discharges with reasonable continuity error in EPASWMM 5.0. The model had been updated and expanded over the years to account for changes in the combined sewer system, but it had not been re-calibrated during the development of the 2012 revisions to the LTCP.

Monthly CSO overflow estimates using the model are reported to the PADEP as part of DELCORA's Annual Municipal Wasteload Management Report (Chapter 94 Report) and monthly with the PADEP electronic Discharge Monitoring Report (e-DMR). The H & H Model is also used as a scenario model to evaluate potential upgrades to the CSO system.

The original DELCORA H&H model was developed and calibrated for the 1999 LTCP. The model was updated and expanded over the years to account for changes in the CSO system, but it was not re-calibrated during the development of the 2012 LTCP (Weston, 2012). Section V.A.14 of the 2015 Consent Decree requires DELCORA to update and calibrate the H&H Model to include hydrologic representations of all areas tributary to the Model Area. The project team reviewed the 2012 model in order to:

- Assess adequacy of the original model for use in DELCORA's LTCPU.
- Identify gaps with the original model in meeting the requirements in the Consent Decree.
- Identify updates required to reflect current hydrologic and hydraulic conditions of DELCORA's collection system.
- Determine refinements needed for the model update.

Results from the review of the 2012 H&H Model were presented in the *Hydrologic and Hydraulic Model Update and Calibration Plan* (Greeley and Hansen, 2015). DELCORA completed the expansion and revisions to the H&H model in the summer of 2017, and it now includes all of Model Area and more accurately reflects the current collection system conditions. .

The revised H&H model uses Gauge Adjusted Radar Rainfall (GARR) data to estimate the frequency and volume of CSO overflows and to evaluate long-term strategies for minimizing CSO overflows. Precipitation breaks of at least 12 hours are used to establish separate storm events.

8.2 H & H Modeling Capabilities

The H & H Model simulates runoff from the CSO service areas into the sewers and then routes the flow through the major trunk sewers, CSO regulator structures, and the interceptors to the Western Regional Treatment Plant. A number of hydraulic modeling software packages are available, including EPA SWMM5, InfoSWMM, InfoWorks, Mike Urban and PCSWMM. For this H&H Model update, EPA SWMM, Version 5.0, Build 5.0.022 and Innovyze InfoSWMM Version 14.5 Update 4 were selected as the modeling software. EPA SWMM5 is a fully dynamic model and has been used extensively throughout the United States and abroad to assess CSO, flooding and water quality issues. It can be applied to simulate single events or long periods of time in a continuous mode. It can estimate runoff flow from several subcatchment basins and route the flow through the sewer system to treatment facilities or to the receiving waters. InfoSWMM uses the current EPA SWMM 5 engine as its computational solution and is fully integrated with ArcGIS which provides greater flexibility of importing model network from existing GIS database and preparing initial model inputs from existing datasheets. InfoSWMM was used during the model development and the calibration phase.

8.2.1 Combined Sewer System Model

The InfoSWMM model has the following capabilities for modeling DELCORA's combined sewer system:

- A user-friendly, ArcGIS integrated graphical interface for cost-effective use and updating.
- A physical based model with model formulations explicitly linked to actual conditions in the field as input by the user.
- Simulates the hydraulic conditions of the modeled trunk sewers, interceptors, gravity sewers, force mains, pump stations, and treatment plant during dry and wet weather.
- Evaluates CSO control alternatives and interceptor capacities.
- Can be periodically updated to reflect the implementation of the CSO control plan and increased development within the service areas.
- Estimates of Run-off from combined sewer areas.
- Estimates wet weather flows from separate sewered areas (rainfall derived inflow and infiltration (RDII)).
- Real-Time Control operations.
- Technical and regulatory credibility (developed from U.S. EPA SWMM software).

8.3 Data Collected

The data requirements needed for the sewer system model include

- Physical characteristics of the sewer system, which are used to configure the model specifically for DELCORA's collection system. (The physical characteristics of the sewer system are described in Section 3 of this report)
- Land use data, which influences the amount of runoff delivered to the sewer system. (See information presented in Section 3 of this report)
- Rainfall data, which are used as inputs to the model. (The collection of rainfall data is for validation and calibration is described in Section 4 of this report. Rainfall data for use as the typical hydrologic period is described in Section 7 of this Report)
- Flow monitoring data, which are used to calibrate and validate the collection system model output. (The collection of flow monitoring data is described in Section 4 of this report)

The model update is based on information obtained from a variety of sources including DELCORA's input, GIS, record drawings and field survey. Other documents pertaining to standard/actual operating procedures for CSO regulators, pump stations and the WRTP were also used to set up real time controls in the model. The model network consists of all major interceptors and force mains and extends to all active overflow points. The datum for the model is NGVD 29.

8.4 H & H Model Development

The development of a sewer system model is complicated and includes many components. The following paragraphs describe how the data described in the previous section are used in the model development.

8.4.1 H & H Model Inputs

Inputs to the Model include rainfall data and the hydrologic watershed parameters. The watershed parameters pertains to the combined sewer service areas only and were as follows:

- Subcatchment areas
- Percent imperviousness (pavement, rooftops, and structures impervious to rainfall infiltration)
- Subcatchment widths
- Overland slope within the subcatchments
- Depression storage within the subcatchments
- Manning's roughness coefficient for overland flow
- Soil infiltration of rainfall in pervious areas
- Base flow

The rainfall data and watershed parameters are described in the following subsections.

8.4.2 Rainfall Data

Rainfall data within the model represent the average precipitation that falls on an area within a defined time interval. Rainfall data was entered in the model as total rainfall or rainfall intensity occurring within a time interval. The rainfall time interval can be as short as a minute or as long as an hour. Generally, the model results satisfactorily match observed flow monitor data when the rainfall input time interval is at a minimum of 15 minutes. Actual rainfall data recorded at 5-minute frequency were entered into the model for model calibration.

8.4.3 Subcatchment Areas

Subcatchment areas are the discrete surface areas that contribute runoff and overland flow to the combined sewers. Delineation of subcatchments was described in Section 3 of this Report. The model represents a subcatchment as a polygon area with the overland slope perpendicular to the subcatchment width. The point where the runoff enters the sewer is called the point of concentration (receiving node). The major trunk sewers from each CSO service area along with all interceptor sewers and CSO regulators were incorporated into the model.

8.4.4 Percent Imperviousness

The initial percent imperviousness for the combined area was calculated as described in Section 3 of this Report. Then, the impervious percentage values were adjusted during the model calibration process to best simulate the observed hydrologic response over the selection of precipitation events. All open areas not tributary to the sewer system were measured from the aerial photographs and subtracted from the subcatchment areas. The open areas are considered non-point sources, which drain directly to the receiving waters.

8.4.5 Subcatchment Widths

Subcatchment width affects the shape of the runoff hydrograph and is generally an H&H model calibration parameter. Higher peak flow rates and more immediate response to a storm event are simulated when the subcatchment width is increased for the same subcatchment. The initial inputs for the subcatchment width were determined by dividing the total area of the subcatchment by the representative overland flow length in the subcatchment. These initial inputs were adjusted based on model calibration comparisons to data.

8.4.6 Overland Slope

Overland slope is a measure of the steepness of the land in the subcatchments. It is a model input and affects the travel time of overland flow, peak runoff rate, and runoff volume. Steeper slope decreases the travel time, increases the peak runoff rate and increases the runoff volume. The slope of a subcatchment should reflect the average slope along the pathway of overland flow to inlet locations. For the combined sewer subcatchments, slopes from the 2012 H&H model were retained for use in the updated model.

8.4.7 Depression Storage

Some rainfall on the pervious and impervious areas is held in small depressions rather than becoming part of the overland flow. It is defined as the amount of incidental surface depressions that must be filled before runoff typically begins. Initial values for depression storage were described in Section 3 of this Report. For all practical purposes, depression storage is difficult to measure and is typically adjusted during the calibration process.

8.4.8 Manning's "n" Roughness Coefficient

Overland flow travels slower or faster depending on the roughness of the surface in the subcatchment. The higher the roughness coefficient, the greater the friction and the slower the flow travels. Again, this is a model parameter that cannot be practically measured. A typical range of Manning's "n" suggested by the SWMM is 0.011-0.024 for impervious area and 0.06-0.80 for pervious area. The initial values were set to 0.013 for impervious surfaces and 0.15 for pervious surfaces. Roughness is an empirical value and may be treated as a calibration parameter if necessary.

8.4.9 Separate Sewer Areas

The DWF for each separate sewer service area was determined as described in Section 4 and input into the model at the appropriate combined sewer node. To estimate the wet weather impacts on the separate sewer service areas, the flow monitoring data collected during the monitoring program was evaluated.

8.4.9.1 Rainfall Derived Infiltration and Inflow (RDII)

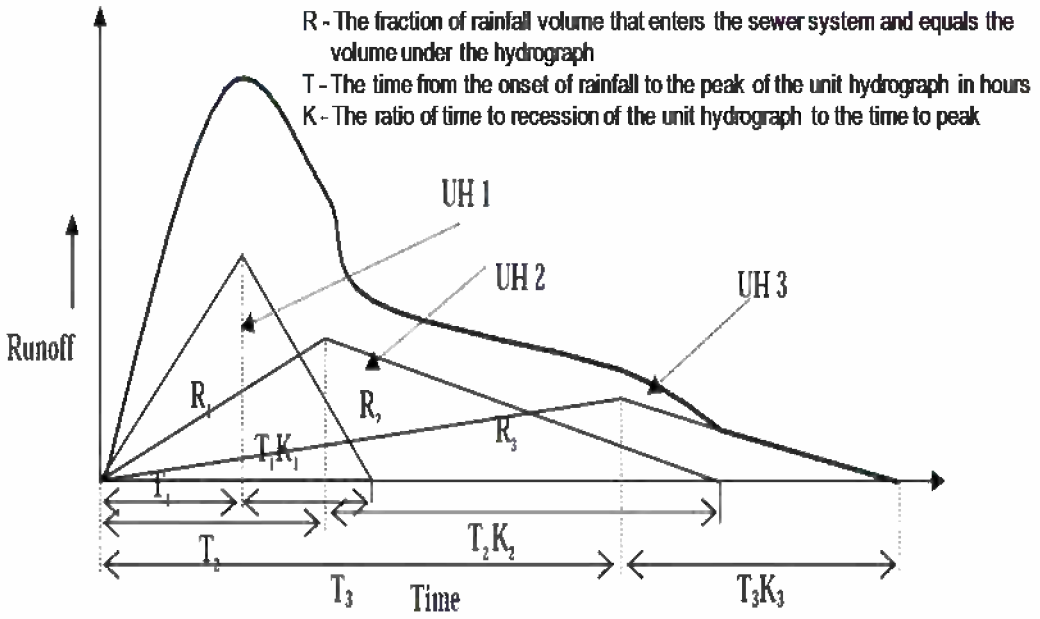
The model uses the RTK unit hydrograph (UH) to estimate RDII into the separated area sewer systems. As shown in Figure 8-1 (Muleta & Boulos, 2008), a RTK UH set contains up to three hydrographs: one for a short-term response (UH1), one for an intermediate-term response (UH2), and one for a long-term response (UH3). UH1 represents the most rapidly responding inflow component and has a short T value, UH2 includes both inflow and infiltration and has a longer T value, and UH3 includes infiltration that may continue long after the storm event has ended and has the longest T value. The unit hydrograph is defined by the following three parameters:

- R: the fraction of rainfall volume that enters the sewer system and equals to the volume under the hydrograph,
- T: the time from the onset of rainfall event to the peak of the unit hydrograph in hours, and
- K: the ratio of time to recession of the unit hydrograph to the time to peak.

The same set of RDII parameters were applied in the same metershed because of the availability of the flow hydrograph for model calibration. The initial values of RTK were estimated using the RDII Analyst tool in the InfoSWMM. The RTK values are calibration parameters to be refined during model calibration.

Rainfall and sewershed area information was needed for RDII calibration. Subcatchment areas were estimated as described in Section 3. Rainfall and flow data from the monitoring program (see Section 4) were used for the calibration.

Figure 8-1: RTK Unit Hydrographs



Source: M.K. Muleta and P.F. Boulos, Analysis and Calibration of RDII and Design of Sewer Collection Systems, ASCE Conference Proceedings 316, 642 (2008)

8.4.10 Soil Infiltration

Infiltration parameters modestly influence the runoff hydrograph from the combined sewer system subcatchments by reflecting rainfall absorption into the soil. The H&H model uses the Horton method with infiltration parameters determined based on evaluation of soil types as described in Section 3.

8.4.11 Sewer Mains

Sewer mains are the conveyance element and were simulated as conduits in the model. The following input information was entered into the H&H model:

- Conduit ID
- Shape
- Number of barrels
- Upstream and downstream nodes
- Upstream and downstream offset
- Dimension (length, diameter/depth)
- Manning's roughness coefficient
- Minor loss coefficient (entry loss, exit loss, average loss)
- Flap gate installed or not (set at no flap gate for most of the sewer mains)

Most of the pipe input parameters, including upstream and downstream nodes, dimension, shape, number of barrels, and flap gate information, were found or estimated from record drawings, design drawings and sewer gravity main GIS shapefiles. For pipes that do not begin or end at the invert of the upstream or downstream node, an offset value was provided to describe the difference from the invert of the pipe to the invert of the upstream or downstream node.

Manning's roughness coefficient is related to the pipe material. The initial input of the Manning's n for different materials is summarized in Table 8-1. The Manning's n may be changed during calibration to account for minor loss or additional sediment depositions in the pipe.

The initial minor loss for pipe will be set at zero for most pipes. For those pipes with sharp turns, a higher minor loss was applied.

Table 8-1: Manning's Roughness Coefficient for Sewer Mains

Pipe Material	Manning's N
Polyvinyl Chloride (PVC)	0.011
Reinforced Concrete Pipe (RCP)	0.013
Ductile Iron (DI)	0.013
Cast Iron (CI)	0.013
Corrugated Metal Pipe (CMP)	0.020
Masonry	0.025
Unknown	0.013

8.4.12 Manholes

Sewer manholes were simulated as junction nodes in the model. The following information was entered into the H&H model:

- Node ID
- Invert
- Maximum Depth (approximated as the difference from manhole rim and manhole invert)
- Surcharge Depth

8.4.13 CSO Outfalls

CSO outfalls will be simulated as outfall nodes in the model. The following information was entered into the model:

- Outfall ID
- Type (free, normal, fixed stage, tidal stage, time series, stage-flow, flap gate)
- Invert
- Boundary conditions

Outfall characteristics were described in Section 3.

8.4.14 Flow Diversion Structure

As described in Section 3, most of the flow diversion structures are similar to Brown and Brown type regulators. The key components required for modeling these structures were described in Section 3.

Regulator Gates

Regulator gates will be simulated as orifices in the updated model. The following information was entered into the model:

- Regulator Gate ID
- Upstream and downstream nodes
- Type
- Shape (two shapes: circle, rectangular)
- Dimension (Height, Width)
- Discharge Coefficient

Characteristics of the regulator gates were described in Section 3. All regulator gates are modeled as rectangular except for REG_004_Gate which is modeled as a circular orifice. The updated model includes real time control rules for opening and closing of the gates based on levels in the float chamber and regulator limit settings

Orifices

Characteristics of the orifice plates are described in Section 3. The following information was entered into the model:

- Orifice ID
- Upstream and downstream nodes
- Type (two types: side, bottom)
- Shape (two shapes: circle, rectangular)
- Dimension (Height, Width, Crest Height)
- Discharge Coefficient

8.4.15 Weirs

Diversion weirs will be simulated as weirs in the model. Characteristics of the weirs are described in Section 3. The following information was entered into the model:

- Weir ID
- Upstream and downstream nodes
- Type (four potential weir types: transverse, sideflow, V-notch, trapezoidal)
- Dimension (Height, Weir Length, Weir Crest Height)
- Coefficient of Discharge
- Number of End Contractions

8.5 Summary

The 2012 H&H model was updated as described above. A summary of the key revisions is presented in Table 8-2. The detailed layout of the updated model is shown in Figure 8-2 and Figure 8-3.

Table 8-2: Summary of Revised H&H Model

Review Item	2012 Model Review Observation	Comments	Updated Model
Model Software	- EPA SWMM 5.0		Innovyze InfoSWMM version 14.5
Vertical Datum	- NAVD 88	- To be verified	- NGVD29
General Sub Models	- EPASWMM for the runoff model - Horton Equation for the infiltration model - Hydrodynamic wave for the flow routing model	- All these choices are commonly seen in collection system modeling practices	
Rain Gauge	- One (1) rain gage, located at the Western Regional Treatment Plant (WRTP)	- One rain gauge is not sufficient for the entire service area in the model	- Seven (7) rain gauges, as shown in Section 2 - Additional GARR analysis performed
Service Area	- 67 subcatchments, all for combined area - One set of Horton infiltration parameters are applied to most of the subcatchments (66 out of 67 subcatchments) - The infiltration parameters applied in the model is equivalent to infiltration parameters for soil type C/D	- All service area including separated area that contribute flow to the DELCORA collection system should be included in the model - Combined area delineation will be checked to include any changes along the years - Soil type need to be checked to verify Horton infiltration parameters in all subcatchments	- 114 subcatchments, 53 for combined area and 61 for separated areas - Combined area was modified to include newly separated areas. - Horton infiltration parameters applied to 56 out of 114 subcatchments - Horton infiltration parameters varied based on identified soil types -

Review Item	2012 Model Review Observation	Comments	Updated Model
Sewer Manhole	- 736 storage nodes. - All sewer manholes are simulated as storage units in the model. - The majority of the storage units (732 out of the 736) have a diameter of 4-ft, and the rest (4 units) have a surface area of 100 square feet (sf.) (equivalent to 10'x10'). - All storage units are set-up with a ponding area of 9,999 sf. to allow excess water to collect atop of the nodes and be re-introduced into the system as conditions permit.	- Sewer manholes will be simulated as common junction node - This will help with SSO evaluation in the collection system	- 860 common junction nodes. - The majority of the common junction nodes (836 out of the 860) have a diameter of 4-ft, and the rest (4 units) have a surface area of 100 square feet (sf.) (equivalent to 10'x10'). - There are 35 imaginary junctions created to receive flow from the subcatchments gravity network not included in the model network
CSO Outfall	- 29 outfall nodes - All CSO outfalls are free outfall	- All outfalls are located in the Delaware River in the tidal reach, a tidal stage instead of free outfall should be assigned to the outfalls - Outfall ID 101 has dry weather input of 1.76 cfs, it represents WRTP in the model	- 24 CSO outfall nodes - Tidal data is assigned to 24 outfalls using time series - Wherever tide gates are installed, a real time control is applied

Review Item	2012 Model Review Observation	Comments	Updated Model
Sewer Mains	- 735 conduit links. - Negative slopes at Nodes 73803 and 70709 not matching the GIS. - Pipe connectivity is not consistent with the GIS in Subcatchment EA1, 25A. - Pipe size and connectivity is not consistent with the GIS around Node: 5201242, 5201234. - Pipe size is not consistent with the GIS around Node: 52018-52015. - Pipe size is not consistent with the GIS around Node: 531-527, 522-517, 516-513, 510020301-5100202, 403-NCPS, 40801-40801A, 32405-32404, and 1110402-11103. - Pipe size and slope are not consistent with the GIS around Node: 422-4140. - NREG06 outfall pipe direction is opposite.	- All the negative slopes and inconsistencies need to be checked with the most updated GIS and record drawings during the model update	- 817 conduit links. - 45 imaginary conduit links created to receive flows from subcatchment gravity network not included in the model

Review Item	2012 Model Review Observation	Comments	Updated Model
CSO Regulators	- 34 orifice links. - All CSO regulators are simulated using orifices to intercept dry weather flows and partial wet weather flows to the collection system, and with elevated conduits to convey extra flows to the CSO outfalls. - Approximately 75% of the orifices (25 out of 34) are modeled with Real Time Control (RTC) to mimic regulator gate opening based on level. - None of the regulator diverting weir structures is simulated in the model.	- Diverting weir structures need to be added in the model - The slopes of all overflow pipes connected to the CSO outfalls need to verified - All orifice opening dimensions verified will be verified - All the RTC rules regulating orifice opening will be verified with actual operation	- 44 orifice links. - CSO regulators are simulated using orifices and float-operated gates to intercept dry weather flows and partial wet weather flows to the collection system, and with conduits set a verified inverts to convey extra flows to the CSO outfalls. Exceptions occur at several regulators where orifices have been removed and at one regulator where the float and gate have been removed. - Approximately 57% of the orifices (25 out of 45) are modeled with Real Time Control (RTC) to mimic regulator gate opening based on level. - Regulator diverting weir structures added to the model. - All regulator characteristics were verified using record drawings excepting Regulator 17 which was field verified.
Pump Station	- No pump station is included in the model	- All pump stations that contribute flow to the DELCORA collection system should be added to the model, with related force mains	- Pump stations added to model. - Related force mains added to model

Review Item	2012 Model Review Observation	Comments	Updated Model
Dry Weather Flow	- 94 dry weather flow (DWF) inputs - Total DWF is 7.01 MGD - No diurnal curve - DWF does not include all the separated service areas that contribute to the DELCORA system -	- DWF should be updated to include all the service areas that contribute to the DELCORA system - Weekday and weekend diurnal curve should be included in the model to effectively simulate dry weather diurnal pattern	- 114 dry weather flow (DWF) inputs - Total DWF is 29.57 MGD - DWF analysis was performed on all flow meters in separated and combined areas as well as pump stations - Weekday and weekend diurnal curves were generated as well as overall, weekday, weekend and monthly DWF factors.
RDII	- No rainfall-derived infiltration/inflow (RDII) element was found in the model	- RDII should be included in the model to estimate reasonable wet weather inflow from RDII	- RDII was included in the model to estimate reasonable wet weather inflow from RDII

8.6 H & H Model Calibration

Model credibility is developed through model calibration and validation. Model calibration involves application of the model to known external inputs (e.g., rainfall), evaluation of the model's ability to replicate monitored conditions (e.g., flow and volume), and adjustment of key model parameters as needed until an acceptable level of agreement is reached between simulated and monitored conditions.

The collection system H&H Model was calibrated in conjunction with the flow monitoring and sampling program. The H & H Model was calibrated by running the model with rainfall data collected from selected storms and then comparing the calculated results to the actual flow monitoring data collected. The model parameters were adjusted and the process repeated until the calculated results approximated the actual flow monitor measurements. Goals for the model calibration included:

- To match visually the shape of the curve between model and flow monitor.
- To match model runoff volumes (volume under curve) to actual runoff volumes.
- To match model runoff peak flow rates to actual runoff peak flow rates.

Once the model was calibrated to the selected storms, at least one additional storm was run through the model to validate that the model was sufficiently calibrated.

Figure 8-2: Updated H&H Model Layout

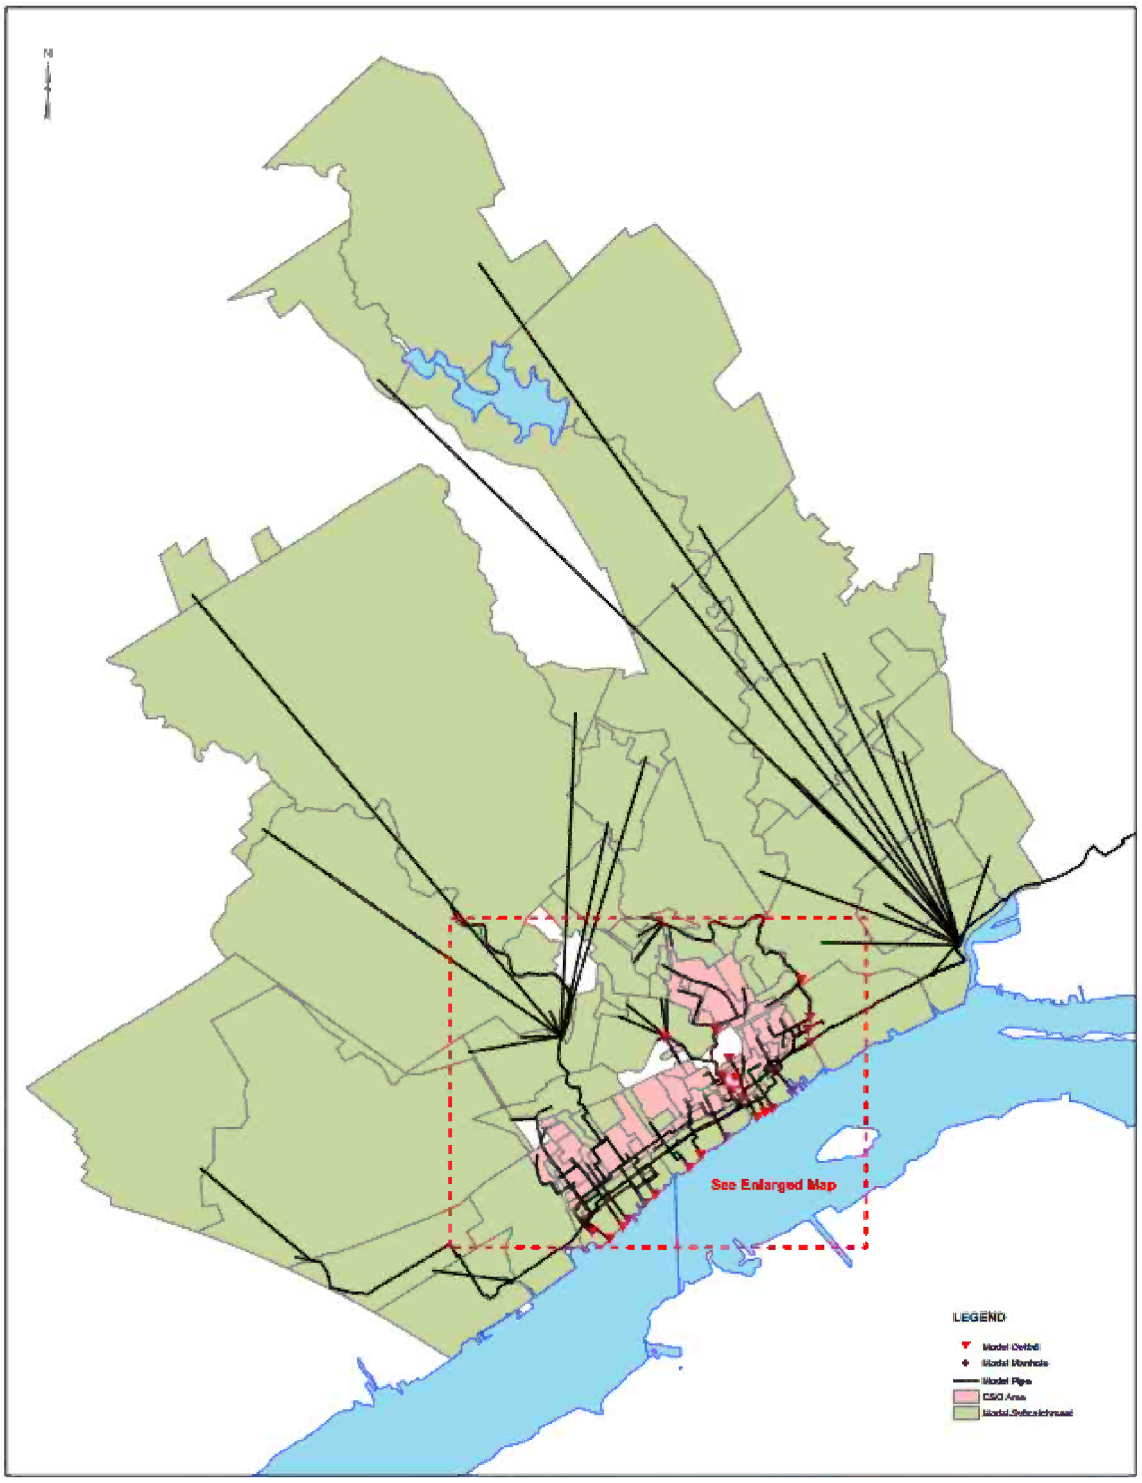


Figure 8-3: Updated H&H Model Layout – CSS Area

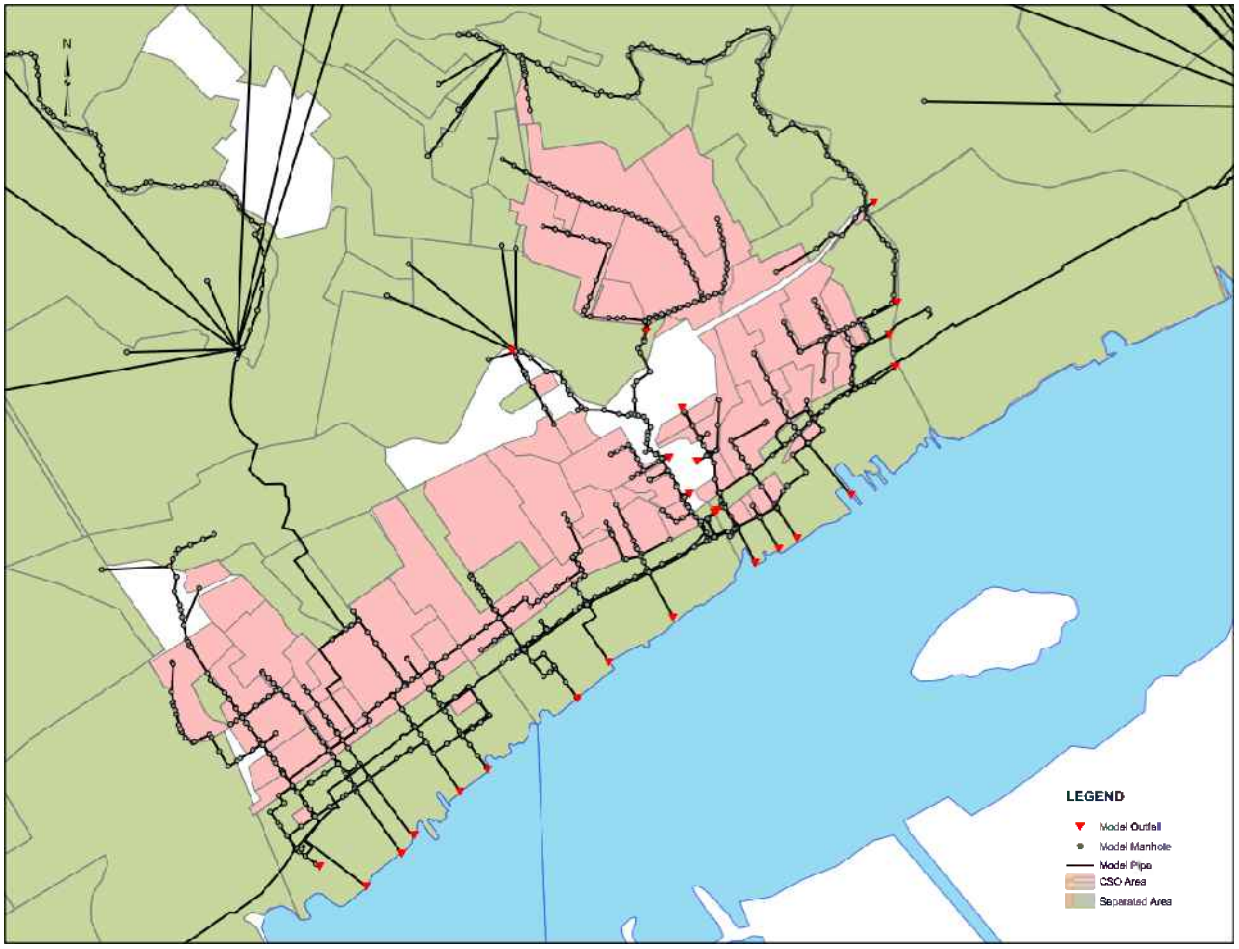

8.6.1 Dry Weather Flow Calibration

Dry weather flow (DWF) analysis was based on the rainfall and flow monitoring results. DWF distribution in the collection system was based on land use data. Weekday, weekend and monthly diurnal factors from the DWF analysis were applied for each flow meter service area. Upstream meters in the system were calibrated first, then flows through the system to the pumps stations and to the WRTP were balanced. Figure 4-4 shows the arrangement of the meters in the system and meter identification.

DWF calibration will adhere to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be within 1 hour of the observed,
- The simulated peak flow will be within 10% of the observed flow, and
- The simulated flow volume over 24 hours will be within 10% of observed flow.

The dry weather calibration shows that model and the flow monitors are not all within the goal of ten percent. There are a number of reasons for the differences. The accuracy of flow monitors in large pipes is reduced as the flows get smaller. The dry weather flows are very small, especially in comparison to the wet weather flows. Dry weather flow also has a diurnal curve. The model does not replicate the dry weather flow diurnal curve, but takes the average of the diurnal curve and uses that as a constant dry weather flow. This could cause some discrepancy between the model and metered flows.

After the dry weather calibration was considered to be satisfactory, the model was calibrated for wet weather periods as described below.

8.6.2 Wet Weather Calibration

Wet weather flow (WWF) includes surface runoff from the combined area, RDII from the entire service area, and connected rooftops, if any, from the separated area. RDII parameters will be developed based on the separated area, and surface runoff parameters will be adjusted for the combined area to calibrate the system response to the wet weather conditions.

Four (4) wet weather events were selected for wet weather calibration. Final selections include wet weather events with various rainfall intensities and volume. Larger storm events will have more weighting factor in the calibration process because the large events are the ones that dominate the total overflow volume.

WWF calibration will adhere to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be similar having regard to the duration of the event,
- The simulated peak flow for significant peaks will be within the range of -10% to +10%,
- The simulated flow volume will be within the range of -10% to +10%,

The four storms were selected for calibration of the collection system model met all the desired storm characteristics as describe in Section 4 of this Report. The May 29, 2016 storm was a 1.82-inch storm with a duration of approximately 11 hours and a maximum intensity of 0.78 in/hr. The September 28, 2016 storm was a 2.36-inch storm with a duration of 47 hours and a maximum intensity of 0.37 inches/hour. The November 29, 2016 storm was a 1.08 inch storm with a duration of 14 hours and a maximum intensity of 0.21 in/hr. The July 28, 2016 rain event was a 1.26-inch storm with a duration on 19 hours and a maximum intensity of 0.74 in/hr. Data on these storms is in shown in Table 8-3.

Table 8-3: Wet Weather Events for Model Calibration and Validation

Event ID	Start Time	Stop Time	Rainfall Duration (hr)	Rainfall Depth* (inches)	Max. Intensity (in/hr)	Used in Calibration	Used in Validation
E1	5/29/16 19:00	5/30/16 5:00	11.00	1.82	0.78	C	
E2	9/28/16 12:00	9/30/16 10:00	47.00	2.36	0.37	C	
E3	11/29/16 7:00	11/29/16 20:00	14.00	1.08	0.21	C	
E4	3/30/17 21:00	4/1/17 3:00	31.00	1.83	0.25		V
E5	5/21/16 11:00	5/22/16 21:00	35.00	1.71	0.33		V
E6	7/28/16 15:00	7/29/16 9:00	19.00	1.26	0.74	C	
*At Chester PS rain gauge							

The figures in Appendix B show the observed and simulated flow for the model calibration. Also included in Appendix B are plots of modeled versus monitored (i.e., observed) volumes and peak flows. A well calibrated model will result in plotted values that are close to a one-to-one relationship. These one-to-one plots can be found in Appendix B.

8.7 H & H Model Validation

According to USEPA's Guidance on Monitoring and Modeling (1999), "validation is the process of testing the calibrated model using one or more independent data set(s) of rainfall data." DELCORA's sewer system model was validated with rainfall from two rain events (May 21, 2016 and March 30, 2017). The May 21, 2016 rain event was a 1.71-inch storm with a duration of 35 hours and a maximum intensity of 0.33 in/hr. The March 30, 2017 storm was a 1.83 inch storm with a duration of 31 hours and a maximum intensity of 0.25 in/hr. The rainfall data for these storms is shown on Table 8-3 above. These storms were chosen for their size, intensity and because there were no rain events for five days before the storm. The figures in Appendix B show the observed and simulated flows for the model validation.

Also included in Appendix B are plots of modeled versus monitored (i.e., observed) volumes and peak flows. A well-calibrated model will result in plotted values that are close to a one to one relationship. These one-to-one plots can be found in Appendix B.

8.8 H & H Model Results

Following calibration, the typical hydrologic period (1994 to 1996) was used as the rainfall input to the H&H model. The hourly rainfall for the period 1994 to 1996 had been previously determined to be representative of annual average conditions with respect to rainfall amount (volume), number of rainfall events per year, rainfall duration, and rainfall intensity and has been discussed in Section 7.

A summary of estimated volume, frequency and duration of CSO discharge events based from the calibrated H&H model using the typical hydrologic period is presented in Appendix C. The total annual average CSO overflow volume was approximately 300 MG for the typical hydrologic period. The dry weather flows and their monthly factors in the calibration model are based on the flow monitoring period (March 2016 through March 2017). For future model application, the dry weather flows should be based on future flow projections and the monthly factors should be adjusted accordingly.

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Hydrologic and Hydraulic Model Update and Calibration Plan. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP).

EPA hereby approves the plan with the understanding that the term "two days" as stated in paragraph 5.1.2.1 (Dry Weather Overflow Analysis) shall mean 48 hours.

Thank you for your continued cooperation with this matter. Please do not hesitate to contact me at (215)814-2097 if you have any questions.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Disantis:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Typical Hydrologic Period Report (Updated April 2016). EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). EPA hereby approves the subject plan.

Thank you for your continued cooperation with this matter. Please do not hesitate to contact me at (215) 814-2097 if you have any questions.

Sincerely,

Andrew F. Seligman, Environmental Scientist

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Existing Service Area Characterization Report dated August 15, 2017. EPA accepts and approves the subject report.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

Executive Summary

BACKGROUND

The Delaware County Regional Water Quality Control Authority (DELCORA) is a municipal authority originally organized under the Pennsylvania Municipal Authorities Act of 1945 (P.L. 382), as amended and supplemented, pursuant to action taken by the Delaware County Council on October 20, 1971. Under County of Delaware Ordinance 2002-1, the term of existence of DELCORA was extended to January 15, 2052.

DELCORA is in the process of developing a Long Term Control Plan (LTCP) for the Combined Sewer System (CSS) as part of a Consent Decree entered with the United States Environmental Protection Agency (USEPA) and the Pennsylvania Department of Environmental Protection (PADEP). As part of this comprehensive effort, a Public Participation Program is being implemented to inform, seek input from, and educate the public (i.e., private citizens, businesses, special interest groups, local government, State government, and the Federal government) in the decision-making process for selecting and developing the appropriate LTCP CSO controls for the CSS.

PURPOSE

The purpose of this report is to document DELCORA's Public Participation Plan (PPP) for the LTCPU. The PPP shall describe how DELCORA will inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies.

The goals of the PPP during the development of the CSO LTCPU include addressing requirements of the United States Environmental Protection Agency (USEPA) Combined Sewer Overflow (CSO) Control Policy (dated April 19, 1994) by *"employing a process that actively involves the affected public in the decision-making to select the long-term CSO controls. The affected public includes rate payers, industrial users of the sewer system, persons who reside downstream from the CSOs, persons who use and enjoy these downstream waters, and any other interested persons."* Additionally, in accordance with Section V.A.17 (page 19) of the Consent Decree between the United States of America, the Commonwealth of Pennsylvania, Department of Environmental Protection, and DELCORA, which was lodged on August 17, 2015, the PPP *shall describe in detail how DELCORA will inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies. The plan shall specifically describe how the LTCP update process will: (i) address the impact of DELCORA's CSOs and LTCP on environmental justice populations, (ii) seek input from communities that may have historically borne a disproportionate share of the negative environmental consequences resulting from DELCORA;s CSOs, and (iii) ensure that the LTCP and selected CSO Control Measures will not impose a disproportionate share of negative*

environmental consequences on such communities in the future. The plan shall also include a schedule for DELCORA's implementation of the plan.

To be consistent with the requirements of the EPA CSO Control Policy and the Consent Decree, this PPP has been prepared to specifically describe how the LTCP update process will:

i. *Address the impact of DELCORA's CSOs and LTCP on environmental justice communities.*

ii. *Seek input from communities that may have historically borne a disproportionate share of the negative environmental consequences resulting from DELCORA's CSOs.*

iii. *Ensure that the LTCP and selected CSO Control Measures will not impose a disproportionate share of negative environmental consequences on such communities in the future.*

iv. *Include a schedule for DELCORA's implementation of the plan.*

PUBLIC AND STAKEHOLDER MEETINGS

The USEPA "Combined Sewer Overflows Guidance for Long-Term Control Plan," dated August 1995, indicates that public participation and Agency interactions should occur at the following steps of the LTCP development process:

1. System Characterization
2. Development and Evaluation of Alternatives for CSO Controls
3. Selection and Implementation of the Long-Term Plan

This PPP has been developed to actively involve the affected public in each of the above steps via Public Participation Meetings and other methods as further described herein. In addition to these minimum requirements, one additional Public Participation Meeting will be considered prior to the required meetings (listed above) to inform the public early in the planning process about the scope and goals of the program. In summary, the Public Participation Meetings to be held will be as follows:

Meeting No. 1: Scope and Purpose of the Study
Meeting No. 2: System Characterization
Meeting No. 3: Development and Evaluation of Alternatives for CSO Controls
Meeting No. 4: Selection and Implementation of the Long-Term Plan

In addition to the above stated Public Participation Meetings, DELCORA will also be holding stakeholder meetings with various agencies, authorities, and special interest groups throughout the course of the LTCP program.

Beyond the above referenced Public Participation Meetings and Stakeholder Meetings, a concerted effort will also be made to make the public aware of the CSO LTCPU development process and to actively involve and educate them about CSO issues and the selection of the CSO control elements through various media, including the following:

1. Update and Educational Material in Sewer Bills
2. CSO Website
3. CSO Newsletters in the form of mail inserts and/or emails
4. Handouts
5. Literature and Documentation will be made available by DELCORA at municipal buildings and public library

Section 1 Introduction

1.1 Background of DELCORA's Facilities

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the safe collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1. The total service area served by DELCORA is approximately 82,977 acres, as shown on Figure 1-2, which illustrates that DELCORA serves a significant and widespread portion of Delaware County. The combined sewer area simulated in the original model, also shown in Figure 1-2, is located within the Chester City. It comprises approximately 49% of the Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows.

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western service area discharges to the Western Regional Treatment Plant (WRTP). The Eastern service area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWD-SWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are to be directed to the PWD-SWPCP. As such, dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

Under National Pollutant Discharge Elimination System (NPDES) Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall 001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow (CSO) outfalls (002-026, 032, 033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

There are a total of 26 combined sewer overflow (CSO) outfalls listed with 25 discharge points (Outfalls 009 and 010 both discharge at Outfall 009) in DELCORA's existing NPDES Permit.

1.2 Purpose of Public Participation Plan

The purpose of this Public Participation Plan (PPP) is to present and document DELCORA's Public Participation Program for the LTCPU. The PPP outlines the methods that DELCORA will utilize to actively facilitate public involvement in the decision-making process to develop and select the long term CSO controls.

The goals of the PPP during the development of the CSO LTCPU include addressing requirements of the United States Environmental Protection Agency (USEPA) Combined Sewer Overflow (CSO) Control Policy (dated April 19, 1994) by *"employing a process that actively involves the affected public in the decision-making to select the long-term CSO controls. The affected public includes rate payers, industrial users of the sewer system, persons who reside downstream from the CSOs, persons who use and enjoy these downstream waters, and any other interested persons."* Additionally, in accordance with Section V.A.17 (page 19) of the Consent Decree between the United States of America, the Commonwealth of Pennsylvania, Department of Environmental Protection, and DELCORA, which was lodged on August 17, 2015, the PPP *shall describe in detail how DELCORA will inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies. The plan shall specifically describe how the LTCP update process will: (i) address the impact of DELCORA's CSOs and LTCP on environmental justice populations, (ii) seek input from communities that may have historically borne a disproportionate share of the negative environmental consequences resulting from DELCORA;s CSOs, and (iii) ensure that the LTCP and selected CSO Control Measures will not impose a disproportionate share of negative environmental consequences on such communities in the future. The plan shall also include a schedule for DELCORA's implementation of the plan.*

1.3 Public Participation Plan Overview

As part of the Long Term Control Plan Update (LTCPU), this Public Participation Plan (PPP) has been developed to involve key decision makers as described in Section 3.2 for developing and selecting appropriate LTCP objectives for the CSS communities.

To be consistent with the requirements of the EPA CSO Control Policy and the Consent Decree, this PPP has been prepared to specifically describe how the LTCP update process will:

i. *Address the impact of DELCORA's CSOs and LTCP on environmental justice communities.*

ii. *Seek input from communities that may have historically borne a disproportionate share of the negative environmental consequences resulting from DELCORA's CSOs.*

DELCORA'S SERVICE AREA

iii. *Ensure that the LTCP and selected CSO Control Measures will not impose a disproportionate share of negative environmental consequences on such communities in the future.*

iv. *Include a schedule for DELCORA's implementation of the plan.*

The USEPA "Combined Sewer Overflows Guidance for Long-Term Control Plan," dated August 1995, indicates that public participation and Agency interactions should occur at the following steps of the LTCP development process:

1. System Characterization
2. Development and Evaluation of Alternatives for CSO Controls
3. Selection and Implementation of the Long-Term Plan

This PPP has been developed to actively involve the affected public in each of the above steps via Public Participation Meetings and other methods as further described herein. In addition to these minimum requirements, one additional Public Participation Meeting will be considered prior to the required meetings (listed above) to inform the public early in the planning process about the scope and goals of the program. In summary, the Public Participation Meetings to be held will be as follows:

Meeting No. 1: Scope and Purpose of the Study
Meeting No. 2: System Characterization
Meeting No. 3: Development and Evaluation of Alternatives for CSO Controls
Meeting No. 4: Selection and Implementation of the Long-Term Plan

In addition to the above stated Public Participation Meetings, DELCORA will also be holding stakeholder meetings with various agencies, authorities, and special interest groups throughout the course of the LTCPU program.

Beyond the above referenced Public Participation Meetings and Stakeholder Meetings, a concerted effort will also be made to make the public aware of the CSO LTCPU development process and to actively involve and educate them about CSO issues and the selection of the CSO control elements through various media, include the following:

1. Update and Educational Material in Sewer Bills
2. CSO Website
3. CSO Newsletters
4. Handouts
5. Literature and Documentation

During the course of the LTCPU development and selection process, the public will have the opportunity to be informed, participate in discussions, and provide input through the above meetings.

Section 2 Public Meetings and Engagement Tools

2.1 Objective

The main objective of public meetings and the engagement tools that will be implemented are to foster public awareness and actively facilitate public involvement by taking into consideration public input during the decision making process and selection of the final long term CSO controls.

2.2 Inputs During Public Participation Process

During the public participation process, DELCORA and the Engineering and Program Management Consultant, Greeley and Hansen, will present Public Outreach Material and receive questions and comments.

DELCORA will maintain a website containing information about the Authority and the CSO system. Residents can also report problems or concerns with DELCORA through requests for information. Requests for information will be directed to DELCORA at 610-876-5523 and DELCORA can also be reached by email at ltcpinfo@delcora.org. Comments may also be received through DELCORA's CSO LTCPU website at www.delcora.org.

The comments received will be given consideration during the progress of the program and for the development and selection of the CSO controls.

2.3 Facilities Description and Location

The public meetings will be held at the following four locations. The exact time and location of the meetings will be advertised in advance of the meetings and as described in Section 2.6.

1. **Chester City Hall**
   Address: 1 E. 4th Street Chester, PA 19013

2. **Ridley Township Municipal Building**
   Address: 100 MacDade Boulevard Folsom, PA 19033

3. **Chester City Hall**
   Address: 1 E. 4th Street Chester, PA 19013

4. **Aston Township Administration Building**
   Address: 5021 Pennell Road, Aston, PA 19014

The public meeting locations will be held at different locations in order to maximize the likelihood of attendance for residents and stakeholders. The facilities will have ample meeting space. These locations serve a vital role in Delaware County as the central meeting place and serves as a gathering place for the local community, as well as the hosting of numerous public events, including public information meetings, and are all free to the public.

2.4 Responsiveness Summary

After each public meeting, a Responsiveness Summary will be prepared. Each Responsiveness Summary will include notifications and information that will be made available to the public at the following meeting. This will include a summary of the meeting presentation and attendance; statements, comments, and questions raised by the public, followed by DELCORA's responses.

When preparing the Responsiveness Summary, special attention will be given to address the public statements, comments, and questions, along with DELCORA's responses.

A final copy of the Responsiveness Summary will be provided and reviewed at the subsequent public meeting and a copy will also be placed on DELCORA's CSO LTCPU website. In addition to this the responsiveness summary will also be available at an offline repository location at municipal buildings and/or public library.

2.5 Public Engagement Tools

The public engagement program will be developed in collaboration with DELCORA and the Engineering and Program Management Consultant. This program will include multiple tools nested in primarily the two following strategies:

1. Direct Engagement Strategy

   This strategy will be implemented at the Public Meetings, as well as the Stakeholder Meetings, and will address the complex issues of the LTCP program by providing an opportunity for public participation that is active, interactive, encouraging people to provide ideas and comments and continue to learn about DELCORA's CSO LTCPU program and its objectives. The rationale behind DELCORA's CSO LTCPU will be discussed with the public as part of the engagement program. This strategy will involve stakeholder interactions, use of public meeting talking points, and education based presentations in-line with the requirements of the development process of the LTCP.

2. Digital Engagement Strategy

   This strategy will actively engage the public in providing feedback and comments through the use of digital technology. This will help provide ample information when

people want to know more about the program and its progress. The use of the DELCORA website with a CSO link and notification updates will broaden the range of people that can participate in this program. DELCORA's website will add new content on a regular basis and DELCORA will keep the website updates with the progress milestones of the LTCPU. People will be encouraged to participate by leaving comments or inputs. Informational materials could be posted on the website, as well. This could include advertisements for public meetings, information from communities and other stakeholders, the Responsiveness Summaries from the Public Meetings, project areas and photos, construction notices, as well as key project dates and milestones.

2.6 Public Meeting Descriptions

It is anticipated that there will be four public engagement meetings and each meeting will include elements of the strategies listed above. Meetings will be developed to sync with the needs of the development of the LTCPU. The key points that will be addressed through these public engagement strategies include the following in order to be consistent with the USEPA "Combined Sewer Overflows Guidance for Long-Term Control Plan," dated August 1995:

1. System Characterization
2. Development and Evaluation of Alternatives for CSO Controls
3. Selection and Implementation of the Long-Term Plan

The first public meeting will be used to brief the public on the history, scope and purpose of the study and to obtain their general views on the study. At this meeting a general presentation with information on DELCORA and its CSO LTCPU program will be given to the public. This meeting will provide an effective forum to obtain inputs from interested individuals and organizations. The power point presentation will be provided to the public for review a week in advance of the meeting. The presentation materials will be available for access to the public on DELCORA's CSO LTCPU website under the Combined Sewer System tab.

The second public meeting will focus on updating the public on the scope of activities that make-up system characterization, analysis of existing data and development of the monitoring and modeling programs, identification and status of implementation of the Nine Minimum Controls, and the process for evaluating alternative CSO controls. DELCORA and the Engineering and Program Management Consultant will focus on providing a power-point presentation with hand-outs with the following information to the public as it is developed during this phase, as relevant:

- Scope of monitoring and assessment programs for system characterization
- The watershed approach to CSO control planning
- Identification of watersheds in the CSO area
- Identification and quantification of non-CSO sources
- Existing sewer system conditions and problems (e.g., flooding, basement backups)

- Quantification of CSO flows and loads and impacts of CSOs on receiving waters
- Results of CSS and receiving water monitoring programs
- Development and calibration of the CSS and receiving water models
- Identification and implementation status of the NMC
- Process for evaluating alternatives

DELCORA will interact between various municipal and permitting authorities to reach agreement on the data, information and analysis that is needed to support the development of long-term CSO control plan and review of applicable water quality standards (WQS) as well as implementation procedures. This agreement on the data as well as the power-point presentation will be provided to the public for review a week in advance of the meeting.

The goals of the third public meeting will be to actively involve the public in the development of the alternative solutions that protect the receiving streams, as well as to consider the financial impacts to the community as a whole. During this third Public Meeting, DELCORA and the Engineering and Program Management Consultant will provide a power-point presentation with handouts. The opportunity for citizens to be actively involved in the development of alternatives that provide solutions to protect the local waterways will be provided. Any suggestions, comments and financial impacts to the community will be considered. The following key information will be presented to the public:

- Water quality goals for each receiving water segment
- CSO control goals for each receiving water segment as developed under the presumption and/or demonstration approach options
- Types of control alternatives available to meet CSO control goals
- CSO control alternatives identified to meet the control goals
- Process of evaluating and comparing various alternatives for CSO control

DELCORA will continue to fund and implement the CSO control measures that are currently being implemented under the 1999 LTCP to reduce the frequency, volume, and pollutant load of CSO discharges to local waterways. Additionally, early action CSO control projects will continue to be identified and implemented, where appropriate. Additional CSO control alternatives would be selected based on their water quality impacts, their ease of implementation, and their cost effectiveness. During the Public Participation process, various CSO control measures investigated through engineering analysis will be presented at the third public meeting by the Engineering and Program Management Consultant on behalf of DELCORA. The type and features of the CSO control measures to be considered for each element of the LTCPU would also be based on the nature of the problem, project constraints, and analysis of existing data. Some of the major CSO mitigation measures that would be considered are listed below:

- Capacity Recovery in the existing CSS
- CSO Regulator Improvement Program
- Sewer System Cleaning/Flushing to avoid backups

- Sewer/ CSO Regulator replacement
- Tide Gate Maintenance or replacement
- Reduction of FOG in the sewers
- Outfall Maintenance Program;
- Private Property I/I Elimination
- Outfall Combined Wastewater Diversion and Separation
- Outfall Consolidation, Relocation, or Elimination
- Additional Conveyance Systems
- Inlet Replacement Program
- Downspout Disconnect Program

Presentations will be provided to the public and other listed stakeholders (as discussed in Section 3) on the various advantages and disadvantages of these control measures for further inputs and comments.

The fourth public meeting will discuss and present progress on the development and selection of the alternatives for implementation of the Long-Term Plan. Once the alternatives have been evaluated in detail, but prior to selection of specific CSO controls, the public will be informed of each alternative and ranked based on preference in a draft report. The results of the evaluation will be summarized in an executive summary. The extent of implementation of each alternative evaluated will be based on public input. The schedule and financing method will also be described in the report prior to selection.

During the CSO control measures evaluation stage, alternative measures that can reduce the impact of CSO discharges will typically fall into one of the following four categories:

1. Source Control Technologies/Alternatives - eliminating or preventing pollution before it is created.

2. Collection System Control Reducing Technologies/Alternatives – reducing the discharge volume, concentration, or frequency.

3. Storage Technologies/Alternatives - capturing all or some of the discharge and then releasing for treatment.

4. Treatment Technologies/Alternatives - treating as much as possible.

After assembling a list of possible control alternatives, the necessary preliminary screening will be conducted in order to better evaluate which control alternatives have the highest potential to protect receiving water quality. The selected alternatives will be screened against evaluation

criteria that were selected based upon characteristics of CSO discharges that are measurable and can impact the receiving water. The preliminary screening criteria are as follows:

- Flow reduction
- BOD reduction
- DO improvement
- Settleable solids removal
- Bacteria reduction
- Floatables reduction
- Toxic materials reduction
- Implementation and operation factors

The final CSO control alternatives will be prioritized based on their potential to reduce the CSO discharge frequency and pollutant load to each water body, their cost effectiveness, and on the financial capability. The following impact points will be considered while implementing the final CSO control alternatives:

- CSO Impacts - Sensitive Areas
- CSO Impacts - Water Quality Objectives
- CSO Impacts - Pollutant Load by Water Body
- CSO Control Technology - Pollutant Load Reduction by Water Body
- CSO Control Technology - Cost Effectiveness

During this meeting, the alternative rankings will be presented and discussed thoroughly. The technical solutions will be presented in a simple format with information covering background of project, description of facility, level of control needed, any impacts, and mitigation measures to be taken, as well as the cost. Graphs will be used to present each alternative along with benefits, resource requirements and cost.

DELCORA will continue to interact with municipal and permitting authorities even in this phase with sharing of technical information. CSO control measure performance will be discussed with regulatory authorities to reach agreement. DELCORA will consult with permitting authorities to ensure consistency with the CSO Control Policy provisions regarding CSOs occurring in sensitive areas and show that all reasonable options in developing a list of final alternatives for evaluation have been studied while incorporating all identified concerns.

During all meetings, an agenda will be developed, distributed to the public and followed during the presentations. One person will be designated to take meeting notes and collect public comment sheets so all views are recorded. In addition, written comments from the public will be accepted until one month after the date of the public meetings described above. As previously discussed, after each public meeting, a Responsiveness Summary will be prepared. Each Responsiveness Summary will include notifications and information that will be made available to the public at the following meeting, as well as on DELCORA's CSO LTCPU website.

DELCORA will submit to the regulatory authorities any technical memorandums, interim reports, meeting minutes, and the Responsiveness Summary for comments. Once comments are received, DELCORA will respond to each agency.

Information will be presented to the public in the most understandable manner and in a format that is most appropriate for the public. Any technical information or complex charts will be avoided. Additionally a review of the responsiveness summary from the prior meetings will occur at the second, third and fourth public meetings.

The presentation materials will be available for access to the public at offline repositories as stated in the Executive Summary and DELCORA's CSO LTCPU website under Combined Sewer System tab at least a week in advance of all scheduled meetings. Public will be notified for these materials through the public notice for the meetings.

The public's input will be actively solicited by receiving questions and comments as it relates to the presentation. Public will be advised that there will be an opportunity to raise questions, provide comments and give ideas at the meeting as well. Public will be informed that they have 30 days to submit questions and comments. Last slide of every presentation will have contact information to submit questions and comments. A copy of each presentation will be provided as handout to the participants. At each public meeting public can submit comments and ideas will be solicited.

Public will be informed through a notice in the form of an advertisement prior to the scheduled meetings to raise comments and questions. The public will be encouraged to ask questions as the presentation proceeds and will be asked to provide any comments in writing, as well. Comments arising from all public meeting presentations can be submitted by one of the following methods within 30 days after the scheduled meeting:

- By Mail:
  DELCORA
  P.O. Box 999
  Chester, PA 19016-0999
- By Phone: 610-876-5523
- By Email: ltcpinfo@delcora.org.
- By Website: www.delcora.org.

2.7 Meeting Schedule

Public meetings will be held over the course of the LTCPU development effort to describe how DELCORA will inform and actively solicit input to its updated LTCPU from stakeholders, including the public, customer communities, and the regulatory agencies. Public meetings will be held as described in Section 2.6. The proposed schedule for these meetings is as follows (subject to coordination with USEPA):

Table 2-1: Public Meeting Schedule

Meetings	Description	Scheduled
Meeting No. 1	Scope and Purpose of the Study	1st Quarter of 2016
Meeting No. 2	System Characterization	3rd Quarter of 2017
Meeting No. 3	Development and Evaluation of Alternatives for CSO Controls	4th Quarter of 2017
Meeting No. 4	Selection and Implementation of the Long-Term Plan	3rd Quarter of 2018

The detailed meeting schedule for the implementation of the PPP has been attached herein as Attachment A.

2.8 Meeting Advertisement

The public will be invited through advertisements on DELCORA's CSO LTCPU website in advance.

The public meeting notice will also be advertised in the following local newspapers or circulations:

1. Chester Spirit
2. Delaware County Daily Times
3. Philadelphia Inquirer
4. Press Newspaper

Per the requirements of Pennsylvania's Sunshine Act (provided herein as Attachment C), DELCORA will give public notice of its meetings not less than three (3) days in advance of the meeting and shall give public notice of its remaining meetings. DELCORA shall also give public notice of any special meeting or rescheduled meeting at least 24 hours in advance of the time of the convening of the meeting specified in the notice.

The definition of the "Public Notice" per Pennsylvania's Sunshine Act is as follows:

"(1) For a meeting:

(i) Publication of notice of the place, date and time of a meeting in a newspaper of general circulation, as defined by 45 Pa.C.S. Â§ 101 (relating to definitions), which is published and circulated in the political subdivision where the meeting will be held, or in a newspaper of general circulation

which has a bona fide paid circulation in the political subdivision equal to or greater than any newspaper published in the political subdivision.

(ii) Posting a notice of the place, date and time of a meeting prominently at the principal office of the agency holding the meeting or at the public building in which the meeting is to be held.

(iii) Giving notice to parties under section 709(c) (relating to public notice).

(2) For a recessed or reconvened meeting:

(i) Posting a notice of the place, date and time of the meeting prominently at the principal office of the agency holding the meeting or at the public building in which the meeting is to be held.

(ii) Giving notice to parties under section 709(c).”

Section 3 Stakeholder Members

3.1 Purpose

In addition to the Public Meetings and Engagement Tools as described in Section 2, a group comprising of stakeholder members will be formed for this PPP. The stakeholder meetings will be held on an as-needed basis throughout the course of the LTCP program. These meetings will provide an opportunity for active input and consultation on the LTCP development process. These meetings will also provide an effective forum for an in-depth exchange of information, ideas, and results as the LTCP process moving forward.

3.2 Selection of Members

To reflect a balance of perspectives, stakeholder members may consist of representatives from the public, customer communities, regulatory agencies, and special interest groups. The list of stakeholders considered by DELCORA is provided below. These members will provide inputs through stakeholder meetings. DELCORA will be scheduling independent meetings with each of these stakeholders. These meetings will be beyond the public meetings that are described in Section 2 of this PPP. Presentations will be made to these stakeholders throughout the CSO LTCPU program. A sample copy of this presentation has been provided herein as Attachment B1.

1. Darby Creek Joint Authority
2. Central Delaware County Authority
3. Muckinipates Authority
4. Delaware River Basin Commission
5. Radnor, Haverford, Marple Authority
6. Southern Delaware County Authority
7. Southwest Delaware County Municipal Authority
8. Middletown Township Sewer Authority
9. Chester Environmental Partnership
10. Department of Environmental Protection - Southeast Regional Office
11. Delaware County Planning Department
12. State Elected Officials
13. Local Municipal Officials
14. National Association for the Advancement of Colored People (NAACP)
15. Chester City Council
16. Pennsylvania Resource Council
17. Chester, Ridley & Crum Creek Watershed Association
18. Chester Water Authority (CWA)
19. Delaware County Public Relations Department

20. Delaware Riverkeeper
21. PA Sea Grant
22. Delaware County Council
23. Delaware County Chamber of Commerce
24. Industrial Contributors
25. Chester Business Association

The contact information for the stakeholders will be maintained accurately in a database throughout the project. The potential stakeholders will be identified by DELCORA and the Engineering and Program Management Consultant.

3.3 Meeting Site, Format and Time

Meetings will convene in a meeting room at a predetermined and mutually agreed upon location. The location of the meeting will be coordinated with the Stakeholder member(s). Some of these meetings will also be held at DELCORA's Western Regional Treatment Plant (WRTP). DELCORA will chair each meeting and provide an update on the progress and status of current issues. The following public participation team members from DELCORA may be present at the meetings:

1. Bob Willert – Executive Director
   a. Email: willertr@delcora.org
   b. Contact Number: 610-876-5523 ext. 110

2. Ed Bothwell – Director of Engineering
   a. Email: bothwelle@delcora.org
   b. Contact Number: 610-876-5523 ext. 216

3. Michael DiSantis – Director of Operations & Maintenance
   a. Email: disantism@delcora.org
   b. Contact Number: 610-876-5523 ext. 264

4. Robert Powell – Business Development & Strategic Planning Manager
   a. Email: powellr@delcora.org
   b. Contact Number: 610-876-5523 ext. 127

5. John Pileggi – Controller
   a. Email: pileggij@delcora.org
   b. Contact Number: 610-876-5523 ext. 118

The meeting will then be opened for discussion, questions, and comments. DELCORA will provide the stakeholder an opportunity to sign-up to receive updates on the project and information covering items like agenda and educational materials.

Following each meeting, a brief summary of the meeting will be prepared and distributed to all participants.

Section 4 Public Information Plan

4.1 Notices and Advertisements

To encourage public awareness of, and involvement in, the public meetings, notifications and background information will be made available to the public at least three (3) days prior to each meeting as required by Pennsylvania's Sunshine Act (provided herein as Attachment C). Access to public information will be provided as required by the Pennsylvania Right-to-Know Law Act 3 of 2008 (provided herein as Attachment D).

Sample copies of Public Education and Outreach Materials have been provided under Attachments B1, B2, B3 and B4. These material samples include Stakeholders' powerpoint presentation, public education brochures, newspaper press release and a sample screen shot of what the DELCORA's CSO LTCPU website may look like.

Announcements will be communicated to the public through the following media devices:

- Local Newspapers: Advance notices of public meetings will be published in at least four local newspapers in accordance with Pennsylvania's Sunshine Act (see Section 2.8).

- Internet Websites: Notices of the public meetings will also be placed on DELCORA's website with a CSO LTCPU Link (www.delcora.org).

- Notice by Mail: A list of citizens and representatives of businesses, interest groups, federal government, local government, regulatory agencies, neighboring jurisdictions, and inter-jurisdictional agencies will be developed and accumulated as the study progresses. Any person or group who provided a name and address will be added to the list. Persons on the mailing list will be sent special notices of upcoming public meetings, as well as the responsiveness summaries for each meeting.

4.2 Public Education and Involvement

A concerted effort will be made to make the public aware of the CSO LTCPU development process and to actively involve and educate them about CSO issues through the following media:

1. Updates and Educational Material in Sewer Bills – A public meeting notice will be prepared and this mailing insert will be included in sewer bills mailed out to DELCORA customers.

The topics discussed in the mailing insert will be as follows:

- Definition of combined sewers and how they function
- Explanation of the LTCPU development effort
- Invitation for the public to become involved and provide input
- Illustration of how a combined sewer system functions
- Reporting of any dry weather overflows
- The role of littering in causing dry weather overflows
- Illustrations of how a CSO regulator structure functions during dry and wet weather

2. CSO Website – DELCORA will create a special section of its Internet website devoted exclusively to CSO issues. This section of the website will be called "Combined Sewer System". The website will include information on the nature of CSOs, maps showing the location of outfalls, descriptions of the LTCPU development process, CSO monitoring results, information on pollution prevention, ways in which the public can get involved, previous meeting responsiveness summaries, and an option to post comments or questions on the program. Notices for public meetings will also be posted on the website. The website will provide a means to sign up to receive any newsletters. A downloadable copy of the newsletter will be uploaded to the CSO website as well.

3. CSO Newsletters – Project updates will be sent out to the mailing list created through the first public meeting, as well as subsequent requests from the public and interested stakeholders. The mailing lists will be developed using the sign-in sheets and also all the billed customers. The sign-in sheet will include a means to opt for a preferred method for receiving or not newsletters. The preferred options would be a digital copy by email or a hardcopy by mail. The topics discussed in these newsletters will include the following:

   - Explanation of combined sewers, CSO's, and the LTCPU process
   - Schedule for public meetings
   - Netting system demonstration project
   - Monitoring program update and illustration

4. Handouts - For each public meeting and stakeholder meeting, handouts will be prepared regarding information presented. These handouts will be made available to everyone who attends. These handouts will be designed for the general audience and serve to provide an overview of the LTCP update. These documents will provide information on the history, background, and approach taken by DELCORA to control CSOs, and will include information on how members of the public and interested

stakeholders can actively provide input and/or comments. These documents will be uploaded to the CSO LTCPU section of the DELCORA website, as well.

5. Literature and Documentation – Responsiveness summaries for the public meetings will be prepared for each public meeting. These summaries will also include responses to any comments received from previous meetings. These documents will be made available at the next meeting and uploaded to the CSO LTCPU section of the DELCORA website. Literature and Documentation will also be made available by DELCORA at the following municipal building and public library locations:

   DELCORA Administration Building
   100 East Fifth Street
   Chester, PA 19013

   J. Lewis Crozer Library
   620 Engle Street
   Chester, PA 19013

   Marcus Hook Municipal Building
   1015 Green Street
   Marcus Hook, PA 19061

   Ridley Township Building
   100 MacDade Blvd.
   Folsom, PA 19033

   Upland Borough Office
   224 Castle Avenue
   Brookhaven, PA 19015

   Chester Township
   1150 Engle Street
   Chester, PA 19013

6. Presentations to Stakeholder Members – Presentations will be made to other selected DELCORA stakeholder members as listed below. A sample copy of this presentation has been provided herein as Attachment B1.

   - Darby Creek Joint Authority
   - Central Delaware County Authority
   - Muckinipates Authority
   - Delaware River Basin Commission

- Radnor, Haverford, Marple Authority
- Southern Delaware County Authority
- Southwest Delaware County Municipal Authority
- Middletown Township Sewer Authority
- Chester Environmental Partnership
- Department of Environmental Protection - Southeast Regional Office
- Delaware County Planning Department
- State Elected Officials
- Local Municipal Officials
- National Association for the Advancement of Colored People (NAACP)
- Chester City Council
- Pennsylvania Resource Council
- Chester, Ridley & Crum Creek Watershed Authority
- Chester Water Authority (CWA)
- Delaware County Public Relations Department
- Delaware Riverkeeper
- PA Sea Grant
- Delaware County Council
- Delaware County Chamber of Commerce
- Industrial Contributors
- Chester Business Association

Presentation materials will cover introduction and progress on the LTCPU program. The purpose of these meetings are to actively solicit input from the stakeholder members at each phase of the program and present progress in the scheduled meetings.

Combined Sewer Overflow - Long Term Control Plan Update

DELCORA

Public Participation Meeting No. 1

LTCPU Scope and Purpose

March 15, 2016

Chester City Hall Community Room

1 E. 4th Street, Chester, PA

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Public Participation Plan Goals

- DELCORA's goals and objectives for the Public Participation Program are to :
  - Inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies
  - Educate the public
  - Address public concerns

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

General Information

- DELCORA is the Delaware County Regional Water Quality Authority, established in 1971, responsible for collecting, conveying and treating wastewater in the greater Philadelphia Area including 42 Municipalities in Delaware and Chester County.

DELCORA Mission

"Provide environmentally responsible and cost effective wastewater management services to the citizens, businesses, and industries of Southeastern Pennsylvania"

Delaware County Regional Water Quality Control Authority

DELCORA

Delaware County, PA

DELCORA Service Area

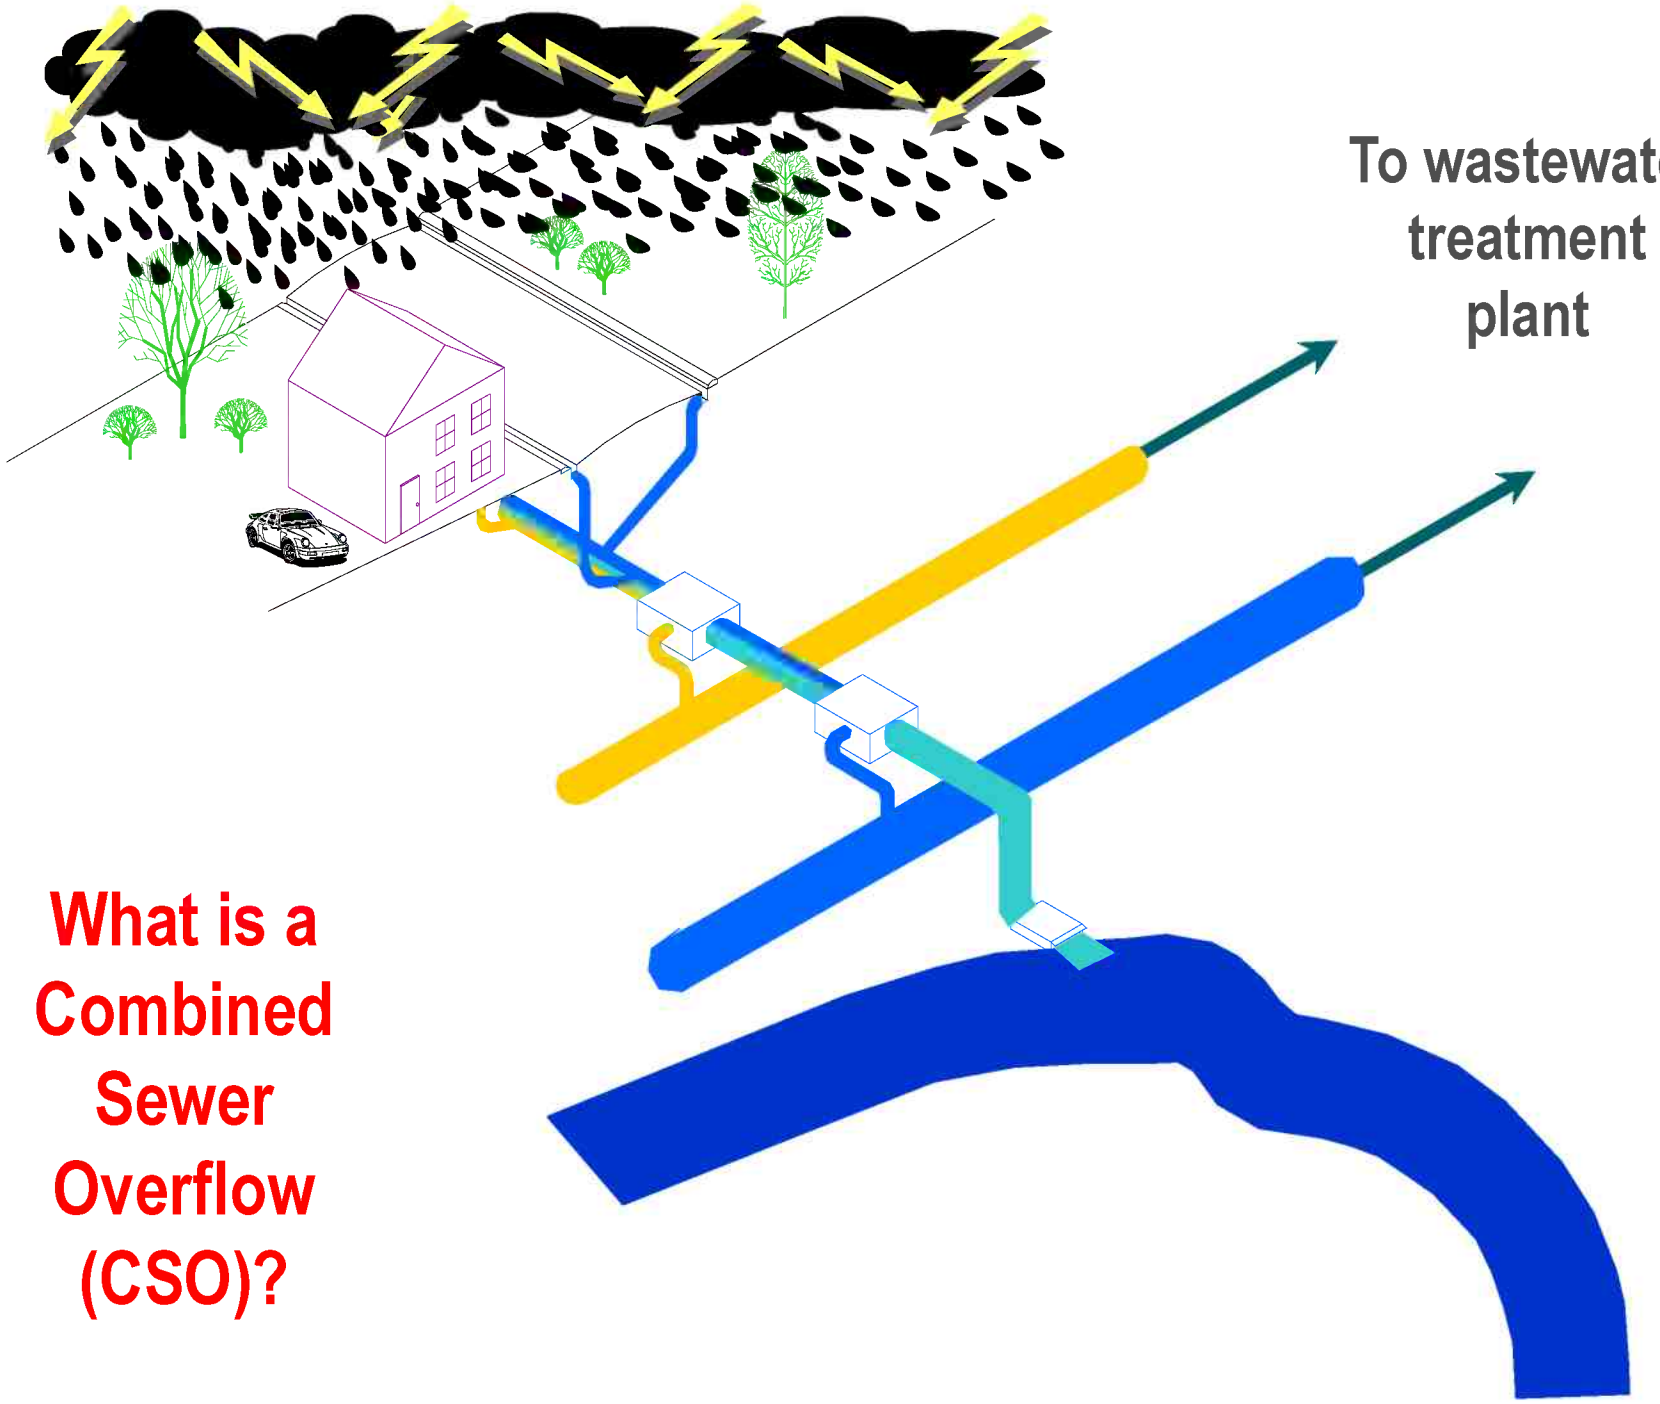
GREELEY AND HANSEN

What is a Combined Sewer Overflow (CSO)?



Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Definitions

- **LTCP:** The Long Term Control Plan is the document that lays out how DELCORA will maintain the outfalls and reduce the flow and/or treat the discharge from the outfalls to the water ways to meet the requirements of the Clean Water Act.
- **Sanitary Sewer:** The system that contains only waste from bathrooms, sinks, washers etc.
- **Storm Sewer:** Run off from streets.
- **Combined Sewer System:** Pipe that has both sanitary sewage and storm water in it.
- **Combined Sewer Overflow:** An overflow is the relief point in the combined sewer system that allows the extra flow when it rains to be discharged directly to streams and rivers.
- EPA: United States Environmental Protection Agency
- DEP: Pennsylvania Department of Environmental Protection

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

History of Combined Sewer System

- In the early 1900's the City of Chester's Combined Sewer System was constructed.
  - This was, at the time, a typical engineering practice in Urban areas.
- In 1971 DELCORA became the owner of the existing Sanitary and Combined Sewer System in the City of Chester.
- Discharges from CSOs are authorized through the National Pollutants Discharge Elimination System (NPDES) permit during Wet Weather Flow.

Delaware County Regional Water Quality Control Authority

DELCORA

Delaware County, PA

DELCORA Combined Sewer Area

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

History of EPA LTCPs

- LTCP Consent Decrees/Order for various wastewater systems not only throughout Pennsylvania, but the entire country.
  - Washington DC, New York City, Richmond,
- Current Pennsylvania communities already impacted by LTCP Consent Decree Costs & Fines:
  - Williamsport
  - Scranton
  - Harrisburg
  - Pittsburgh

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Philadelphia LTCP

- DELCORA is currently contributing to the Philadelphia LTCP.
  - Philadelphia's LTCP has an overall price tag of over $2 Billion over 25 years.
  - DELCORA's proportionate share of the Philadelphia LTCP is $178 million over 15 years due to the term of our contract with Philadelphia.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA LTCP Background

- In 1999 in response to increased environmental regulations, DELCORA implemented an LTCP for the DELCORA Combined Sewer System in the City of Chester.
- The LTCP identified capital improvements and operation and maintenance practices to reduce overflows.
- From 1999-2009 DELCORA spent in excess of $5 million on improvements and contributions to the City of Chester that resulted in decreased volume of overflows, reduced debris in overflows, provided remote monitoring of the system, and improved routine maintenance.
- In 2009, the DEP and EPA determined that DELCORA's LTCP was no longer in compliance with increased regulations of the Clean Water Act. In response, DELCORA began working with DEP and EPA to update the LTCP.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCP Background (Continued)

- In 2012, DELCORA submitted a revised LTCP to DEP and EPA.
- A key element in DELCORA's revised plan position was that the CSOs are only found in the City of Chester and the financial burden on the City of Chester residents must be considered.
- In 2014, DEP and EPA determined that DELCORA's revised LTCP required further evaluation and development so the Department of Justice was assigned to pursue a Consent Decree.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA Consent Decree

- The Consent Decree was agreed to by DELCORA on July 1, 2015 and signed into effect by the Dept. of Justice (DOJ) in November 2015. The Consent Decree is a legally binding agreement between DELCORA, EPA , and DEP in which DELCORA agrees to update the current LTCP.
- Generally, the Consent Decree consists of:
  - Compliance Measures
  - Milestones for plan update and implementation
  - Civil penalty
  - Stipulated penalties for non-compliance
- DELCORA has been given 42 months (3½ years) to develop a plan and 20 total years to implement the plan. When projects are complete and on-line, sewer fee charges will include costs for the updated LTCP.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU Summary – Where We Are

- Hired expert consultants with a good track record as well as experience specifically related to the LTCP.
  - Greeley & Hansen: Engineering Consultant for the LTCP
  - Municipal & Financial Services Group: Rate Model Consultant
  - Blank Rome: Law Firm
- 100% compliance to date with Consent Decree
  - Submitted to date :
    - Public Participation Plan
    - Hydrologic and Hydraulic Model Update and Calibration Plan
    - Typical Hydrologic Period Plan
    - Semi-Annual Report
    - Sensitive Areas and Pollutants of Concern Report
  - To be Submitted by May 17, 2016
    - Draft FCA and Alternative Evaluation Report

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Financial Capability Assessment (FCA)

- The Consent Decree requires DELCORA to submit a DRAFT FCA by May 17, 2016 and FINAL FCA at the end of the project.
- Financial Capability Assessment's (FCA's) purpose is to determine the affordability of the LTCP.
- Develop fair, equitable, and legal cost share for conveyance, storage, and treatment of wet weather flows

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Financial Capability Assessment (FCA)

Financial Capability Matrix

Permittee Financial Capability Indicators Score (Socioeconomic, Debt & Financial Indicators)	Residential Indicator (Cost Per Household as a % of MHI)		
	Low (1.0% and Below)	Mid-Range (Between 1.0% and 2.0%)	High (2.0% and Above)
Weak (1.5 and Below)	Medium Burden	High Burden	High Burden
Mid-Range (Between 1.5 and 2.5)	Low Burden	Medium Burden	High Burden
Strong (2.5 and Above)	Low Burden	Low Burden	Medium Burden

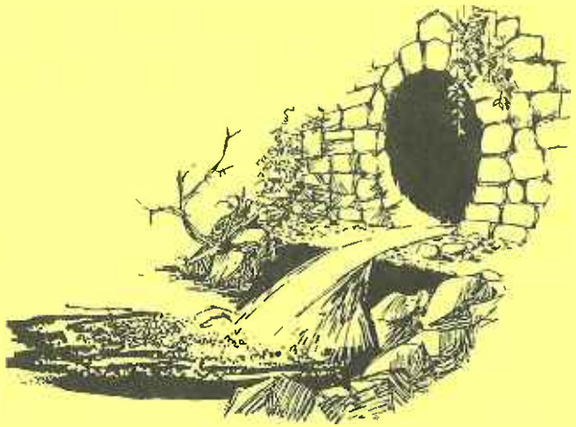
2011

DELCORA CSO LONG TERM CONTROL PLAN 2011

PLAN UPDATE



Community Education Series

100 East Fifth Street
P.O. Box 999
Chester, PA 19016-0999

What is a Combined Sewer Overflow (CSO)?

Some communities collect both rainwater runoff and sanitary wastewater in the same sewer. These are called "Combined Sewers". Sometimes when it rains, sewers do not have enough capacity to carry all the rainwater and wastewater and the treatment plant is not large enough to treat the total combined flow. In these situations, the combined wastewater overflows untreated into the nearest body of water, streams or rivers, creating a combined sewer overflow.

In the case of storm water from the street, whatever litter, also known as floatables, that is in the street washes into the CSO and either to the treatment plant or directly into our community's streams, rivers, and water bodies. Inlets help to keep trash and other floatables out of the sewer system.

PROGRAM ACTIVITIES

Under the current CSO Long Term Control Plant (LTCP), DELCORA provides $75,000.00 per year to the City of Chester to replace storm-water inlets. The DELCORA program will act in concert with the City's efforts to replace the inlets with a PennDOT approved type M inlet. Inlets are the openings adjacent to the roadway curb that direct stormwater runoff to the sewer system. The type M inlet is installed in the roadway. It has steel grates that prevent trash from entering the sewer.

Inlets are replaced to reduce the amount of litter and other floatables that enter the sewer system. These pollutants clog the system, causing sewer backups, and increase treatment costs by adding non-biodegradable material to the waste stream. Replacement helps keep our streams and waterways cleaner.

DELCORA also replaces the regulators in the sewer system to maximize flow to the treatment plant. Regulators direct the wastewater to the treatment plants. To date DELCORA has replaced 15 of 25 regulators.

The US. Environmental Protection Agency (EPA) ordered DELCORA to update its LTCP. The new plan was submitted February 1, 2011. EPA Approval is pending. New technologies were investigated and cost estimates were prepared. It is likely that sewer rates will increase as a result.

DELCORA'S LONG TERM CONTROL PLAN

- Identifies all Combined Sewer Overflow (CSO) Locations
- Prohibits all dry weather discharges
- Requires proper operation and maintenance of all CSO flow control regulators
- Requires an Inlet Replacement Program
- Maximizes flow treated at the Plant
- Schedules replacement of all CSO regulators over a 20 year period
- Outlines a detailed monitoring and upkeep schedule of all CSO regulators
- Develops implementation for a sewer cleaning program targeting segments with the greatest CSO impact
- Requires a Public Education program. A meeting was held November 17, 2011.

What are the benefits of the CSO Long Term Control Plan?

- A cleaner & healthier environment to live and work in.
- A planned program of level expenditures, helping to keep sewer rates stable. However, the USEPA's required update of the Plan may require more upgrades of the sewer system. It is likely that rates will increase.
- Citizen response, participation and input.
- A better citizen understanding of why the program is needed.
- Regular, monitored cleaning and repair of our sewer system.
- Improved stewardship of our water resources.

LEARN TO IDENTIFY CSO OUTFALLS

There are 28 CSO outfalls in the Chester area; thirteen drain to the Delaware River, ten to the Chester Creek and five to the Ridley Creek.

All outfalls are marked by a sign.

How you can help.

- Disconnect your downspouts from your sewer lateral.
- Don't litter! Keep trash out of sewer inlets.
- Keep grease, fats, and oils out of your drains.
- Use environment friendly cleaning agents and cleansers.
- Properly dispose of hazardous wastes.
- Dispose of prescription drugs and personal care products properly.
- Conserve your water usage.
- Learn more about CSO's.
- Remember—Clean water is everybody's business.

Want to learn more?

DELCORA welcomes and encourages your input. Additionally, tours of the treatment plant can be arranged for civic, school or church groups.

If you would like to review a complete copy of the 2011 proposed DELCORA CSO Long Term Control Plan 2011, please call or fill out the form below and mail to "Administration/CSO Information". We will gladly schedule a time during daily business hours when you can visit our Administrative offices and review the plan.

How to Safeguard Your Home and the Environment by Disconnecting Downspouts

Stop Sewer Backups

Connected downspouts — what are they?

Many older homes, especially in cities, have gutters connected directly to the sanitary sewer. This means that rain from the roof runs directly into the sewer. Not all downspouts that look like this picture are connected to the sanitary sewer; some may empty into a storm drain. Call your local sewer system authority or public works department to find out if your connected downspout empties into the sanitary sewer.

Why is this a problem?

The problem is too much water. Sanitary sewer systems can only handle a certain amount of water. During a rainstorm, water gets into the sewer from connected downspouts and other sources. When there is too much water for the system, the excess has to go somewhere, and that somewhere is often somebody's basement, a manhole, or a nearby creek or river. Municipalities have a legal requirement to stop water from overflowing out of sewers. Even if the water does not overflow, it's still a problem, because the wastewater treatment plant has to treat the extra water.

Why should you care?

Sewage backups and overflows are messy, costly, and a threat to health and the environment.

Cleaning house. When there is a sewer backup into a house, the homeowner may have to pay the cost to clean up, repair damage, and replace ruined carpets and furniture. Basic homeowner's insurance often does not cover this damage (unless the policy has an added clause or "rider").

Health. Raw sewage contains microorganisms that can cause diseases such as hepatitis, giardiasis, and gastroenteritis.

Long term environmental damage. Raw sewage in streams and lakes can cause illnesses in fish, kill aquatic life, and make the water unusable for swimming, fishing, and as a drinking water source.

Higher costs mean higher utility rates. The utility ends up treating the extra water, and may even have to increase the size of the treatment plant. The utility may also have to pay fines when raw sewage is released to the environment. Increased utility costs are passed along to consumers as rate increases.

What can you do?

You should check to see whether disconnecting your home's downspouts can help solve the problem. Disconnection is usually a simple, relatively inexpensive process. The steps are shown on the inside of this brochure. Your local sewer system authority or public works department should be able to tell whether your downspouts are connected to the sanitary sewer and, if so, whether disconnection makes sense.

You can also let other people know why downspouts need to be disconnected and how sewer overflows cost the entire community.

How to Disconnect Your Downspout

Check Before You Start

The steps outlined below are general guidelines for disconnecting downspouts and do not apply in all situations. Contact your local sewer system authority or public works department to see what specific guidance is available and to obtain information on local conditions, materials, and regulations. You may want, or be required, to hire a professional contractor or plumber to do the work. In some areas, an inspection of the disconnection is also required. Be aware, too, that some municipalities discourage or prohibit downspout disconnection due to local zoning or concerns about runoff.

Use of the information provided in this brochure is voluntary. The organizations that prepared this brochure assume no responsibility for consequences arising from its use and specifically disclaim all liability for damages of any kind arising out of or resulting from the use of the information in this brochure.

1. Tools and materials you are likely to need:

- safety glasses
- work gloves
- hammer
- chisel
- hacksaw
- measuring tape
- screw driver
- trowel or other digging tools
- bucket (for concrete)
- spare gutter pipe
- splash block
- gutter "elbows" or other discharge devices
- flexible/corrugated pipe
- concrete mix (or other permanent, weatherproof sealant)
- plastic boot cap

2. Safety

Make sure that you have the safety equipment that you need, including work gloves and safety glasses. Many disconnections involve hammering and sawing which can be hazardous to your eyes. Aluminum gutters can be extremely sharp after being cut, so protect your hands with work gloves.

3. Call before digging

If you bury part of your discharge pipe, remember that even digging a shallow trench can sever a utility line. To be safe, call your local utilities (most jurisdictions have a "call before you dig" hot line) to make sure you avoid digging near service lines.

Disconnection Steps

STEP 1 — Remove downspout from boot

Unless your gutter downspout can be easily lifted out of the boot, you'll need to cut it just a few inches above the boot—making sure that you've left enough room for the downspout "elbow" or other end-of-pipe device.

© Blair Communications

© Blair Communications

STEP 2 — Remove the boot (Optional)

You can leave the boot in place, or remove the boot for a more finished look. To remove the boot, cut it with a hacksaw, or hammer and chisel. Be sure to wear safety glasses, and remove sharp edges that remain on the pipe after cutting.

STEP 3 — Seal the boot

The boot must be permanently sealed to keep water from entering the sewer line. There are different ways to seal the pipe so before proceeding, check to find out what approach is recommended for your area. Some jurisdictions suggest the following method:

© Blair Communications

The pipe can be sealed with concrete or other material that makes a permanent, weatherproof seal. Before starting, check the pipe to make sure that you will not block any other junction (such as your washing machine draining into the same pipe). Then push balled-up newspaper tightly three or four inches down into the boot. Make sure that the fit is snug, otherwise the concrete could actually block the sewer. Carefully pour the concrete or other material that gives a permanent weatherproof seal into the pipe, and smooth the top surface.

Other areas do not recommend using newspaper and suggest the use of friction or sewer plugs, which are often available from licensed contractors.

STEP 4 — Redirect rainwater with end-of-pipe device(s)

The last step is to redirect the rainwater away from the house. The exact approach depends on individual conditions. It is important that the rainwater discharges a safe distance from your foundation (three or four feet is usually enough), that the runoff is not a nuisance to your neighbors, or causes other problems, like discharging across a sidewalk so that ice forms in the winter.

© Blair Communications

Sometimes all that is needed is an "elbow" pipe to the bottom of the gutter downspout and a plastic or concrete splashblock. Other situations (such as sloping ground) may require a different solution. There are a number of devices available designed to channel the rainwater away from your home (ask a hardware store to recommend the best one for your needs).

Check with your local sewer system authority or public works department for other redirection options in your area.

Disconnection is usually a simple, relatively inexpensive process.

Special Situations

Steep Slopes

If the gutter is next to a steep slope, be careful that the discharge from the new downspout will not wash away soil on the hillside. There are two ways to avoid this: attach a pipe long enough to drain the rainwater to a safe area, or install an attachment that controls how fast water comes out of the gutter. Always make sure that you are not draining water onto a neighbor's property and that runoff from your downspouts does not cause erosion or flooding of your neighbor's yard. Do not discharge stormwater too close to your property line.

© Blair Communications

© Blair Communications

Extended Boot

Some older homes have boots that extend several feet above the ground. You can leave the boot in place and permanently seal the top of the pipe (step 3) or you can remove the tall boot. If you remove the boot, you will usually need to install a new section of gutter pipe and then an end-of-pipe device (step 4).

Inadequate Drainage

Some gutters may be located on very flat ground with no place for the water to drain. One solution is to pipe the water safely away from the house with a pipe attached to the downspout's "elbow." Another option is to use a device that will disperse the water enough so that it doesn't form a puddle. Make sure that it is draining away from your foundation.

2006

- ✓ **Look for and check your** *sewer cleanout.* The cleanout usually is a small pipe, about 4 inches in diameter, outside your house or business that is used to access the service lateral for cleaning the sewer line. You can find it near the house, where the service lateral comes out, and/or near the street, where the service lateral connects to the main sewer line. Make sure the cap to the cleanout pipe is on and has not been damaged by a lawn mower or something else. Replace missing caps; otherwise, rain can get into the sewer line, causing it to overflow.

- ✓ **Avoid pouring grease down your sink.** When the grease cools in the sewer line, it can form clogs and blockages, which then can cause the sewer to overflow or back up into buildings. The grease also can contribute to restricted flow in your home plumbing and service laterals, resulting in costly repairs.

- ✓ **Avoid planting trees and shrubs above or near the service lateral** that runs from your building to the street. Roots can enter and clog sewers, causing them to back up and overflow.

- ✓ **Learn about your local sewer system.** Contact your local sewer authority or department of public works. and ask them to describe how the system works. Ask for the general location of the main sewer lines and treatment plant(s) and what type of monitoring is being conducted to detect SSOs.

- ✓ **Support local programs that aim to improve the way your sanitary sewer system is maintained and operated.** Proper operation and maintenance of the sanitary sewer system are key to preventing the damage caused by SSOs and prolong the life of the sewer system, saving taxpayer dollars.

This brochure is provided by Citizens Environmental Research Institute and funded by the U.S. Environmental Protection Agency, Cooperative Agreement Assistance I.D. No. CX824853-01. For more information about SSO's contact:

TOP SEVEN TERMS FOR BETTER UNDERSTANDING SSOs:

1. INFILTRATION. The water entering a sanitary sewer system through pipe joints, line breaks or cracks.

2. INFLOW. Rainwater from roofs, pavements, yards, manholes, and manhole covers that flows directly into a sanitary sewer.

3. SERVICE LATERAL. The sewer pipe that connects a house or other building to the main sewer line in the street.

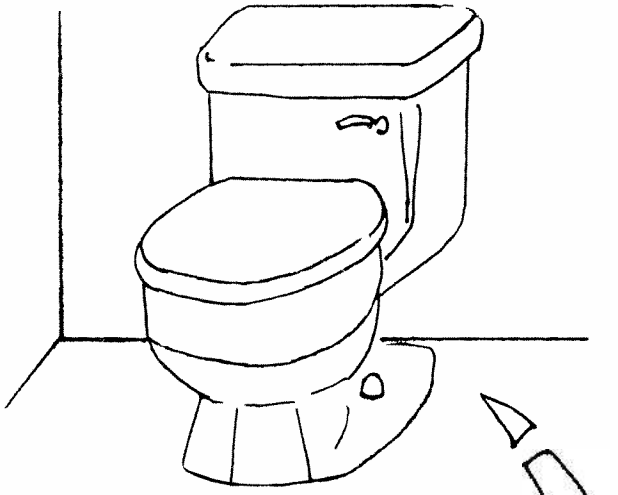
4. SEWER CLEANOUT. A small pipe with a cap, located near the place in a house or other building where the service lateral enters. The cleanout is used to free blockages that may form in the service lateral.

5. PATHOGENS. Organisms in raw sewage that cause diseases, including cholera, dysentery, hepatitis, and gastroenteritis.

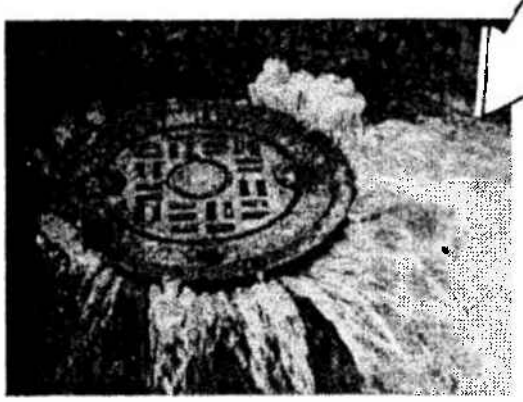
6. MANHOLE & MANHOLE COVER. A structure, usually found in a street, parking area, or sidewalk, that is used to provide access to the main underground sewer lines.

7. COLLECTION SYSTEM. The series of progressively larger pipes through which sewage is carried from homes and businesses to a treatment plant. The collection system includes service laterals and the main sewer lines.

SANITARY SEWER OVERFLOWS



What are they?
Why are they a problem?
What can we do about them?



A Citizens Guide

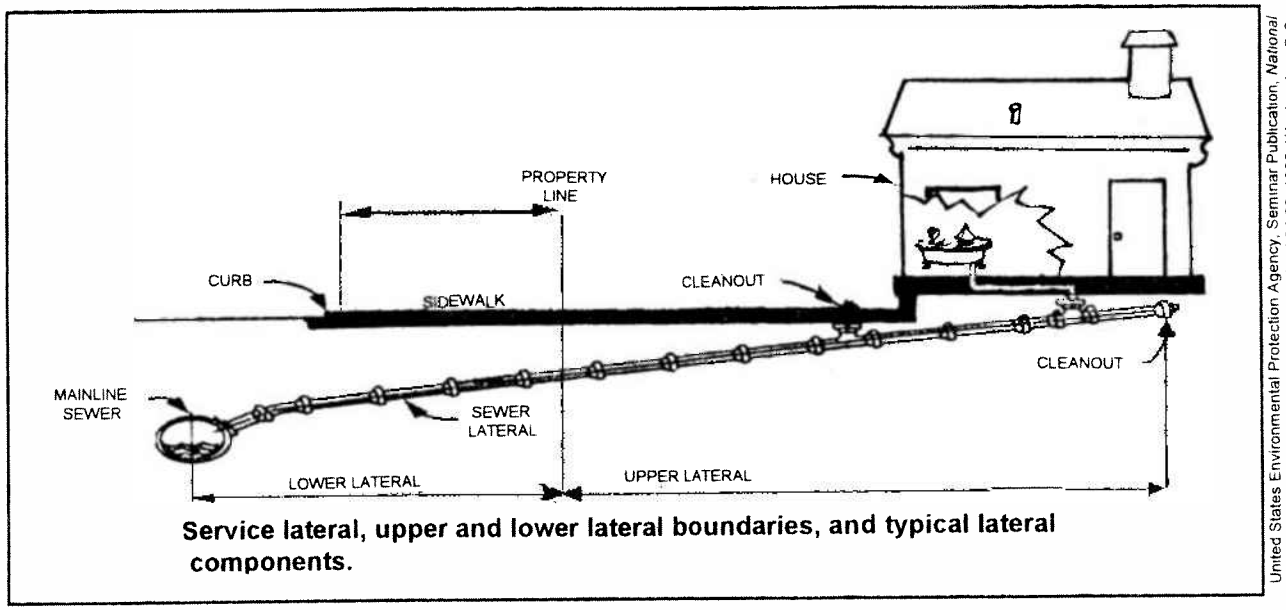
What is a Separate Sanitary Sewer and what is its purpose?

A *Separate Sanitary Sewer* collects and carries household and industrial sewage from individual buildings such as homes and commercial businesses through a series of progressively larger sewer pipes called the *collection system*. A *separate* sanitary sewer system is different from a *combined* system, which carries sewage and storm water runoff together. Separate sanitary sewer systems are not designed to carry rain water.

The primary purpose of a separate sanitary sewer is to protect public health and the environment. Raw sewage contains disease-causing organisms, which can make people sick if they become directly exposed. Raw sewage also can contain toxic chemicals and offensive odors. The sanitary sewer system carries the raw sewage away from homes and businesses to a treatment plant, where most of the harmful organisms are destroyed, odors are controlled, and the level of toxic chemicals is reduced.

Why are Sanitary Sewer Overflows a public health, environmental and economic problem?

Sanitary Sewer Overflows (SSOs) occur when raw or partially diluted sewage is discharged from a sewer collection system before it reaches the sewage treatment plant. SSOs threaten public health because they can cause people to be directly exposed to disease-causing germs called *pathogens*, such as *E. coli* and *Cryptosporidium*, which are present in sewage. SSOs also can have negative impacts on the natural environment, causing poor water quality in lakes, rivers and streams, and polluting groundwater, which may be used for drinking water purposes. SSOs can cause economic damage as well, hurting water-dependent businesses, such as commercial fishing and tourism. SSOs that result in basement flooding not only are unhealthy, but also are extremely unpleasant and costly to clean up. Where these chronically occur, property values may be reduced.



Service lateral, upper and lower lateral boundaries, and typical lateral components.

United States Environmental Protection Agency, Seminar Publication, *National Conference on Sanitary Sewer Overflows* April 24-26, 1995, Washington D C

How might you be contributing to the problem of SSOs?

Many property owners are not aware that the maintenance of the sewer line connection between a home or a business (i.e. "upper lateral" in figure) and the main sewer line in the street usually is their responsibility. When poorly constructed or improperly maintained, these connections, called *service laterals,* frequently cause raw sewage to back up in basements.

The connection of roof-gutter downspouts or sump-pump drains directly to the service lateral adds excess water to the main sewer lines, and can contribute to raw sewage being discharged into the streets (**SSO**) and other public areas. Homes and small businesses, such as restaurants, can contribute to SSOs by disposing grease into the sewer line. When grease cools, it can form blockages, which then cause the sewer to overflow.

What should you do when you identify an SSO?

Make sure that people are kept away from the area of the overflow, typically a *manhole* cover. This is especially important for children and pets who may play near the overflow area (e.g. street, public park, or local stream). Report the sewer overflow immediately to the local health department, the sewer operator, and the state environmental agency. Precautions then can be taken by them to reduce the risk of public exposure to raw sewage by monitoring the impact of the overflow and ensuring proper cleanup.

What can you do to prevent and reduce SSOs?

You can prevent and reduce SSOs if you:

- ✓ **Make sure the basement sump pump does not connect to your sewage drain pipes or to a sink or floor drain in your basement.** Such connections are illegal. The water from these pumps can overload the sewer, causing it to overflow raw sewage into a stream, the street, or someone else's basement.

- ✓ **Inspect the gutters** on your house or business to see if the downspout connects to a sewer line. Such connections are illegal in many communities. **If the gutters are connected to the sewer line, have them disconnected—the runoff water from the roof can contribute to an SSO.**

2008

What Restaurant and Building Owners Need to Know About Grease Traps or Interceptors

Restaurants, large buildings, such as apartment complexes; and other commercial establishments may have grease traps or interceptors that keep grease out of the sewer system. For a grease trap or interceptor to work correctly, it must be properly

1. **Designed (sized and manufactured to handle the amount that is expected),**
2. **Installed (level, vented, etc.), and**
3. **Maintained (cleaned and serviced on a frequent basis).**

Solids should never be put into grease traps or interceptors. Routine, often daily, maintenance of grease traps and interceptors is needed to ensure that they properly reduce or prevent blockages.

Be cautious of chemicals and additives (including soaps and detergents) that claim to dissolve grease. Some of these additives simply pass grease down pipes where it can clog the sewer lines in another area.

Fat-Free Sewers

How to Prevent Fats, Oils, and Greases from Damaging Your Home and the Environment

Fats, Oils, and Greases aren't just bad for your arteries and your waistline; they're bad for sewers, too.

Sewer overflows and backups can cause health hazards, damage home interiors, and threaten the environment. An increasingly common cause of overflows is sewer pipes blocked by grease. Grease gets into the sewer from household drains as well as from poorly maintained grease traps in restaurants and other businesses.

Where does the grease come from?

Most of us know grease as the byproduct of cooking. Grease is found in such things as:

- Meat fats
- Lard
- Cooking oil
- Shortening
- Butter and margarine
- Food scraps
- Baking goods
- Sauces
- Dairy products

Too often, grease is washed into the plumbing system, usually through the kitchen sink. Grease sticks to the insides of sewer pipes (both on your property and in the streets). Over time, the grease can build up and block the entire pipe.

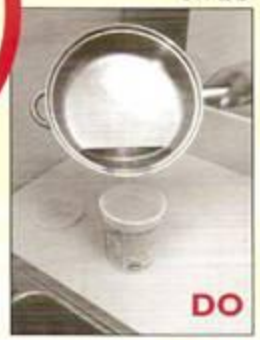
Home garbage disposals do not keep grease out of the plumbing system. These units only shred solid material into smaller pieces and do not prevent grease from going down the drain.

Commercial additives, including detergents, that claim to dissolve grease may pass grease down the line and cause problems in other areas.

© James L. Graham, Jr., P.E.

The results can be:

- Raw sewage overflowing in your home or your neighbor's home;
- An expensive and unpleasant cleanup that often must be paid for by **you, the homeowner;**
- Raw sewage overflowing into parks, yards, and streets;
- Potential contact with disease-causing organisms; and
- An increase in operation and maintenance costs for local sewer departments, which causes higher sewer bills for customers.



© NYCDEP

What we can do to help

The easiest way to solve the grease problem and help prevent overflows of raw sewage is to keep this material out of the sewer system in the first place.

There are several ways to do this.

1) Never pour grease down sink drains or into toilets.
2) Scrape grease and food scraps from trays, plates, pots, pans, utensils, and grills and cooking surfaces into a can or the trash for disposal (or recycling where available).
3) Do not put grease down garbage disposals. Put baskets/strainers in sink drains to catch food scraps and other solids, and empty the drain baskets/strainers into the trash for disposal.
4) Speak with your friends and neighbors about the problem of grease in the sewer system and how to keep it out. Call your local sewer system authority if you have any questions.

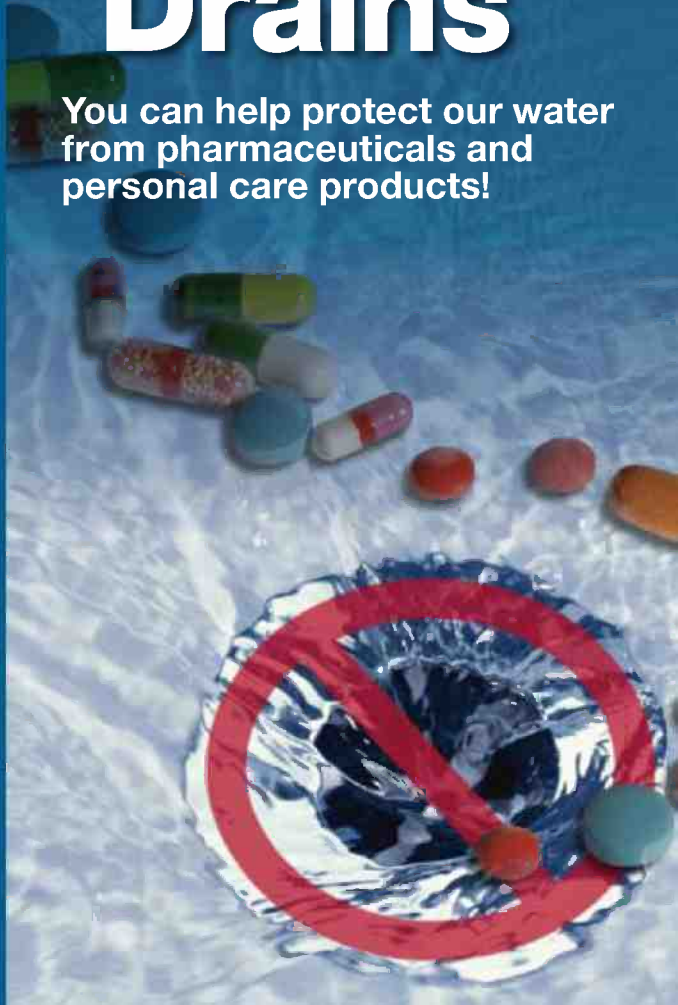
Drug-Free Drains

You can help protect our water from pharmaceuticals and personal care products!



You can help

protect our water from pharmaceuticals and personal care products!

Every day the average adult uses nine personal care products that contain 126 unique compounds that could end up in our water. In addition to traces of products like shampoo, toothpaste, sunscreen, and cosmetics, minute amounts of prescription and over-the-counter drugs also make their way into water. They should be limited or prevented from entering our environment.

Due to our increased use of these products and greater analytical sensitivity, very tiny amounts of compounds and drugs can be detected in conventional treatment plant outflow and end up in creeks, streams, and rivers. While there is no evidence these traces pose a risk to human health, scientists can sometimes find interference with aquatic organisms, and studies continue. Meanwhile, it's prudent to control what we put into water, and everyone's help is important.

In addition to following product recommendations for use and disposal and decreasing use when possible, you can help keep water clean by simply not flushing unused medication down the toilet! Controlling what goes down the drain is the easiest and most effective way to protect the environment, and you can start today!

Help keep our drains drug-free!

For more information on how to dispose of household products, please visit:

http://www.wef.org/AboutWater/ForThePublic/FactSheets/FactSheetDocuments/HouseholdWaste.htm

Visit the White House Office of National Drug Control Policy consumer guidance for the Proper Disposal of Prescription Drugs at

http://www.whitehousedrugpolicy.gov/drugfact/factsht/proper_disposal.html

Every year Delaware County residents pay millions of dollars to treat rainwater in the sanitary sewer systems!

That's tens of thousands of dollars wasted each week and it's paid for through your sewer fees!

Your sewer lateral is the pipe from your house to the sewer main in your street. You own the sewer lateral under your yard.

Leaky sewer laterals, connected downspouts, and sump pumps allow rainwater to enter the sanitary sewer system.

Once that rainwater mixes with the sewage, it must be treated at the sewage treatment plant.

You are responsible for properly maintaining your sewer lateral to stop rainwater from entering the sanitary sewer system.

A well-maintained lateral protects public health and the environment and can help you save money.

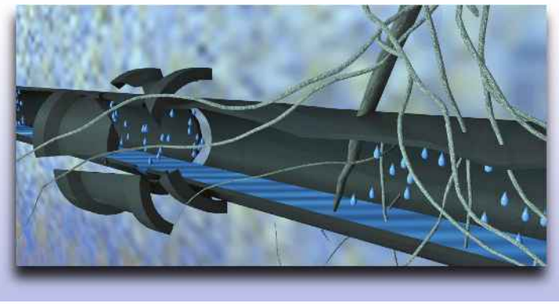
Sewer laterals need to be inspected periodically. If you have not inspected, repaired, or replaced your lateral, it could be failing.

Failing laterals have old-age cracks, loose pipe joints, and tree roots, which let rainwater into the sewer system.

Rainwater also enters the lateral through connected downspouts, basement sump pumps, foundation drains, and driveway drains.

When rainwater is allowed into your lateral, the sewer mains can overload, leading to a backup of raw sewage in basements.

Sewage is foul smelling, very difficult to clean up, and it can make your family very sick. It is a nightmare if sewage backs up into a house, damaging furniture, children's toys, irreplaceable family photos, or an entertainment/recreational area.



DELCORA
100 East Fifth Street
P.O. Box 999
Chester, PA 19016-0999

Stop Throwing Money down the Drain!

How to Safeguard your Home, Community, and Environment

SEWAGE TREATMENT PLANTS ARE DESIGNED TO TREAT THE WASTEWATER FROM THE HOMES, BUSINESSES, AND INDUSTRIES IN YOUR COMMUNITY. BUT WHEN CONNECTED DOWNSPOUTS, SUMP PUMPS, AND LEAKY LATERALS LET RAINWATER INTO THE SYSTEM, THE EXTRA WATER CAN OVERLOAD THE SEWAGE TREATMENT FACILITY.

If extra water overwhelms the treatment facility, raw sewage may overflow manholes into the streets.

Raw sewage may even be discharged from the treatment facility directly into streams and rivers in your community.

Raw sewage in public areas can make people very sick! And raw sewage in creeks and streams is an environmental disaster!

A QUALIFIED PLUMBER CAN FIND PROBLEMS IN YOUR SEWER LATERAL AND HELP FIND ANY IMPROPER CONNECTIONS USING ONE OF THE FOLLOWING TECHNIQUES:

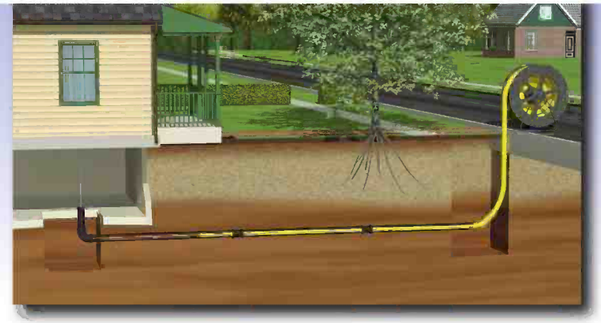
- **Visual inspection** - A special camera is pushed through your lateral. The plumber can view the lateral's interior on a video screen and see any problems.

- **Dye testing** - A non-toxic dye is dripped into locations around your house, including downspouts and the soil above the lateral. Dye appearing in nearby manholes indicates problems.

- **Smoke testing** - A special, non-toxic smoke is pumped from the sewer main into your lateral and monitored to see where the smoke appears. Smoke escaping from the pipe up through the ground indicates a break in the pipe. Smoke escaping from the downspout indicates an improper connection.

IF A DOWNSPOUT OR SUMP PUMP IS CONNECTED TO YOUR LATERAL, YOU MUST HAVE IT DISCONNECTED.

IF YOUR LATERAL HAS CRACKS, LOOSE PIPE JOINTS, OR TREE ROOTS, YOU MUST HAVE IT REPAIRED OR REPLACED.



YOU CAN HAVE YOUR LATERAL REPAIRED IN SEVERAL WAYS:

- **Open cut excavation** is the traditional method of digging out your lateral for removal and replacement.

- **Slip lining** (pictured left) does not require extensive excavation. A winch pulls a flexible, liner pipe into place inside your existing pipe.

- **Pipe bursting** is like slip lining except a small, metal ram is pulled through your existing pipe. The ram breaks the pipe and pushes the pieces into the soil, pulling a new pipe into place behind it.

- **CIPP (cured-in-place pipe)** involves a felt tube, saturated with glue, being inflated inside your existing damaged pipe. Once the glue has set, the felt tube liner is left in place and the repair is complete.

AS LATERALS AGE WITHOUT BEING INSPECTED OR REPAIRED, THE COST GOES UP TO TREAT RAINWATER AND THE CHANCE INCREASES FOR A SEWAGE BACKUP IN YOUR BASEMENT.

Everyone knows how important it is to maintain your property and home. It is just as important to maintain your sewer lateral even though you cannot see it.

You must inspect your sewer lateral to ensure that you are not contributing to the problem.

The Delaware County Regional Water Quality Control Authority (DELCORA) exists to protect and improve the quality of life of our communities.

OR WATCH A FREE VIDEO ON THE INTERNET: WWW.DELCORA.ORG

Function of Sump Pumps & Downspouts

Rainwater can enter the basement through many sources. The job of a sump pump is to divert the water from inside your basement to a location outside of the house. A sump pump is usually installed in a sump pit which stores the water. When this water reaches a certain level, it triggers the sump pump which pumps the water back outside, away from the house. A downspout's purpose is to direct water from the roof gutters away from the house.

The Problem of Inflow

Inflow is caused by improperly connected foundation (footing) drains, sump pumps, and downspouts. Instead of directing the clear rain water outside and away from the house, it directs the water into the sanitary sewer system. Inflow is a problem because it creates an extra water burden for the sanitary sewer system, and when this system is overloaded, sewage can back up into our streets, buildings, and your home. It also means that our utility bills are higher because we are collectively paying for the unnecessary treatment of clean water!

Rules and Regulations

Inflow is a problem for all of Delaware County's communities and sanitary sewer systems. All municipalities have adopted ordinances which make it illegal to have improper connections to the sanitary sewer. Fees and other enforcement measures can be used to achieve compliance. To avoid fines make sure your sump pumps and downspouts discharge properly.

Homeowners have an impact on preventing or causing the problem of inflow. Your community and neighbors are relying on you to take responsibility for making sure that your connections are not contributing to the problem.

For more information regarding what is being done about inflow in your community, contact your local municipality or sewer author-

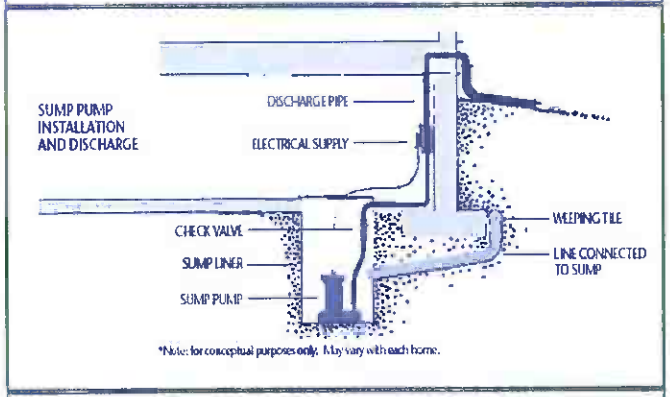
Disconnecting & Redirecting Your Sump Pump & Downspouts

In wet weather it only takes a few improperly connected sump pumps to cause a sanitary sewer backup into basements, streets and waterways.

How Do I Know If My Sump Pump Is Improperly Connected?

Your sump pump is improperly connected to the sanitary sewer if it is connected to the drain or sink in your basement. Unless you are sure your basement drain is not connected to the sanitary sewer, your sump pump is probably improperly connected.



Proper sump pump discharge connections are to the outside of the house only!

How Do I Know If My Downspout Is Improperly Connected?

If your downspouts disappear into the ground rather than discharging into your yard, they may be connected to the sanitary sewer. While connections to the *storm* sewer are permitted, connections to the *sanitary* sewer must be disconnected and redirected.

Downspouts that look like this could be connected to the sanitary sewer.

Disconnecting Your Sump Pump

If your sump pump discharges to the sanitary system in any way, the discharge must be re-directed out of the sanitary sewer system. The change could be as simple as directing the discharge outside the house through a hose. If you aren't familiar with the work, contact a plumbing professional, your local municipality, or your sewer authority for more information.

Each household or business that redirects their stormwater out of the sanitary sewer helps solve the problem of sewage backing up into basements, streets, and waterways.

Disconnecting Your Downspout

Disconnecting your downspout from the sanitary sewer is easy to do yourself.

1. Cut the downspout, leaving enough space to insert the elbow.

2. Tightly cap the end of the pipe sticking out of the ground that leads to the sanitary sewer.

3. Attach an elbow to the end of the downspout and use an appropriate extension to direct the water away from your home.

Where Should I Direct the Flow of My Disconnected Sump Pump and Downspout?

Water should be discharged away from your house or it may seep back into your basement. It should flow to an area where it can seep into the ground or be stored for later use. Direct flow to:

Raingarden

Lawn

Trees

Rain Barrel

Never direct stormwater into a sanitary sewer or onto a neighboring property!

ATTACHMENT B3

SAMPLE PRESS RELEASE

August 18, 2015

DELCORA Enters Agreement with EPA to Invest in Major Infrastructure Improvements in City of Chester

Authority will seek to reduce overflows from City's combined wastewater system

Chester, PA - The Delaware County Regional Water Quality Control Authority (DELCORA) announced today that is has entered into a settlement agreement with the Environmental Protection Agency (EPA) to make improvements to the combined sewer and stormwater drainage system in the City of Chester to address issues related to the overflow of the system during high rain events.

Under the consent decree, negotiated in good faith by and between DELCORA and the EPA, DELCORA has 42 months to develop a long-term plan to control and reduce overflows from the City of Chester's combined sewer and stormwater system and 20 years to implement the plan. Contrary to public reports stating the project could cost up to $200 million, DELCORA said it has not determined the cost of the long-term control plan and would be unable to do so for up to another three years when development of the plan is completed.

DELCORA inherited Chester's antiquated system in 1971 when it took over the operations of wastewater treatment from the City. The system was constructed in the early 1900s and the combined sewer system – which includes one pipe that combines both sewer and stormwater runoff – was a typical engineering practice at the time in urban areas.

When DELCORA assumed control of the system in the 1970s, discharges from the system were in compliance with the agency's permits, but as new technologies have developed in recent years, the EPA has become more stringent in its interpretation of the Clean Water Act as it relates to combined sewer systems. Over the past several years, the EPA has entered into consent decrees and issued civil penalties for wastewater systems in many urban communities in Pennsylvania and across the country, including Philadelphia, Williamsport, Scranton, Harrisburg, and Pittsburgh.

Currently, the City of Philadelphia is in the process of implementing a $2 billion long-term control plan following its consent decree with the EPA. DELCORA is funding $178 million over 15 years for the improvements because part of its wastewater system flows into the City's system.

"We take our commitment to the environment and our customers very seriously," said Robert Willert, Executive Director of DELCORA. "During a 10-year period, from 1999 to 2009 DELCORA developed a long-term control plan and invested $5 million in infrastructure improvements to address the issues of overflows during rain events that impacted the combined wastewater system in Chester."

Willert said that the $5 million infrastructure investment included upgrades to regulators, which control the flow and discharge of wastewater during rain events. DELCORA also paid the City of Chester $750,000 to put in place new storm water inlets on city streets that help stop trash and debris from flowing into the combined system, which could lead to backups and the unnecessary discharge of wastewater from the system.

Willert noted that industrial wastewater is kept separate from the combined system and that DELCORA has worked to mitigate the problem by requiring that new projects – such as PPL Park and the reconstruction of Route 291 – divert water to a separate stormwater system that is distinct from the combined system that exists throughout most of Chester.

DELCORA has brought on a team of experts to help develop the long-term control plan, including an engineering firm that specializes in the issue of combined wastewater systems and a municipal and financial service firm to help develop a rate model for customers to fund the needed improvements. Under the consent decree with the EPA, DELCORA will also pay a $1.375 million penalty to the state and federal government.

The Delaware County Regional Water Quality Control Authority (DELCORA) is a municipal authority that owns, operates, and maintains wastewater facilities that serve approximately 500,000 people in the greater Philadelphia area, including 42 municipalities in Delaware and Chester Counties.

About DELCORA

Delaware County residents and businesses generate over 100 million gallons of wastewater every day. This wastewater must be collected, conveyed, and treated in a safe, effective way to prevent the contamination of our community's streams, rivers, and general water supply. DELCORA has been providing this vital function to our communities for over three decades. As a result, the citizens of our region enjoy clean, healthy water.

Combined Sewer System

Combined Sewer System

Combined sewer systems are sewers that are designed to collect rainwater runoff, domestic sewage, and industrial wastewater in the same pipe. Most of the time, combined sewer systems transport all of their wastewater to a sewage treatment plant, where it is treated and then discharged to a water body. During periods of heavy rainfall or snowmelt, however, the wastewater volume in a combined sewer system can exceed the capacity of the sewer system or treatment plant. For this reason, combined sewer systems are designed to overflow occasionally and discharge excess wastewater directly to nearby streams, rivers, or other water bodies.

These overflows, called combined sewer overflows (CSOs), contain not only stormwater but also untreated human and industrial waste, toxic materials, and debris. They are a major water pollution concern for the approximately 772 cities in the U.S. that have combined sewer systems.

Section 715. **Jurisdiction and venue of judicial proceedings**
Section 716. **Confidentiality**

The General Assembly of the Commonwealth of Pennsylvania hereby enacts as follows:

Section 701. Short title of chapter

This chapter shall be known and may be cited as the Sunshine Act.

Section 702. Legislative findings and declaration

(a) **Findings.** The General Assembly finds that the right of the public to be present at all meetings of agencies and to witness the deliberation, policy formulation and decisionmaking of agencies is vital to the enhancement and proper functioning of the democratic process and that secrecy in public affairs undermines the faith of the public in government and the public's effectiveness in fulfilling its role in a democratic society.

(b) **Declarations.** The General Assembly hereby declares it to be the public policy of this Commonwealth to insure the right of its citizens to have notice of and the right to attend all meetings of agencies at which any agency business is discussed or acted upon as provided in this chapter.

Section 703. Definitions

The following words and phrases when used in this chapter shall have the meanings given to them in this section unless the context clearly indicates otherwise:

"Administrative action." The execution of policies relating to persons or things as previously authorized or required by official action of the agency adopted at an open meeting of the agency. The term does not, however, include the deliberation of agency business.

"Agency." The body, and all committees thereof authorized by the body to take official action or render advice on matters of agency business, of all the following: the General Assembly, the executive branch of the government of this Commonwealth, including the Governor's Cabinet when meeting on official policymaking business, any board, council, authority or commission of the Commonwealth or of any political subdivision of the Commonwealth or any State, municipal, township or school authority, school board, school governing body, commission, the boards of trustees of all State-aided colleges and universities, the councils of trustees of all State-owned colleges and universities, the boards of trustees of all State-related universities and all community colleges or similar organizations created by or pursuant to a statute which declares in substance that the organization performs or has for its purpose the performance of an essential governmental function and through the joint action of its members exercises

governmental authority and takes official action. The term shall include the governing board of any nonprofit corporation which by a mutually binding legal written agreement with a community college, or State-aided, State-owned or State-related institution of higher education is granted legally enforceable supervisory and advisory powers regarding the degree programs of the institution of higher education. The term does not include a caucus or a meeting of an ethics committee created under rules of the Senate or House of Representatives.

"Agency business." The framing, preparation, making or enactment of laws, policy or regulations, the creation of liability by contract or otherwise or the adjudication of rights, duties and responsibilities, but not including administrative action.

"Caucus." A gathering of members of a political party or coalition which is held for purposes of planning political strategy and holding discussions designed to prepare the members for taking official action in the General Assembly.

"Conference." Any training program or seminar, or any session arranged by State or Federal agencies for local agencies, organized and conducted for the sole purpose of providing information to agency members on matters directly related to their official responsibilities.

"Deliberation." The discussion of agency business held for the purpose of making a decision.

"Emergency meeting." A meeting called for the purpose of dealing with a real or potential emergency involving a clear and present danger to life or property.

"Executive session." A meeting from which the public is excluded, although the agency may admit those persons necessary to carry out the purpose of the meeting.

"Litigation." Any pending, proposed or current action or matter subject to appeal before a court of law or administrative adjudicative body, the decision of which may be appealed to a court of law.

"Meeting." Any prearranged gathering of an agency which is attended or participated in by a quorum of the members of an agency held for the purpose of deliberating agency business or taking official action.

"Official action."

(1) Recommendations made by an agency pursuant to statute, ordinance or executive order.

(2) The establishment of policy by an agency.

(3) The decisions on agency business made by an agency.

(4) The vote taken by any agency on any motion, proposal, resolution, rule, regulation, ordinance, report or order.

"Political subdivision." Any county, city, borough, incorporated town, township, school district, intermediate unit, vocational school district or county institution district.

"Public notice."

(1) For a meeting:

(i) Publication of notice of the place, date and time of a meeting in a newspaper of general circulation, as defined by 45 Pa.C.S. Â§ 101 (relating to definitions), which is published and circulated in the political subdivision where the meeting will be held, or in a newspaper of general circulation which has a bona fide paid circulation in the political subdivision equal to or greater than any newspaper published in the political subdivision.

(ii) Posting a notice of the place, date and time of a meeting prominently at the principal office of the agency holding the meeting or at the public building in which the meeting is to be held.

(iii) Giving notice to parties under section 709(c) (relating to public notice).

(2) For a recessed or reconvened meeting:

(i) Posting a notice of the place, date and time of the meeting prominently at the principal office of the agency holding the meeting or at the public building in which the meeting is to be held.

(ii) Giving notice to parties under section 709(c).

"Special meeting." A meeting scheduled by an agency after the agency's regular schedule of meetings has been established.

Section 704. Open meetings

Official action and deliberations by a quorum of the members of an agency shall take place at a meeting open to the public unless closed under section 707 (relating to exceptions to open meetings), 708 (relating to executive sessions) or 712 (relating to General Assembly meetings covered).

Section 705. Recording of votes

In all meetings of agencies, the vote of each member who actually votes on any resolution, rule, order, regulation, ordinance or the setting of official policy must be publicly cast and, in the case of roll call votes, recorded.

Section 706. Minutes of meetings, public records and recording of meetings

Written minutes shall be kept of all open meetings of agencies. The minutes shall include:

(1) The date, time and place of the meeting.

(2) The names of members present.

(3) The substance of all official actions and a record by individual member of the roll call votes taken.

(4) The names of all citizens who appeared officially and the subject of their testimony.

Section 707. Exceptions to open meetings

(a) **Executive session**. An agency may hold an executive session under section 708 (relating to executive sessions).

(b) **Conference**. An agency is authorized to participate in a conference which need not be open to the public. Deliberation of agency business may not occur at a conference.

(c) **Certain working sessions**. Boards of auditors may conduct working sessions not open to the public for the purpose of examining, analyzing, discussing and deliberating the various accounts and records with respect to which such boards are responsible, so long as official action of a board with respect to such records and accounts is taken at a meeting open to the public and subject to the provisions of this chapter.

Section 708. Executive sessions

(a) **Purpose**. An agency may hold an executive session for one or more of the following reasons:

(1) To discuss any matter involving the employment, appointment, termination of employment, terms and conditions of employment, evaluation of performance, promotion or disciplining of any specific prospective public officer or employee or current public officer or employee employed or appointed by the agency, or former public officer or employee, provided, however, that the individual employees or appointees whose rights could be adversely affected may request, in writing, that the matter or matters be discussed at an open meeting. The agency's decision to discuss such matters in executive session shall not serve to adversely affect the due process rights granted by law, including those granted by Title 2 (relating to administrative law and procedure). The provisions of this paragraph shall not apply to any meeting involving the appointment or selection of any person to fill a vacancy in any elected office.

(2) To hold information, strategy and negotiation sessions related to the negotiation or arbitration of a collective bargaining agreement or, in the absence of a collective bargaining unit, related to labor relations and arbitration.

(3) To consider the purchase or lease of real property up to the time an option to purchase or lease the real property is obtained or up to the time an agreement to purchase or lease such property is obtained if the agreement is obtained directly without an option.

(4) To consult with its attorney or other professional advisor regarding information or strategy in connection with litigation or with issues on which identifiable complaints are expected to be filed.

(5) To review and discuss agency business which, if conducted in public, would violate a lawful privilege or lead to the disclosure of information or confidentiality protected by law, including matters related to the initiation and conduct of investigations of possible or certain violations of the law and quasi-judicial deliberations.

(6) For duly constituted committees of a board or council of trustees of a State-owned, State-aided or State-related college or university or community college or of the Board of Governors of the State System of Higher Education to discuss matters of academic admission or standings.

(b) **Procedure.** The executive session may be held during an open meeting, at the conclusion of an open meeting, or may be announced for a future time. The reason for holding the executive session must be announced at the open meeting occurring immediately prior or subsequent to the executive session. If the executive session is not announced for a future specific time, members of the agency shall be notified 24 hours in advance of the time of the convening of the meeting specifying the date, time, location and purpose of the executive session.

(c) **Limitation.** Official action on discussions held pursuant to subsection (a) shall be taken at an open meeting. Nothing in this section or section 707 (relating to exceptions to open meetings) shall be construed to require that any meeting be closed to the public, nor shall any executive session be used as a subterfuge to defeat the purposes of section 704 (relating to open meetings).

Section 709. Public notice

(a) **Meetings.** An agency shall give public notice of its first regular meeting of each calendar or fiscal year not less than three days in advance of the meeting and shall give public notice of the schedule of its remaining regular meetings. An agency shall give public notice of each special meeting or each rescheduled regular or special meeting at least 24 hours in advance of the time of the convening of the meeting specified in the notice. Public notice is not required in the case of an emergency meeting or a conference. Professional licensing boards within the Bureau of Professional and Occupational Affairs of the Department of State of the Commonwealth shall include in the public notice each matter involving a proposal to revoke, suspend or restrict a license.

(b) **Notice**. With respect to any provision of this chapter that requires public notice to be given by a certain date, the agency, to satisfy its legal obligation, must give notice in time to allow it to be published or circulated within the political subdivision where the principal office of the agency is located or the meeting will occur before the date of the specified meeting.

(c) **Copies**. In addition to the public notice required by this section, the agency holding a meeting shall supply, upon request, copies of the public notice thereof to any newspaper of general circulation in the political subdivision in which the meeting will be held, to any radio or television station which regularly broadcasts into the political subdivision and to any interested parties if the newspaper, station or party provides the agency with a stamped, self-addressed envelope prior to the meeting.

(d) **Meeting of the General Assembly in Capitol Complex**. Notwithstanding any provision of this section to the contrary, in case of sessions of the General Assembly, all meetings of legislative committees held within the Capitol Complex where bills are considered, including conference committees, all legislative hearings held within the Capitol Complex where testimony is taken and all meetings of legislative commissions held within the Capitol Complex, the requirement for public notice thereof shall be complied with if, not later than the preceding day:

(1) The supervisor of the newsroom of the State Capitol Building in Harrisburg is supplied for distribution to the members of the Pennsylvania Legislative Correspondents Association with a minimum of 30 copies of the notice of the date, time and place of each session, meeting or hearing.

(2) There is posting of the copy of the notice at public places within the Main Capitol Building designated by the Secretary of the Senate and the Chief Clerk of the House of Representatives.

(e) **Announcement**. Notwithstanding any provision of this chapter to the contrary, committees may be called into session in accordance with the provisions of the Rules of the Senate or the House of Representatives and an announcement by the presiding officer of the Senate or the House of Representatives. The announcement shall be made in open session of the Senate or the House of Representatives.

Section 710. Rules and regulations for conduct of meetings

Nothing in this chapter shall prohibit the agency from adopting by official action the rules and regulations necessary for the conduct of its meetings and the maintenance of order. The rules and regulations shall not be made to violate the intent of this chapter.

Section 710.1 Public participation

(a) **General rule**. Except as provided in subsection (d), the board or council of a political subdivision, or of an authority created by a political subdivision shall provide a reasonable opportunity at each advertised regular meeting and advertised special meeting for residents of the political subdivision or of the authority created by a political subdivision or for taxpayers of the political subdivision or of the authority created by a political subdivision or for both, to comment on matters of concern, official action or deliberation which are or may be before the board or council prior to taking official action. The board or council has the option to accept all public comment at the beginning of the meeting. If the board or council determines that there is not sufficient time at a meeting for residents of the political subdivision or of the authority created by a political

subdivision or for taxpayers of the political subdivision or of the authority created by the political subdivision or for both to comment, the board or council may defer the comment period to the next regular meeting or to a special meeting occurring in advance of the next regular meeting.

(b) **Limitation on judicial relief**. If a board or council of a political subdivision or an authority created by a political subdivision has complied with the provisions of subsection (a), the judicial relief under section 713 (relating to business transacted at unauthorized meeting void) shall not be available on a specific action solely on the basis of lack of comment on that action.

(c) **Objection**. Any person has the right to raise an objection at any time to a perceived violation of this chapter at any meeting of a board or council of a political subdivision or an authority created by a political subdivision.

(d) **Exception**. The board or council of a political subdivision or of an authority created by a political subdivision which had, before Jan. 1, 1993, established a practice or policy of holding special meetings solely for the purpose of public comment in advance of advertised regular meetings shall be exempt from the provisions of subsection (a).

Section 711. Use of equipment during meetings

(a) **Recording devices**. Except as provided in subsection (b), a person attending a meeting of an agency shall have the right to use recording devices to record all the proceedings. Nothing in this section shall prohibit the agency from adopting and enforcing reasonable rules for their use under section 710 (relating to rules and regulations for conduct of meetings).

(b) **Rules of the Senate and House of Representatives.** The Senate and House of Representatives may adopt rules governing the recording or broadcast of their sessions and meetings and hearings of committees.

Section 712. General Assembly meetings covered

Notwithstanding any other provision, for the purpose of this chapter, meetings of the General Assembly which are covered are as follows: all meetings of committees where bills are considered, all hearings where testimony is taken and all sessions of the Senate and the House of Representatives. Not included in the intent of this chapter are caucuses or meetings of any ethics committee created pursuant to the Rules of the Senate or the House of Representatives.

Section 713. Business transacted at unauthorized meeting void

A legal challenge under this chapter shall be filed within 30 days from the date of a meeting which is open, or within 30 days from the discovery of any action that occurred at a meeting which was not open at which this chapter was violated, provided that, in the case of a meeting which was not open, no legal challenge may be commenced more than one year from the date of said meeting. The court may enjoin any challenged action until a judicial determination of the legality of the meeting at which the action was adopted is reached. Should the court determine that the meeting did not meet the requirements of this chapter, it may in its discretion find that any or all official action taken at the meeting shall be invalid. Should the court determine that the meeting met the requirements of this chapter, all official action taken at the meeting shall be fully effective.

Section 714. Penalty

(a) **Fines and costs.** Any member of any agency who participates in a meeting with the intent and purpose by that member of violating this chapter commits a summary offense and shall, upon conviction, be sentenced to pay:

(1) For a first offense, the costs of prosecution plus a fine of at least $100 and, in the discretion of the sentencing authority, of not more than $1,000.

(2) For a second or subsequent offense, the costs of prosecution plus a fine of at least $500 and, in the discretion of the sentencing authority, of not more than $2,000.

(b) **Payment.** An agency shall not make a payment on behalf of or reimburse a member of an agency for a fine or cost resulting from the member's violation of this section.

Section 714.1. Attorney fees

If the court determines that an agency willfully or with wanton disregard violated a provision of this chapter, in whole or in part, the court shall award the prevailing party reasonable attorney fees and costs of litigation or an appropriate portion of the fees and costs. If the court finds that the legal challenge was of a frivolous nature or was brought with no substantial justification, the court shall award the prevailing party reasonable attorney fees and costs of litigation or an appropriate portion of the fees and costs.

Section 715. Jurisdiction and venue of judicial proceedings

The Commonwealth Court shall have original jurisdiction of actions involving State agencies and the courts of common pleas shall have original jurisdiction of actions involving other agencies to render declaratory judgements or to enforce this chapter by injunction or other remedy deemed appropriate by the court. The action may be brought by any person where the agency whose act is complained of is located or where the act complained of occurred.

Section 716. Confidentiality

All acts and parts of acts are repealed insofar as they are inconsistent with this chapter, excepting those statutes which specifically provide for the confidentiality of information. Those deliberations or official actions which, if conducted in public, would violate a lawful privilege or lead to the disclosure of information or confidentiality protected by law, including matter related to the investigation of possible or certain violations of the law and quasi-judicial deliberations, shall not fall within the scope of this chapter.

The General Assembly of the Commonwealth of Pennsylvania hereby enacts as follows:

CHAPTER 1. PRELIMINARY PROVISIONS

Section 101. Short title.

This act shall be known and may be cited as the Right-to-Know Law.

Section 102. Definitions.

The following words and phrases when used in this act shall have the meanings given to them in this section unless the context clearly indicates otherwise:

"Administrative proceeding." A proceeding by an agency the outcome of which is required to be based on a record or documentation prescribed by law or in which a statute or regulation is particularized in application to individuals. The term includes an appeal.

"Agency." A Commonwealth agency, a local agency, a judicial agency or a legislative agency.

"Aggregated data." A tabulation of data which relate to broad classes, groups or categories so that it is not possible to distinguish the properties of individuals within those classes, groups or categories.

"Appeals officer." As follows:

(1) For a Commonwealth agency or a local agency, the appeals officer designated under section 503(a).

(2) For a judicial agency, the individual designated under section 503(b).

(3) For a legislative agency, the individual designated under section 503(c).

(4) For the Attorney General, State Treasurer, Auditor General and local agencies in possession of criminal investigative records, the individual designated under section 503(d).

"Commonwealth agency." Any of the following:

(1) Any office, department, authority, board, multistate agency or commission of the executive branch; an independent agency; and a State-affiliated entity. The term includes:

(i) The Governor's Office.

(ii) The Office of Attorney General, the Department of the Auditor General and the Treasury Department.

(iii) An organization established by the Constitution of Pennsylvania, a statute or an executive order which performs or is intended to perform an essential governmental function.

(2) The term does not include a judicial or legislative agency.

"Confidential proprietary information." Commercial or financial information received by an agency:

(1) which is privileged or confidential; and

(2) the disclosure of which would cause substantial harm to the competitive position of the person that submitted the information.

"Financial record." Any of the following:

(1) Any account, voucher or contract dealing with:

(i) the receipt or disbursement of funds by an agency; or

(ii) an agency's acquisition, use or disposal of services, supplies, materials, equipment or property.

(2) The salary or other payments or expenses paid to an officer or employee of an agency, including the name and title of the officer or employee.

(3) A financial audit report. The term does not include work papers underlying an audit.

"Homeland security." Governmental actions designed to prevent, detect, respond to and recover from acts of terrorism, major disasters and other emergencies, whether natural or manmade. The term includes activities relating to the following:

(1) emergency preparedness and response, including preparedness and response activities by volunteer medical, police, emergency management, hazardous materials and fire personnel;

(2) intelligence activities;

(3) critical infrastructure protection;

(4) border security;

(5) ground, aviation and maritime transportation security;

(6) biodefense;

(7) detection of nuclear and radiological materials; and (8) research on next-generation securities technologies.

"Independent agency." Any board, commission or other agency or officer of the Commonwealth, that is not subject to the policy supervision and control of the Governor. The term does not include a legislative or judicial agency.

"Judicial agency." A court of the Commonwealth or any other entity or office of the unified judicial system.

"Legislative agency." Any of the following:

(1) The Senate.

(2) The House of Representatives.

(3) The Capitol Preservation Committee.

(4) The Center for Rural Pennsylvania.

(5) The Joint Legislative Air and Water Pollution Control and Conservation Committee.

(6) The Joint State Government Commission.

(7) The Legislative Budget and Finance Committee.

(8) The Legislative Data Processing Committee.

(9) The Independent Regulatory Review Commission.

(10) The Legislative Reference Bureau.

(11) The Local Government Commission.

(12) The Pennsylvania Commission on Sentencing.

(13) The Legislative Reapportionment Commission.

(14) The Legislative Office of Research Liaison.

(15) The Legislative Audit Advisory Commission.

"Legislative record." Any of the following relating to a legislative agency or a standing committee, subcommittee or conference committee of a legislative agency:

(1) A financial record.

(2) A bill or resolution that has been introduced and amendments offered thereto in committee or in legislative session, including resolutions to adopt or amend the rules of a chamber.

(3) Fiscal notes.

(4) A cosponsorship memorandum.

(5) The journal of a chamber.

(6) The minutes of, record of attendance of members at a public hearing or a public committee meeting and all recorded votes taken in a public committee meeting.

(7) The transcript of a public hearing when available.

(8) Executive nomination calendars.

(9) The rules of a chamber.

(10) A record of all recorded votes taken in a legislative session.

(11) Any administrative staff manuals or written policies.

(12) An audit report prepared pursuant to the act of June 30, 1970 (P.L.442, No.151) entitled, "An act implementing the provisions of Article VIII, section 10 of the Constitution of Pennsylvania, by designating the Commonwealth officers who shall be charged with the function of auditing the financial transactions after the occurrence thereof of the Legislative and Judicial branches of the government of the Commonwealth, establishing a Legislative Audit Advisory Commission, and imposing certain powers and duties on such commission."

(13) Final or annual reports required by law to be submitted to the General Assembly.

(14) Legislative Budget and Finance Committee reports.

(15) Daily Legislative Session Calendars and marked calendars.

(16) A record communicating to an agency the official appointment of a legislative appointee.

(17) A record communicating to the appointing authority the resignation of a legislative appointee.

(18) Proposed regulations, final-form regulations and final-omitted regulations submitted to a legislative agency.

(19) The results of public opinion surveys, polls, focus groups, marketing research or similar efforts designed to measure public opinion funded by a legislative agency.

"Local agency." Any of the following:

(1) Any political subdivision, intermediate unit, charter school, cyber charter school or public trade or vocational school.

(2) Any local, intergovernmental, regional or municipal agency, authority, council, board, commission or similar governmental entity.

"Office of Open Records." The Office of Open Records established in section 1310.

"Personal financial information." An individual's personal credit, charge or debit card information; bank account information; bank, credit or financial statements; account or PIN numbers and other information relating to an individual's personal finances.

"Privilege." The attorney-work product doctrine, the attorney-client privilege, the doctor-patient privilege, the speech and debate privilege or other privilege recognized by a court interpreting the laws of this Commonwealth.

"Public record." A record, including a financial record, of a Commonwealth or local agency that:

(1) is not exempt under section 708;

(2) is not exempt from being disclosed under any other Federal or State law or regulation or judicial order or decree; or

(3) is not protected by a privilege.

"Record." Information, regardless of physical form or characteristics, that documents a transaction or activity of an agency and that is created, received or retained pursuant to law or in connection with a transaction, business or activity of the agency. The term includes a document, paper, letter, map, book, tape, photograph, film or sound recording, information stored or maintained electronically and a data-processed or image- processed document.

"Requester." A person that is a legal resident of the United States and requests a record pursuant to this act. The term includes an agency.

"Response." Access to a record or an agency's written notice to a requester granting, denying or partially granting and partially denying access to a record.

"Social services." Cash assistance and other welfare benefits, medical, mental and other health care services, drug and alcohol treatment, adoption services, vocational services and training, occupational training, education services, counseling services, workers' compensation services and unemployment compensation services, foster care services, services for the elderly, services for individuals with disabilities and services for victims of crimes and domestic violence.

"State-affiliated entity." A Commonwealth authority or Commonwealth entity. The term includes the Pennsylvania Higher Education Assistance Agency and any entity established thereby, the Pennsylvania Gaming Control Board, the Pennsylvania Game Commission, the Pennsylvania Fish and Boat Commission, the Pennsylvania Housing Finance Agency, the Pennsylvania Municipal Retirement Board, the State System of Higher Education, a community college, the Pennsylvania Turnpike Commission, the Pennsylvania Public Utility Commission, the Pennsylvania Infrastructure Investment Authority, the State Public School Building Authority, the Pennsylvania Interscholastic Athletic Association and the Pennsylvania Educational Facilities Authority. The term does not include a State-related institution.

"State-related institution." Includes:

(1) Temple University.

(2) The University of Pittsburgh.

(3) The Pennsylvania State University.

(4) Lincoln University.

"Terrorist act." A violent or life-threatening act that violates the criminal laws of the United States or any state and appears to be intended to:

(1) intimidate or coerce a civilian population;

(2) influence the policy of a government; or

(3) affect the conduct of a government by mass destruction, assassination or kidnapping.

"Trade secret." Information, including a formula, drawing, pattern, compilation, including a customer list, program, device, method, technique or process that:

(1) derives independent economic value, actual or potential, from not being generally known to and not being readily ascertainable by proper means by other persons who can obtain economic value from its disclosure or use; and

(2) is the subject of efforts that are reasonable under the circumstances to maintain its secrecy.

The term includes data processing software obtained by an agency under a licensing agreement prohibiting disclosure.

CHAPTER 3. REQUIREMENTS AND PROHIBITIONS

Section 301. Commonwealth agencies.

(a) Requirement. — A Commonwealth agency shall provide public records in accordance with this act.

(b) Prohibition. — A Commonwealth agency may not deny a requester access to a public record due to the intended use of the public record by the requester unless otherwise provided by law.

Section 302. Local agencies.

(a) Requirement. — A local agency shall provide public records in accordance with this act.

(b) Prohibition. — A local agency may not deny a requester access to a public record due to the intended use of the public record by the requester unless otherwise provided by law.

Section 303. Legislative agencies.

(a) **Requirement.** — A legislative agency shall provide legislative records in accordance with this act.

(b) **Prohibition.** — A legislative agency may not deny a requester access to a legislative record due to the intended use of the legislative record by the requester.

Section 304. Judicial agencies.

(a) **Requirement.** — A judicial agency shall provide financial records in accordance with this act or any rule or order of court providing equal or greater access to the records.

(b) **Prohibition.** — A judicial agency may not deny a requester access to a financial record due to the intended use of the financial record by the requester.

Section 305. Presumption.

(a) **General rule.** — A record in the possession of a Commonwealth agency or local agency shall be presumed to be a public record. The presumption shall not apply if:

(1) the record is exempt under section 708;

(2) the record is protected by a privilege; or

(3) the record is exempt from disclosure under any other Federal or State law or regulation or judicial order or decree.

(b) **Legislative records and financial records.** — A legislative record in the possession of a legislative agency and a financial record in the possession of a judicial agency shall be presumed to be available in accordance with this act. The presumption shall not apply if:

(1) the record is exempt under section 708;

(2) the record is protected by a privilege; or

(3) the record is exempt from disclosure under any other Federal or State law, regulation or judicial order or decree.

Section 306. Nature of document.

Nothing in this act shall supersede or modify the public or nonpublic nature of a record or document established in Federal or State law, regulation or judicial order or decree.

CHAPTER 5. ACCESS

Section 501. Scope of chapter.

This chapter applies to all agencies.

Section 502. Open-records officer.

(a) **Establishment.** —

(1) An agency shall designate an official or employee to act as the open-records officer.

(2) For a legislative agency other than the Senate or the House of Representatives, the open-records officer designated by the Legislative Reference Bureau shall serve as the open-records officer. Notwithstanding paragraph (1), a political party caucus of a legislative agency may appoint an open-records officer under this section.

(b) **Functions.** —

(1) The open-records officer shall receive requests submitted to the agency under this act, direct requests to other appropriate persons within the agency or to appropriate persons in another agency, track the agency's progress in responding to requests and issue interim and final responses under this act.

(2) Upon receiving a request for a public record, legislative record or financial record, the open-records officer shall do all of the following:

(i) Note the date of receipt on the written request.

(ii) Compute the day on which the five-day period under section 901 will expire and make a notation of that date on the written request.

(iii) Maintain an electronic or paper copy of a written request, including all documents submitted with the request until the request has been fulfilled. If the request is denied, the written request shall be maintained for 30 days or, if an appeal is filed, until a final determination is issued under section 1101(b) or the appeal is deemed denied.

(iv) Create a file for the retention of the original request, a copy of the response, a record of written communications with the requester and a copy of other communications. This subparagraph shall only apply to Commonwealth agencies.

Section 503. Appeals officer.

(a) **Commonwealth agencies and local agencies.** — Except as provided in subsection (d), the Office of Open Records established under section 1310 shall designate an appeals officer under section 1101(a)(2) for all:

(1) Commonwealth agencies; and

(2) local agencies.

(b) **Judicial agencies.** — A judicial agency shall designate an appeals officer to hear appeals under Chapter 11.

(c) **Legislative agencies.** —

(1) Except as set forth in paragraph (2), the Legislative Reference Bureau shall designate an appeals officer to hear appeals under Chapter 11 for all legislative agencies.

(2) Each of the following shall designate an appeals officer to hear appeals under Chapter 11:

(i) The Senate.

(ii) The House of Representatives.

(d) **Law enforcement records and Statewide officials.** —

(1) The Attorney General, State Treasurer and Auditor General shall each designate an appeals officer to hear appeals under Chapter 11.

(2) The district attorney of a county shall designate one or more appeals officers to hear appeals under Chapter 11 relating to access to criminal investigative records in possession of a local agency of that county. The appeals officer designated by the district attorney shall determine if the record requested is a criminal investigative record.

Section 504. Regulations and policies.

(a) **Authority.** — An agency may promulgate regulations and policies necessary for the agency to implement this act. The Office of Open Records may promulgate regulations relating to appeals involving a Commonwealth agency or local agency.

(b) **Posting.** — The following information shall be posted at each agency and, if the agency maintains an Internet website, on the agency's Internet website:

(1) Contact information for the open-records officer.

(2) Contact information for the Office of Open Records or other applicable appeals officer.

(3) A form which may be used to file a request.

(4) Regulations, policies and procedures of the agency relating to this act.

Section 505. Uniform form.

(a) **Commonwealth and local agencies.** — The Office of Open Records shall develop a uniform form which shall be accepted by all Commonwealth and local agencies in addition to any form used by the agency to file a request under this act. The uniform form shall be published in the Pennsylvania Bulletin and on the Office of Open Record's Internet website.

(b) **Judicial agencies.** — A judicial agency or the Administrative Office of Pennsylvania Courts may develop a form to request financial records or may accept a form developed by the Office of Open Records.

(c) **Legislative agencies.** — A legislative agency may develop a form to request legislative records or may accept the form developed by the Office of Open Records.

Section 506. Requests.

(a) **Disruptive requests.** —

(1) An agency may deny a requester access to a record if the requester has made repeated requests for that same record and the repeated requests have placed an unreasonable burden on the agency.

(2) A denial under this subsection shall not restrict the ability to request a different record.

(b) **Disaster or potential damage.** —

(1) An agency may deny a requester access:

(i) when timely access is not possible due to fire, flood or other disaster; or

(ii) to historical, ancient or rare documents, records, archives and manuscripts when access may, in the professional judgment of the curator or custodian of records, cause physical damage or irreparable harm to the record.

(2) To the extent possible, the contents of a record under this subsection shall be made accessible to a requester even when the record is physically unavailable.

(c) **Agency discretion.** — An agency may exercise its discretion to make any otherwise exempt record accessible for inspection and copying under this chapter, if all of the following apply:

(1) Disclosure of the record is not prohibited under any of the following:

(i) Federal or State law or regulation.

(ii) Judicial order or decree.

(2) The record is not protected by a privilege.

(3) The agency head determines that the public interest favoring access outweighs any individual, agency or public interest that may favor restriction of access.

(d) **Agency possession.** —

(1) A public record that is not in the possession of an agency but is in the possession of a party with whom the agency has contracted to perform a governmental function on behalf of the agency, and which directly relates to the governmental function and is not exempt under this act, shall be considered a public record of the agency for purposes of this act.

(2) Nothing in this act shall be construed to require access to any other record of the party in possession of the public record.

(3) A request for a public record in possession of a party other than the agency shall be submitted to the open records officer of the agency. Upon a determination that the record is subject to access under this act, the open records officer shall assess the duplication fee established under section 1307(b) and upon collection shall remit the fee to the party in possession of the record if the party duplicated the record.

Section 507. Retention of records.

Nothing in this act shall be construed to modify, rescind or supersede any record retention policy or disposition schedule of an agency established pursuant to law, regulation, policy or other directive.

CHAPTER 7 PROCEDURE

Section 701. Access.

(a) **General rule.** — Unless otherwise provided by law, a public record, legislative record or financial record shall be accessible for inspection and duplication in accordance with this act. A record being provided to a requester shall be provided in the medium requested if it exists in that medium; otherwise, it shall be provided in the medium in which it exists. Public records, legislative records or financial records shall be available for access during the regular business hours of an agency.

(b) **Construction.** — Nothing in this act shall be construed to require access to any computer either of an agency or individual employee of an agency.

Section 702. Requests.

Agencies may fulfill verbal, written or anonymous verbal or written requests for access to records under this act. If the requester wishes to pursue the relief and remedies provided for in this act, the request for access to records must be a written request.

Section 703. Written requests.

A written request for access to records may be submitted in person, by mail, by e-mail, by facsimile or, to the extent provided by agency rules, any other electronic means. A written request must be addressed to the open-records officer designated pursuant to section 502. Employees of an agency shall be directed to forward requests for records to the open-records officer. A written request should identify or describe the records sought with sufficient specificity to enable the agency to ascertain which records are being requested and shall include the name and address to which the agency should address its response. A written request need not include any explanation of the requester's reason for requesting or intended use of the records unless otherwise required by law.

Section 704. Electronic access.

(a) **General rule.** — In addition to the requirements of section 701, an agency may make its records available through any publicly accessible electronic means.

(b) **Response.** —

(1) In addition to the requirements of section 701, an agency may respond to a request by notifying the requester that the record is available through publicly accessible electronic means or that the agency will provide access to inspect the record electronically.

(2) If the requester is unwilling or unable to access the record electronically, the requester may, within 30 days following receipt of the agency notification, submit a written request to the agency to have the record converted to paper. The agency shall provide access to the record in printed form within five days of the receipt of the written request for conversion to paper.

Section 705. Creation of record.

When responding to a request for access, an agency shall not be required to create a record which does not currently exist or to compile, maintain, format or organize a record in a manner in which the agency does not currently compile, maintain, format or organize the record.

Section 706. Redaction.

If an agency determines that a public record, legislative record or financial record contains information which is subject to access as well as information which is not subject to access, the agency's response shall grant access to the information which is subject to access and deny access to the information which is not subject to access. If the information which is not subject to access is an integral part of the public record, legislative record or financial record and cannot be separated, the agency shall redact from the record the information which is not subject to access, and the response shall grant access to the information which is subject to access. The agency may not deny access to the record if the information which is not subject to access is able to be redacted. Information which an agency redacts in accordance with this subsection shall be deemed a denial under Chapter 9.

Section 707. Production of certain records.

(a) **General rule.** — If, in response to a request, an agency produces a record that is not a public record, legislative record or financial record, the agency shall notify any third party that provided the record to the agency, the person that is the subject of the record and the requester.

(b) **Requests for trade secrets.** — An agency shall notify a third party of a request for a record if the third party provided the record and included a written statement signed by a representative of the third party that the record contains a trade secret or confidential proprietary information.

Notification shall be provided within five business days of receipt of the request for the record. The third party shall have five business days from receipt of notification from the agency to provide input on the release of the record. The agency shall deny the request for the record or release the record within ten business days of the provision of notice to the third party and shall notify the third party of the decision.

(c) **Transcripts.** —

(1) Prior to an adjudication becoming final, binding and nonappealable, a transcript of an administrative proceeding shall be provided to a requester by the agency stenographer or a court reporter, in accordance with agency procedure or an applicable contract.

(2) Following an adjudication becoming final, binding and nonappealable, a transcript of an administrative proceeding shall be provided to a requester in accordance with the duplication rates established in section 1307(b).

Section 708. Exceptions for public records.

(a) **Burden of proof.** —

(1) The burden of proving that a record of a Commonwealth agency or local agency is exempt from public access shall be on the Commonwealth agency or local agency receiving a request by a preponderance of the evidence.

(2) The burden of proving that a legislative record is exempt from public access shall be on the legislative agency receiving a request by a preponderance of the evidence.

(3) The burden of proving that a financial record of a judicial agency is exempt from public access shall be on the judicial agency receiving a request by a preponderance of the evidence.

(b) **Exceptions.** — Except as provided in subsections (c) and (d), the following are exempt from access by a requester under this act:

(1) A record the disclosure of which:

(i) would result in the loss of Federal or State funds by an agency or the Commonwealth; or

(ii) would be reasonably likely to result in a substantial and demonstrable risk of physical harm to or the personal security of an individual.

(2) A record maintained by an agency in connection with the military, homeland security, national defense, law enforcement or other public safety activity that if disclosed would be reasonably likely to jeopardize or threaten public safety or preparedness or public protection activity or a record that is designated classified by an appropriate Federal or State military authority.

(3) A record, the disclosure of which creates a reasonable likelihood of endangering the safety or the physical security of a building, public utility, resource, infrastructure, facility or information storage system, which may include:

(i) documents or data relating to computer hardware, source files, software and system networks that could jeopardize computer security by exposing a vulnerability in preventing, protecting against, mitigating or responding to a terrorist act;

(ii) lists of infrastructure, resources and significant special events, including those defined by the Federal Government in the National Infrastructure Protections, which are deemed critical due to their nature and which result from risk analysis; threat assessments; consequences assessments; antiterrorism protective measures and plans; counterterrorism measures and plans; and security and response needs assessments; and

(iii) building plans or infrastructure records that expose or create vulnerability through disclosure of the location, configuration or security of critical systems, including public utility systems, structural elements, technology, communication, electrical, fire suppression, ventilation, water, wastewater, sewage and gas systems.

(4) A record regarding computer hardware, software and networks, including administrative or technical records, which, if disclosed, would be reasonably likely to jeopardize computer security.

(5) A record of an individual's medical, psychiatric or psychological history or disability status, including an evaluation, consultation, prescription, diagnosis or treatment; results of tests, including drug tests; enrollment in a health care program or program designed for participation by persons with disabilities, including vocation rehabilitation, workers' compensation and unemployment compensation; or related information that would disclose individually identifiable health information.

(6) (i) The following personal identification information:

(A) A record containing all or part of a person's Social Security number; driver's license number; personal financial information; home, cellular or personal telephone numbers; personal e-mail addresses; employee number or other confidential personal identification number.

(B) A spouse's name; marital status, beneficiary or dependent information.

(C) The home address of a law enforcement officer or judge.

(ii) Nothing in this paragraph shall preclude the release of the name, position, salary, actual compensation or other payments or expenses, employment contract, employment-related contract or agreement and length of service of a public official or an agency employee.

(iii) An agency may redact the name or other identifying information relating to an individual performing an undercover or covert law enforcement activity from a record.

(7) The following records relating to an agency employee:

(i) A letter of reference or recommendation pertaining to the character or qualifications of an identifiable individual, unless it was prepared in relation to the appointment of an individual to fill a vacancy in an elected office or an appointed office requiring Senate confirmation.

(ii) A performance rating or review.

(iii) The result of a civil service or similar test administered by a Commonwealth agency, legislative agency or judicial agency. The result of a civil service or similar test administered by a local agency shall not be disclosed if restricted by a collective bargaining agreement. Only test scores of individuals who obtained a passing score on a test administered by a local agency may be disclosed.

(iv) The employment application of an individual who is not hired by the agency.

(v) Workplace support services program information.

(vi) Written criticisms of an employee.

(vii) Grievance material, including documents related to discrimination or sexual harassment.

(viii) Information regarding discipline, demotion or discharge contained in a personnel file. This subparagraph shall not apply to the final action of an agency that results in demotion or discharge.

(ix) An academic transcript.

(8) (i) A record pertaining to strategy or negotiations relating to labor relations or collective bargaining and related arbitration proceedings. This subparagraph shall not apply to a final or executed contract or agreement between the parties in a collective bargaining procedure.

(ii) In the case of the arbitration of a dispute or grievance under a collective bargaining agreement, an exhibit entered into evidence at an arbitration proceeding, a transcript of the arbitration or the opinion. This subparagraph shall not apply to the final award or order of the arbitrator in a dispute or grievance procedure.

(9) The draft of a bill, resolution, regulation, statement of policy, management directive, ordinance or amendment thereto prepared by or for an agency.

(10) (i) A record that reflects:

(A) The internal, predecisional deliberations of an agency, its members, employees or officials or predecisional deliberations between agency members, employees or officials and members, employees or officials of another agency, including predecisional deliberations relating to a budget recommendation, legislative proposal, legislative amendment, contemplated or proposed policy or course of action or any research, memos or other documents used in the predecisional deliberations.

(B) The strategy to be used to develop or achieve the successful adoption of a budget, legislative proposal or regulation.

(ii) Subparagraph (i)(A) shall apply to agencies subject to 65 Pa.C.S. Ch. 7 (relating to open meetings) in a manner consistent with 65 Pa.C.S. Ch. 7. A record which is not otherwise exempt from access under this act and which is presented to a quorum for deliberation in accordance with 65 Pa.C.S. Ch. 7 shall be a public record.

(iii) This paragraph shall not apply to a written or Internet application or other document that has been submitted to request Commonwealth funds.

(iv) This paragraph shall not apply to the results of public opinion surveys, polls, focus groups, marketing research or similar effort designed to measure public opinion.

(11) A record that constitutes or reveals a trade secret or confidential proprietary information.

(12) Notes and working papers prepared by or for a public official or agency employee used solely for that official's or employee's own personal use, including telephone message slips, routing slips and other materials that do not have an official purpose.

(13) Records that would disclose the identity of an individual who lawfully makes a donation to an agency unless the donation is intended for or restricted to providing remuneration or personal tangible benefit to a named public official or employee of the agency, including lists of potential donors compiled by an agency to pursue donations, donor profile information or personal identifying information relating to a donor.

(14) Unpublished lecture notes, unpublished manuscripts, unpublished articles, creative works in progress, research-related material and scholarly correspondence of a community college or an institution of the State System of Higher Education or a faculty member, staff employee, guest speaker or student thereof.

(15) (i) Academic transcripts

(ii) Examinations, examination questions, scoring keys or answers to examinations. This subparagraph shall include licensing and other examinations relating to the qualifications of an individual and to examinations given in primary and secondary schools and institutions of higher education.

(16) A record of an agency relating to or resulting in a criminal investigation, including:

(i) Complaints of potential criminal conduct other than a private criminal complaint.

(ii) Investigative materials, notes, correspondence, videos and reports.

(iii) A record that includes the identity of a confidential source or the identity of a suspect who has not been charged with an offense to whom confidentiality has been promised.

(iv) A record that includes information made confidential by law or court order.

(v) Victim information, including any information that would jeopardize the safety of the victim.

(vi) A record that, if disclosed, would do any of the following:

(A) Reveal the institution, progress or result of a criminal investigation, except the filing of criminal charges.

(B) Deprive a person of the right to a fair trial or an impartial adjudication.

(C) Impair the ability to locate a defendant or codefendant.

(D) Hinder an agency's ability to secure an arrest, prosecution or conviction.

(E) Endanger the life or physical safety of an individual.

This paragraph shall not apply to information contained in a police blotter as defined in 18 Pa.C.S. § 9102 (relating to definitions) and utilized or maintained by the Pennsylvania State Police, local, campus, transit or port authority police department or other law enforcement agency or in a traffic report except as provided under 75 Pa.C.S. § 3754(b) (relating to accident prevention investigations).

(17) A record of an agency relating to a noncriminal investigation, including:

(i) Complaints submitted to an agency.

(ii) Investigative materials, notes, correspondence and reports.

(iii) A record that includes the identity of a confidential source, including individuals subject to the act of December 12, 1986 (P.L.1559, No.169), known as the Whistleblower Law.

(iv) A record that includes information made confidential by law.

(v) Work papers underlying an audit.

(vi) A record that, if disclosed, would do any of the following:

(A) Reveal the institution, progress or result of an agency investigation, except the imposition of a fine or civil penalty, the suspension, modification or revocation of a license, permit, registration, certification or similar authorization issued by an agency or an executed settlement agreement unless the agreement is determined to be confidential by a court.

(B) Deprive a person of the right to an impartial adjudication.

(C) Constitute an unwarranted invasion of privacy.

(D) Hinder an agency's ability to secure an administrative or civil sanction.

(E) Endanger the life or physical safety of an individual.

(18) (i) Records or parts of records, except time response logs, pertaining to audio recordings, telephone or radio transmissions received by emergency dispatch personnel, including 911 recordings.

(ii) This paragraph shall not apply to a 911 recording, or a transcript of a 911 recording, if the agency or a court determines that the public interest in disclosure outweighs the interest in nondisclosure.

(19) DNA and RNA records.

(20) An autopsy record of a coroner or medical examiner and any audiotape of a postmortem examination or autopsy, or a copy, reproduction or facsimile of an autopsy report, a photograph, negative or print, including a photograph or videotape of the body or any portion of the body of a deceased person at the scene of death or in the course of a postmortem examination or autopsy taken or made by or caused to be taken or made by the coroner or medical examiner. This exception shall not limit the reporting of the name of the deceased individual and the cause and manner of death.

(21) (i) Draft minutes of any meeting of an agency until the next regularly scheduled meeting of the agency.

(ii) Minutes of an executive session and any record of discussions held in executive session.

(22) (i) The contents of real estate appraisals, engineering or feasibility estimates, environmental reviews, audits or evaluations made for or by an agency relative to the following:

(A) The leasing, acquiring or disposing of real property or an interest in real property.

(B) The purchase of public supplies or equipment included in the real estate transaction.

(C) Construction projects.

(ii) This paragraph shall not apply once the decision is made to proceed with the lease, acquisition or disposal of real property or an interest in real property or the purchase of public supply or construction project.

(23) Library and archive circulation and order records of an identifiable individual or groups of individuals.

(24) Library archived and museum materials, or valuable or rare book collections or documents contributed by gift, grant, bequest or devise, to the extent of any limitations imposed by the donor as a condition of the contribution.

(25) A record identifying the location of an archeological site or an endangered or threatened plant or animal species if not already known to the general public.

(26) A proposal pertaining to agency procurement or disposal of supplies, services or construction prior to the award of the contract or prior to the opening and rejection of all bids; financial information of a bidder or offeror requested in an invitation for bid or request for proposals to demonstrate the bidder's or offeror's economic capability; or the identity of members, notes and other records of agency proposal evaluation committees established under 62 Pa.C.S. § 513 (relating to competitive sealed proposals).

(27) A record or information relating to a communication between an agency and its insurance carrier, administrative service organization or risk management office. This paragraph shall not apply to a contract with an insurance carrier, administrative service organization or risk management office or to financial records relating to the provision of insurance.

(28) A record or information:

(i) identifying an individual who applies for or receives social services; or

(ii) relating to the following:

(A) the type of social services received by an individual;

(B) an individual's application to receive social services, including a record or information related to an agency decision to grant, deny, reduce or restrict benefits, including a quasi-judicial decision of the agency and the identity of a caregiver or others who provide services to the individual; or

(C) eligibility to receive social services, including the individual's income, assets, physical or mental health, age, disability, family circumstances or record of abuse.

(29) Correspondence between a person and a member of the General Assembly and records accompanying the correspondence which would identify a person that requests assistance or constituent services. This paragraph shall not apply to correspondence between a member of the General Assembly and a principal or lobbyist under 65 Pa.C.S. Ch. 13A (relating to lobbyist disclosure).

(30) A record identifying the name, home address or date of birth of a child 17 years of age or younger.

(c) Financial records. — The exceptions set forth in subsection (b) shall not apply to financial records, except that an agency may redact that portion of a financial record protected under subsection (b)(1), (2), (3), (4), (5), (6), (16) OR (17). An agency shall not disclose the identity of an individual performing an undercover or covert law enforcement activity.

(d) Aggregated data. — The exceptions set forth in subsection (b) shall not apply to aggregated data maintained or received by an agency, except for data protected under subsection (b)(1), (2), (3), (4) or (5).

(e) Construction. — In determining whether a record is exempt from access under this section, an agency shall consider and apply each exemption separately.

CHAPTER 9 AGENCY RESPONSE

Section 901. General rule.

Upon receipt of a written request for access to a record, an agency shall make a good faith effort to determine if the record requested is a public record, legislative record or financial record and whether the agency has possession, custody or control of the identified record, and to respond as promptly as possible under the circumstances existing at the time of the request. All applicable fees shall be paid in order to receive access to the record requested. The time for response shall not exceed five business days from the date the written request is received by the open-records officer for an agency. If the agency fails to send the response within five business days of receipt of the written request for access, the written request for access shall be deemed denied.

Section 902. Extension of time.

(a) **Determination.** — Upon receipt of a written request for access, the open-records officer for an agency shall determine if one of the following applies:

(1) the request for access requires redaction of a record in accordance with section 706;

(2) the request for access requires the retrieval of a record stored in a remote location;

(3) a timely response to the request for access cannot be accomplished due to bona fide and specified staffing limitations;

(4) a legal review is necessary to determine whether the record is a record subject to access under this act;

(5) the requester has not complied with the agency's policies regarding access to records;

(6) the requester refuses to pay applicable fees authorized by this act; or

(7) the extent or nature of the request precludes a response within the required time period.

(b) **Notice.** —

(1) Upon a determination that one of the factors listed in subsection (a) applies, the open-records officer shall send written notice to the requester within five business days of receipt of the request for access under subsection (a).

(2) The notice shall include a statement notifying the requester that the request for access is being reviewed, the reason for the review, a reasonable date that a response is expected to be provided and an estimate of applicable fees owed when the record becomes available. If the date that a response is expected to be provided is in excess of 30 days, following the five business days allowed for in section 901, the request for access shall be deemed denied unless the requester has agreed in writing to an extension to the date specified in the notice.

(3) If the requester agrees to the extension, the request shall be deemed denied on the day following the date specified in the notice if the agency has not provided a response by that date.

Section 903. Denial.

If an agency's response is a denial of a written request for access, whether in whole or in part, the denial shall be issued in writing and shall include:

(1) A description of the record requested.

(2) The specific reasons for the denial, including a citation of supporting legal authority.

(3) The typed or printed name, title, business address, business telephone number and signature of the open-records officer on whose authority the denial is issued.

(4) Date of the response.

(5) The procedure to appeal the denial of access under this act.

Section 904. Certified copies.

If an agency's response grants a request for access, the agency shall, upon request, provide the requester with a certified copy of the record if the requester pays the applicable fees under section 1307.

Section 905. Record discard.

If an agency response to a requester states that copies of the requested records are available for delivery at the office of an agency and the requester fails to retrieve the records within 60 days of the agency's response, the agency may dispose of any copies which have not been retrieved and retain any fees paid to date.

CHAPTER 11. APPEAL OF AGENCY DETERMINATION

Section 1101. Filing of appeal.

(a) **Authorization.** —

(1) If a written request for access to a record is denied or deemed denied, the requester may file an appeal with the Office of Open Records or judicial, legislative or other appeals officer designated under section 503(d) within 15 business days of the mailing date of the agency's response or within 15 business days of a deemed denial. The appeal shall state the grounds upon which the requester asserts that the record is a public record, legislative record or financial record and shall address any grounds stated by the agency for delaying or denying the request.

(2) Except as provided in section 503(d), in the case of an appeal of a decision by a Commonwealth agency or local agency, the Office of Open Records shall assign an appeals officer to review the denial.

(b) **Determination.** —

(1) Unless the requester agrees otherwise, the appeals officer shall make a final determination which shall be mailed to the requester and the agency within 30 days of receipt of the appeal filed under subsection (a).

(2) If the appeals officer fails to issue a final determination within 30 days, the appeal is deemed denied.

(3) Prior to issuing a final determination, a hearing may be conducted. The determination by the appeals officer shall be a final order. The appeals officer shall provide a written explanation of the reason for the decision to the requester and the agency.

(c) **Direct interest.** —

(1) A person other than the agency or requester with a direct interest in the record subject to an appeal under this section may, within 15 days following receipt of actual knowledge of the appeal but no later than the date the appeals officer issues an order, file a written request to provide information or to appear before the appeals officer or to file information in support of the requester's or agency's position.

(2) The appeals officer may grant a request under paragraph (1) if:

(i) no hearing has been held;

(ii) the appeals officer has not yet issued its order; and

(iii) the appeals officer believes the information will be probative.

(3) Copies of the written request shall be sent to the agency and the requester.

Section 1102. Appeals officers.

(a) **Duties.** — An appeals officer designated under section 503 shall do all of the following:

(1) Set a schedule for the requester and the open- records officer to submit documents in support of their positions.

(2) Review all information filed relating to the request. The appeals officer may hold a hearing. A decision to hold or not to hold a hearing is not appealable. The appeals officer may admit into evidence testimony, evidence and documents that the appeals officer believes to be reasonably probative and relevant to an issue in dispute. The appeals officer may limit the nature and extent of evidence found to be cumulative.

(3) Consult with agency counsel as appropriate.

(4) Issue a final determination on behalf of the Office of Open Records or other agency.

(b) **Procedures.** — The Office of Open Records, a judicial agency, a legislative agency, the Attorney General,

Auditor General, State Treasurer or district attorney may adopt procedures relating to appeals under this chapter.

(1) If an appeal is resolved without a hearing, 1 Pa. Code Pt. II (relating to general rules of administrative practice and procedure) does not apply except to the extent that the agency has adopted these chapters in its regulations or rules under this subsection.

(2) If a hearing is held, 1 Pa. Code Pt. II shall apply unless the agency has adopted regulations, policies or procedures to the contrary under this subsection.

(3) In the absence of a regulation, policy or procedure governing appeals under this chapter, the appeals officer shall rule on procedural matters on the basis of justice, fairness and the expeditious resolution of the dispute.

CHAPTER 13. JUDICIAL REVIEW

Section 1301. Commonwealth agencies, legislative agencies and judicial agencies.

(a) **General rule.** — Within 30 days of the mailing date of the final determination of the appeals officer relating to a decision of a Commonwealth agency, a legislative agency or a judicial agency issued under section 1101(b) or the date a request for access is deemed denied, a requester or the agency may file a petition for review or other document as might be required by rule of court with the Commonwealth Court. The decision of the court shall contain findings of fact and conclusions of law based upon the evidence as a whole. The decision shall clearly and concisely explain the rationale for the decision.

(b) **Stay.** — A petition for review under this section shall stay the release of documents until a decision under subsection (a) is issued.

Section 1302. Local agencies.

(a) **General rule.** — Within 30 days of the mailing date of the final determination of the appeals officer relating to a decision of a local agency issued under section 1101(b) or of the date a request for access is deemed denied, a requester or local agency may file a petition for review or other document as required by rule of court with the court of common pleas for the county where the local agency is located. The decision of the court shall contain findings of fact and conclusions of law based upon the evidence as a whole. The decision shall clearly and concisely explain the rationale for the decision.

(b) **Stay.** — A petition for review under this section shall stay the release of documents until a decision under subsection (a) is issued.

Section 1303. Notice and records.

(a) **Notice.** — An agency, the requester and the Office of Open Records or designated appeals officer shall be served notice of actions commenced in accordance with section 1301 or 1302 and shall have an opportunity to respond in accordance with applicable court rules.

(b) **Record on appeal.** — The record before a court shall consist of the request, the agency's response, the appeal filed under section 1101, the hearing transcript, if any, and the final written determination of the appeals officer.

Section 1304. Court costs and attorney fees.

(a) **Reversal of agency determination.** — If a court reverses the final determination of the appeals officer or grants access to a record after a request for access was deemed denied, the court may award reasonable attorney fees and costs of litigation or an appropriate portion thereof to a requester if the court finds either of the following:

(1) the agency receiving the original request willfully or with wanton disregard deprived the requester of access to a public record subject to access or otherwise acted in bad faith under the provisions of this act; or

(2) the exemptions, exclusions or defenses asserted by the agency in its final determination were not based on a reasonable interpretation of law.

(b) **Sanctions for frivolous requests or appeals.** — The court may award reasonable attorney fees and costs of litigation or an appropriate portion thereof to an agency or the requester if the court finds that the legal challenge under this chapter was frivolous.

(c) **Other sanctions.** — Nothing in this act shall prohibit a court from imposing penalties and costs in accordance with applicable rules of court.

Section 1305. Civil penalty.

(a) **Denial of access.** — A court may impose a civil penalty of not more than $1,500 if an agency denied access to a public record in bad faith.

(b) **Failure to comply with court order.** — An agency or public official who does not promptly comply with a court order under this act is subject to a civil penalty of not more than $500 per day until the public records are provided.

Section 1306. Immunity.

(a) **General rule.** — Except as provided in sections 1304 and 1305 and other statutes governing the release of records, no agency, public official or public employee shall be liable for civil penalties resulting from compliance or failure to comply with this act.

(b) **Schedules.** — No agency, public official or public employee shall be liable for civil or criminal damages or penalties under this act for complying with any written public record retention and disposition schedule.

Section 1307. Fee limitations.

(a) **Postage.** — Fees for postage may not exceed the actual cost of mailing.

(b) **Duplication.** —

(1) Fees for duplication by photocopying, printing from electronic media or microfilm, copying onto electronic media, transmission by facsimile or other electronic means and other means of duplication shall be established:

(i) by the Office of Open Records, for Commonwealth agencies and local agencies;

(ii) by each judicial agency; and

(iii) by each legislative agency.

(2) The fees must be reasonable and based on prevailing fees for comparable duplication services provided by local business entities.

(3) Fees for local agencies may reflect regional price differences.

(4) The following apply to complex and extensive data sets, including geographic information systems or integrated property assessment lists.

(i) Fees for copying may be based on the reasonable market value of the same or closely related data sets.

(ii) Subparagraph (i) shall not apply to:

(A) a request by an individual employed by or connected with a newspaper or magazine of general circulation, weekly newspaper publication, press association or radio or television station, for the purpose of obtaining information for publication or broadcast; or

(B) a request by a nonprofit organization for the conduct of educational research.

(iii) Information obtained under subparagraph (ii) shall be subject to paragraphs (1), (2) and (3).

(c) **Certification.** — An agency may impose reasonable fees for official certification of copies if the certification is at the behest of the requester and for the purpose of legally verifying the public record.

(d) **Conversion to paper.** — If a record is only maintained electronically or in other nonpaper media, duplication fees shall be limited to the lesser of the fee for duplication on paper or the fee for duplication in the original media as provided by subsection (b) unless the requester specifically requests for the record to be duplicated in the more expensive medium.

(e) **Enhanced electronic access.** — If an agency offers enhanced electronic access to records in addition to making the records accessible for inspection and duplication by a requester as required by this act, the agency may establish user fees specifically for the provision of the enhanced electronic access, but only to the extent that the enhanced electronic access is in addition to making the records accessible for inspection and duplication by a requester as required by this act. The user fees for enhanced electronic access may be a flat rate, a subscription fee for a period of time, a per-transaction fee, a fee based on the cumulative time of system access or any other reasonable method and any combination thereof. The user fees for enhanced electronic access must be reasonable, must be approved by the Office of Open Records and may not be established with the intent or effect of excluding persons from access to records or duplicates thereof or of creating profit for the agency.

(f) **Waiver of fees.** — An agency may waive the fees for duplication of a record, including, but not limited to, when:

(1) the requester duplicates the record; or

(2) the agency deems it is in the public interest to do so.

(g) **Limitations.** — Except as otherwise provided by statute, no other fees may be imposed unless the agency necessarily incurs costs for complying with the request, and such fees must be reasonable. No fee may be imposed for an agency's review of a record to determine whether the record is a public record, legislative record or financial record subject to access in accordance with this act.

(h) **Prepayment.** — Prior to granting a request for access in accordance with this act, an agency may require a requester to prepay an estimate of the fees authorized under this section if the fees required to fulfill the request are expected to exceed $100.

Section 1308. Prohibition.

A policy or regulation adopted under this act may not include any of the following:

(1) A limitation on the number of records which may be requested or made available for inspection or duplication.

(2) A requirement to disclose the purpose or motive in requesting access to records.

Section 1309. Practice and procedure.

The provisions of 2 Pa.C.S. (relating to administrative law and procedure) shall not apply to this act unless specifically adopted by regulation or policy.

Section 1310. Office of Open Records.

(a) **Establishment.** — There is established in the Department of Community and Economic Development an Office of Open Records.

The office shall do all of the following:

(1) Provide information relating to the implementation and enforcement of this act.

(2) Issue advisory opinions to agencies and requesters.

(3) Provide annual training courses to agencies, public officials and public employees on this act and 65 Pa.C.S. Ch. 7 (relating to open meetings).

(4) Provide annual, regional training courses to local agencies, public officials and public employees.

(5) Assign appeals officers to review appeals of decisions by Commonwealth agencies or local agencies, except as provided in section 503(d), filed under section 1101 and issue orders and opinions. The office shall employ or contract with attorneys to serve as appeals officers to review appeals and, if necessary, to hold hearings on a regional basis under this act. Each appeals officer must comply with all of the following:

(i) Complete a training course provided by the Office of Open Records prior to acting as an appeals officer.

(ii) If a hearing is necessary, hold hearings regionally as necessary to ensure access to the remedies provided by this act.

(iii) Comply with the procedures under section 1102(b).

(6) Establish an informal mediation program to resolve disputes under this act.

(7) Establish an Internet website with information relating to this act, including information on fees, advisory opinions and decisions and the name and address of all open records officers in this Commonwealth.

(8) Conduct a biannual review of fees charged under this act.

(9) Annually report on its activities and findings to the Governor and the General Assembly. The report shall be posted and maintained on the Internet website established under paragraph (7).

(b) **Executive director.** — Within 90 days of the effective date of this section, the Governor shall appoint an executive director of the office who shall serve for a term of six years. Compensation shall be set by the Executive Board established under section 204 of the act of April 9, 1929 (P.L.177, No.175), known as The Administrative Code of 1929. The executive director may serve no more than two terms.

(c) **Limitation.** — The executive director shall not seek election nor accept appointment to any political office during his tenure as executive director and for one year thereafter.

(d) **Staffing.** — The executive director shall appoint attorneys to act as appeals officers and additional clerical, technical and professional staff as may be appropriate and may contract for additional services as necessary for the performance of the executive director's duties. The compensation of attorneys and other staff shall be set by the Executive Board. The appointment of attorneys shall not be subject to the act of October 15, 1980 (P.L.950, No.164), known as the Commonwealth Attorneys Act.

(e) **Duties.** — The executive director shall ensure that the duties of the Office of Open Records are carried out and shall monitor cases appealed to the Office of Open Records.

(f) **Appropriation.** — The appropriation for the office shall be in a separate line item and shall be under the jurisdiction of the executive director.

CHAPTER 15. STATE-RELATED INSTITUTIONS

Section 1501. Definition.

As used in this chapter, "State-related institution" means any of the following:

(1) Temple University.

(2) The University of Pittsburgh.

(3) The Pennsylvania State University.

(4) Lincoln University.

Section 1502. Reporting.

No later than May 30 of each year, a State-related institution shall file with the Governor's Office, the General Assembly, the Auditor General and the State Library the information set forth in section 1503.

Section 1503. Contents of report.

The report required under section 1502 shall include the following:

(1) Except as provided in paragraph (4), all information required by Form 990 or an equivalent form, of the United States Department of the Treasury, Internal Revenue Service, entitled the Return of Organization Exempt From Income Tax, regardless of whether the State-related institution is required to file the form by the Federal Government.

(2) The salaries of all officers and directors of the State-related institution.

(3) The highest 25 salaries paid to employees of the institution that are not included under paragraph (2).

(4) The report shall not include information relating to individual donors.

Section 1504. Copies and posting.

A State-related institution shall maintain, for at least seven years, a copy of the report in the institution's library and shall provide free access to the report on the institution's Internet website.

CHAPTER 17. STATE CONTRACT INFORMATION

Section 1701. Submission and retention of contracts.

(a) **General rule.** — Whenever any Commonwealth agency, legislative agency or judicial agency shall enter into any contract involving any property, real, personal or mixed of any kind or description or any contract for personal services where the consideration involved in the contract is $5,000 or more, a copy of the contract shall be filed with the Treasury Department within ten days after the contract is fully executed on behalf of the Commonwealth agency, legislative agency or judicial agency or otherwise becomes an obligation of the Commonwealth agency, legislative agency or judicial agency. The provisions of this chapter shall not apply to contracts for services protected by a privilege. The provisions of this chapter shall not apply to a purchase order evidencing fulfillment of an existing contract but shall apply to a purchase order evidencing new obligations. The following shall apply:

(1) Each Commonwealth agency, legislative agency and judicial agency shall submit contracts in a form and structure mutually agreed upon by the Commonwealth agency, legislative agency or judicial agency and the State Treasurer.

(2) The Treasury Department may require each Commonwealth agency, legislative agency or judicial agency to provide a summary with each contract, which shall include the following:

(i) Date of execution.

(ii) Amount of the contract.

(iii) Beginning date of the contract.

(iv) End date of the contract, if applicable.

(v) Name of the agency entering into the contract.

(vi) The name of all parties executing the contract.

(vii) Subject matter of the contract.

Each agency shall create and maintain the data under this paragraph in an ASCII-delimited text file, spreadsheet file or other file provided by Treasury Department regulation.

(b) **Retention.** — Every contract filed pursuant to subsection (a) shall remain on file with the Treasury Department for a period of not less than four years after the end date of the contract.

(c) **Accuracy.** — Each Commonwealth agency, legislative agency and judicial agency is responsible for verifying the accuracy and completeness of the information that it submits to the State Treasurer. The contract provided to the Treasury Department pursuant to this chapter shall be redacted in accordance with applicable provisions of this act by the agency filing the contract to the Treasury Department.

(d) **Applicability.** — The provisions of this act shall not apply to copies of contracts submitted to the Treasury Department, the Office of Auditor General or other agency for purposes of audits and warrants for disbursements under section 307, 401, 402 or 403 of the act of April 9, 1929 (P.L.343, No.176), known as The Fiscal Code.

Section 1702. Public availability of contracts.

(a) **General rule.** — The Treasury Department shall make each contract filed pursuant to section 1701 available for public inspection either by posting a copy of the contract on the Treasury Department's publicly accessible Internet website or by posting a contract summary on the department's publicly accessible Internet website.

(b) **Posting.** — The Treasury Department shall post the information received pursuant to this chapter in a manner that allows the public to search contracts or contract summaries by the categories enumerated in section 1701(a)(2).

(c) **Request to review or receive copy of contract.** — The Treasury Department shall maintain a page on its publicly accessible Internet website that includes instructions on how to review a contract on the Internet website.

(d) **Paper copy.** — A paper copy of a contract may be requested from the agency that executed the contract in accordance with this act.

CHAPTER 31. MISCELLANEOUS PROVISIONS

Section 3101. Applicability.

This Act shall apply to requests for information made after December 31, 2008.

Section 3101.1. Relation to other laws.

If the provisions of this act regarding access to records conflict with any other federal or state law, the provisions of this act shall not apply.

Section 3101.2. Severability.

All provisions of this act are severable.

Section 3102. Repeals.

Repeals are as follows:

(1) The General Assembly declares as follows:

(i) The repeal under paragraph (2)(i) is necessary to effectuate Chapter 17.

(ii) The repeals under paragraph (2)(ii) and (iii) are necessary to effectuate this act.

(2) The following acts and parts of acts are repealed:

(i) Section 1104 of the act of April 9, 1929 (P.L.177, No.175), known as The Administrative Code of 1929.

(ii) The act of June 21, 1957 (P.L.390, No.212), referred to as the Right-to-Know Law.

(iii) 62 Pa.C.S. § 106.

Section 3103. References.

Notwithstanding 1 PA.C.S. § 1937(B), a reference in a statute or regulation to the act of June 21, 1957 (P.L.390, No.212), referred to as the Right-to-Know Law, shall be deemed a reference to this act.

Section 3104. Effective date.

This act shall take effect as follows:

(1) The following provisions shall take effect immediately:

(i) Sections 101, 102 and 1310.

(ii) This section.

(2) Chapters 15 and 17 and sections 3102(1)(I) and 3102(2)(I) shall take effect July 1, 2008.

(3) The remainder of this act shall take effect January 1, 2009.

CERTIFIED MAIL

Mr. Robert Willert, Executive Director
Delaware County Regional Quality Control Authority
100 East Fifth Street
Chester, PA 19013

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the revised Delaware County Regional Quality Control Authority (DELCORA) Public Participation Plan (PPP) dated April 14, 2016. EPA has consulted with the Pennsylvania Department of the Environment (PADEP). EPA accepts the revised PPP and therefore it is now approved.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

COMBINED SEWER OVERFLOW (CSO)
LONG-TERM CONTROL PLAN UPDATE (LTCPU)
PUBLIC MEETINGS

Please join DELCORA for a series of public meetings on our Combined Sewer Overflow Long-Term Control Plan Update.

Learn about DELCORA's combined sewer system and the proposed strategies for significantly reducing combined sewer overflows to our rivers and streams. Please give us your feedback on items discussed at the scheduled meeting below.

1ST MEETING

TOPIC: Scope and Purpose of the Study
WHEN: Tuesday, March 15, 2016 at 6:00 PM (EST)
WHERE: Chester City Hall
Community Room (Room entrance facing Rt 291)
1 E. 4th Street, Chester, PA - 19013

General Email: ltcpinfo@delcora.org
General Phone Number: 610-876-5523

DELCORA Long Term Control Plan Update
PUBLIC MEETING NO. 1 NOTES

Meeting Title: PUBLIC MEETING NO 1

Date / Time: March 15, 2016 6:00 PM

Prepared By: Marlene Finizio

Location: Chester City Hall

Reviewed By: Michael Hope

Distributed: 4/12/16

Attendees:
Edwin Bothwell, DELCORA
Michael DiSantis, DELCORA
John Pileggi, DELCORA
Robert Willert, DELCORA
Lindsey Isler, DELCORA
Michael Hope, Greeley and Hansen
Marlene Finizio, Greeley and Hansen
See also Public Sign in Sheet

DELCORA held the first of a series of Long Term Control Plan Update (LTCPU) Public Meetings on Tuesday, March 15, 2016. The first public meeting was held to present to the public the Scope of Work and Purpose of the LTCP Update. DELCORA's goal of each public meeting is to inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies. The public meeting was held to as part of the Public Participation Plan. There were approximately 6 individuals from the public in attendance.

The following items were discussed and presented at the first public meeting:

- DELCORA General Introduction and Opening Remarks
- DELCORA Public Participation Plan Program Goals
- Review of DELCORA Service Area
- Combined Sewer Overflow (CSO) Definition and History
- History of Other USEPA LTCPs
- Background of DELCORA Long-Term Control Plan (LTCP)
- Review of DELCORA Consent Decree (CD) Requirements
- Financial Capabilities Assessment (FCA)
- Summary of Where We Are and Next Phase
- Listing of Future Public Meetings
- Public Locations for Review of Available Literature and Documentation
- Contact Information for DELCORA, Questions and DELCORA Website

A representative from the Chester Environmental Planning (CEP) was in attendance and commented on the meeting schedule. DELCORA indicated to the Chester Environmental Planning (CEP) that another meeting may be scheduled in May. **See the attached Public Comment and Response sheet.**

DELAWARE COUNTY REGIONAL WATER QUALITY AUTHORITY

LONG TERM CONTROL PLAN UPDATE

PUBLIC PARTICIPATION MEETING NO. 1
LTCPU SCOPE AND PURPOSE
March 15, 2016

RESPONSES TO PUBLIC COMMENTS

1. Comment: Why is there so much time between First and Second Public meetings?

   Response: ***The DELCORA Long Term Control Plan Update program was initiated in August 2015 along with the lodging of the DELCORA USEPA Consent Decree. Each Public Meeting was scheduled in coordination with Milestones in the program.***

   The first public meeting was held in March 2016 to allow time to develop substantial documentation and a schedule for discussion and presentation. The March 15th LTCPU kick-off meeting was to introduce the LTCPU program scope and purpose to the public.

   The second public meeting is scheduled in the 3rd quarter of 2017 to coincide with the system characterization milestone. Per the Public Participation Plan, DELCORA will hold a minimum of four (4) public meetings; however, other meetings will be scheduled as needed. DELCORA indicated that another meeting may be held in May 2016.

   The most important public meeting will be the third meeting to get input from the public on the LTCPU alternatives. This third meeting will be held in Chester City. The first meeting with USEPA was in January 2016.

2. Comment: Will there be timeline in the document handout?

   Response: ***A basic project schedule showing the timeline will be posted on the DELCORA website.***

Combined Sewer Overflow - Long Term Control Plan Update

DELCORA

Public Participation Meeting No. 1

LTCPU Scope and Purpose

March 15, 2016

Chester City Hall Community Room

1 E. 4th Street, Chester, PA

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Public Participation Plan Goals

- DELCORA's goals and objectives for the Public Participation Program are to :
  - Inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies
  - Educate the public
  - Address public concerns

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

General Information

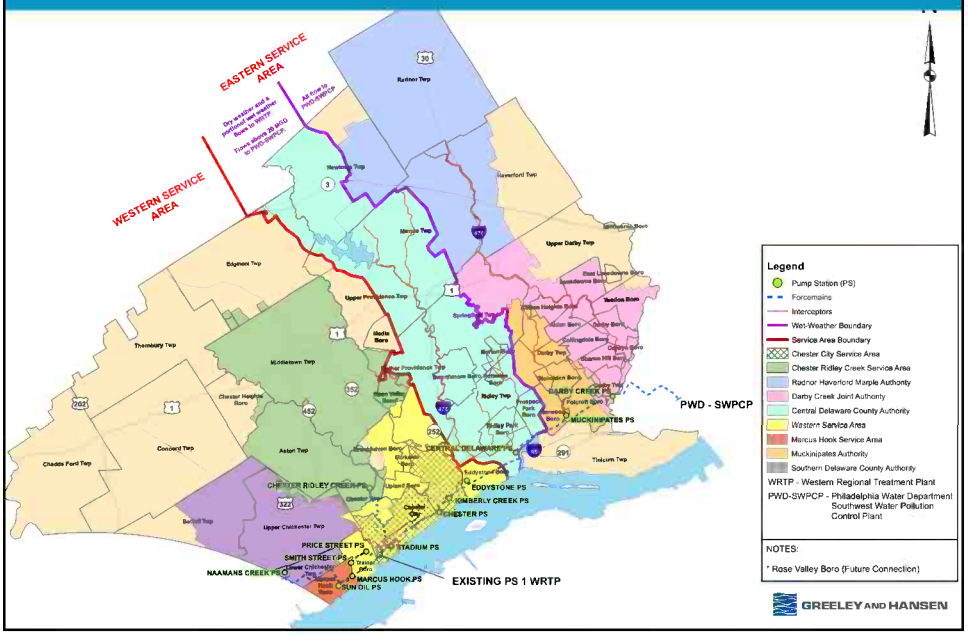
- DELCORA is the Delaware County Regional Water Quality Authority, established in 1971, responsible for collecting, conveying and treating wastewater in the greater Philadelphia Area including 42 Municipalities in Delaware and Chester County.

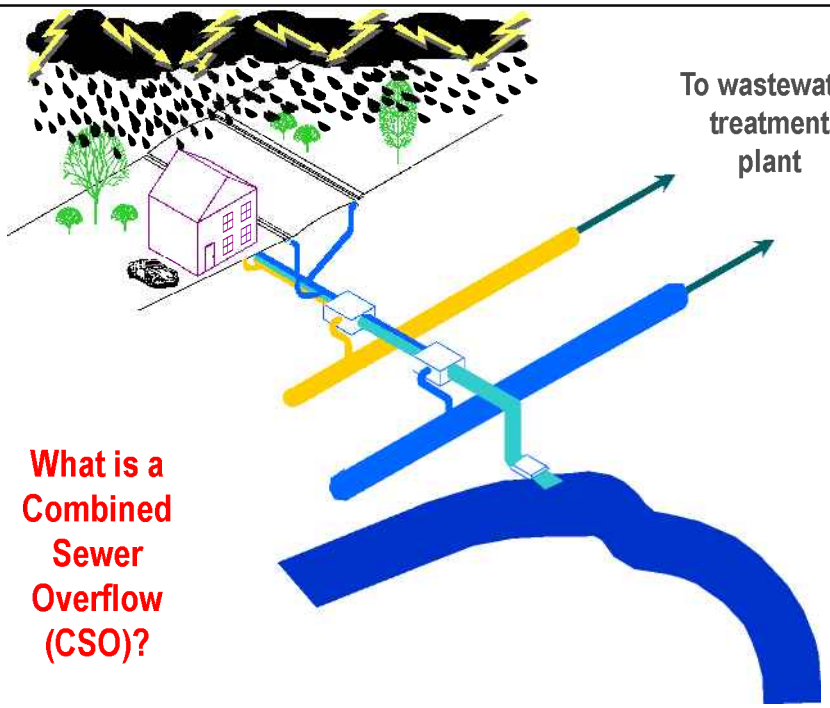
DELCORA Mission

"Provide environmentally responsible and cost effective wastewater management services to the citizens, businesses, and industries of Southeastern Pennsylvania"

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA Service Area





DELCORA

Definitions

- **LTCP:** The Long Term Control Plan is the document that lays out how DELCORA will maintain the outfalls and reduce the flow and/or treat the discharge from the outfalls to the water ways to meet the requirements of the Clean Water Act.
- **Sanitary Sewer:** The system that contains only waste from bathrooms, sinks, washers etc.
- **Storm Sewer:** Run off from streets.
- **Combined Sewer System:** Pipe that has both sanitary sewage and storm water in it.
- **Combined Sewer Overflow:** An overflow is the relief point in the combined sewer system that allows the extra flow when it rains to be discharged directly to streams and rivers.
- EPA: United States Environmental Protection Agency
- DEP: Pennsylvania Department of Environmental Protection

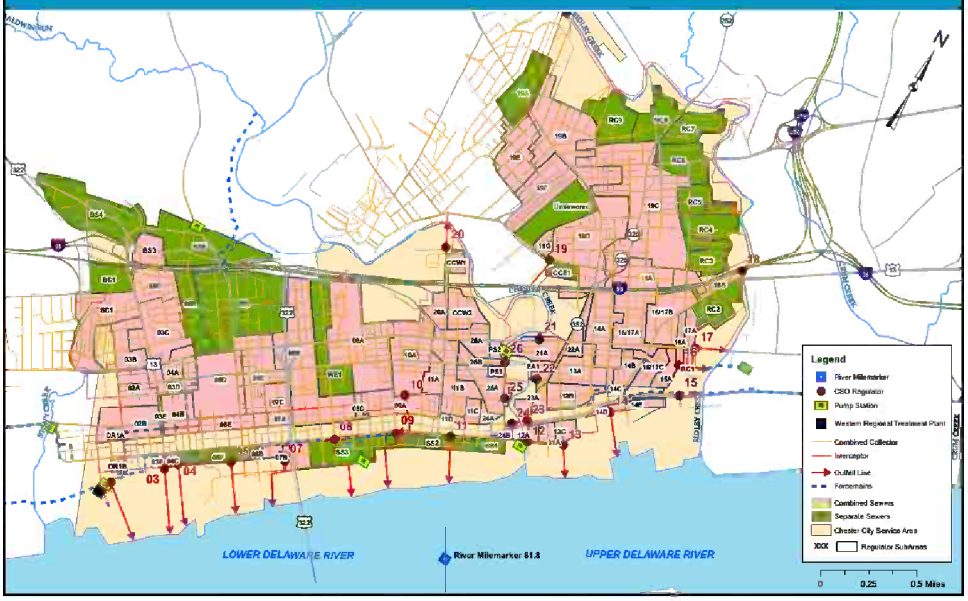
Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

History of Combined Sewer System

- In the early 1900's the City of Chester's Combined Sewer System was constructed.
  - This was, at the time, a typical engineering practice in Urban areas.
- In 1971 DELCORA became the owner of the existing Sanitary and Combined Sewer System in the City of Chester.
- Discharges from CSOs are authorized through the National Pollutants Discharge Elimination System (NPDES) permit during Wet Weather Flow.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA Combined Sewer Area



Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

History of EPA LTCPs

- LTCP Consent Decrees/Order for various wastewater systems not only throughout Pennsylvania, but the entire country.
  - Washington DC, New York City, Richmond,
- Current Pennsylvania communities already impacted by LTCP Consent Decree Costs & Fines:
  - Williamsport
  - Scranton
  - Harrisburg
  - Pittsburgh

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Philadelphia LTCP

- DELCORA is currently contributing to the Philadelphia LTCP.
  - Philadelphia's LTCP has an overall price tag of over $2 Billion over 25 years.
  - DELCORA's proportionate share of the Philadelphia LTCP is $178 million over 15 years due to the term of our contract with Philadelphia.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA LTCP Background

- In 1999 in response to increased environmental regulations, DELCORA implemented an LTCP for the DELCORA Combined Sewer System in the City of Chester.
- The LTCP identified capital improvements and operation and maintenance practices to reduce overflows.
- From 1999-2009 DELCORA spent in excess of $5 million on improvements and contributions to the City of Chester that resulted in decreased volume of overflows, reduced debris in overflows, provided remote monitoring of the system, and improved routine maintenance.
- In 2009, the DEP and EPA determined that DELCORA's LTCP was no longer in compliance with increased regulations of the Clean Water Act. In response, DELCORA began working with DEP and EPA to update the LTCP.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCP Background (Continued)

- In 2012, DELCORA submitted a revised LTCP to DEP and EPA.
- A key element in DELCORA's revised plan position was that the CSOs are only found in the City of Chester and the financial burden on the City of Chester residents must be considered.
- In 2014, DEP and EPA determined that DELCORA's revised LTCP required further evaluation and development so the Department of Justice was assigned to pursue a Consent Decree.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA Consent Decree

- The Consent Decree was agreed to by DELCORA on July 1, 2015 and signed into effect by the Dept. of Justice (DOJ) in November 2015. The Consent Decree is a legally binding agreement between DELCORA, EPA , and DEP in which DELCORA agrees to update the current LTCP.
- Generally, the Consent Decree consists of:
  - Compliance Measures
  - Milestones for plan update and implementation
  - Civil penalty
  - Stipulated penalties for non-compliance
- DELCORA has been given 42 months (3½ years) to develop a plan and 20 total years to implement the plan. When projects are complete and on-line, sewer fee charges will include costs for the updated LTCP.

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU Summary – Where We Are

- Hired expert consultants with a good track record as well as experience specifically related to the LTCP.
  - Greeley & Hansen: Engineering Consultant for the LTCP
  - Municipal & Financial Services Group: Rate Model Consultant
  - Blank Rome: Law Firm
- 100% compliance to date with Consent Decree
  - Submitted to date :
    - Public Participation Plan
    - Hydrologic and Hydraulic Model Update and Calibration Plan
    - Typical Hydrologic Period Plan
    - Semi-Annual Report
    - Sensitive Areas and Pollutants of Concern Report
  - To be Submitted by May 17, 2016
    - Draft FCA and Alternative Evaluation Report

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Financial Capability Assessment (FCA)

- The Consent Decree requires DELCORA to submit a DRAFT FCA by May 17, 2016 and FINAL FCA at the end of the project.
- Financial Capability Assessment's (FCA's) purpose is to determine the affordability of the LTCP.
- Develop fair, equitable, and legal cost share for conveyance, storage, and treatment of wet weather flows

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Financial Capability Assessment (FCA)

Financial Capability Matrix

Permittee Financial Capability Indicators Score (Socioeconomic, Debt & Financial Indicators)	Residential Indicator (Cost Per Household as a % of MHI)		
	Low (1.0% and Below)	Mid-Range (Between 1.0% and 2.0%)	High (2.0% and Above)
Weak (1.5 and Below)	Medium Burden	High Burden	High Burden
Mid-Range (Between 1.5 and 2.5)	Low Burden	Medium Burden	High Burden
Strong (2.5 and Above)	Low Burden	Low Burden	Medium Burden

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU Summary – Next Phase

- Sampling
- Flow Monitoring and Precipitation Monitoring Installation
- Data Analysis
- Model Development
- System Characterization
- Development and Evaluation of Alternatives for CSO Controls
- Selection and Implementation of the Long-Term Plan
- Continued Public and Stakeholder Involvement

Discussion - Q&A

COMBINED SEWER OVERFLOW (CSO)
LONG-TERM CONTROL PLAN UPDATE (LTCPU)
PUBLIC MEETINGS

Please join DELCORA for a series of public meetings on our Combined Sewer Overflow Long-Term Control Plan Update.

Learn about DELCORA's combined sewer system and the proposed strategies for significantly reducing combined sewer overflows to our rivers and streams. Please give us your feedback on items discussed at the scheduled meeting below.

2ND MEETING

TOPIC: Scope and Purpose of the Study
WHEN: Tuesday, June 27, 2017 at 6:00 PM (EST)
WHERE: Ridley Township Municipal Building
100 MacDade Boulevard, Folsom, PA 19033

General Email: ltcpinfo@delcora.org
General Phone Number: 610-876-5523

DELCORA Long Term Control Plan Update
PUBLIC MEETING NO. 2 NOTES

Meeting Title: PUBLIC MEETING NO 2

Date / Time: June 27, 2017 6:00 PM

Prepared By: Marlene Finizio

Location: **Ridley Township Municipal Building**
100 E. MacDade Boulevard
Folsom, PA

Reviewed By: Michael Hope

Distributed: 7/12/17

Attendees:
Robert Willert, DELCORA

DELCORA held the Second of a series of Long Term Control Plan Update (LTCPU) Public Meetings on Tuesday, June 27, 2017 at the Ridley Township Municipal Building, 100 E. MacDade Boulevard, Folsom, PA. The second public meeting was held to present to the public the LTCPU System Characterization for the LTCP Update. DELCORA's goal of each public meeting is to inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies. The public meeting was held to as part of the Public Participation Plan. There were approximately 6 individuals from the public in attendance. One representative from the University of Pennsylvania was present at the meeting.

The following items were discussed and presented at the first public meeting:

- DELCORA General Introduction and Opening Remarks
- DELCORA Public Participation Plan Program Goals
- Review of DELCORA Service Area
- Combined Sewer Overflow (CSO) Definition and History
- History of Other USEPA LTCPs
- Background of DELCORA Long-Term Control Plan (LTCP)
- Review of DELCORA Consent Decree (CD) Requirements
- Financial Capabilities Assessment (FCA)
- Summary of Where We Are and Next Phase
- LTCPU System Characterization
- LTCPU Sensitive Areas
- Listing of Future Public Meetings
- Public Locations for Review of Available Literature and Documentation
- Contact Information for DELCORA, Questions and DELCORA Website

Poster Boards were situated at the door of the Ridley Township Municipal Building to encourage public attendance and direct the public to the meeting room. Photos of Public Meeting No. 2 are shown below. **See the attached Public Comment and Response sheet.**

DELAWARE COUNTY REGIONAL WATER QUALITY AUTHORITY

LONG TERM CONTROL PLAN UPDATE

PUBLIC PARTICIPATION MEETING NO. 2
LTCPU DEVELOPMENT AND EVALUATION OF ALTERNATIVES FOR CSO CONTROLS
June 27, 2017

RESPONSES TO PUBLIC COMMENTS

1. Comment: How often does it happen that flow is sent to the WRTP from Central Pump Station?

   Response: ***Only when it rains and the flow is over 20 MGD at the Pump Station.***

2. Comment: Are any of the industrial users such as Kimberly Clark or Sun Oil impacting the CSO's System?

   Response: ***All Industries connect to the WRTP via force main. No, the industrial discharges do not have an impact on the CSO area or contribute to the CSOs.***

3. Comment: There is no primary contact on the Delaware? I have seen water skiing in this area.

   Response: ***South of mile marker 81.8, the Delaware River is designated for primary contact. The Delaware River is designated for secondary contact north of mile marker 81.8.***

4. Comment: Is fishing allowed from the embankment?

   Response: ***The Coast Guard does not allow fishing in this area.***
   (Doctor Marilyn Howarth): The Delaware River is not a body of water that fish should be eaten from.

5. Comment: Is there contact at the boat dock?

   Response: ***The boat launch is in the primary contact area of the Delaware River.***

6. Comment: Are water sampling results from both wet and dry weather sampling available for public review?

   Response: ***Sampling results are not currently available but will be published in the Water Quality Modeling Report when it is completed. The report will be available to the public on the DELCORA website.***

7. Comment: You mentioned that water quality information was gathered from the community groups. Which ones were used and how did you reach out?

   Response: ***The information is available on STORIT website.***

8. Comment: Did you ask Sierra Club for Data?

   Response: ***Only Federal or State databases were used.***

9. Comment: What are the beneficial uses of the receiving streams?

   Response: ***The Ridley and Chester Creeks are both designated for secondary contact.***

10. Comment: Is there swimming or drinking water use?

    Response: ***There are no drinking water intakes in the streams. Also, no swimming or full body immersion is allowed.***

11. Comment: Are the Chester and Ridley Creeks impaired by nutrients?

    Response: ***They are impaired by siltation.***

12. Comment: Are you going to continue rainfall and flow monitoring?

    Response: ***DELCORA is not anticipating doing any additional flow monitoring at this time. Sampling will resume after the CSO controls are implemented, to verify that the alternatives are reducing the quantity and frequency of CSOs.***

13. Comment: Philadelphia's LTCP that promotes the use of green infrastructure has gotten a lot of positive recognition. Are these types of projects good for Chester?

    Response: ***Yes. DELCORA is working with the City of Chester to develop a GI plan. Their consultant is working with DELCORA to evaluate Green Infrastructure. Green Infrastructure is required to be evaluated by the Consent Decree. At this time, we are not sure how many alternatives will be Green Infrastructure, but it is an option that is being looked at.***

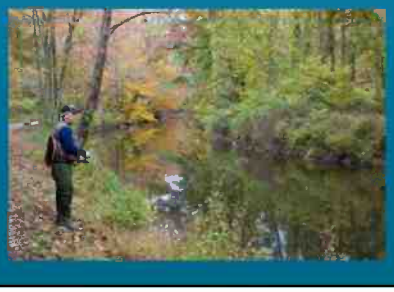
  - Williamsport
  - Scranton
  - Harrisburg
  - Pittsburgh



9

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Philadelphia LTCP

DELCORA is Currently Contributing to Philadelphia LTCP

- *The Philadelphia LTCP is currently being re-negotiated with EPA. The initial amount of the Philadelphia LTCP was approximately $2.2 billion. A recent Philadelphia bond document stated that the revised cost could be around $4.5 billion. It is uncertain what the outcome of the negotiations will be.*
- *DELCORA's proportionate share of Philadelphia's LTCP is dependent on the results of the Philadelphia – EPA negotiation. DELCORA's initial share as of 2013 was approximately $175 million. DELCORA is waiting for Philadelphia to confirm its revised cost. The term of the DELCORA - PWD contract runs from 2013 to 2028.*

10

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA LTCP Background

- In 1999 in response to increased environmental regulations, DELCORA implemented an LTCP for the DELCORA Combined Sewer System in the City of Chester.
- The LTCP identified capital improvements and operation and maintenance practices to reduce overflows.
- From 1999-2009 DELCORA spent in excess of $5 million on improvements and contributions to the City of Chester that resulted in decreased volume of overflows, reduced debris in overflows, provided remote monitoring of the system, and improved routine maintenance.
- In 2009, the DEP and EPA determined that DELCORA's LTCP was no longer in compliance with increased regulations of the Clean Water Act. In response, DELCORA began working with DEP and EPA to update the LTCP.

11

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCP Background (Continued)

- In 2012, DELCORA submitted a revised LTCP to DEP and EPA.
- A key element in DELCORA's revised plan position was that the CSOs are only found in the City of Chester and the financial burden on the City of Chester residents must be considered.
- In 2014, DEP and EPA determined that DELCORA's revised LTCP required further evaluation and development so the Department of Justice was assigned to pursue a Consent Decree.

12

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

DELCORA Consent Decree

- The Consent Decree was agreed to by DELCORA on July 1, 2015 and signed into effect by the Dept. of Justice (DOJ) in November 2015. The Consent Decree is a legally binding agreement between DELCORA, EPA , and DEP in which DELCORA agrees to update the current LTCP.
- Generally, the Consent Decree consists of:
  - Compliance Measures
  - Milestones for Plan Update and Implementation
  - Civil Penalty
  - Stipulated Penalties for Non-Compliance
- DELCORA has been given 42 months (3½ years) to develop a plan and 20 total years to implement the plan. When projects are complete and on-line, sewer fee charges will include costs for the updated LTCP.

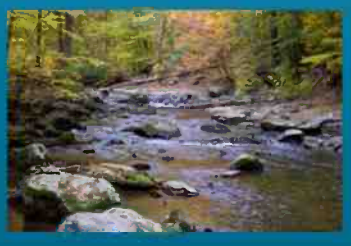
LTCPU Summary – Where We Are

- Hired Expert Consultants with Good Track Records as Well as Experience Specifically Related to LTCP
  - Greeley & Hansen: Engineering Consultant for the LTCP
  - Municipal & Financial Services Group: Rate Model Consultant
  - Blank Rome: Law Firm
- 100% Compliance to Date with Consent Decree
  - Reports Submitted to Date :
    - Public Participation Plan
    - Hydrologic and Hydraulic Model Update and Calibration Plan
    - Typical Hydrologic Period Plan
    - Semi-Annual Reports for 2015 and 2016
    - Sensitive Areas and Pollutants of Concern Report



14

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU Summary – Where We Are

- 100% Compliance to Date with Consent Decree (Continued)
  - Reports Submitted to Date (Continued):
    - Draft Financial Capabilities Assessment (FCA) Report
    - Alternative Evaluation Approach
    - Rainfall and Flow Monitoring Quarterly Reports for 1st , 2nd, 3rd, and 4th Quarters
    - Water Quality Monitoring and Modeling Work Plan
    - Water Quality Monitoring and Modeling Quality Assurance Project Plan

15

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

Financial Capability Assessment (FCA)

- The Consent Decree Requires DELCORA to Submit a DRAFT FCA by May 17, 2016 and a FINAL FCA at End of Project. The Draft FCA was submitted on May 13, 2016.
- FCA's Purpose is to Determine Affordability of LTCP
- Develop Fair, Equitable, and Legal Cost Share for Conveyance, Storage and Treatment of Wet Weather Flows

Notes:
(1) CSO Regulator #010 Discharges to Delaware River through CSO Outfall #009
(2) No Mechanical Regulator Used for this Outfall
(3) Regulator No Longer Connected to Combined Sewer System, but has not yet been Deleted from NPDES Permit

24

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU System Characterization

- Receiving Water Characteristics
- Receiving Waters: Delaware River (Downstream of R.M. 81.8), Delaware River (Upstream of R.M. 81.8), Chester Creek, and Ridley Creek
- Parameters Considered: DRBC WQR, PA Code, NPDES Permit, CSO Guidance Document, 303(d) List, Detected at Plant Influent.
- Identified Pollutants of Concern (POCs) for each Receiving Water Body
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - Escherichia Coli (E. Coli) Bacteria

25

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU System Characterization

- Combined Sewer System Modeling
  - Based on EPA Storm Water Management Model (SWMM)
- Simulates Runoff and Flow of Sewage Through Collection System During Storm Events
- Used to Estimate Existing (Baseline) CSO Discharge Volume to Receiving Water Bodies
- Used to Evaluate Effect of Proposed CSO Control Alternatives on CSO Discharge Volume
  - Helps Evaluate Effectiveness of Proposed Alternative

26

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU System Characterization

- Water Quality Modeling
  - Software - Environmental Fluid Dynamics Code (EFDC)
- Simulate Effect of CSOs on Water Quality of Receiving Streams under Existing Conditions (Baseline)
- Used to Evaluate Effect of Proposed CSO Control Alternatives on Water Quality

27

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU System Characterization

- Final System Characterization Report
  - Submit Report to USEPA by August 2017
  - Baseline H&H Modeling Results
- Final Water Quality Modeling Results Report Complete and Submitted by February 2018

28

Delaware County Regional Water Quality Control Authority
DELCORA
Delaware County, PA

LTCPU Sensitive Areas

- Sensitive Areas
- Conducted Survey to Assist in Designated Use Determination Per Consent Decree
- The CSO Control Policy states the six (6) criteria for defining an area as a "Sensitive Area" include:
  1. Designated Outstanding National Resource Waters
  2. National Marine Sanctuaries
  3. Waters with Threatened or Endangered Species and Their Habitat
  4. Waters with Primary Contact Recreation
  5. Public Drinking Water Intakes or Their Designated Protected Areas
  6. Shellfish Beds

Future Public Meetings

- **3nd Meeting – December 5, 2017**
  - Topic: **Development and Evaluation of Alternatives for CSO Controls**
  - When: 4th Quarter 2017
  - Where: Chester City Hall
    1 E. 4th Street; Chester, PA 19103
- **4th Meeting**
  - Topic: **Selection and Implementation of the Long-Term Plan**
  - When: 3rd Quarter 2018
  - Where: Aston Township Administration Building
    5021 Pennell Road; Aston, PA 19014

31

Delaware County Regional Water Quality Control Authority

COMBINED SEWER OVERFLOW (CSO)
LONG-TERM CONTROL PLAN UPDATE (LTCPU)
PUBLIC MEETINGS

Please join DELCORA for a series of public meetings on our Combined Sewer Overflow Long-Term Control Plan Update.

Learn about DELCORA's combined sewer system and the proposed strategies for significantly reducing combined sewer overflows to our rivers and streams. Please give us your feedback on items discussed at the scheduled meeting below.

3rd MEETING

TOPIC:	**Development and Evaluation of Alternatives for CSO Controls**
WHEN:	**Tuesday, December 5, 2017 at 6:00 PM (EST)**
WHERE:	**Chester City Hall** **Community Room (Room entrance facing Rt 291)** **1 E. 4th Street, Chester, PA - 19013**

General Email: ltcpinfo@delcora.org
General Phone Number: 610-876-5523

DELCORA Long Term Control Plan Update
PUBLIC MEETING NO. 3 NOTES

Meeting Title: PUBLIC MEETING NO 3

Date / Time: December 05, 2017 6:00 PM

Prepared By: Marlene Finizio

Location: Chester City Hall

Reviewed By: Michael Hope

Distributed: 12/13/17

Attendees:

Charles Hurst, DELCORA
John Pileggi, DELCORA
Robert Willert, DELCORA
Lindsey Isler, DELCORA
Michael Hope, Greeley and Hansen
Marlene Finizio, Greeley and Hansen
See Attached Public Sign in Sheet

DELCORA held the 3rd Long Term Control Plan Update (LTCPU) Public Meetings on Tuesday, December 05, 2017. The third public meeting was held to present to the public LTCPU Development and Evaluation of Alternatives for CSO Controls of the LTCP Update. DELCORA's goal of each public meeting is to inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies. The public meeting was held to as part of the Public Participation Plan.

The following items were discussed and presented at the third public meeting:

1. DELCORA General Introduction and Opening Remarks
2. DELCORA Public Participation Plan Program Goals
3. Review of DELCORA Service Area and Combined Sewer Area
4. Chester City Municipal Separate Storm Sewer System (MS$) area
5. Combined Sewer System VS separate Sewer system
6. LTCP Summary – Completed
7. LTCPU 42-Month Program Schedule & Milestones
8. LTCPU Alternative Evaluation
9. Review of National CSO policy Requirements
10. Review of DELCORA Consent Decree (CD) Requirements
11. Review of USEPA CSO Guidance for LTCP's
12. Review of the Preliminary Screening purpose and methodology
13. Preliminary Screening requirements of the Consent Decree. Retain technologies as required by Consent Order regardless of ranking.
    - Partial and Complete Separation of Sewer
    - Deep Tunnel Storage
    - Expansion of Primary and Secondary Capacity of WRTP
    - Green Infrastructure
14. Alternatives Evaluation and Next Steps
15. LTCP Program Schedule
16. LTCPU Consent Decree Early Action Item
17. Future Public Meetings
18. Literature and Documentation –
    - Listing of Future Public Meetings
    - Public Locations for Review of Available Literature and Documentation

19. DELCORA Website Information address and information available on their website.
20. Contact Information for DELCORA, Questions and DELCORA Website

A lengthy question and comments session occurred after the presentation was completed. The list of questions/ comments with responses to comments is attached.

There were approximately 37 individuals from the public in attendance including Mayor of the Chester City. Individuals from Chester City Council, Chester City Engineer and Chester

See attached Public Comment and Response sheet.

ACTION ITEMS:

1. DELCORA will make the schedule for the LTCP Update Program available on their website.
2. DELCORA will upload the public meeting notes with sign in sheet to their website.

DELAWARE COUNTY REGIONAL WATER QUALITY AUTHORITY

LONG TERM CONTROL PLAN UPDATE

PUBLIC PARTICIPATION MEETING NO. 3
LTCPU DEVELOPMENT AND EVALUATION OF ALTERNATIVES FOR CSO CONTROLS
December 5, 2017

RESPONSES TO PUBLIC COMMENTS

1. Comment: How is the City of Chester's stormwater management plan different from DELCORA's plan that was just presented?

   Response: ***The green area on the right of the figure is the separate sewer area. The City of Chester owns the stormwater infrastructure in this area and it is controlled by The City's Stormwater Authority. The pink area on the left of the figure is the combined sewer area. DELCORA owns and operates the combined sewers and is responsible for treating the combined sewage that enters this system. DELCORA is tasked with reducing combined sewer overflows from the EPA and PADEP, which is the purpose of the Long Term Control Plan presented at this meeting. DELCORA is not involved with controlling separated stormwater.***

2. Comment: Where does the new [City of Chester] Stormwater Authority come into play?

   Response: ***DELCORA is charged with operating and maintaining the combined sewers and cannot answer for the Stormwater Authority.***

3. Comment: Will a percentage of what is paid on our sewer bills go toward the DELCORA CSO Long Term Control Plan?

   Response: ***Yes. Development and implementation of the LTCP has a financial cost. We are working with EPA to determine what those costs will be, but we expect them to be significant. As a proactive measure, DELCORA is putting money aside to pay for the LTCP now and using come of that money to upgrade the pump station.***

4. Comment: That makes sense. So, in other words the rates will go up over time?

   Response: ***That is correct.***

5. Comment: Does the City have a stormwater plan?

   Response: ***Yes, but only the Chester City Stormwater Authority can speak to their plan. DELCORA coordinated with the Chester City Engineer to delineate the separated sewer areas from the combined sewer areas using various field techniques. This work was mandated by the EPA and DOJ as part of the Consent Decree.***

6. Comment: Thank you for the presentation, it was very informative. How did the Long Term Control Plan come about? Was it mandated by the EPA and the Department of Justice that you do this? Was there a fine involved?

   Response: ***As mentioned at the top of the presentation, DELCORA reached a consent decree with the USEPA and PADEP and enforced by the DOJ, requiring DELCORA to submit an updated Long Term Control Plan. DELCORA did receive fines, but they were revised. CSO remediation can become very costly, so DELCORA has consistently advocated for the residents and businesses of Chester. At the same time, DELCORA is working toward meeting the requirements of the Consent Decree.***

7. Comment: If expansion at the WRTP was a viable option and was approved by the EPA and DEP, where would the funding come from? Would the cost be spread across customers?

   Response: ***DELCORA will examine many options for funding, but it usually falls on the customers. And it's not just the City of Chester customers, but any customer who is connected to DELCORA's sewer system.***

8. Comment: With DELCORA's nearly 50 years' experience it seems like the perfect option is to expand.

   Response: ***Plant expansion is one of many options that DELOCRA is looking at. It may seem like the most appropriate option on the surface, but a deeper understanding of all alternatives is needed first. That is the purpose of this meeting: to inform the public of the options that DELCORA is looking at for CSO control. Many of these alternatives may be more than DELCORA is capable of implementing. So the next step is to examine each option that is acceptable to the EPA and DEP and narrow down the list by performance and cost effectiveness. It's not the just City of Chester, but it's all of Delaware County that will be charged with this cost. That is the basis for how much money we need to spend according to the EPA and PADEP.***

9. Comment: I agree that the best option seems like expanding the WRTP. It makes a lot more sense because citizens can see where you are investing their money and it is a lot more tangible than some other options.

   Response: ***DELCORA is seriously looking at that option and has discussed it with several consulting engineers.***

10. Comment: Could you give a better estimate of the cost to install separate lines throughout the city?

Response: ***It would be a large number. Factored in with the geography of the City and the configuration of the system means that actually implementing this solution would be very difficult. Across the country there are hundreds of communities like Chester with combined systems. By and large these communities don't really separate unless it's a really conducive situation for separation. For instance, the area by Memorial park would be a good area for it because it can be done without a lot of impact on the neighborhood and the cost would be manageable. But most of the CSO communities, they're building tunnels, storage tanks, and some of the other things we talked about because separation is costly and can have a huge community impact.***

11. Comment: Which is safer to citizens' health, a combined sewer system or a separated system? What causes a 'Flint' problem? Is living in a combined sewer area a cause for concern?

Response: ***Flint is on everyone's minds right now. The good news for the City of Chester is that its drinking water comes from miles away. From a public health perspective, there are hundreds of communities that have combined systems. The mere presence of a combined system doesn't pose a public health threat. What poses a significant health risk in Flint is bad chemistry corroding existing drinking water distribution pipes. As you can see on this map of Delaware County, Chester is the only part of Delaware County that has these combined sewers and they are not used to convey drinking water.***

12. Comment: Is stormwater coming from upstream communities affecting runoff in the City of Chester because we are downstream from those communities?

Response: ***Stormwater from upstream communities generally does not make it into Chester or into the combined sewer system. For instance Ridley is prone to flooding during heavy rainfall but drains to Darby Creek, which runs right into the Delaware. The stormwater runoff from these areas does not run along the ground and make it into Chester's system. They have a separate pipe system that takes it to the creeks. These communities have MS4 permits to discharge stormwater into the creeks and are responsible to make sure that their wastewater is not getting into the stormwater system.***

13. Comment: If the plant were expanded, would the entire service area be part of the payment?

Response: ***It depends on which residents and businesses would be tied in to the system. DELCORA has been looking at different options. Although there would be a certain cost to build facilities, the thought is that a portion of that cost would be offset by redirecting the flow from the Central and Eastern Service areas that currently goes to Philadelphia.***

14. Comment: Where is your plant located?

Response: ***On the Delaware River waterfront at Booth Street.***

15. Comment: What is the focus of this plan for Chester?

Response: ***With this LTCP DELCORA's main focus is on the health and financial stability of its stakeholders. The focus for Chester is to limit the CSOs, which will in turn limit the amount of bacteria that goes into the streams, by capturing more flow and treating it safely and economically. Untreated wastewater can make you sick and hurt your pocketbooks.***

16. Comment: There is talk about cutting regulations at the federal level. What if they cut back your regulations?

Response: ***The bottom line is that we are bound by EPA and PADEP regulations. We need to work with these regulators to allow us to implement innovative solutions, such as blending at the WRTP. There are examples of that in other states. So if it is a safe, effective, and cost-effective solution we need to work with the regulators to advocate for what makes sense for our stakeholders, regardless of the political climate.***

17. Comment: What's the ratio of the area DELCORA is handling versus the City of Chester?

Response: ***We have been working very well with the City of Chester. Starting five years ago, DELCORA has had regular meetings with the City to collaborate and work on different projects to separate sewers. An example is the [Route] 291 project that was completed by DELCORA and the City of Chester. Working together allows us to get more bang for our buck.***

18. Comment: How much are we paying for Long Term Control currently?

Response: ***Right now DELCORA is just paying for the engineering cost to come up with all of these alternatives and produce a finished Long Term Control Plan. The capital cost of the LTCP will be determined when the LTCP is finished.***

19. Comment: How much of the engineering cost is being charged back to your customers?

Response: ***So far, none of it is because it's a capital plan with a capital cost. We are waiting for the project to be finished before we start charging the customers.***

20. Comment: What did Chester do with the $750,000 you gave them to put in new stormwater inlets?

Response: ***As part of the 1999 Long Term Control Plan we had in place, DELCORA paid the City $75,000 a year over a number of years to replace the stormwater inlets. So, from 1999 to about 2009-2010 at $75,000 a year, that totaled approximately $750,000. With that money the City replaced a certain amount of stormwater inlets per year. The new inlets have grates over them which are designed to prevent trash such as water bottles from going into the sewers and going into the streams. Once trash collects in these areas it is very difficult and costly to clean.***

Response: *(City Engineer) As the City engineer, I administered one year of that project myself. And we replaced about 16 inlets with that $75,000.*

21. Comment: What's going on with the pollution reduction plan?

Response: *(City Engineer): There is a pollution reduction plan, yes. The city has adopted a pollution reduction plan. It was presented in July and sent to the state in September.*

Response: ***If you have those types of questions, you can go to the city and they have those types of documents. They have an open records policy, so can look at the documents firsthand.***

22. Comment: Who cleans the stormwater inlets/grates?

Response: ***The City cleans the box [inlet] and grate. DELCORA cleans the CSO regulators and combined sewers.***

23. Comment: Unfortunately from the perspective of the residents, everything seems like it is addressing the same problem but each entity is charging a different fee. I understand there is storm sewers and combined sewers. But I do not understand why there is a City stormwater fee if we are paying DELCORA to address the stormwater issue in these areas.

Response: ***DELCORA is trying to address the stormwater that is going into its combined sewer collection system that causes CSOs. DELCORA cannot speak to the questions relating to the City of Chester Stormwater Authority or other entities.***

Combined Sewer Overflow - Long Term Control Plan Update

DELCORA

Public Participation Meeting No. 3

LTCPU Development and Evaluation of Alternatives for CSO Controls

December 5, 2017

Chester City Hall Community Room

1 E. 4th Street, Chester, PA

General Information

- DELCORA is the Delaware County Regional Water Quality Control Authority, established in 1971, responsible for collecting, conveying and treating wastewater in the greater Philadelphia Area including 42 Municipalities in Delaware and Chester County.

DELCORA Mission

"Provide environmentally responsible and cost effective wastewater management services to the citizens, businesses, and industries of Southeastern Pennsylvania"

Why Are We Here?

- From 1999-2009 DELCORA spent in excess of $5 million on improvements and contributions to the City of Chester that resulted in decreased volume of overflows, reduced debris in overflows, provided remote monitoring of the system, and improved routine maintenance.
- In 2009, the DEP and EPA determined that DELCORA's LTCP was no longer in compliance with increased regulations of the Clean Water Act. In response, DELCORA began working with DEP and EPA to update the LTCP.
- In 2014, DEP and EPA determined that DELCORA's revised LTCP required further evaluation and development.
- In 2015 DELCORA signed with EPA the Long Term Control Plan Consent Decree.

Public Participation Plan Goals

- DELCORA's Goals and Objectives for the Public Participation Program are to:
  - Inform and Solicit Input to Updated LTCP from Stakeholders, including Public, Customer Communities and Regulatory Agencies
  - Educate the Public
  - Address Public Concerns

Scope of Meeting

- This Public Meeting (12/5/17) is to:
  - Review DELCORA Service Area
  - Summarize Current Status of LTCP
  - Describe CSO Control Technologies
  - Describe Next Steps Towards Development of Long Term Control Plan Update
  - Questions and Comments

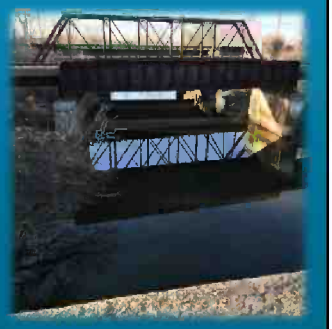
LTCPU Summary - Completed

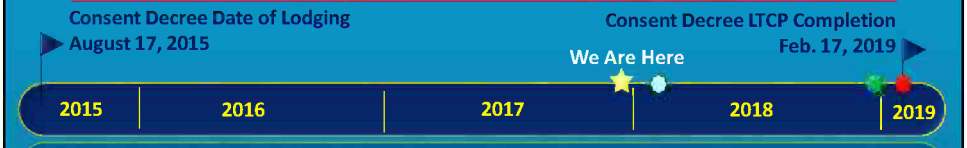
- Hired Expert Consultants with Good Track Records as Well as Experience Specifically Related to LTCP
  - Greeley & Hansen: Engineering Consultant for the LTCP
  - Municipal & Financial Services Group: Rate Model Consultant
  - Blank Rome: Law Firm
- **100% Compliant to Date with Consent Decree**
  - **Reports Submitted to Date**
    - ✓ Public Participation Plan
    - ✓ Hydrologic and Hydraulic (H&H) Model Update and Calibration Plan
    - ✓ Typical Hydrologic Period Plan
    - ✓ Semi-Annual Reports for 2015, 2016 & 2017
    - ✓ Sensitive Areas and Pollutants of Concern Report

LTCPU Summary - Completed

- 100% Compliant - Reports Submitted to Date (Continued):
  - ✓ Draft Financial Capabilities Assessment (FCA) Report
  - ✓ Alternative Evaluation Approach
  - ✓ Rainfall and Flow Monitoring Quarterly Reports for 1st , 2nd, 3rd, and 4th Quarters
  - ✓ Water Quality Monitoring and Modeling Work Plan
  - ✓ Water Quality Monitoring and Modeling Quality Assurance Project Plan
  - ✓ Study Area Collection System Model Report
  - ✓ Existing Service Area Characterization Report



LTCPU 42-Month Program Schedule & Milestones



Reports to Be Completed:

- ★ Public Participation Meeting - December 5, 2017
- ● Water Quality Monitoring and Modeling Report - Feb. 17, 2018
- ● Early Action Item, Complete PS-6 - December 2018
- ● Updated LTCP Final Report - Feb. 17, 2019
  - Includes Development and Comparison of Alternatives
- ● Updated Nine Minimum Controls Plan - Feb. 17, 2019

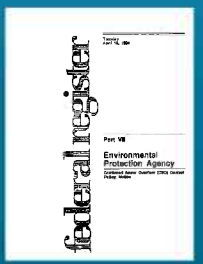
● Consent Decree Due Dates

LTCPU Alternatives Evaluation

- Review Regulatory Requirements
- Purpose of Preliminary Screening of CSO Alternatives
- Available Technologies
- Review Preliminary Screening Evaluation Method
- Alternatives Evaluation Next Steps
- Schedule
- Questions and Comments

National CSO Policy Requirements

- National CSO Policy
  - Consider reasonable range of alternatives.
  - Consider expansion of POTW secondary and primary capacity.
  - Sufficient to Make Reasonable Assessment of Cost and Performance
  - Selected Controls should be sufficient to meet CWA requirements.

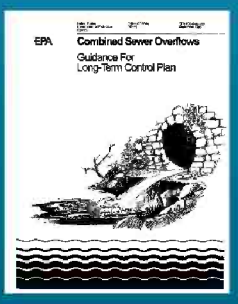


Consent Decree Requirements

- Consent Decree
  - *Consists of:*
    - *Technology screening process*
    - *Detailed evaluation of specific CSO control alternatives*
    - *Selection of an appropriate range of proposed CSO controls to achieve compliance with the Clean Water Act."*
    - *Does not consider cost-effectiveness (at the preliminary screening phase)*
- Specific technologies considered feasible by Consent Decree and must be carried forward for further evaluation.
  - Partial and Complete Separation of Sewers
  - Deep Tunnel Storage
  - Expansion of Primary and Secondary Capacity of WRTP
  - Green Infrastructure

USEPA CSO Guidance for LTCPs

- CSO Guidance for Long Term Control Plan
  - *"Can include technologies, operating strategies, public policies and regulations, or other measures that would contribute to some aspect of CSO control. Control measures can generally be classified under one of the following categories:*
    - *Source Controls*
    - *Collection System Controls*
    - *Storage Technologies*
    - *Treatment Technologies"*



Preliminary Screening

- Purpose of Preliminary Screening
  - Identify alternatives that best meet CSO Control Alternatives with least overall impacts and are worthy of additional evaluation.
    - Meet regulatory requirements.
    - Reduce Pollutants of Concern (bacteria) and/or volume reduction.

Preliminary Screening

- Pollutants of Concern (POCs) Approved by USEPA
- Bacteria: Fecal Coliform, E. Coli, and Enterococcus
- Other Sources of Bacteria from Tributary Flows to Chester and Ridley Creeks:
  - Pets, Wildlife, Livestock and Stormwater Runoff (Urban and Agricultural)

Preliminary Screening

- Methodology
  - Develop comprehensive list of technologies for each type of CSO Control Measure (Source, Collection System, Storage, Treatment).
  - Assign levels of effectiveness at reaching CSO Control Goals for reduction in bacteria or CSO volume

High Medium Low None

Preliminary Screening

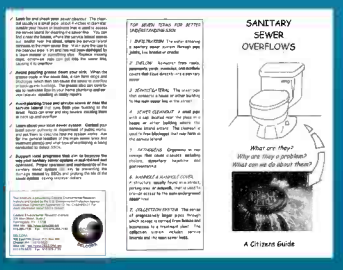
- High Significant Impact on CSO Control Goal and is Among Best Technologies Available
- Medium Effective at Achieving CSO Control Goal but is Not Considered Among Most Effective
- Low Minor Impact on CSO Control Goal
- None Zero or Negative Effect on CSO Control Goals

Preliminary Screening

- Retain technology if level of effectiveness is "HIGH" or "MEDIUM" based on volume or bacteria reduction.
- Retain technologies as required by Consent Order regardless of ranking.
  - Partial and Complete Separation of Sewers
  - Deep Tunnel Storage
  - Expansion of Primary and Secondary Capacity of WRTP
  - Green Infrastructure
- Develop alternatives from retained technologies.

Source Control

- Impact Quality or Quantity of Runoff Entering CSS; Reduce Volumes, Peak Flows or Pollutant Discharge
- Source Control Alternatives
  - Stormwater Management
  - Public Education and Outreach
  - Ordinance Enforcement
  - Good Housekeeping
  - Green Infrastructure
    - Buildings
    - Impervious Areas
    - Pervious Areas

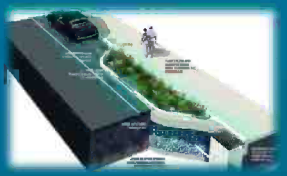


Green Infrastructure

- Green Infrastructure is an approach to water management that protects, restores or mimics the natural water cycle.
- Treats stormwater locally at the source.
- Includes rain gardens, bioswales, permeable pavement, green roofs, downspout disconnections, etc.

Green Infrastructure: Community Impacts

- **Environmental Impact:** Low Bacteria and Medium Volume Reduction
- **Social Impact**
  - Potential Development of Green Spaces in Areas Without It
  - Bioswales may reduce parking and narrow streets.
- **Financial Impact:** Costs of green infrastructure have been higher than gray; may have an impact on rates if used for LTCP compliance



Examples of Green Infrastructure Projects

Collection System Control Technology

- Reduce CSO volume and frequency by removing or diverting stormwater runoff to maximize capacity of collection system.
- Collection System Control Technology Alternatives
  - Inflow/Infiltration Control
  - Operation and Maintenance
  - Combined Sewer Separation
  - Combined Sewer Optimization

Inflow and Infiltration Reduction

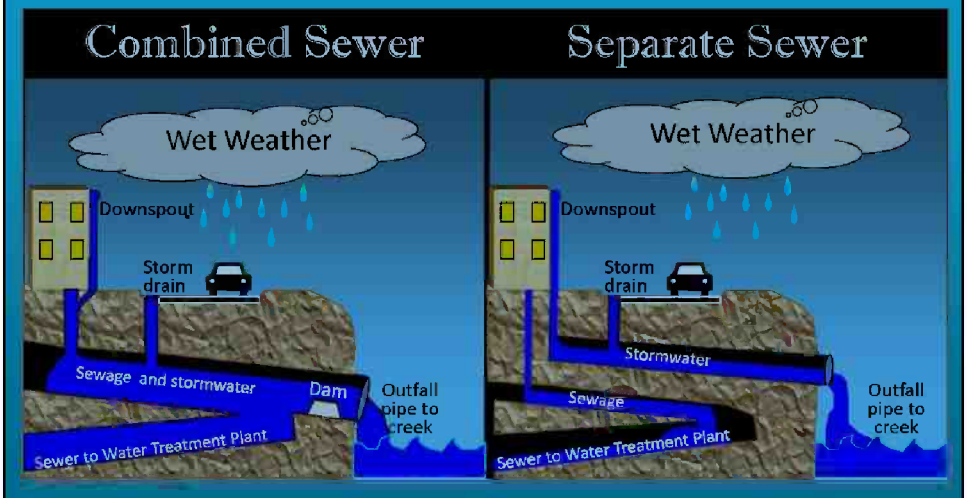
- I&I is water that enters Collection System through cracks, joints, etc.
- Rainfall and Groundwater Driven
- Some I&I is expected

- If removed, frees up capacity that would otherwise be available for combined sewage and adds to CSOs.

Inflow and Infiltration: Community Impacts

- **Environmental Impact:** Low Bacteria Reduction and Medium Volume Reduction
- **Social Impact:** Repairs on Private Property Required by Homeowners
- **Financial Impact:** Can be cost effective if sources of I/I are easily identified.

Combined Sewer Separation



Source: City of Alexandria, https://www.alexandriava.gov/uploadedFiles/tes/oeq/CSSPermitInfoMeetingandPublicHearingPresentation08052013.pdf

Combined Sewer Separation: Community Impacts

- **Environmental Impact:** Highly Effective in Reducing CSOs
- **Social Impact:** Disruptive to Affected Areas Due to Street Closures and Construction Access
- **Financial Impacts**
  - High Costs Due to Street Construction and Replacement
  - Long Construction Duration

Storage Technology

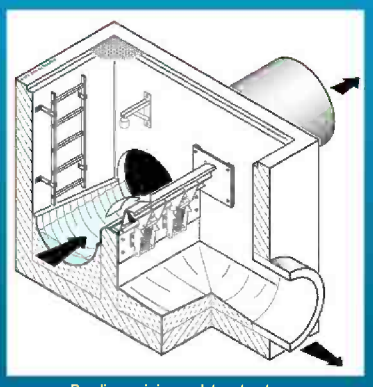
- Reduce overflows by capturing and storing excess wet weather flows.
- Control release of combined sewage back into system once treatment and conveyance capacity have been restored.
- Does not prevent water from entering Combined Sewer System or treat bacterial loads in CSO discharge; effective at reducing or eliminating CSO events.
- Storage Technology Alternatives
  - In Line Storage
  - Off Line Storage

Increased Collection System Storage

- Capture and hold volume until conveyance and treatment capacity return.
  - In line storage uses existing collection system for storage.
  - Off line storage includes the construction of Storage Tanks and Tunnels.

In Line Storage: Community Impacts

- **Environmental Impact:** High Bacteria and High Volume Reduction
- **Social Impact:** Minimal Impact on Community During Construction
- **Financial Impact:** Very Cost Effective Using Existing Infrastructure



Bending weir in regulator structure

Off-Line Storage: Community Impacts

Deep Tunnels

- **Environmental Impact:** Highly Effective in Reducing CSOs
- **Social Impact:** Construction Disturbances at Each Shaft Location which May be Sited in Locations to Minimize Public Disturbance
- **Financial Impact:** Cost Effective at High Removal Volumes

Off-Line Storage: Community Impacts

Storage Tanks

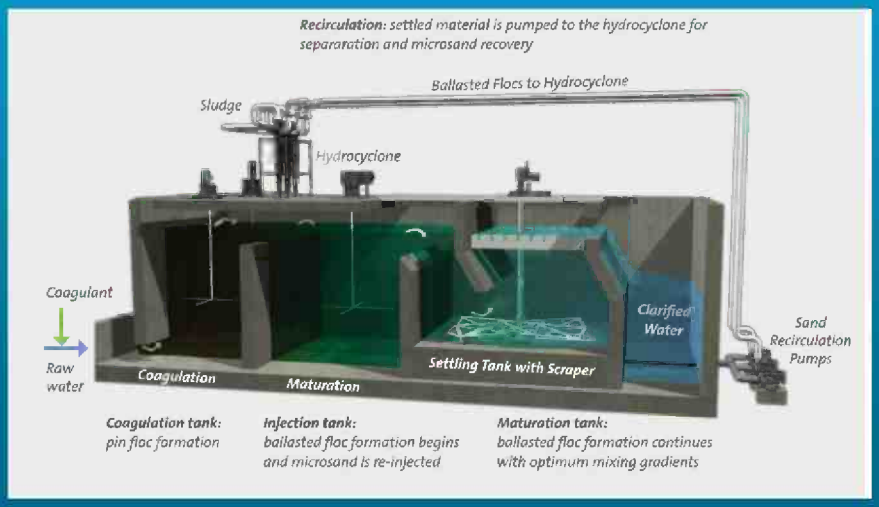
- **Environmental Impact:** Highly Effective in Reducing CSOs
- **Social Impact:**
  - Construction Disturbances at Tank Location Only
  - Can be Buried Under Playgrounds, Parking Lots or Other Community Structures
- Financial Impact: Cost Effective at High Removal Volumes

Examples of Storage Tank Projects from Methuen Construction Co.

Treatment Technology

- Reduce pollutant loads to receiving waters by treating wet weather flows.
- Addresses different pollutant constituents like settleable solids, floatables or bacteria.
- LTCPU will contain provisions for handling, treatment and ultimate disposal of sludge and residuals .
- Treatment Technology Alternatives
  - CSO Facility - Satellite Treatment
  - WRTP - Additional Treatment Plant Capacity, Wet Weather Blending
  - Industrial - Industrial Pretreatment

Satellite Treatment of CSO Discharge



Satellite Treatment Facility: Community Impacts

- **Environmental Impact:** High reduction of bacteria and CSO volume with disinfection
- **Social Impact:** Construction in collection system isolated to selected site.
- **Financial Impact:** Additional cost required for treatment equipment and disinfection.

Treatment or Storage at WRTP

- Convey additional flow to WRTP for treatment; Plant is already at Wet Weather Capacity so would require plant expansion.
- Use Study Area Collection System Model to evaluate sending additional flow to WRTP in order to consider potential overflow reduction.

Secondary Treatment Bypass

- Convey additional flow to WRTP for treatment.
- Blend primary treated effluent with secondary/biological treated effluent.
- Alleviates plant expansion needs to handle additional flows.
- Additional conveyance required.

Improvements at WRTP: Community Impacts

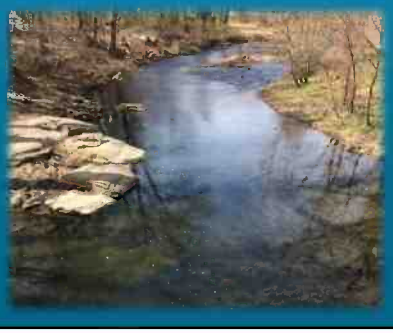
- Environmental Impact: High Bacteria and CSO volume reduction
- Social Impact:
  - No repairs on private property
  - Minimal street closures
- Financial Impact: Cost Effective Due to Available Land on Existing Plant Site and Shared Services with Existing Plant Operations

Alternatives Evaluation Next Steps

- LTCP CSO Control Alternative Evaluation
  - Alternatives Development and Modeling
  - Alternatives Cost / Performance Evaluation
  - Rating, Ranking and Recommendation
  - Financial Plan

LTCPU Program Schedule

- Consent Decree Deadlines and Schedule
  - Final Water Quality Monitoring and Modeling Report submitted by February 2018.
  - Final LTCPU Report due to USEPA by February 2019.
  - Early Action Items - End of 2018



LTCPU Consent Decree Early Action Item

- Consent Decree requires Early Action Combined Sewer Overflow Control Measures to reduce Combined Sewer Overflows.
  - New Pump Station - PS-6
    - Increased Capacity of Existing Pump Station at Western Regional Treatment Plant
    - Anticipated $15 Million Construction Cost
    - To be Completed by December 31, 2018

LTCPU Consent Decree Early Action Items

Future Public Meetings

- **4th Meeting**

  Topic: **Selection and Implementation of the Long-Term Plan**

  When: 3rd Quarter 2018

  Where: Aston Township Administration Building
  5021 Pennell Road; Aston, PA 19014

Literature and Documentation

- Literature and Documentation will be Made available by DELCORA at the following public locations and on the DELCORA Website:
  - **DELCORA Administration Building**
    100 East Fifth Street; Chester, PA 19013
  - **Lewis Crozer Library**
    620 Engle Street; Chester, PA 19013
  - **Marcus Hook Municipal Building**
    1015 Green Street; Marcus Hook, PA 19061
  - **Ridley Township Building**

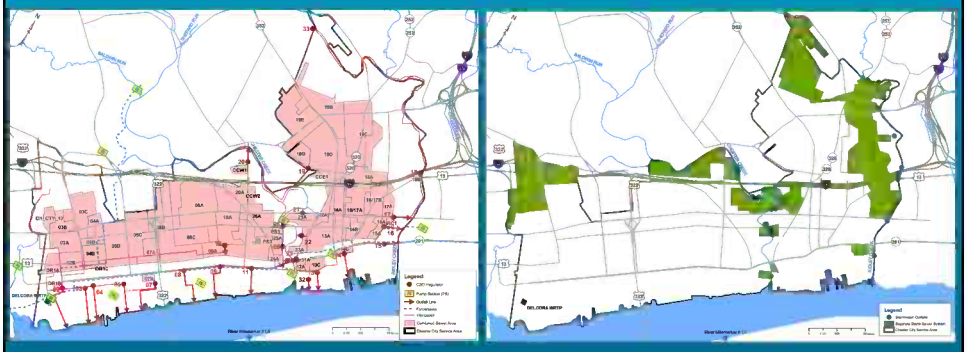
Discussion - Q&A

Combined Sewer vs. Chester City's MS4



End of Presentation

COMBINED SEWER OVERFLOW (CSO)
LONG-TERM CONTROL PLAN UPDATE (LTCPU)
PUBLIC MEETINGS

Please join DELCORA for a series of public meetings on our Combined Sewer Overflow Long-Term Control Plan Update.

Learn about DELCORA's combined sewer system and the proposed strategies for significantly reducing combined sewer overflows to our rivers and streams. Please give us your feedback on items discussed at the scheduled meeting below.

4th MEETING

TOPIC:	**Selection and Implementation of the Long-Term Plan**
WHEN:	**Wednesday, September 26, 2018 at 5:00-6:30 PM EST)**
WHERE:	**Aston Township Administration Building**
	5021 Pennell Road, Aston, PA 19014
	General Email: ltcpinfo@delcora.org
	General Phone Number: 610-876-5523

DELCORA Long Term Control Plan Update
PUBLIC MEETING NO. 4 NOTES

Meeting Title: PUBLIC MEETING NO 4

Date / Time: September 26, 2018 5:00 PM

Prepared By: Marcus Mathieson

Location: Aston Township Admin. Bldg.

Reviewed By: Jean Malfronte

Distributed: 9/26/18

Attendees:

Charles Hurst, DELCORA
John Pileggi, DELCORA
Mike DiSantis, DELCORA
Lindsey Isler, DELCORA
Michael Hope, Greeley and Hansen
Jean Malafronte, Greeley and Hansen
Marcus Mathieson, Greeley and Hansen
See Attached Public Sign in Sheet

DELCORA held the 4th Long Term Control Plan Update (LTCPU) Public Meetings on Wednesday, September 26, 2018 at 5:00 PM at the Aston Township Admin. Bldg. The fourth Public was originally advertised as starting at 6:00 however the start time had to be adjusted to 5:00 PM. The meeting was re-advertised to inform residents that the start was adjusted to 5:00 PM. The forth public meeting was held to present to the public LTCPU Development and Evaluation of Alternatives for CSO Controls of the LTCP Update. DELCORA's goal of each public meeting is to inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies. The public meeting was held to as part of the Public Participation Plan.

The following items were discussed and presented at the fourth public meeting:

1. DELCORA General Introduction and Opening Remarks
2. DELCORA Public Participation Plan Program Goals
3. Review of DELCORA Service Area and Combined Sewer Area
4. Chester City Municipal Separate Storm Sewer System (MS4) area
5. Combined Sewer System VS separate Sewer system
6. LTCPU 42-Month Program Schedule & Milestones
7. LTCP Completed Early Action Items and System Improvements to Date
8. Review of National CSO Policy Requirements for the Alternative Analysis
9. LTCPU Alternative Analysis
10. "Knee-of-the-Curve" Analysis and the Recommended Plan for the Selected Alternative
11. LTCP Implementation Schedule and Milestones
12. Available Literature and Documentation Locations for Public Review
13. DELCORA Website Information address and information available on their website.
14. Contact Information for DELCORA, Questions and DELCORA Website

There were no individuals from the public in attendance. Meeting was adjourned at approximately 5:30. There were two DELCORA consultants that arrived at the meeting location after adjournment. DELCORA met separately with the two consultants on November 1, 2018 and provided a hardcopy of the Public Meeting No. 4 presentation and handout materials and reviewed the materials with them. They had no

questions or feedback that would influence the LTCPU. They signed the meeting sign-in sheet, see attached.

A Public Briefing Document was posted on the website and delivered to the repositories 2 weeks before this meeting. The Public Briefing Document summarized the DELCORA Recommended Long Term Control Plan to address Combined Sewer Overflows in Chester, Pennsylvania where necessary. Also covered in the summary were the following key issues: (1) an overview of the DELCORA System and Wet Weather Issues, (2) a summary of progress to date, (3) response to public comments to date, (4) review of sensitive areas, (5) the range of alternatives considered, (6) DELCORA's recommended overflow control plan, (7) the implementation schedule and, (8) post construction monitoring of the overflow control program.

There were no questions from the public relating to the public briefing document posted on the Website or mailed.

ACTION ITEMS:

1. DELCORA will upload the public meeting notes with sign in sheet to their website.

Combined Sewer Overflow - Long Term Control Plan Update

DELCORA

Public Participation Meeting No. 4

LTCPU Development and Evaluation of Alternatives for CSO Controls

September 26, 2018

Aston Township Administration Building

5021 Pennell Road, Aston, PA 19014

General Information

- DELCORA is the Delaware County Regional Water Quality Control Authority, established in 1971, responsible for collecting, conveying and treating wastewater in the greater Philadelphia Area including 42 Municipalities in Delaware and Chester County.

DELCORA Mission

"Provide environmentally responsible and cost effective wastewater management services to the citizens, businesses, and industries of Southeastern Pennsylvania"

2

Why Are We Here?

- In April 1999, DELCORA adopted their Long Term Control Plan (LTCP) to comply with the Clean Water Act requirements for the Combined Sewer Overflow (CSO) control policy.
- In 2009, the Department of Environmental Protection (DEP) and Environmental Protection Agency (EPA) determined that DELCORA's LTCP was no longer in compliance with increased regulations of the Clean Water Act. In response, DELCORA began working with DEP and EPA to update the LTCP.
- In 2014, DEP and EPA determined that DELCORA's revised LTCP required further evaluation and development.
- In 2015 DELCORA signed with EPA the Long Term Control Plan Consent Decree.

3

Public Participation Plan Goals

- DELCORA's Goals and Objectives for the Public Participation Program are to:
  - Inform and Solicit Input to Updated LTCP from Stakeholders, including Public, Customer Communities and Regulatory Agencies
  - Educate the Public
  - Address Public Questions/Comments

4

Scope of Meeting

- This Public Meeting (9/26/18) is to:
  - Overview DELCORA Service Area
  - Summarize Work of LTCP Addressing Wet Weather Issues Up to this Point
  - Describe CSO Control Alternatives Evaluation
  - Describe Next Steps Towards Development of Long Term Control Plan Update (LTCPU)
  - Questions and Comments

5

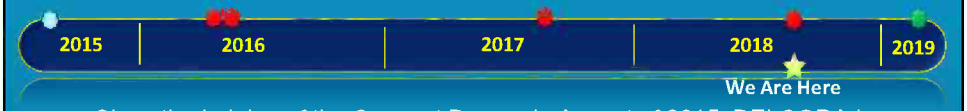
9

LTCPU 42-Month Program Schedule

Consent Decree Date of Lodging
August 17, 2015

Consent Decree LTCP Completion
Feb. 17, 2019



Since the lodging of the Consent Decree in August of 2015, DELCORA has met important milestones in the program:

2016
- Selected a plan to decrease CSOs and evaluated the financial ability of the community to pay for it.
- Identified the bacteria responsible for the pollution, and high-priority areas for CSO reduction.

2017
- An evaluation of historical rainfall on the existing sewer system was conducted. This would help identify the impacts of new technologies.

2018
- Pump Station "PS-6" completed and held last public meeting.

2019
- Submit final reports to the EPA.

10

Early Action Items

- A new pump station near the DELCORA treatment plant was required to be placed in operation by Dec 2018.
  - New Pump Station PS-6 was placed in operation on September 5th, 2018

- Over $150M has been spent on system improvement projects since the original LTCP in 1999.

11

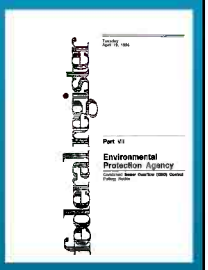
Improvement Costs to Date

- From 1999-2018 DELCORA spent in excess of $150 Million on overall system improvements and contributions to the City of Chester that resulted in decreased volume of overflows, reduced debris in overflows, provided remote monitoring of the system, and improved routine maintenance.
  - Partially separating flow to a CSO regulator
  - Purchasing property for further plant expansion
  - Replacement of older CSO regulator models
  - Research, repair, & replacement for leaking pipes
  - Annual informational flyers mailed to customers

12

National CSO Policy Requirements

- National CSO Policy pertaining to the Alternatives Analysis provides guidance to develop the LTCPU:
  - To meet one of the following (Presumption Approach):
    - No more than an average of 4 overflows a year
    - *Elimination or capture for treatment of at least 85% of combined sewage volume during wet weather events*
    - Elimination or removal of pollutants identified causing water quality impairment during wet weather events



13

LTCPU Alternatives Analysis

- Review Regulatory Requirements
- Describe, screen and compare technologies that can be used to achieve the most economically feasible approach to reducing CSOs that meets water quality standards
- Specific technologies must be considered

14

LTCPU Alternatives Analysis

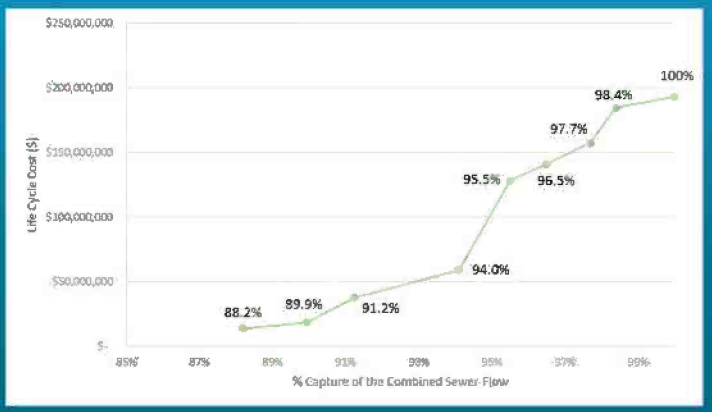
- Elimination or capture of 85% of wet weather flows entering the collection system on a system wide, typical year basis.
  - This level of control is presumed to meet WQS (subject to verification monitoring post-construction).
- Looked at 15 combinations of technologies to reduce CSOs (includes required technologies as per consent order)
- The costs associated for completing all projects in an alternative, as well as their upkeep and operation for 20 years was estimated – this is called the Life Cycle Cost

15

"Knee-of-the-Curve" Analysis

Capture % vs Cost

Knee-of-the Curve Graph for Selected Alternatives



16

Selected CSO Control Technologies

- DELCORA's recommended plan has 3 parts based on the Knee-of-the-Curve Analysis:
  - **88% - Regulator Control Improvements** - Regulator Modifications alone will provide enough CSO control to meet 85% wet weather capture.
  - **94% - Targeted Overflow Reduction** - Further CSO control technologies can target the most frequent CSO areas, but is dependent on financing and plant expansion. Address continued minimization of excessive I/I in areas upstream of the CSO system.
  - **Adaptive Management** - Adapting future projects based on the performance of the completed control technologies.

17

Components of the Selected Alternative

- The alternative providing over 90% capture costs $59.3M ($101M inclusive of 20 year life cycle costs) with:
  - Regulator Modifications
  - Rehabilitation & extension of the West End Interceptor
  - Building a parallel Delaware River Interceptor
  - Partially separating combined sewers north of Veterans Memorial Park
  - Green Stormwater Infrastructure in high frequency CSO areas
- This alternative provides the most affordable and cost-effective CSO control benefits.
- The boat ramp along the Delaware River is a public access point and the wet weather discharge from the adjacent outfall is addressed in this alternative.

18

Selected CSO Control Technologies

Regulator Control Improvements	Life Cycle Costs (Millions $)
Regulator Modifications Estimate	$ 14.2
Targeted Overflow Reduction	
Parallel Delaware River Interceptor	$ 3.6
WE Interceptor Rehab & Extension	$ 2.5
CSO-5 Partial Sewer Separation	$ 4.5
CSO 18 & 19 Green Infrastructure	$ 11.8
Arboretum Tank	$ 10.0
Monitoring and Modeling	$ 5.0
Public Outreach	$ 3.0
Plant Expansion/Upgrade	$ 28.8
Real-Time Control	$ 2.9
Adaptive Management	
Adaptive Management Estimate	$ 10.0
Program Operation Costs	$ 5.0
Total	$ 101.3

19

Implementation of the LTCPU

- Regulator Control Improvements are ongoing.
- Targeted Overflow Reduction projects can be fully implemented within the next 10 years, but depend on:
  - If excessive upstream flow into leaking pipes can be affordably addressed.
  - Eastern Service Area costs do not upset Chester's financial capability.
  - Recommended DELCORA treatment plant expansion approval by the PADEP and USEPA.

20

LTCPU 20-Year Implementation Schedule & Milestones

Consent Decree Date of Lodging
August 17, 2015

Consent Decree LTCP Completion
August 17, 2035

2020 2025 2030 2035

Milestones:

- Early Action Item, Completed PS-6 - September 2018
- Public Participation Meeting - September 26, 2018
- Updated LTCP Final Report & Update NMCs Plan - Feb. 17, 2019
- Regulator Control Improvements and Targeted Overflow Reduction Projects Complete – completed within10 years from regulatory approval
- All projects complete and fully operational; DELCORA is meeting all requirements of the Consent Decree - August 17, 2035

21

Literature and Documentation

- Literature and Documentation will be Made available by DELCORA at the following public locations and on the DELCORA Website:
  - **DELCORA Administration Building**

APPENDIX N

Corvias Green Stormwater Infrastructure Evaluation

- DELCORA Corvias Green Stormwater Infrastructure (GSI) Evaluation dated November 2017

DELCORA

SAC Corvias

Green Stormwater Infrastructure (GSI) Evaluation

Delaware County Regional Water Quality Control Authority (DELCORA)

November
2017

Executive Summary

The Delaware County Regional Water Quality Control Authority (DELCORA) is a municipal wastewater authority that owns, operates, and maintains collection systems that serve southeastern Pennsylvania, including the City of Chester. In 2015, DELCORA and the United States Environmental Protection Agency (EPA) entered a consent decree which mandated DELCORA to develop and implement a Long Term Control Plan (LTCP) to control combined sewer overflow (CSO) discharges. The LTCP strategy requires an evaluation of all CSO control options, including green stormwater infrastructure (GSI).

This report identifies potential areas that are suitable for implementation of GSI and evaluates the areas based on several factors such as life-cycle costs, the ability to develop effective GSI, availability of land, and combined sewer overflow control levels achieved. As part of a parallel effort by the Stormwater Authority of the City of Chester (SAC), additional factors were investigated such as environmental and socioeconomic impacts and benefits to minority and low income neighborhoods. This evaluation includes an applicability and performance assessment of proposed GSI control measures that considers unique sewershed-specific features such as diversion structures/outfalls, receiving waters, and land uses. Finally, this evaluation accounts for and assesses long-term, continual operation and maintenance of proposed GSI.

The top-scoring GSI sites resulting from the evaluation are summarized below, together with the estimated footprint areas, storage volumes, and construction and O&M costs:

Summary of Top-Scoring GSI Sites					
	Providence Avenue Regional Management (CSO 18)	Crozer Street Green Street (CSO 19)	Widener University & Walnut Street (CSO 18)	Edgmont Avenue Green Street (CSO 19)	Estimated Totals
GSI Footprint Area	5,500 sq ft	18,100 sq ft	65,306 sq ft	36,875 sq ft	125,781 sq ft
GSI Storage Volume	31,350 cu ft	33,405 cu ft	60,544 cu ft	67,042 cu ft	192,341 cu ft
Construction Cost Estimate	$600,000	$1.9M	$3.6M	$3.9M	$10.0M
Annual O&M Cost Estimate	$15,000	$15,000	$50,000	$30,000	$110,000

The work described in this report was performed by HDR Engineering, Inc. (HDR) for DELCORA and in conjunction with SAC and Corvias, a private entity assisting SAC to implement a Community-Based Public Private Partnership (CBP3) for their Stormwater Controls Program.

1.0 Introduction

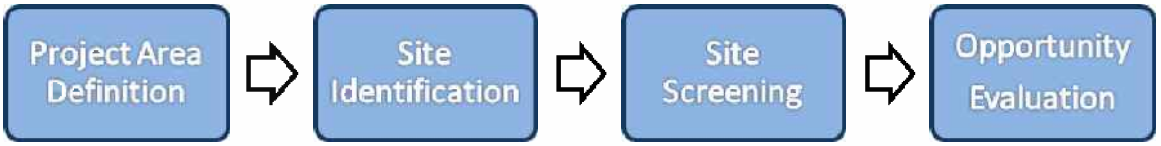
The Delaware County Regional Water Quality Control Authority (DELCORA) operates and maintains publicly-owned treatment works in the City of Chester, Pennsylvania, which collects stormwater and wastewater from residential, commercial, and industrial sources. The collection system has 28 combined sewer overflow (CSO) outfalls that discharge into the Delaware River, Chester Creek, and Ridley Creek.

In 2015, a United States Environmental Protection Agency (EPA) consent decree required DELCORA to evaluate and implement measures to reduce CSO discharges to improve water quality in the Delaware River, Chester Creek, and Ridley Creek.

Concurrently, a Community-Based Public-Private Partnership (CBP3) is being established between the Stormwater Authority of the City of Chester (SAC) and Corvias to plan, design, manage, operate, maintain, and finance the retrofitting of impervious surfaces through the use of integrated green stormwater infrastructure (GSI) practices for a planned 30-year period.

This report summarizes the investigation and evaluation tasks carried out to identify GSI projects in combined sewer system areas of Chester that will help DELCORA meet its consent decree goals.

The evaluation steps detailed in this report and illustrated below were primarily desktop analyses which included collecting baseline data for the project area, identifying and screening parcels with the highest potential for GSI, and evaluating and scoring the top sites.



The following sections detail the opportunity evaluation procedure and the steps undertaken to develop concepts for the sites with the highest potential for GSI.

2.0 Project Area Definition

For the initial evaluation, DELCORA advised that reducing the CSO volumes of outfalls 18, 19, and 22 is the highest priority. The tributary areas to these outfalls are shown in Figure 1 below. During a project meeting held on September 15, 2017, DELCORA shared their plans to separate the tributary to CSO 22 and eventually eliminate the outfall altogether. To prevent any conflict with the separation effort, this report focuses only on opportunities within the tributary areas of CSO 18 and 19.

Source: CSO Tributary Boundary GIS Layer (DELCORA/Greeley and Hansen, 2017)

Figure 1: CSO 18, 19, and 22 Tributary Areas

Reports, documents, and Geographic Information System (GIS) data, as shown in Table 1, were collected from multiple sources to form a baseline understanding of the project area and DELCORA's infrastructure.

It is understood that GIS information for catch basins is not available. Additional information can be collected, as feasible and necessary, during subsequent site investigations if these concepts are advanced to the design phase.

In general, the information received was adequate to carry out the evaluation steps and develop the concepts detailed in this report.

Other Public GIS Layers: • LiDAR Imagery • Contours • Watersheds • Land Use • Historical Markers • NCSS Soil Data	Online – public domain	Downloaded April 2017

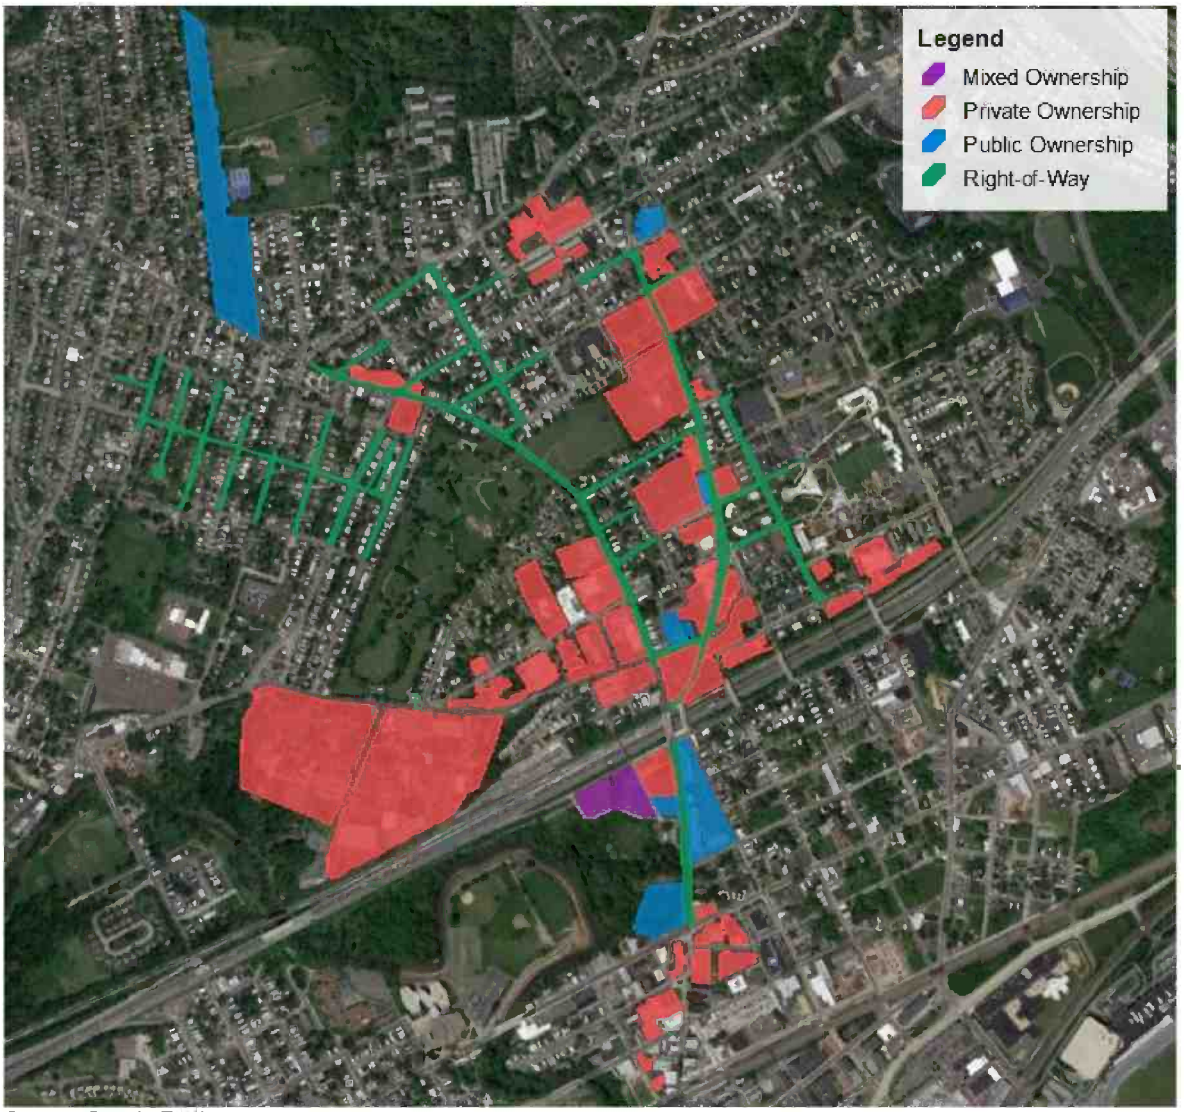
3.0 Site Identification

Using the above information, the first evaluation step involved reviewing parcel data to identify large impervious surfaces and open spaces within the project limits which generate significant runoff to the combined sewer. These sites include:

- Large vacant lots
- Right-of-way corridors greater than 40' wide
- Large publicly-owned parcels or groups of parcels
- Parks and open spaces

- Large private parcels with significant impervious surfaces.

This evaluation step resulted in 61 sites with significant tributary areas that could be managed by GSI practices. These sites are mapped below in Figure 2. This map is color-coded based on ownership type: right-of-way (green), private (red), public (blue), mixed public and private (purple).



Source: Google Earth

Figure 2: Sites with Potential for GSI

4.0 Site Screening

For the screening phase, the 61 sites identified in the previous step were reviewed to determine which sites generated the largest volume of stormwater runoff. These sites have the greatest potential for reducing the volume of water entering the combined sewer system.

During heavy rainfall, all surface types generate runoff which drain to the combined systems and can contribute to CSO events. While impervious surfaces generate a higher rate of runoff, large areas of pervious surfaces can also generate significant runoff volumes. For this reason, the

evaluation specifically targets impervious surfaces, but also considers large pervious areas such as parks and playing fields.

An equivalent acre value was used to calculate a site's total runoff volume. The equivalent acreage of a site was found by adding one quarter of the pervious tributary area to the impervious tributary area. The 0.25 coefficient is a conservative multiplier based on Natural Resources Conservation Service (NRCS) runoff curve numbers for open spaces and lawns with an additional factor of safety to maintain the emphasis on impervious surfaces.

The top sites, based on this screening and organized by CSO outfall tributary area, are listed in Table 2 and mapped in Figure 3. The following locations were also identified in CSO 22, but were subsequently removed from consideration, as noted in Section 1.

- Madison Street Parking Lot,
- Edgmont Avenue South, and
- E12th/Crosby Triangle.

Source: Google Earth

Figure 3: Locations of High-Potential GSI Sites

5.0 Opportunity Evaluation

To evaluate and rank the top sites identified above, a spreadsheet tool was created for scoring various criteria from four primary categories: CSO Volume Reduction, Project Feasibility, Site Suitability, and Community Benefits. Each category consists of defining criteria and is weighted to emphasize important priorities, as detailed in Table 3.

Table 3: Project Evaluation Categories and Criteria

Weight: 50%	**CSO Volume Reduction**
• CSO Effective Tributary Area Managed	
Weight: 25%	**Project Feasibility**
• Design Complexity • Constructability • Utility Conflicts / Constraints (Visual Assessment) • Environmental Remediation (Proximity to Environmental Risk Sites) • Operations and Maintenance Implementation	
Weight: 15%	**Site Suitability**
• Available Land for GSI Practices • Public Safety	
Weight: 10%	**Community Benefits**
• Revitalize Depressed Areas (Social Justice) • Catalyst for New Business and Commerce • Provide Recreation & Education • Environmental Improvement (Greening)	

The ratings for each criterion were based on quantifiable metrics when possible in order to normalize and compare the scoring across all projects. Other ratings such as "Design Complexity" and "Constructability" were based on experience implementing similar GSI practices in other urban areas nationwide. Because the most important categories have heavier weighting, the scores for these criteria had greater consequence for the overall total.

The following data and documents guided the scoring in this evaluation:

- CSO Tributary Maps from DELCORA/Greeley and Hansen to confirm location within the priority CSO tributaries.
- Demographic maps from *Vision 2020 Climate Adaptation Planning Elements* report to determine impact to impoverished areas, location of high-population densities, and proximity to environmental risk zones.
- Google Earth to perform desktop analysis and measure tributary and impervious areas.

For the purpose of this evaluation, it was assumed that the following types of GSI practices would likely be considered for each project during next steps and, specifically, concept development:

- **Bioretention** – vegetated practices within a public or private parcel
- **Tree trenches** – linear tree pits with integrated subsurface storage for runoff
- **Green streets** – combination of right-of-way bioretention or tree trenches, green curb extensions or medians, permeable pavement, and bike paths (where feasible)
- **Permeable pavement** – concrete, brick, or asphalt surfaces that allow runoff to infiltrate to subsurface storage media
- **Green roofs** – vegetated detention layers on flat roof surfaces
- **Subsurface storage** – underground facilities that typically manage stormwater diverted from subsurface drainage structures such as downspouts or separate stormwater pipes. These practices can be designed to infiltrate the stored stormwater or slow-release it back to the system.

6.0 Evaluation Results

Using the information detailed previously, a rating was given for each of the above criteria and entered into the spreadsheet evaluation tool. The spreadsheet then aggregated the scores and applied the weighting factors to each category to derive the total score out of a maximum of 100.

The results for each of the top sites are listed in Table 4 from highest total score to lowest. The table also includes each category score out of the weighted total.

Table 4: Evaluation Results

	Category Scores				
	CSO Volume Reduction	Project Feasibility	Site Suitability	Community Benefits	Total
Project	**50.0**	**25.0**	**15.0**	**10.0**	**100.0**
Providence Avenue	50.0	21.5	11.3	5.1	**88.0**
Crozer Street	50.0	18.0	13.5	4.5	**86.0**
Widener University	50.0	18.5	10.5	6.5	**85.5**
Edgmont Avenue	50.0	14.5	13.5	7.3	**85.3**
Crozer Seminary	50.0	18.0	10.5	3.5	**82.0**
Crozer-Chester Medical Center	50.0	13.5	9.0	4.8	**77.3**
Chester Park	35.0	20.0	11.3	7.5	**73.8**
Madison Street Parking Lot	31.0	19.5	11.5	4.0	**70.0**
Drexel Neumann Academy	25.0	19.5	10.5	6.8	**61.8**
Walnut Street	23.0	17.0	13.5	5.8	**59.3**
Smedley Allied Health High School	23.0	19.5	9.0	7.5	**59.0**
UHS Keystone Center	18.0	19.5	10.5	4.3	**52.3**
Widener Partnership School	16.0	18.0	10.5	7.5	**52.0**
Best Western	17.0	19.5	9.8	4.8	**51.0**
1350 Edgmont Office Building	16.0	19.5	10.5	4.8	**50.8**
Family Dollar	16.0	18.0	10.5	4.8	**49.3**
Days Inn	14.0	19.5	10.5	4.8	**48.8**

For each category column, the highest scores are green, the middle scores are yellow, and the lowest scores are red. The maximum score for each category is listed below the category header. Total scores are out of a maximum of 100.

After initial scoring and during the project meeting held on September 15, 2017, DELCORA advised that Crozer Seminary and Crozer-Chester Medical Center should be assumed to be separately sewered. As a result, these sites were subsequently removed from consideration for this evaluation. DELCORA also requested that Walnut Street be combined with the Widener University concept.

After reviewing the results, DELCORA agreed to proceed with site investigations for the top sites as scored:

- Providence Avenue
- Crozer Street
- Widener University / Walnut Street
- Edgmont Avenue

7.0 Site Investigation Overview

Following the identification of the top four scored opportunities, site investigations were completed to gather further information on each site to inform concept development. The investigations focused on completing the below activities:

- Taking representative site photographs
- Locating surface drainage features such as catch basins, drains, manholes, ditches, and channels
- Recording high and low points, site contours, and other features that may affect surface flow
- Delineating tributary area boundaries within each opportunity area

- Identifying site constraints that may affect GSI construction, functionality, and maintenance such as limited accessibility, site usage and constraints, and existing trees and vegetation.

The information gathered during the site investigations contributed to the development of the proposed GSI concepts presented in Section 8.

8.0 GSI Concept Overviews

8.1 Approach

The approach to developing the proposed GSI concepts is a high-level adaptation of techniques used for GSI planning nationwide. The step-by-step process is detailed below.

The first step was to delineate the tributary for each opportunity area. The **total tributary area** is defined as all the surface area that contributes stormwater runoff to a termination point such as a drain, low point, or waterbody. Tributary areas should be delineated to account for all site runoff from both impervious and pervious surfaces.

After delineating the tributaries, the **total runoff volumes** were determined based on a design storm depth of 1.5 inches. This depth is consistent with design guidance for publicly-funded GSI projects as part of CSO control programs in other cities in the region. The total runoff volume was then calculated by multiplying the design storm depth by the effective tributary area (impervious tributary area plus 25% of the pervious tributary area).

Using the site investigation information, the most suitable GSI types were selected for each area. The preferred option is to utilize vegetated solutions such as **bioretention**. Vegetated solutions offer many co-benefits such as beautification, shading and temperature reduction, environmental enhancement, and relative ease of maintenance.

Where vegetated practices are not feasible due to accessibility issues, traffic and pedestrian usage, or line-of-site constraints, **permeable pavement** was recommended. Permeable pavement practices offer fewer co-benefits, but can be installed in places where vegetated features are not feasible.

Green stormwater infrastructure practices in the right-of-way were considered **green streets**. These practices consist of a combination of bioretention, permeable pavement, and other amenities such as pedestrian crossings and bike lanes. The exact configuration of these components should be finalized during the detailed design stage.

Subsurface storage was the last option considered. These practices manage stormwater in underground chambers and are not visible on the surface; therefore they offer few additional co-benefits. However, in cases of drainage diversions or disconnections, subsurface storage can be used to efficiently manage large volumes of runoff from a regional system by infiltrating the water into the surrounding soil or discharging it back to the combined sewer at a lower peak rate of runoff.

GSI **footprint areas** within each concept were then estimated based on the available space observed during the site investigations. In the right-of-way, GSI practices were assumed to have an average width of five feet, situated within the parking lanes or road

shoulders. Onsite, the GSI footprint areas were sized to maximize the storage volume, up to the total runoff volume, based on site constraints such as available space and mature trees. Estimation of GSI footprint areas for this evaluation did not consider survey or subsurface conditions that may limit siting or sizing of GSI, as this data would be collected as part of design activities.

Based on industry best practices, the ratio of tributary area to footprint area was limited to a maximum of 5:1 for permeable pavements and 20:1 for bioretention where feasible. Higher ratios may require additional pretreatment features or increased maintenance frequencies.

GSI **storage volumes** were estimated using the footprint areas, typical cross-sections, and design components for the respective GSI type. Note that due to site limitations, storage volumes were not always sufficient to manage the total runoff volume.

From the estimated footprint sizes, conceptual cost estimates were established based on typical costs per square foot for construction and maintenance. See Section 8.2 for cost estimation assumptions.

8.2 Assumptions

The concepts presented in Section 8.3 are based solely on the information detailed in this report, information gathered during the site investigation, and direction given by DELCORA.

The tributary and GSI footprint areas are approximate and only based on the available information and observations during the site investigations. At this stage, it is assumed that all open space identified during site investigations will be available to install GSI practices. For this report, only static storage volumes were estimated and infiltration was not taken into account.

During design, the tributary areas and GSI locations will need to be fully investigated and amended as necessary. This may include adding, removing, and modifying GSI practices based on geotechnical investigations, topographic survey, utility coordination, and cost/benefit analyses.

Conceptual cost estimates summarized in Section 8.3 are based on estimated construction and maintenance costs per square foot of GSI footprint. These rates are summarized below (all costs are in current dollars):

- $90-$105 per square foot to construct GSI practices (bioretention or permeable pavement, respectively) within the right-of-way.
- $30-$35 per square foot to construct GSI practices (bioretention or permeable pavement, respectively) within public and private parcels.
- $0.75-$1.25 per square foot **annually** to maintain GSI practices (permeable pavement or bioretention, respectively).
- Subsurface storage cost estimates were based on footprint size, volume of excavation required, and assumed level-of-effort for annual maintenance.

The differences in costs are due to increased expenses when working in the right-of-way and the variability of costs per GSI type. These figures do not include additional costs

such as mobilization, traffic control, utility relocations, or surface amenities. These estimates are based on recent trends in urban GSI development and are considered reasonable for the purposes of preliminary budgeting. The costs shall be confirmed during the detailed design of individual projects.

8.3 Concept Summaries for Top-Scoring Sites

Concepts for the four highest-scoring GSI opportunity areas are summarized in Table 5 below. The cost estimates for construction and operations and maintenance (O&M) included below are conceptual-level only as described in Section 8.2.

Table 5: Summary of GSI Concepts

1 Providence Avenue Regional Management

Proposed GSI: Subsurface Storage

Total Tributary Area: 33.2 acres
- Impervious Area: 30.1 acres
- Pervious Area: 3.1 acres

Total Runoff Volume: 168,215 CF

GSI Footprint Area: 5,500 SF
GSI Storage Volume: 31,350 CF

Construction Cost Estimate: $600,000
Annual O&M Cost Estimate: $15,000

Summary:
DELCORA survey records show the separate stormwater system in this area collects runoff from a tributary area of 33.2 acres and flows south down Providence Avenue. The separate system discharges to the CSO 18 combined sewer system just north of the proposed site in the grassed triangle.

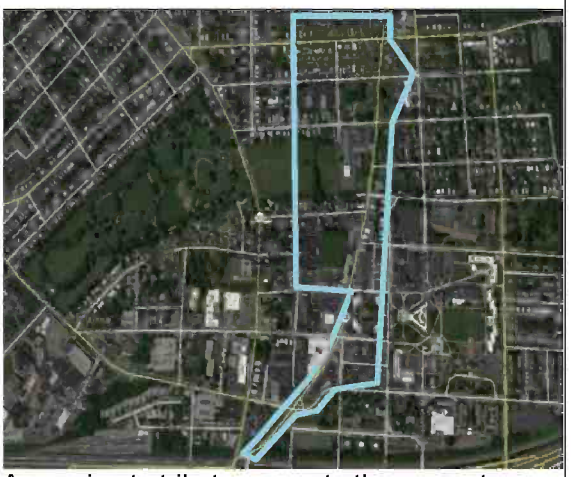
This concept would divert the separate stormwater flow to a regional storage facility installed underground in the grassed triangle area east of Providence Ave, before it enters the CSO 18 combined sewer system. Due to mature trees, the available footprint area for the subsurface storage is approximately 5,500 square feet, which is not sufficient to manage the total runoff volume.

Records from the City of Chester show that this triangle area is owned by Widener University, so a procurement or easement would need to be coordinated with the University. The location and inverts of the existing separate sewer connection and soil infiltration rates will affect the design and need to be confirmed in a subsequent phase.

Overall, this site may be able to manage a large volume of runoff in a relatively small area. While the GSI practices would be underground, surface features or amenities could be added during design and construction to provide community benefits such as benches and other passive recreation. However, due to the small and remote site, co-benefit potential may be minimal.

Secondary options include expanding the subsurface storage to the adjacent parking lot or to the grassed area to the north to increase storage capacity.

Proposed site of regional subsurface storage in grassed traingle



Approximate tributary area to the separate stormwater system in Providence Ave

Grassed triangle viewed from the north

2 Crozer Street Green Street

Proposed GSI: Green Streets

Total Tributary Area: 42.4 acres
- Impervious Area: 25.3 acres
- Pervious Area: 17.1 acres

Total Runoff Volume: 161,276 CF

GSI Footprint Area: 18,100 SF
- Bioretention: 3,000 SF
- Permeable Pavement 15,100 SF

GSI Storage Volume: 33,405 CF
- Bioretention 6,225 CF
- Permeable Pavement 27,180 CF

Construction Cost Estimate: $1.9M
Annual O&M Cost Estimate: $15,000

Summary:
Crozer Street runs east and west through a residential zone in the CSO 19 tributary area. Available data shows that this street is at a low point, receiving stormwater runoff from adjacent streets and properties.

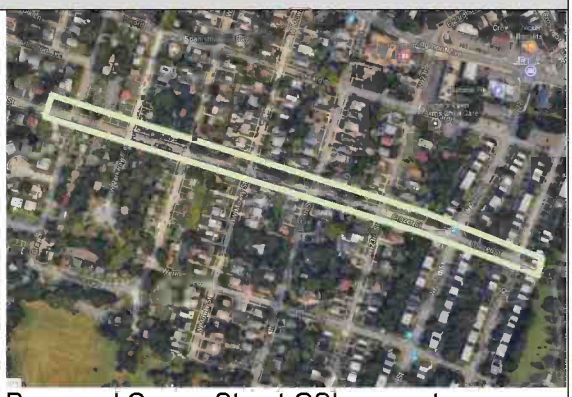
Right-of-way bioretention practices are proposed at the intersections in Crozer Street and its cross-streets. These will be bumped out into the roadway just upstream of the existing catch basins.

Due to the large tributary area, permeable pavement is also proposed in the shoulders of Crozer Street to increase the storage capacity.

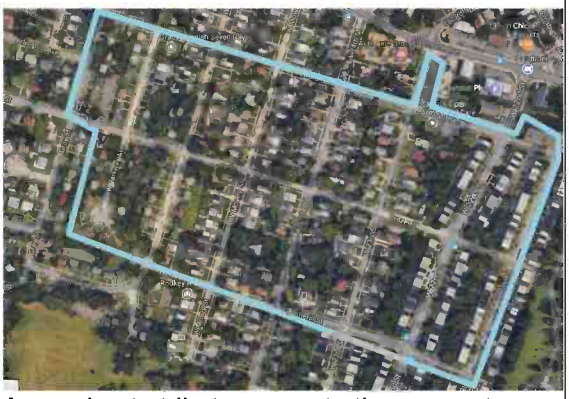
This concept is favorable because it lies entirely within publicly-owned property in low-density, residential areas. The lower relative elevation of Crozer Street also allows the GSI practices to collect runoff from a large area.

This site can also provide community co-benefits such as traffic calming, pedestrian safety, street-level landscaping, and neighborhood beautification.

Crozer Street is narrow in some portions and lined with mature trees, so exact sizes and locations of GSI practices will need to be confirmed after topographic survey during the design phase.



Proposed Crozer Street GSI concept area



Approximate tributary area to the concept

Typical intersection on Crozer Street

3	Widener University / Walnut Street

Proposed GSI: Permeable Pavement

Total Tributary Area: 14.1 acres
- Impervious Area: 11.2 acres
- Pervious Area: 2.9 acres

Total Runoff Volume: 64,978 CF

GSI Footprint Area: 65,306 SF
GSI Storage Volume: 60,544 CF

Construction Cost Estimate: $3.6M
Annual O&M Cost Estimate: $50,000

Summary:
Widener University campus offers many opportunities to collect and manage runoff from impervious areas in the CSO 18 tributary area.

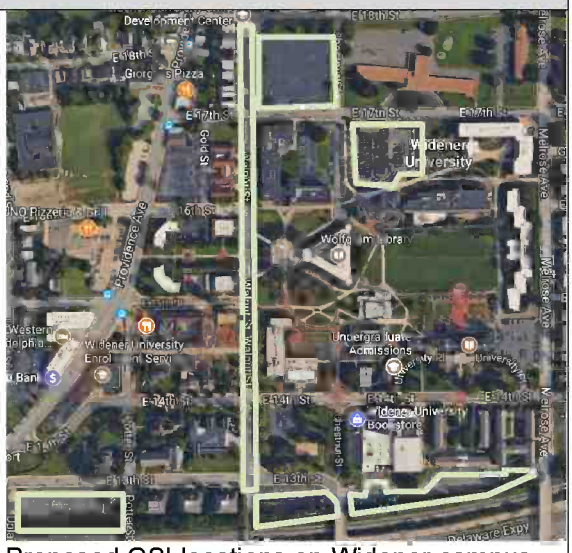
During site visits, several potential locations with large impervious areas were identified. The proposed locations include five parking lots and the right-of-way of Walnut Street, which runs north and south through the campus.

Due to vehicular and pedestrian traffic, parking constraints, and site limitations, the proposed GSI practices are permeable pavements. Both in the parking lots and within the right-of-way, permeable pavement can be installed within existing parking spaces. Brick pavers are recommended in order to be consistent with the campus aesthetics.

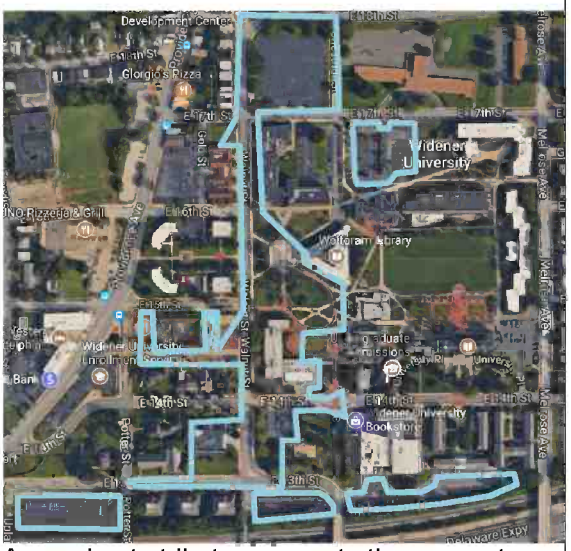
There may be opportunities for bioretention within the wider sections of Walnut Street, around the perimeter of the parking lots, or within the grassed plazas on campus. These opportunities will need to be identified after topographic survey during the design phase. Any designs on private property or affecting campus parking would need to be coordinated with Widener University.

The CSO 18 tributary area boundaries will also need to be confirmed prior to design to ensure that these areas are not separately sewered.

In general, there are several GSI opportunities across the Widener University campus. Widener University could also make an excellent community partner as DELCORA moves forward with their CSO LTCP program.



Proposed GSI locations on Widener campus



Approximate tributary areas to the concepts

On Walnut St. looking north to E 16th St.

4 Edgmont Avenue Green Street

Proposed GSI: Green Streets

Total Tributary Area: 20.8 acres
- Impervious Area: 13.3 acres
- Pervious Area: 7.5 acres

Total Runoff Volume: 82,864 CF

GSI Footprint Area: 36,875 SF
- Bioretention: 2,425 SF
- Permeable Pavement 34,450 SF

GSI Storage Volume: 67,042 CF
- Bioretention 5,032 CF
- Permeable Pavement 62,010 CF

Construction Cost Estimate: $3.9M
Annual O&M Cost Estimate: $30,000

Summary:
Edgmont Avenue runs north and south through Chester and bisects much of the CSO 19 tributary area and is also a main route from the residential areas to the central business district.

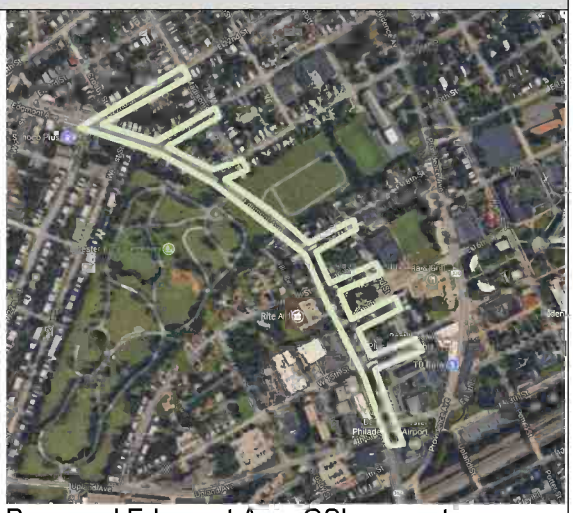
The stormwater runoff in this area is generated by the impervious right-of-way and the adjacent commercial and residential properties.

Due to the narrow streets, parking limitations, and space constraints, permeable pavement is proposed for most of this concept along the shoulders of Edgmont Avenue and its side streets.

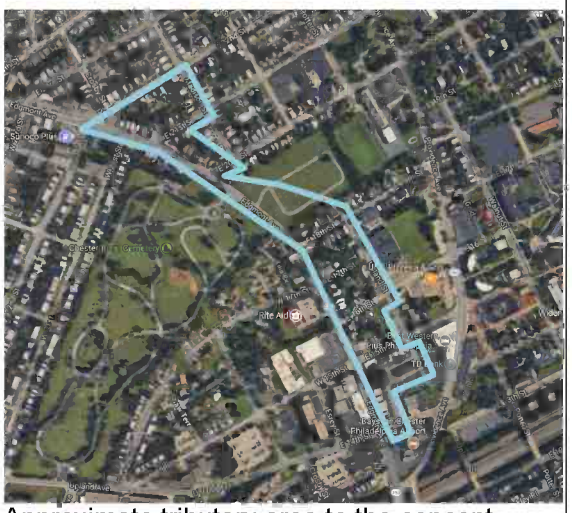
Bioretention practices are proposed in the wider roadway section adjacent to the cemetery and at the larger intersections.

Due to connectivity potential, other amenities such as bike paths may be considered during design, but may not be feasible due to narrow streets.

Actual location and sizes of features would be finalized during design and subject to City of Chester requirements.



Proposed Edgmont Ave. GSI concept area



Approximate tributary area to the concept

Looking north at wider sections of Edgmont Avenue near the cemetery

APPENDIX O

DELCORA Alternatives Analysis Contingency Breakdown

- DELCORA Alternatives Analysis Opinion of Probable Cost Methodology Memorandum dated June 21, 2018

GREELEY AND HANSEN

MEMO

Date: June 21, 2018

To: DELCORA Project File

C: -

From: Brian R. Olson, P.E., CFM, CPESC

Subject: DELCORA Alternatives Analysis Opinion of Probable Cost Methodology

---

The purpose of this memorandum is to provide background about the methodology used to estimate costs for the CSO Control Technologies utilized in the DELCORA Alternatives Analysis.

The opinions of probable construction cost are considered Level 5 estimates, as designated by The Association for the Advancement of Cost Engineering (AACE) Recommended Practice No. 18R-97. The accuracy range for Class 5 estimates is generally within a range of fifty percent less (50%) to one-hundred percent more (100%) than the actual cost. To develop the present worth values of Alternatives, the primary components of the Alternative opinion of probable construction cost methodology is:

- Identify appropriate Alternative cost line items;
- Generate operation and maintenance costs along with contingency and other cost factor percentages; and
- Generate capital and life-cycle cost curves;

Capital Cost Sources and Cost Factors

The sources to develop capital costs include the following:

- Greeley and Hansen project data
- RS Means
- Manufacturer's cost data
- EPA project cost data and cost curves
- South Bend, Indiana CSO Long Term Control Plan Optimization Final Report (South Bend)
- Alexandria, Virginia CSS Long Term Control Plan Update Alternatives – Alternatives Evaluation: Sewer Separation
- Washington Sanitary Sewer Commission: Bladensburg Trunk Sewer Preliminary Design Report
- Anderson, Indiana CSO Long Term Control Plan: Basis for Cost Estimate (Anderson, Indiana)
- Capital Region City Beautiful Water Program Plan: Basis of Cost Opinions (Capital Region)
- District of Columbia Water and Sewer Authority Combined Sewer System Long Term Control Plan Final Report
- Passaic Valley Sewerage Commission Long Term Control Plan Technical Guidance Manual (PVSC TGM)
- The Sewer Authority of the City of Scranton Combined Sewer Overflow Long Term Control Plan (Scranton LTCP)
- Combined Sewer Overflow Long Term Control Plan Update – Basis for Cost Estimates, City of Elkhart, Indiana (Elkhart, Indiana)
- DELCORA Green Stormwater Infrastructure Evaluation – Corvias
- Cost Estimates for Regulator Modification – Waterware

- Long-Term CSO Control Plan – Weston Solutions

All cost items are adjusted to January 2018 dollars accounting for inflationary, escalation, and interest costs using the Engineering News Record Construction Cost Index (ENR-CCI). This index tracks the United States cost of labor and common construction materials on a monthly basis.

The following Table 1 lists capital improvement cost factors that are applied to the capital cost to obtain, in addition to the operation and maintenance present value, the full cost to implement the Alternative.

Table 1: Capital Improvement Cost Factors

Capital Improvement Cost Factor	**Escalation Factor**
Overhead and Profit	15% of Capital Cost
Bonds and Insurance	3% of Capital Cost
Mobilization/Demobilization	5% of Capital Cost
Engineering	10% of Construction Cost
Permitting	3% of Construction Cost
Contingency Factors	**Percent of Capital Cost**
Pipe Installation – Heavy Utilities	45%
Pipe Installation – Light Utilities	30%
Tank/Storage Conduit – Heavy Utilities	50%
Tank/Storage Conduit – Light Utilities	30%
Green Infrastructure – Heavy Utilities	40%
Green Infrastructure – Light Utilities	25%
Regulator/Real Time Control – Difficult Modification	25%
Regulator/Real Time Control – Simple Modification	15%
Pump Station – Difficult Installation	45%
Pump Station – Simple Installation	30%
WWTP Upgrade – Difficult Modification	50%
WWTP Upgrade – Simple Modification	30%
Sewer Separation – Heavy Utilities	45%
Sewer Separation – Light Utilities	30%
Disinfection – Difficult Installation	40%
Disinfection – Simple Installation	25%
Settling/Separation – Difficult Installation	40%
Settling/Separation – Simple Installation	25%

Quantity take offs have not been performed as part of the cost breakdown, such as for clearing and grading, filling, excavation, and restoration. These line items are considered to be part of the contingency factor.

Capital and Life-Cycle Cost Estimates

Control Technology costs can be highly variable due to site constraints, location, and overall feasibility and ease of construction. As previously stated, the cost curves and equations developed are for AACE Level 5 planning purposes only. As further details for the implementation of the Control Technologies present themselves, a more detailed cost breakdown can be completed.

Cost Escalation Factor

In the subsequent capital cost estimate analyses, all costs are escalated to January 2018 using the Engineering News Record Construction Cost Index (ENR-CCI) for Philadelphia. The ENR-CCI value used for January 2018, Philadelphia is 12979.40. In the event base costs are given as a national ENR-CCI escalated value, the following equation is utilized to convert costs to January 2018, Philadelphia.

January 2018, Philadelphia = Original cost * (12979.40/Original National ENR-CCI)

In the event base costs are given as a local Philadelphia cost, the following equation is utilized to convert costs to January 2018, Philadelphia.

January 2018, Philadelphia = Original cost * (12979.40/Original Philadelphia ENR-CCI)

Operation and Maintenance Costs

Operation and maintenance (O&M) costs were estimated by first using the following methodology:

- Operation
  - Labor costs and requirements for the various CSO Control Technologies were based on the average cost of maintaining a single operating post manned by one operator on a 24-hour, year round basis. Local operations labor is approximately $53.60/hour, including fringe benefits. Assuming an eight hour workday, with three shifts per day, for 365 days per year, the average cost for a Continuous Operating Post (COP) would be $470,000. The number of COPs needed for operations purposes can be seen in Table 2 below.
- Maintenance
  - Costs taken as a percentage of the construction cost, as seen in Table X below.

Table 2: O&M Cost Basis

Item	Unit	Cost Basis (per year)
Operation		
Green Infrastructure	-	Included in maintenance cost, see below.
High Rate Clarification	COP	2.0
Pump Station Up to 100 MGD Over 100 MGD	 COP COP	 0.5 2.0
Storage	COP	0.5
Tunnels	COP	1.0
Conveyance Pipelines/Sewer Separation	-	Included in maintenance cost, see below.
Maintenance		
Green Infrastructure Permeable Pavement Bioretention	 SQ-FT SQ-FT	 $0.75 $1.25
High Rate Clarification	% of construction cost	3.0%
Pump Station	% of construction cost	3.0%
Storage	% of construction cost	3.0%
Tunnels	% of construction cost	1.0%
Conveyance Pipelines/Sewer Separation	% of construction cost	0.25%

*Pump station operation for storage and tunnels included in storage and tunnel operation. Only add pump station operation costs if standalone pump station.

This initial method was used to calculate total life-cycle costs when utilizing the capital cost curves. However, per the Consent Decree, it is required to formulate life-cycle cost curves. To do this, operation costs have to be converted to a per-unit basis instead of being calculated on an annual basis. This was calculated by first iterating the percentage of operations cost per unit and then melding that into an overall life-cycle cost per unit. Once the life-cycle cost curve was formulated, the same capital cost curve x-axis units were used to come up with a corresponding total life-cycle cost. Final capital and life-cycle costs were near exact to each other or within a small percentage. This then provided the evidence that the percentage used for operations cost for the per-unit basis was correct.

Present-Worth Calculations

To combine O&M and construction costs for each Control Technology, present worth calculations have to be completed. For this, a discount rate of 2.75% is used (taken from the Rate for Federal Water Projects, NRCS Economics, Department of the Interior) with a life span of 20 years. The following equation is then utilized to calculate the present worth factor to convert from annual O&M costs to present worth.

(P/A, i%, n) = ((1+i)^n -1)/((i(1+i)^n)

This is then multiplied by the annual O&M costs and then added to the construction costs to obtain the total life cycle cost. Salvage value is considered to be $0, as it is assumed no resale value will result from the Control Technologies utilized.

Cost Curve Construction

Once cost curves have been formulated for both capital and life-cycle costs, they are utilized to calculate the full cost of implementation from a life-cycle perspective. Sewer separation is calculated on a per CSO area basis by utilizing the appropriate cost curve. By applying the area of each of the combined sewer areas into the cost curve, the total cost to separate each CSO is summed together to come up with a final life-cycle cost. Sewer separation is presumed to only occur to eliminate all overflows from the combined sewer system.

Both storage tanks and tunnel storage are sized for the required Consent Decree overflow amounts of 0, 2, 4, 6, 8, and 12 overflow events per Typical Year by using results from H&H modeling which includes Pump Station 6 (PS6) is inserted into the associated model. CSO areas are subsequently grouped together to formulate feasible pairings so storage can be lumped together. The locations of storage tanks and tunnels was determined for overall feasibility of installation and size depending on the characteristics of the surrounding area (width of road, location next to buildings, etc.). The locations of utilities (electrical, gas, etc.) is not known, however it is presumed utilities are a large factor considering the combined sewer area is set in an urban location. This is taken into consideration within the contingency added into the overall life-cycle cost. Overall storage volume for each overflow event is determined, with the appropriate cost curve utilized to calculate the associated life-cycle cost. To get flow to the storage tanks and tunnels, transmission mains have to be installed. To calculate the size of the transmission mains, the peak discharges from each regulator was determined. For each group, the max discharge from each regulator was then determined. Using Mannings equation, the diameter was solved for to come up with the correct pipe size based on full flow. A minimum slope was used by determining the shallowest slope along the proposed transmission main schematic, which allowed for a more conservative approach to calculate the diameter of the pipe flowing full. Once the installed pipe diameter was calculated, the appropriate cost curve was used to calculate the total life cycle cost to install the storage tank and tunnel

for each overflow event per Typical Year. Plant expansions also used new or improved conveyance lines, as well as improved pumping capacities to handle increased flow to the WRTP based on the EPA-SWMM modeling. For tunnels, drop shafts were considered in the cost. A drop shaft was assumed to be needed at the beginning and end of every tunnel, and at points where the direction of the pipe changed laterally. Green infrastructure costs were also implemented from the work completed by Corvias, and were added on to the total life-cycle cost calculated for the various Control Technologies.

The following, except for green infrastructure, are the capital and life-cycle cost curves utilized to come up with overall costs for the various Control Technologies.

Green Infrastructure

Opinions of probable construction cost have been developed for the project area by Corvias in a memorandum titled "Green Stormwater Infrastructure (GSI) Evaluation" dated November 2017. In the memorandum Corvias completed an opinion of probable construction cost for proposed green infrastructure Control Technologies in CSO areas 18 and 19. These Technologies consist of permeable pavement, subsurface storage, and green streets/bioretention. According to the memorandum,

"Conceptual cost estimates…are based on estimated construction and maintenance costs per square foot of GSI footprint. These rates are summarized below.

- *$90-105 per square foot to construct GSI practices (bioretention or permeable pavement, respectively) within the right-of-way.*
- *$30-35 per square foot to construct GSI practices (bioretention or permeable pavement, respectively) within public and private parcels.*
- *$0.75-1.25 per square foot annually to maintain GSI practices (permeable pavement or bioretention, respectively)*

The differences in costs are due to increased expenses when working in the right-of-way and the variability of costs per GSI type."

These costs above are in November 2017 dollars, local to Philadelphia, and do not include items such as mobilization, traffic control, utility relocations, or surface amenities.

The overall analysis consists of utilizing the sited green infrastructure Control Technologies proposed by Corvias and does not implement further practices on a systemwide basis. The Consent Decree requirements do not dictate using green infrastructure on a global basis, but rather that they be incorporated in some fashion within the analysis. Given the above costs, and escalated to January 2018 dollar values (Philadelphia) with maintenance included, the following Table 3 gives green infrastructure costs on a per square foot basis.

Table 3: Green Infrastructure Opinion of Probable Construction Cost

Green Infrastructure Practice	**Cost Per Square Foot**
Bioretention – within right-of-way	$91.30
Bioretention – within public and private parcels	$31.30
Permeable pavement – within right-of-way	$105.80
Permeable pavement – within public and private parcels	$35.80

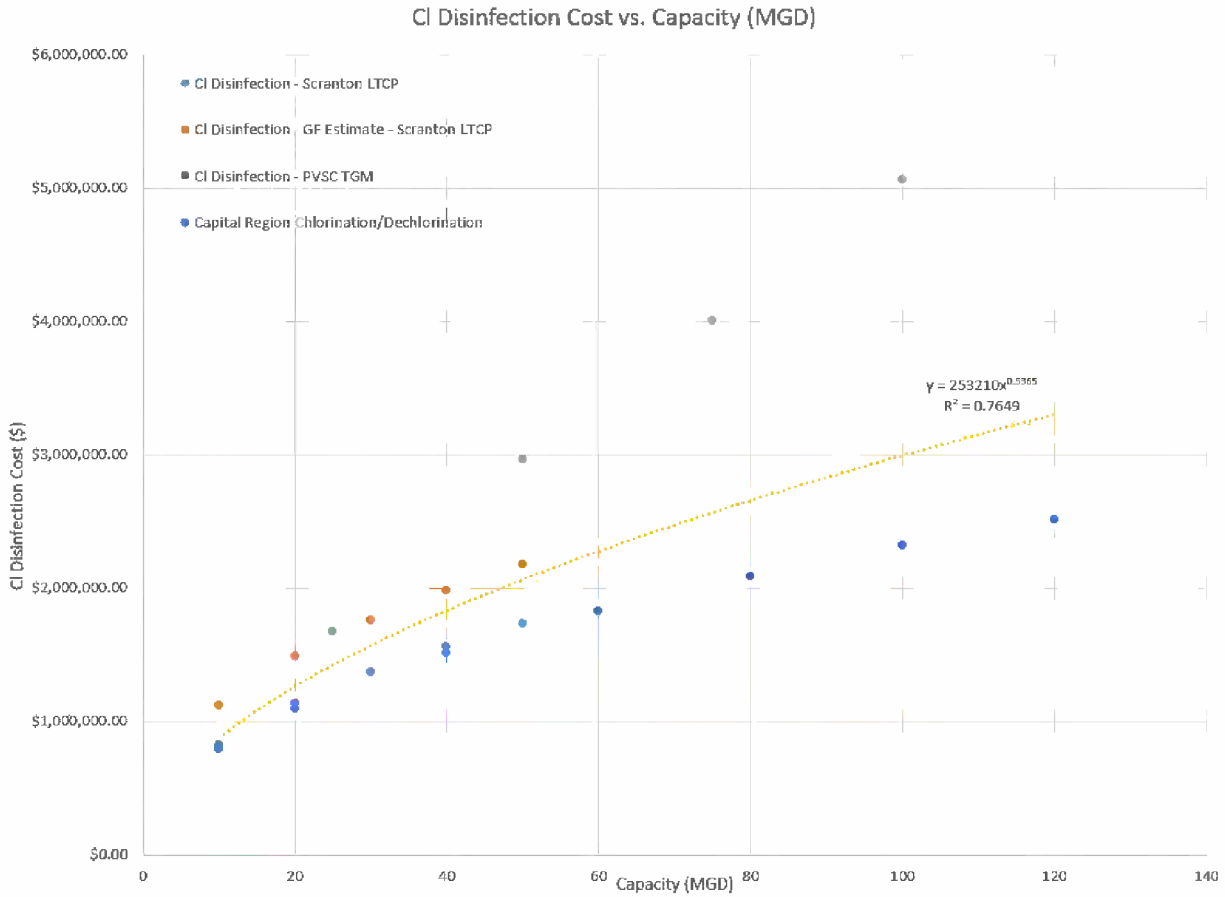
Chlorine Disinfection

The use of chlorine disinfection is recommended for use at satellite high-rate treatment facilities. Data sources include cost curve information from Capital Region, Scranton LTCP, and PVSC TGM. All include the use of chlorine in some form to disinfect stored combined sewer overflow after being treated at a satellite treatment facility. In addition, all sources cross reference equipment costs as obtained from equipment manufacturers. The resulting capital cost curve for chlorine disinfection is the following:

Y = 253,210*x^.5365

Where Y equals the total cost in million dollars and x equals treatment capacity in MGD. This trendline equation can be seen in Figure 1 below, and shows a medium to high R^2 correlation value.

Figure 1: Chlorine Disinfection Capital Cost vs. Capacity (MGD)

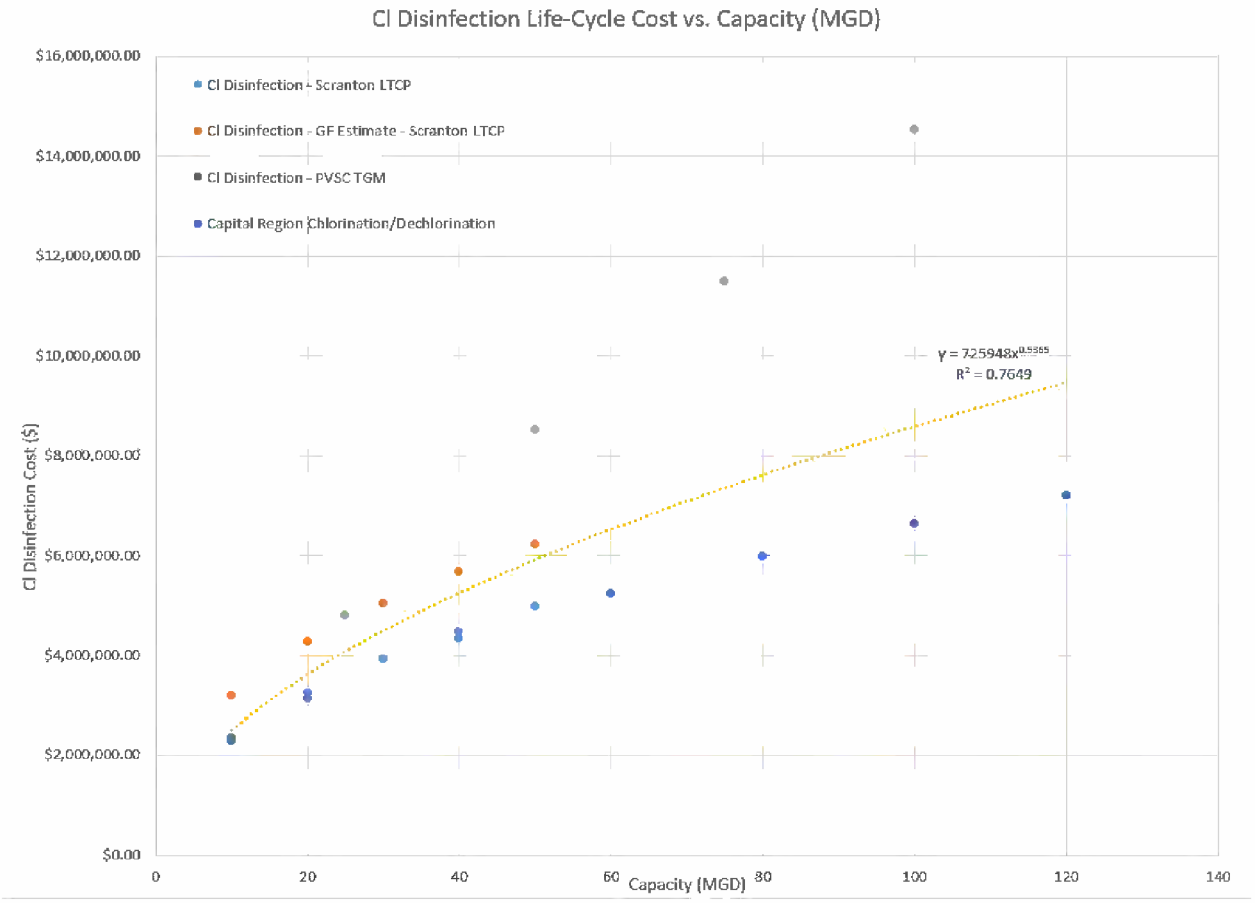


The resulting life-cycle cost curve for chlorine disinfection is the following:

Y = 725,948*x^.5365

Where Y equals the total cost in million dollars and x equals treatment capacity in MGD. This trendline equation can be seen in Figure 2 below, and shows a medium to high R^2 correlation value.

Figure 2: Chlorine Disinfection Life-Cycle Cost vs. Capacity (MGD)



Settling/Separation

Vortex separation is the method utilized for developing cost curves for settling/separation. More specifically cost data is taken from various data sources listed in Section 11.4.2.1 for Storm King, Hydroves, and Sansep separators. The basic premise of a vortex separator is that it produces a self-induced swirling action that encourages the settling of solids at the bottom of the unit, which are then sent to a wastewater treatment plant for treatment. The reason why these separators are so attractive to install is due to its low overall footprint, ease of maintenance, and it overall being a simple process from an operating standpoint. In the development of the cost curve, all sources cross reference equipment manufacturers to ensure accuracy. The resulting capital cost curve for the Storm King unit is the following:

Y=95,305*x+750,265

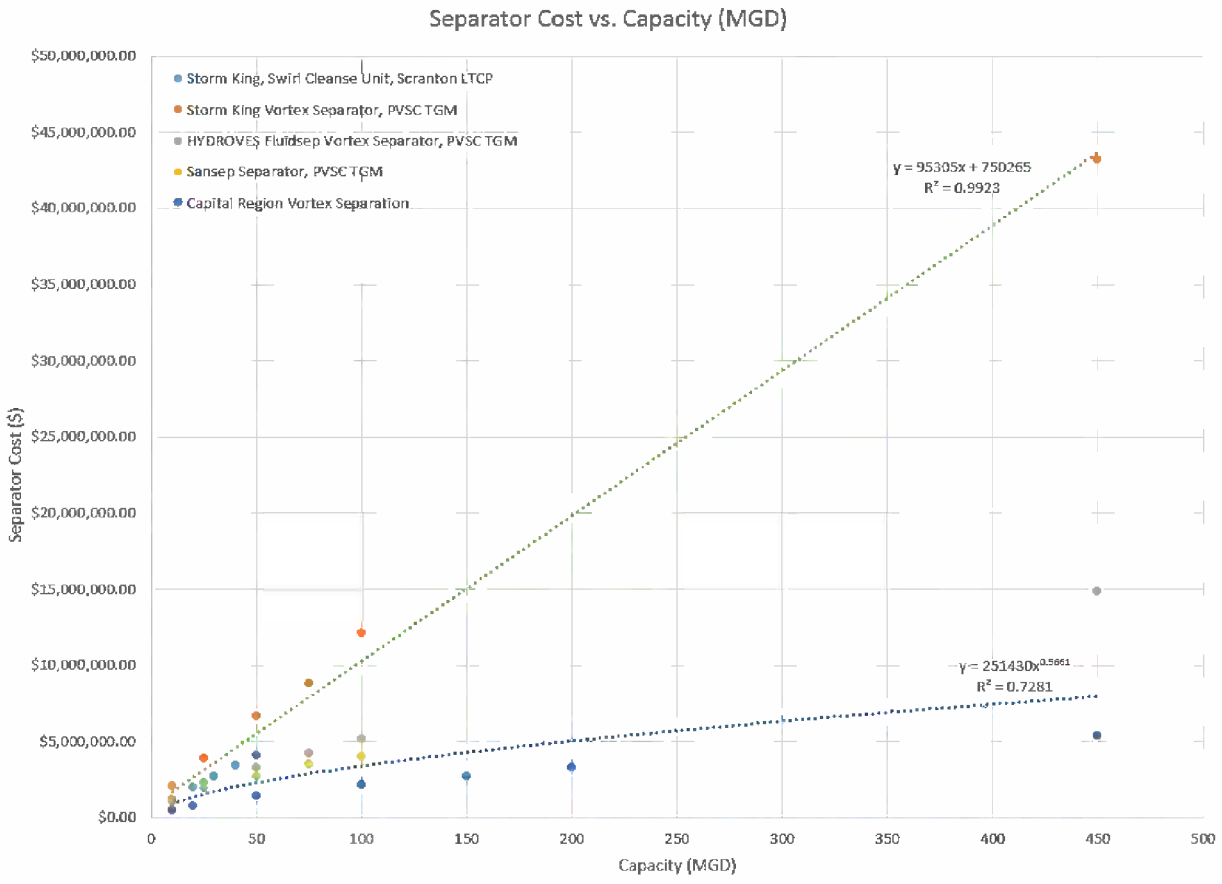
Where Y equals the total cost in million dollars and x equals treatment capacity in MGD.

The resulting capital cost curve for remaining types of settling/separation units, such as the Hydroves and Sansep Separators, is the following:
Y=251,430*X^0.5661

Where Y equals the total cost in million dollars and x equals treatment capacity in MGD.

These trendline equations can be seen in Figure 3 below, with both showing a medium to high R^2 correlation value.

Figure 3: Separator Capital Cost vs. Capacity (MGD)



The resulting life-cycle cost curve for the Storm King unit is the following:

Y=273,236*x+2*10^6

Where Y equals the total cost in million dollars and x equals treatment capacity in MGD.

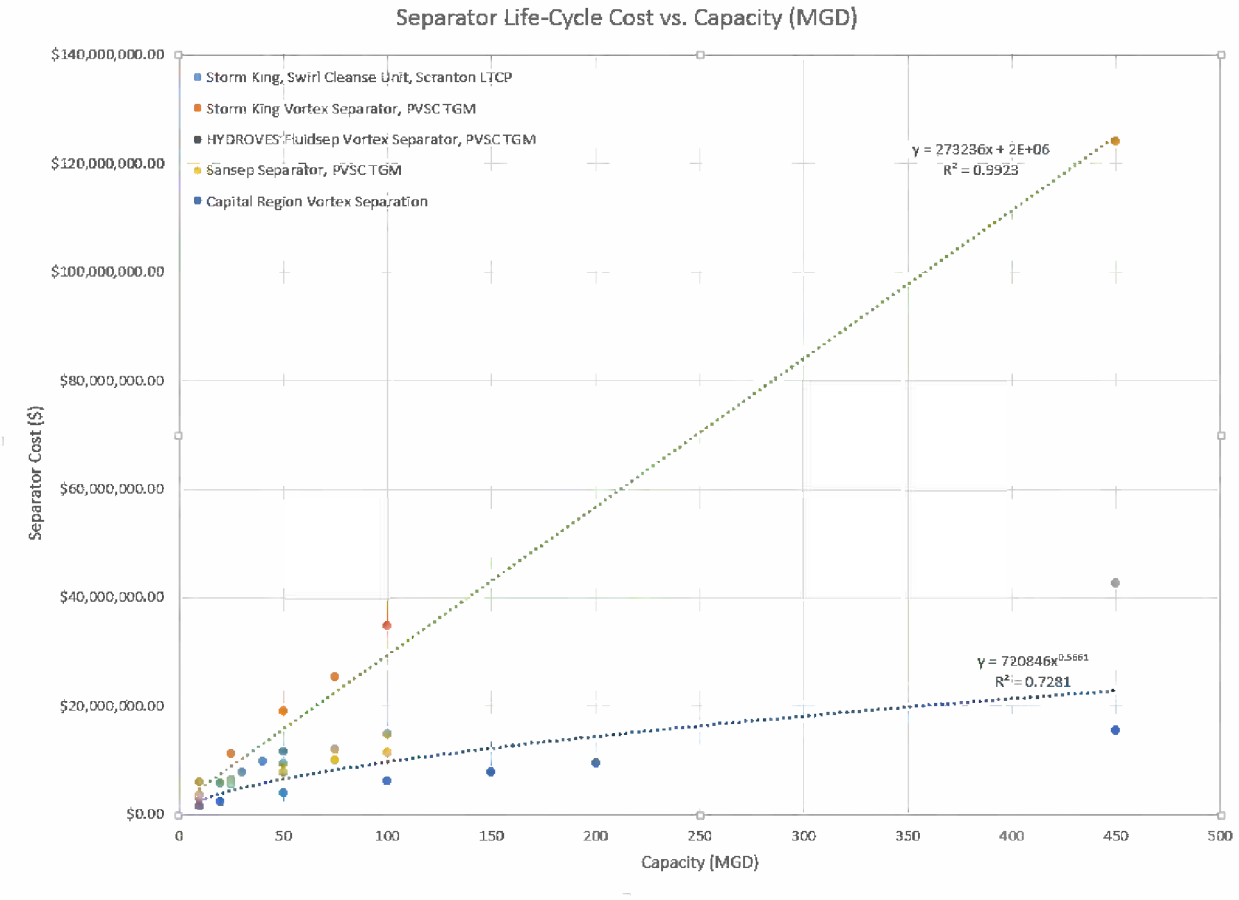
The resulting life-cycle cost curve for remaining types of settling/separation units, such as the Hydroves and Sansep Separators, is the following:

Y=720,846*X^0.5661

Where Y equals the total cost in million dollars and x equals treatment capacity in MGD.

These trendline equations can be seen in Figure 4 below, with both showing a medium to high R^2 correlation value.

Figure 4: Separator Life-Cycle Cost vs Capacity (MGD)



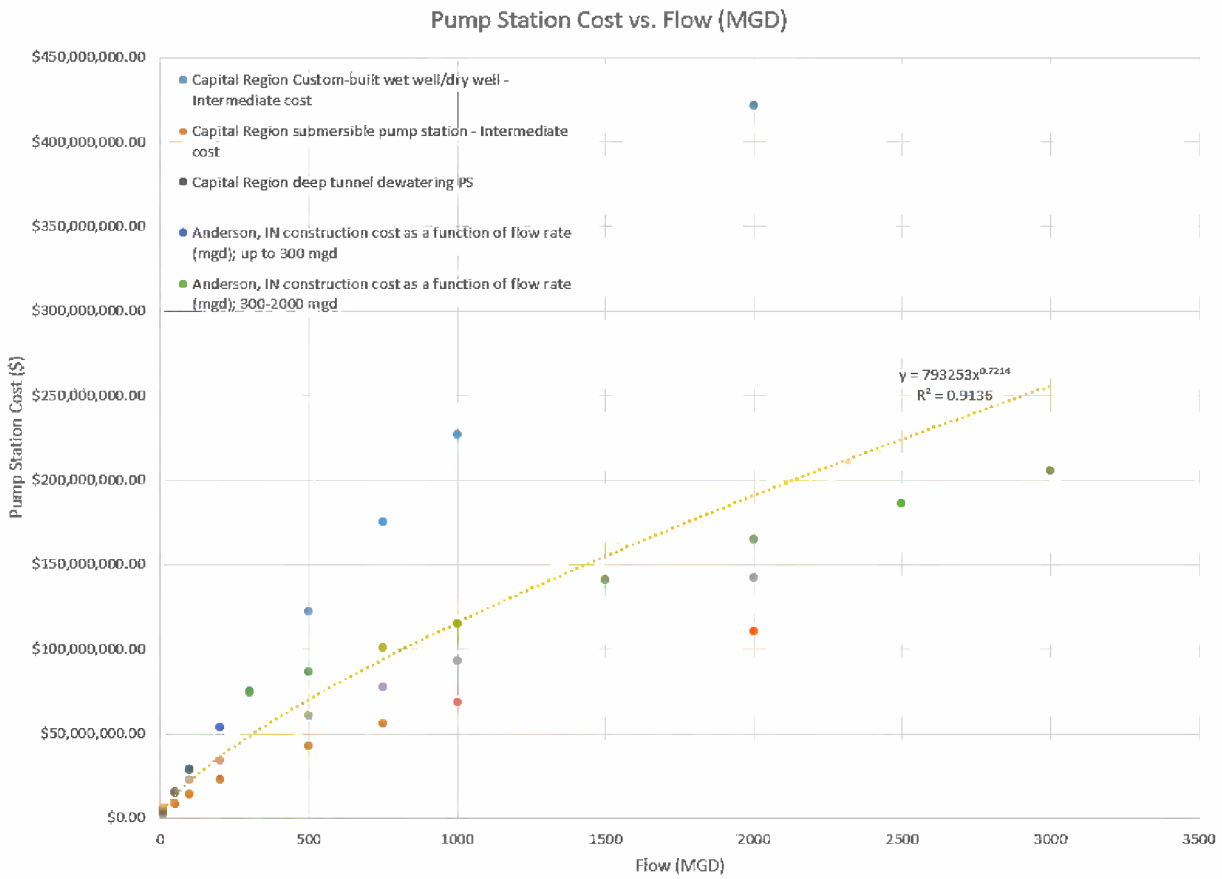
Pump Station

All pump stations in the cost analysis are assumed to be constructed as stand-alone structures and not part of a larger treatment or storage facility and are necessary in order to convey flow from satellite treatment facilities or storage locations. Data sources include cost curve information from Capital Region and Anderson, Indiana. Both sources of data include cost data from actual facilities and EPA cost curves. The Capital Region costs classifies the pump stations as either built wet-well/dry-well facilities or submersible facilities along with giving a range of low, intermediate, and high cost curves to cover the wide variety of pump station installation applications. For the purposes of this exercise the intermediate cost curves were utilized. The resulting capital cost curve for pump stations is the following:

Y=793,253*X^0.7214

Where Y equals the total pump station cost and x equals flow capacity in MGD. The trendline equation can be seen in Figure 5 below, showing a relatively high R^2 correlation value.

Figure 5: Pump Station Capital Cost vs. Flow (MGD)

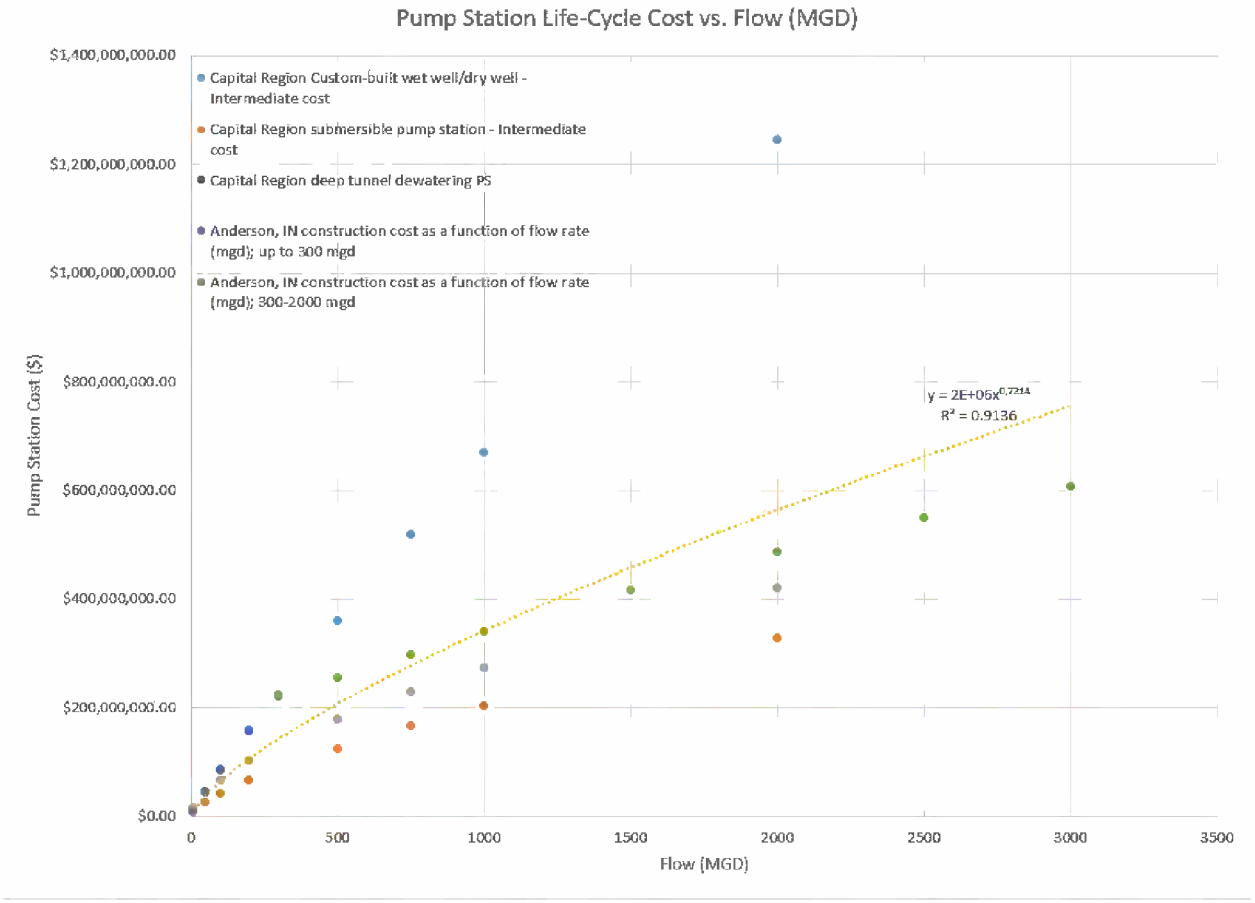


The resulting life-cycle cost curve for pump stations is the following:

Y=2*10^6*X^0.7214

Where Y equals the total pump station cost and x equals flow capacity in MGD. The trendline equation can be seen in Figure 6 below, showing a relatively high R^2 correlation value.

Figure 6: Pump Station Life-Cycle Cost vs. Flow (MGD)



Installed Offline Storage – 15-ft and 22-ft Side-Wall Depth

The purpose of offline storage as a Control Technology in this project is to store flow during peak discharges when interceptors can no longer handle additional flow. Offline storage tanks are located so as to not be on the typical dry weather flow path and only be utilized when needed during wet weather. When free to accept additional flow, the interceptors can slowly accept this additional offline storage and allow it to re-enter the conveyance system. It is assumed that these offline storage volumes would both be fed and discharge via gravity, thus making it a cheaper alternative as pump stations are not needed. However, detailed design is needed to figure out whether this is in fact the case (not needing pump stations).

Cost data is taken from the PVSC TGM. Additional data was mined from Capital Region and Scranton LTCP, however this data did not match up well with the PVSC TGM data. Based on engineering judgment, it was decided to proceed with using cost data from the PVSC TGM. The data utilized for this estimate is for concrete tanks that is inclusive of all ancillary facilities for an offline storage tank. The resulting capital cost curve for installed offline storage – 15-ft side-wall depth is the following:

Y=3E+06*x + 2E+06

Where Y equals the total in million dollars and x equals the tank capacity in MG.

The resulting capital cost curve for installed offline storage – 20-ft side-wall depth is the following:

Y=2E+06*x + 4E+06

Where Y equals the total in million dollars and x equals the tank capacity in MG.

These trendline equations can be seen in Figure 7 and 8 below, with both showing high R^2 correlation.

Figure 7: Installed Offline Storage Capital Cost – 15-ft Side-Wall Depth

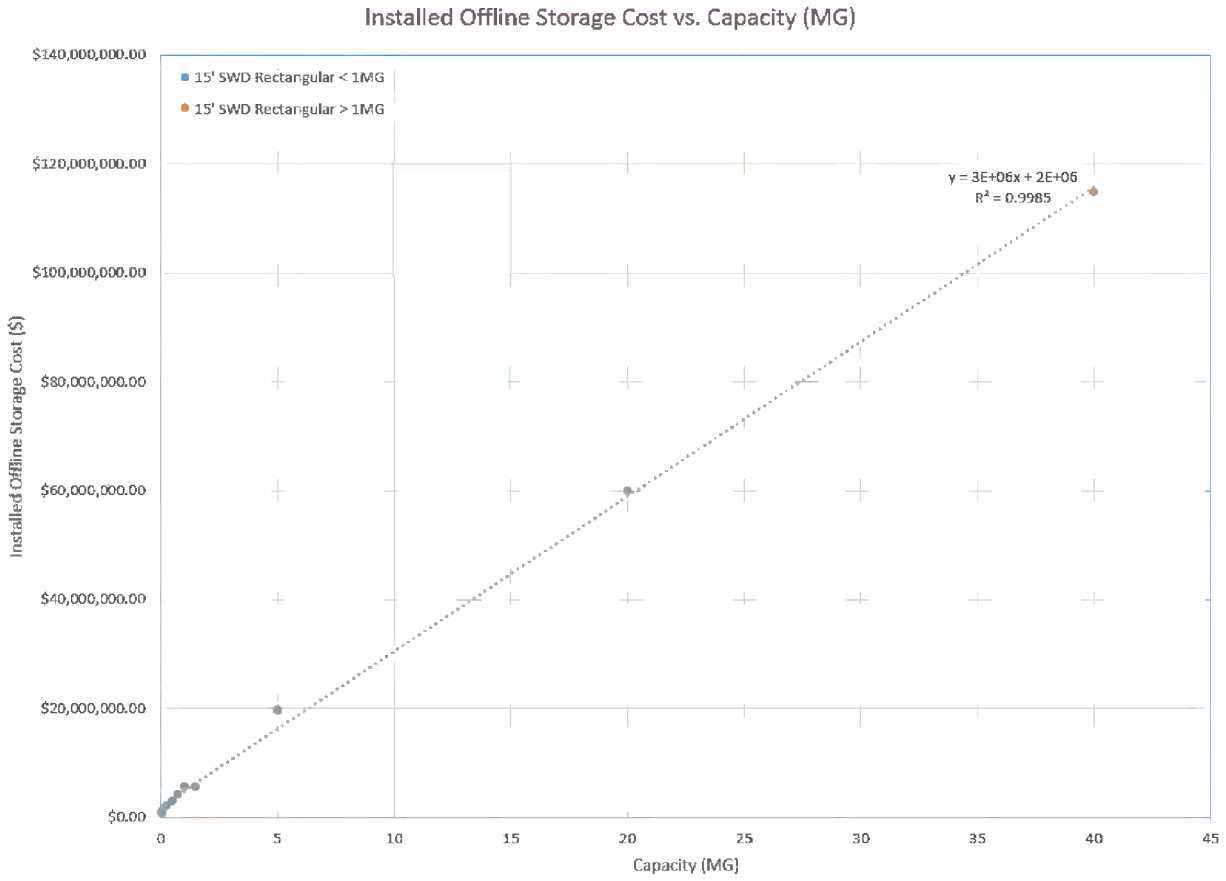


Figure 8: Installed Offline Storage Capital Cost – 22-ft Side-Wall Depth

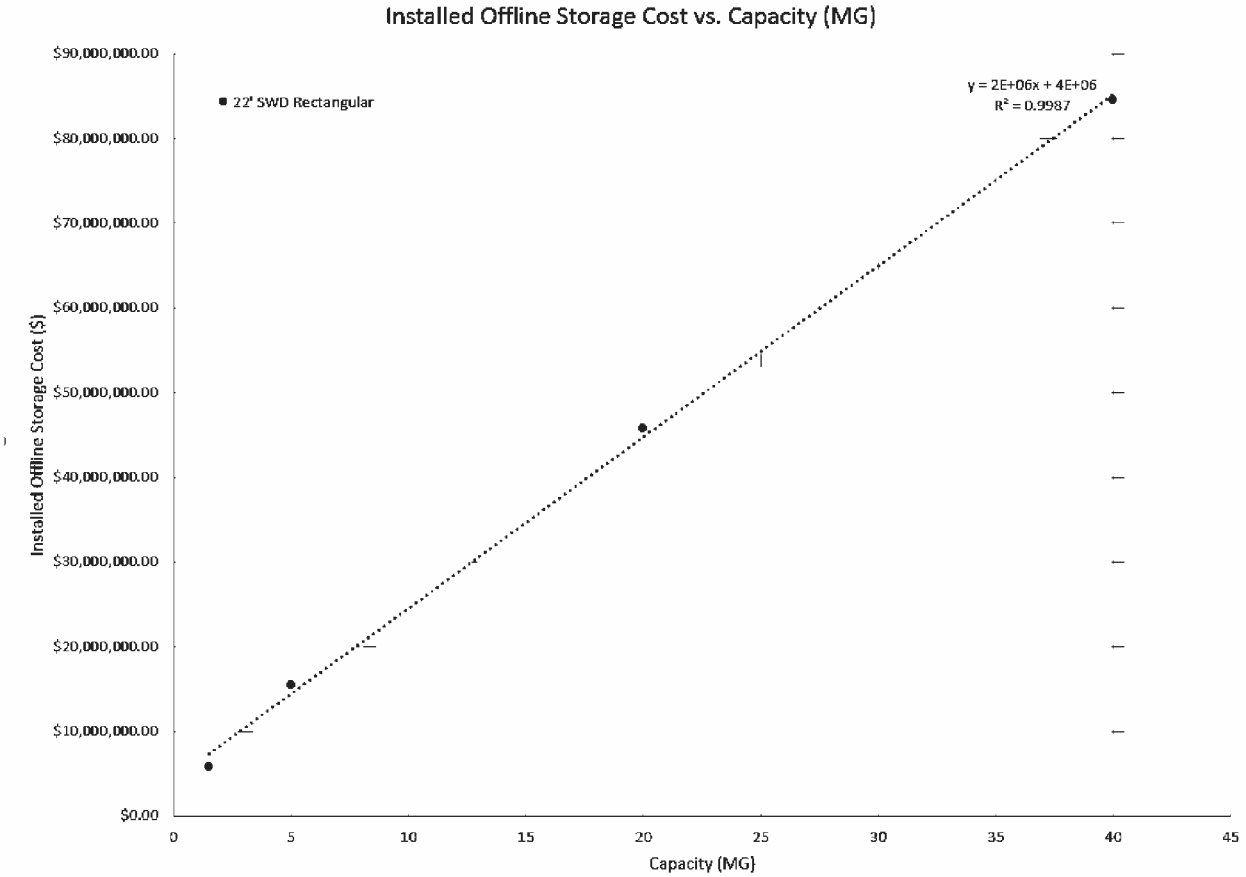

The resulting life-cycle cost curve for installed offline storage – 15-ft side-wall depth is the following:

Y=8E+06*x +6E+06

Where Y equals the total in million dollars and x equals the tank capacity in MG.

The resulting capital cost curve for installed offline storage – 22-ft side-wall depth is the following:

Y=6E+06*x + 1E+07

Where Y equals the total in million dollars and x equals the tank capacity in MG.

These trendline equations can be seen in Figure 9 and 10 below, with both showing high R^2 correlation.

Figure 9: Installed Offline Storage 15' SWD Life-Cycle Cost vs Capacity (MG)

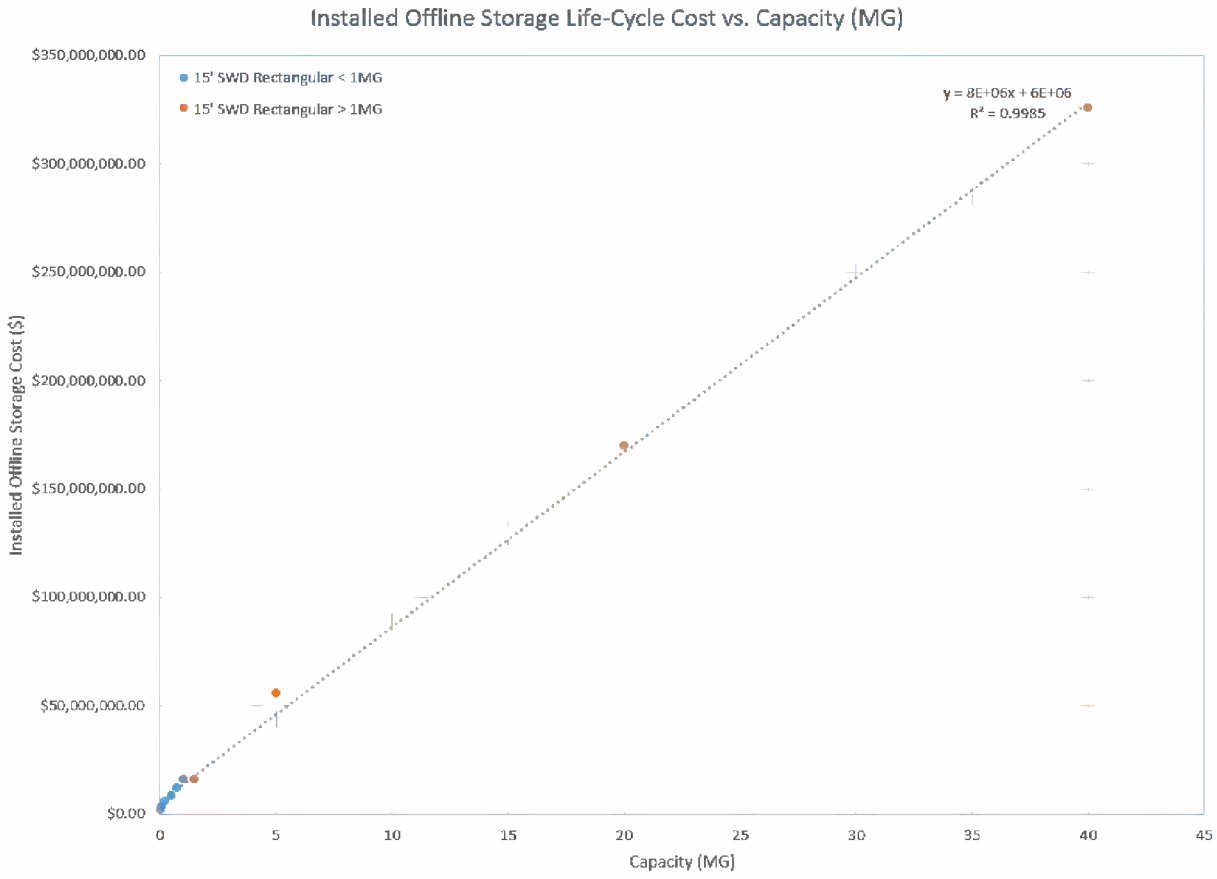

Figure 10: Installed Offline Storage 22' SWD Life-Cycle Cost vs Capacity (MG)

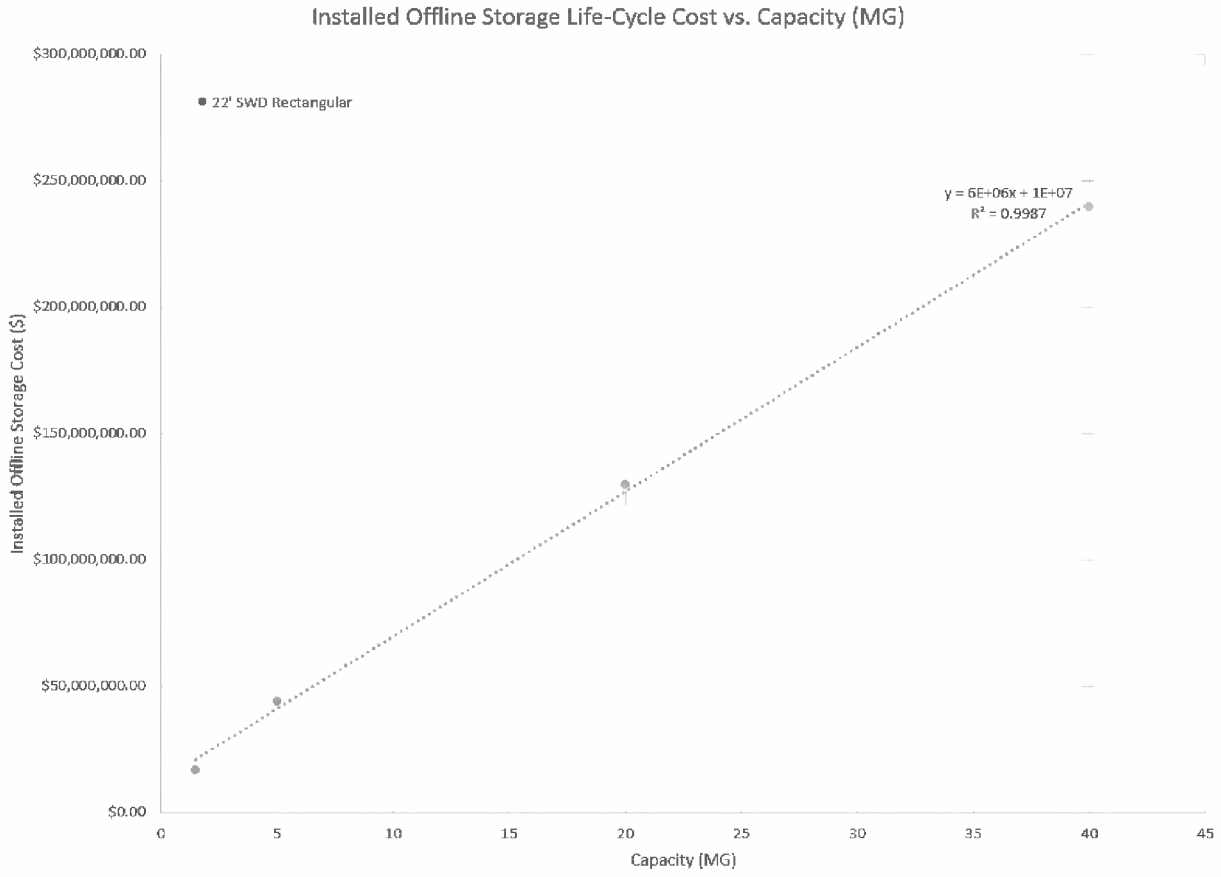

Deep Tunnel Storage

Deep tunnel storage is one of the global Consent Decree requirements that has to be investigated as part of the Alternatives Analysis. Due to the overall complexity of drilling deep tunnels for storage use, this alternative has multiple cost curves to take into account different scenarios. Specific examples include soft ground both below and above groundwater and tunneling within rock for tunnels less than 10,000-ft in length. Similar in use to offline storage, the capture and storage of CSO discharges takes place so as to limit volume within the combined sewer system during wet weather events. Data sources include cost curve information from PVSC TGM and Anderson, Indiana with cost information taken from previously completed projects. It should be noted that drop shafts are not included as part of the per linear foot cost of deep tunneling. The resulting capital cost curve equation for tunneling less than 10,000-ft in soft ground below groundwater is:

Y=263.25*x + 1,652.9

Where Y equals pipe cost per linear foot and x is the size of tunnel in feet.

The resulting capital cost curve equation for tunneling less than 10,000-ft in soft ground above groundwater is:

Y=1,359.1*e^0.0645*x

Where Y equals pipe cost per linear foot and x is the size of the tunnel in feet.

The resulting capital cost curve equation for tunneling less than 10,000-ft in rock is:

Y=203.43*x + 1,273.7

Where Y equals pipe cost per linear foot and x is the size of the tunnel in feet.

The resulting capital cost curve equation for tunneling greater than 10,000-ft is:

Y=187.93*x + 148.3

Where Y equals pipe cost per linear foot and x is the size of the tunnel in feet.

The trendline equations for the above show medium to very high R^2 correlation values.

Figure 11: Deep Tunnel < 10,000-ft Pipe Cost Per Linear Foot vs. Size (feet)

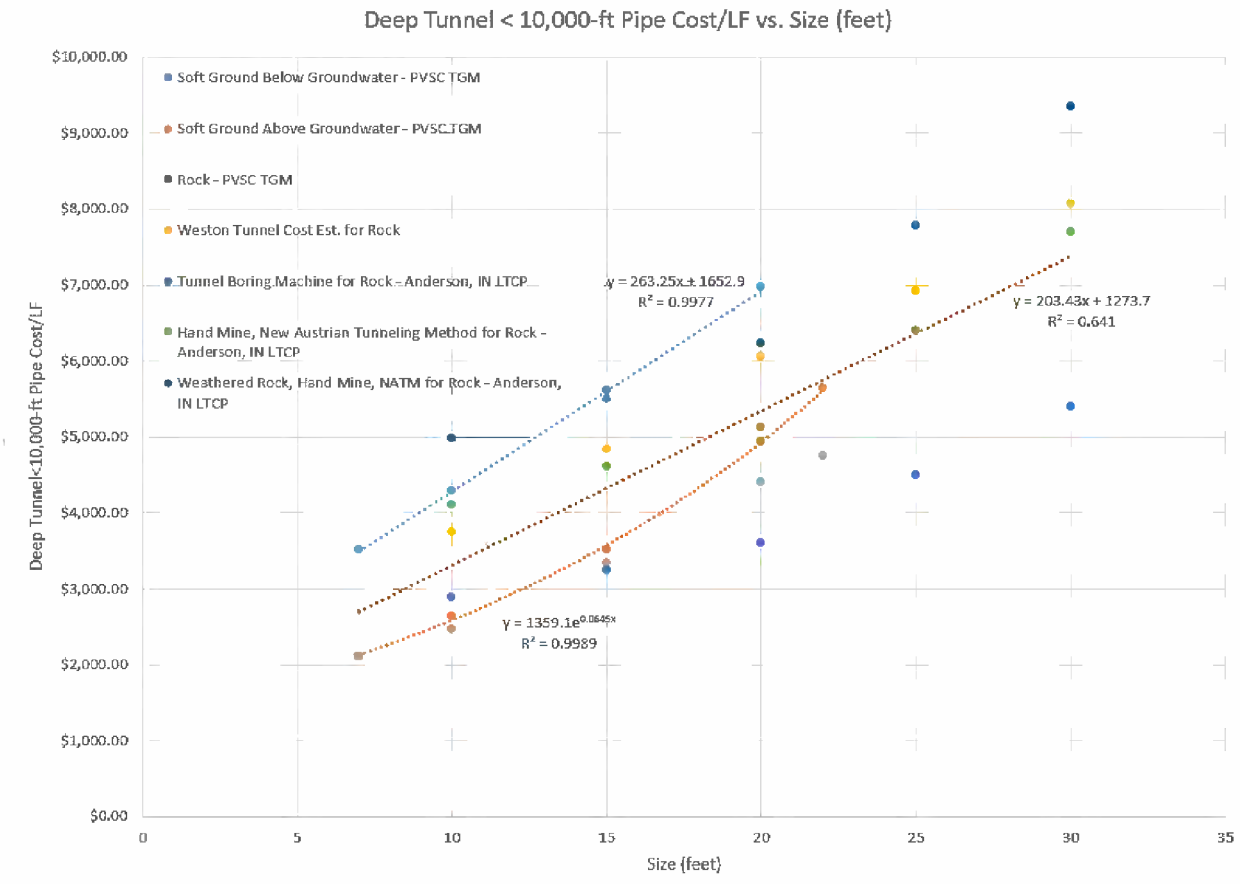

Figure 12: Deep Tunnel > 10,000-ft Pipe Cost Per Linear Foot vs. Size (feet)

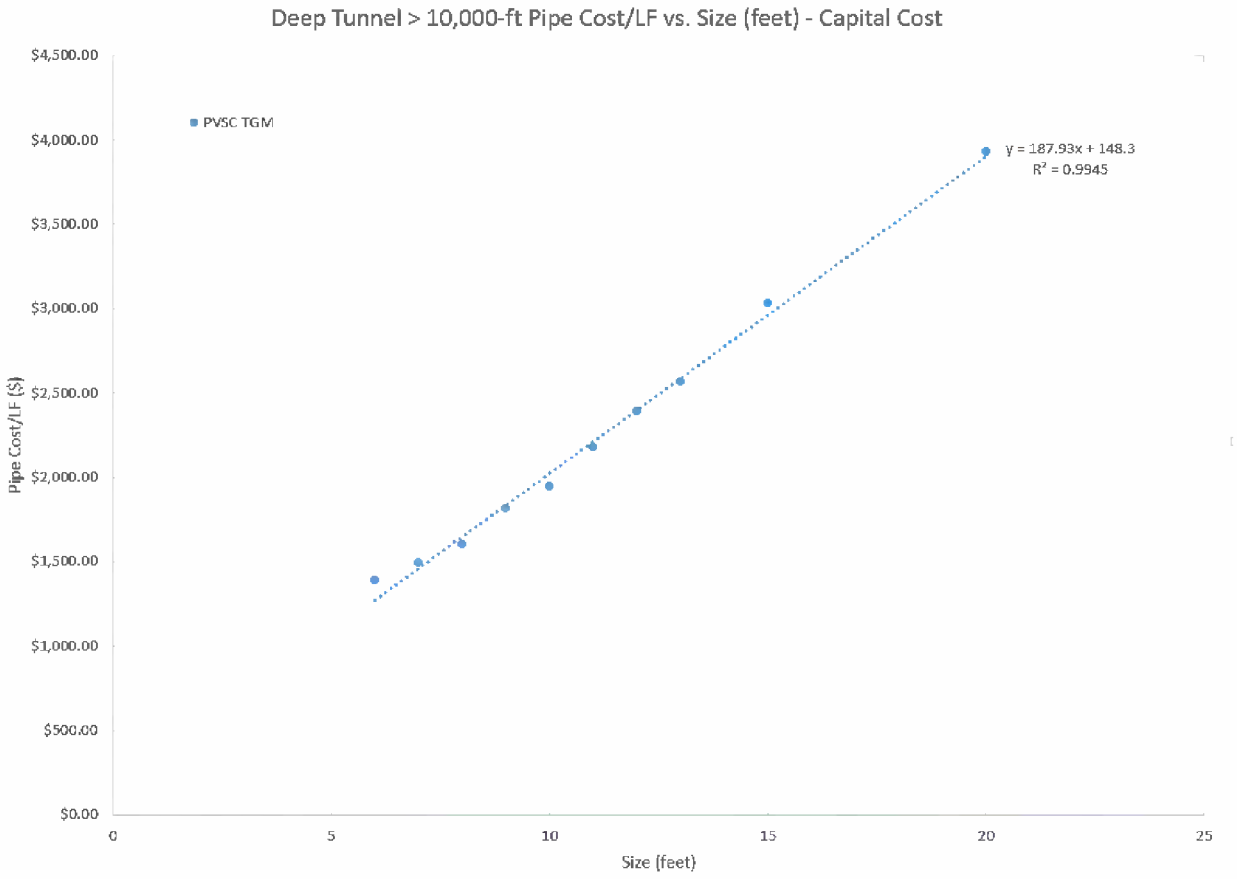

The resulting life-cycle cost curve equation for tunneling less than 10,000-ft in soft ground below groundwater is:

Y=623.16*x + 3,912.6

Where Y equals pipe cost per linear foot and x is the size of tunnel in feet.

The resulting life-cycle cost curve equation for tunneling less than 10,000-ft in soft ground above groundwater is:

Y=3,217.3*e^0.0645*x

Where Y equals pipe cost per linear foot and x is the size of the tunnel in feet.

The resulting capital cost curve equation for tunneling less than 10,000-ft in rock is:

Y=481.55*x + 3,015.2

Where Y equals pipe cost per linear foot and x is the size of the tunnel in feet.

The resulting life-cycle cost curve equation for tunneling greater than 10,000-ft is:

Y=444.85*x + 351.04

Where Y equals pipe cost per linear foot and x is the size of the tunnel in feet.

The trendline equations for the above show medium to very high R^2 correlation values.

Figure 13: Deep Tunnel<10,000-ft Pipe Life-Cycle Cost/LF vs. Size (feet)

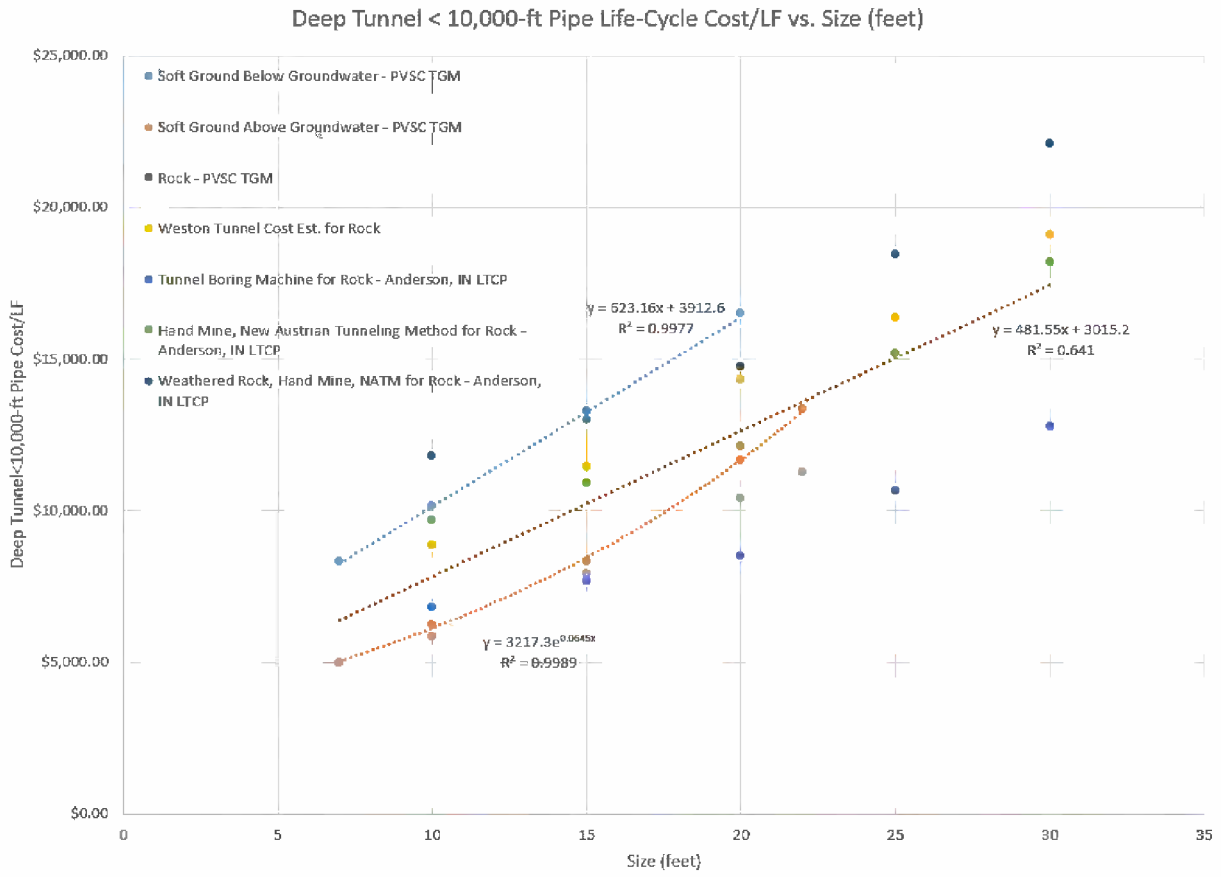

Figure 14: Deep Tunnel>10,000-ft Pipe Life-Cycle Cost/LF vs. Size (feet)

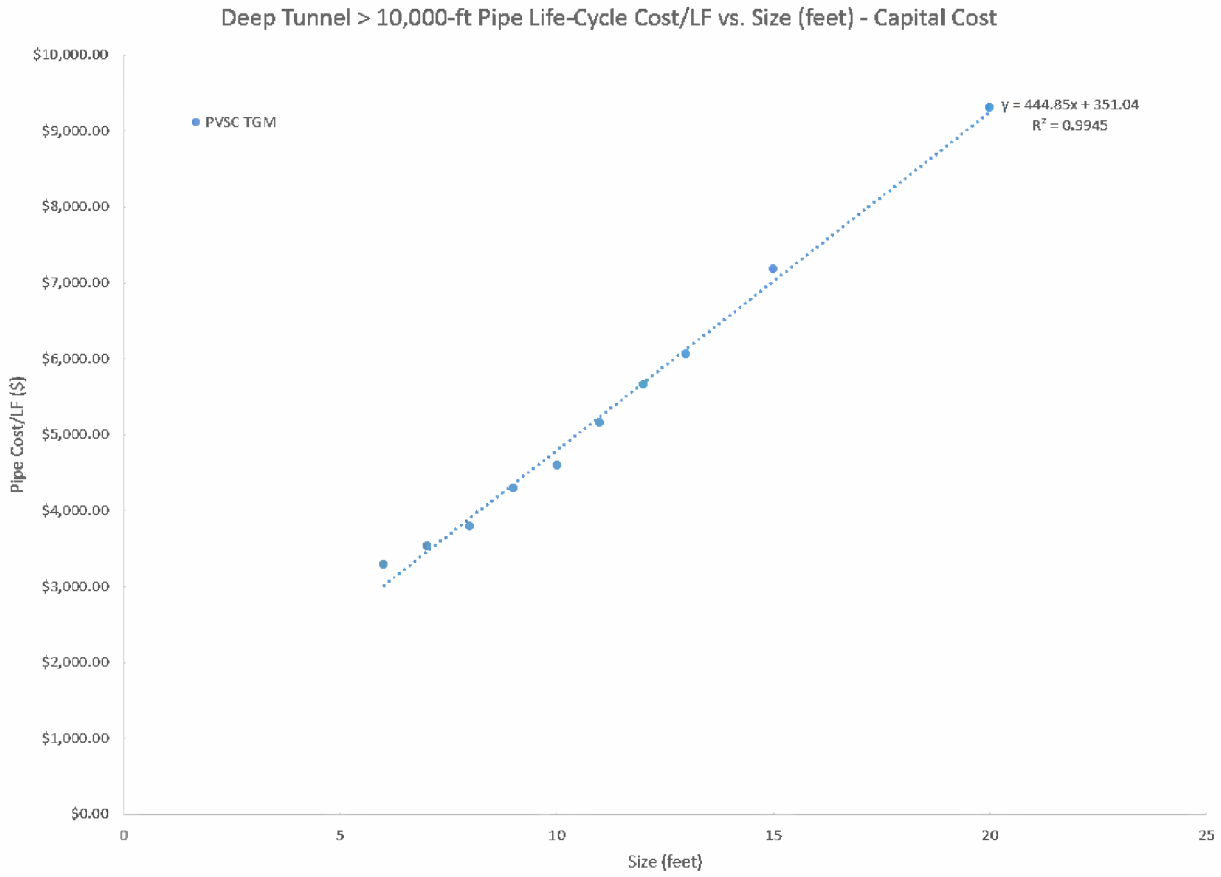


In addition, the use of tunnel drop shafts is needed to convey flow from the ground elevation down to tunnel level. Drop shafts vary in depth depending on the application and typically include tangential inlets, the drop shaft itself, and a deaeration chamber. Cost curves were developed for drop shafts as well, which include cost for tangential inlets and the deaeration chamber in addition to the drop shaft. Data sources for the drop shaft cost curves are PVSC TGM and Anderson, Indiana LTCP. It should be noted that two cost curves exist as the data sources were for different depths of drop shafts from which the data was collected. PVSC TGM assumes no greater than 30-ft depth, whereas Anderson, Indiana assumes a 50-ft depth. The capital cost curve for PVSC TGM – no greater than 30-ft depth is the following:

$Y=1,305.2*\ln(x) - 130.89$

Where Y equals cost per vertical foot of drop shaft and x equals flow capacity of the drop shaft in MGD.

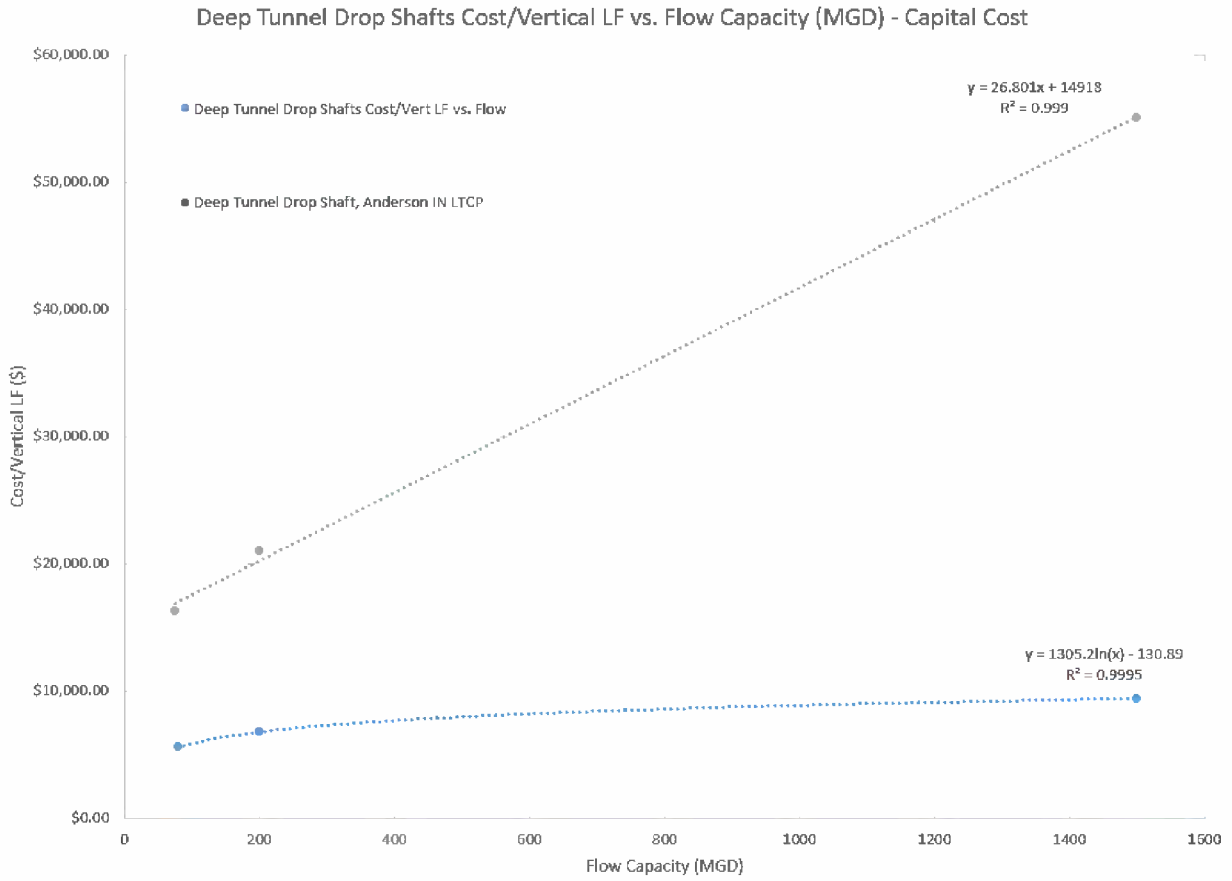
The capital cost curve for Anderson, Indiana – 50-ft depth is the following:

$Y=26.801*x + 14,918$

Where Y equals cost per vertical foot of drop shaft and x equals flow capacity of the drop shaft in MGD.

The trendline equations for the above slow very high R^2 correlation values.

Figure 15: Deep Tunnel Drop Shafts Cost/Vertical Foot vs Flow Capacity (MGD)



The cost curve for PVSC TGM – no greater than 30-ft depth is the following:

Y=3,089.6*ln(x) – 309.84

Where Y equals cost per vertical foot of drop shaft and x equals flow capacity of the drop shaft in MGD.

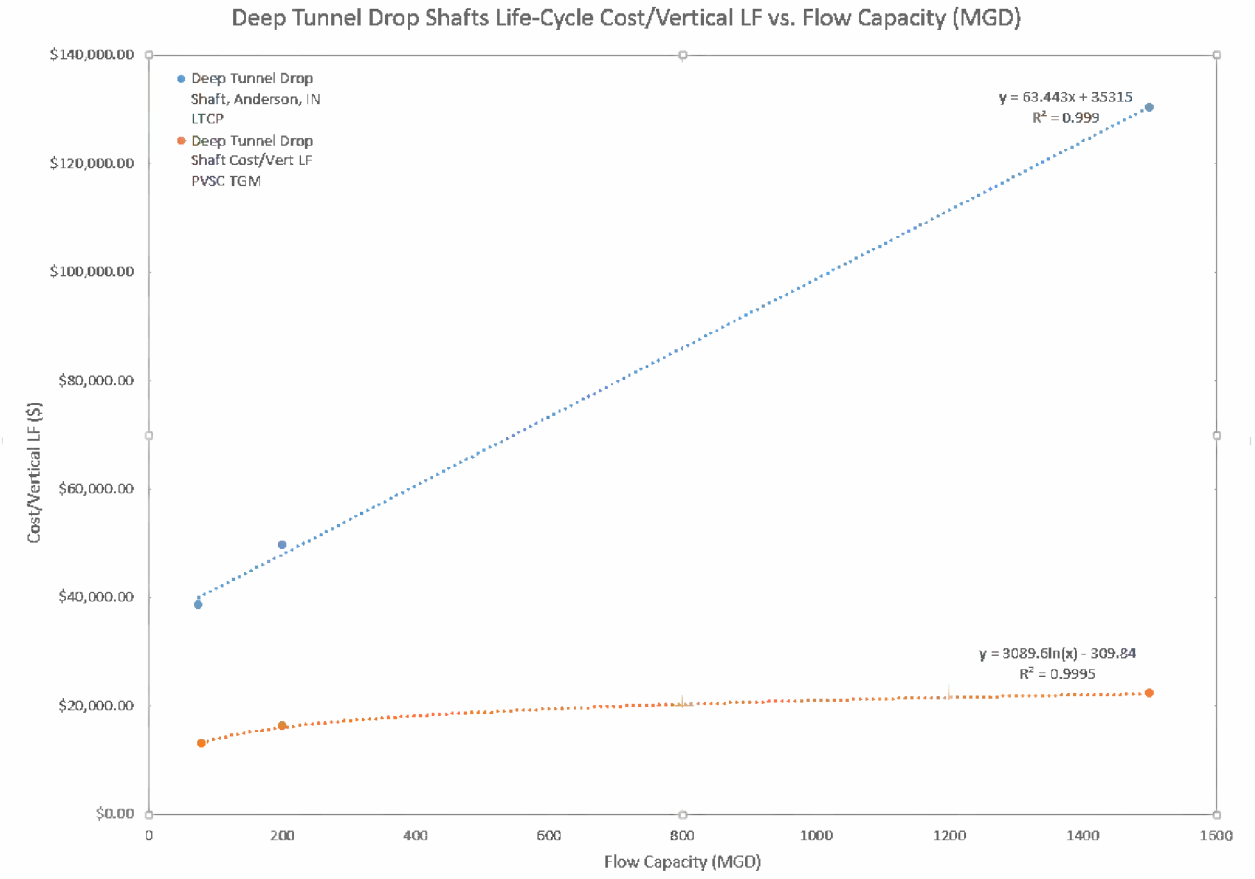
The cost curve for Anderson, Indiana – 50-ft depth is the following:

Y=63.443*x + 35,315

Where Y equals cost per vertical foot of drop shaft and x equals flow capacity of the drop shaft in MGD.

The trendline equations for the above slow very high R^2 correlation values.

Figure 16: Deep Tunnel Drop Shafts Life-Cycle Cost/Vertical LF vs. Flow Capacity (MGD)



Installed Pipe

Pipe installation consists of the means of transmitting CSO discharges to storage areas along with placing parallel interceptor piping to add conveyance where needed. This method of pipe installation does not consist of pipeline storage as deep tunnel storage does. To divert excess flow into a parallel interceptor a diversion structure would be needed, which is not accounted for in these cost curves. In addition, the cost curve takes into account the cost to install the pipe, but does not take into account restoration of the pipe installation. Data sources include cost curve information from PVSC TGM, Anderson, Indiana and Scranton LTCP. Due to pipe needing to be installed at various depths because of utilities and existing connections to pipes, cost curves for various depths of pipes are given at 10-, 15-, 20-, and 25-ft depths. The resulting capital cost curve for installed pipe at 10-ft depth is the following:

Y=10.696*x + 12.935

Where Y equals pipe cost per linear foot and x equals the size of pipe in inches.

The resulting capital cost curve for installed pipe at 15-ft depth is the following:

Y=297.84*e^0.0182*x

Where Y equals pipe cost per linear foot and x equals the size of pipe in inches.

The resulting capital cost curve for installed pipe at 20-ft depth is the following:

443.63*e^0.0167*x

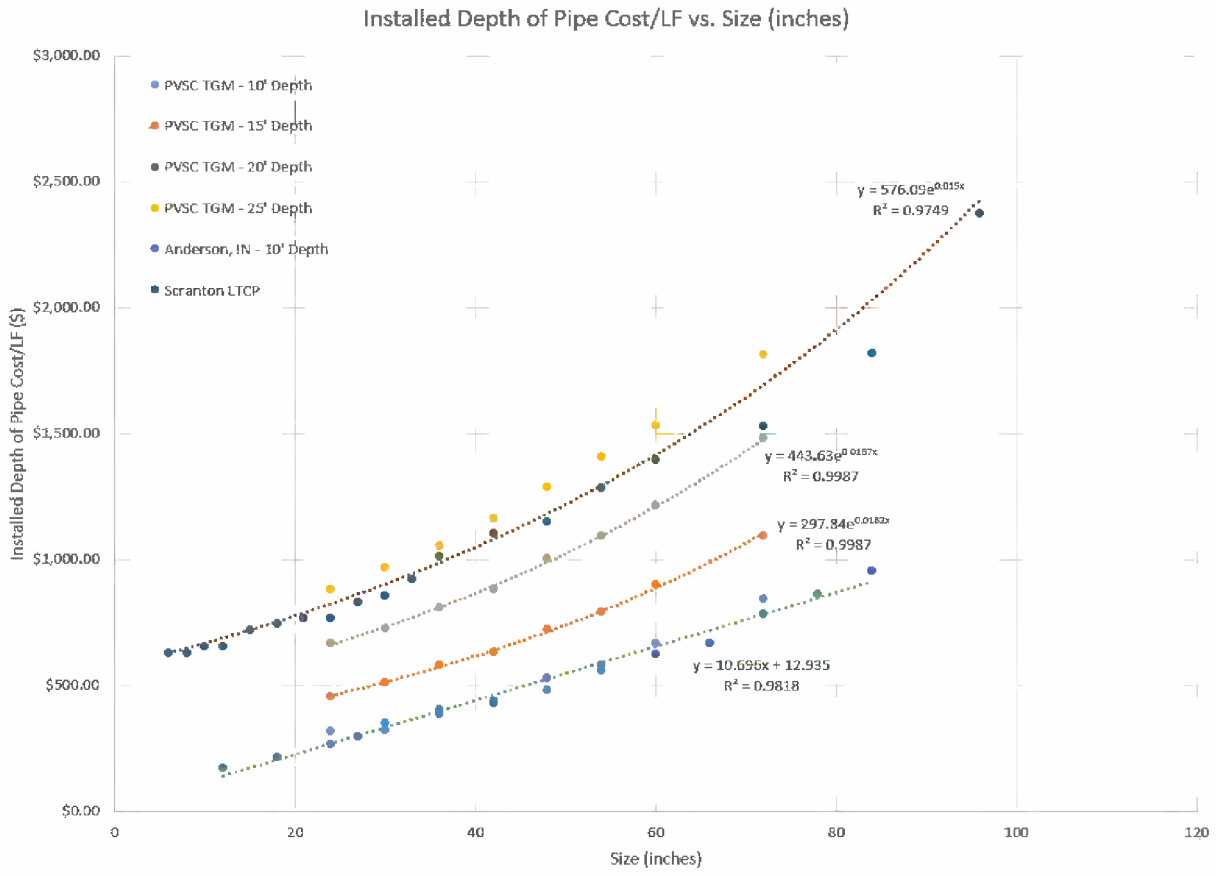
Where Y equals pipe cost per linear foot and x equals the size of pipe in inches.

The resulting capital cost curve for installed pipe at 25-ft depth is the following:

Y=576.09*e^0.015*x

The trendline equations for the above show very high R^2 correlation values.

Figure 17: Installed Depth of Pipe Capital Cost/Linear Foot vs. Size (inches)



The resulting capital cost curve for installed pipe at 10-ft depth is the following:

Y=20.882*x + 13.166

Where Y equals pipe cost per linear foot and x equals the size of pipe in inches.

The resulting capital cost curve for installed pipe at 15-ft depth is the following:

Y=584.47*e^0.0182*x

Where Y equals pipe cost per linear foot and x equals the size of pipe in inches.

The resulting capital cost curve for installed pipe at 20-ft depth is the following:

Y=870.55*e^0.0167*x

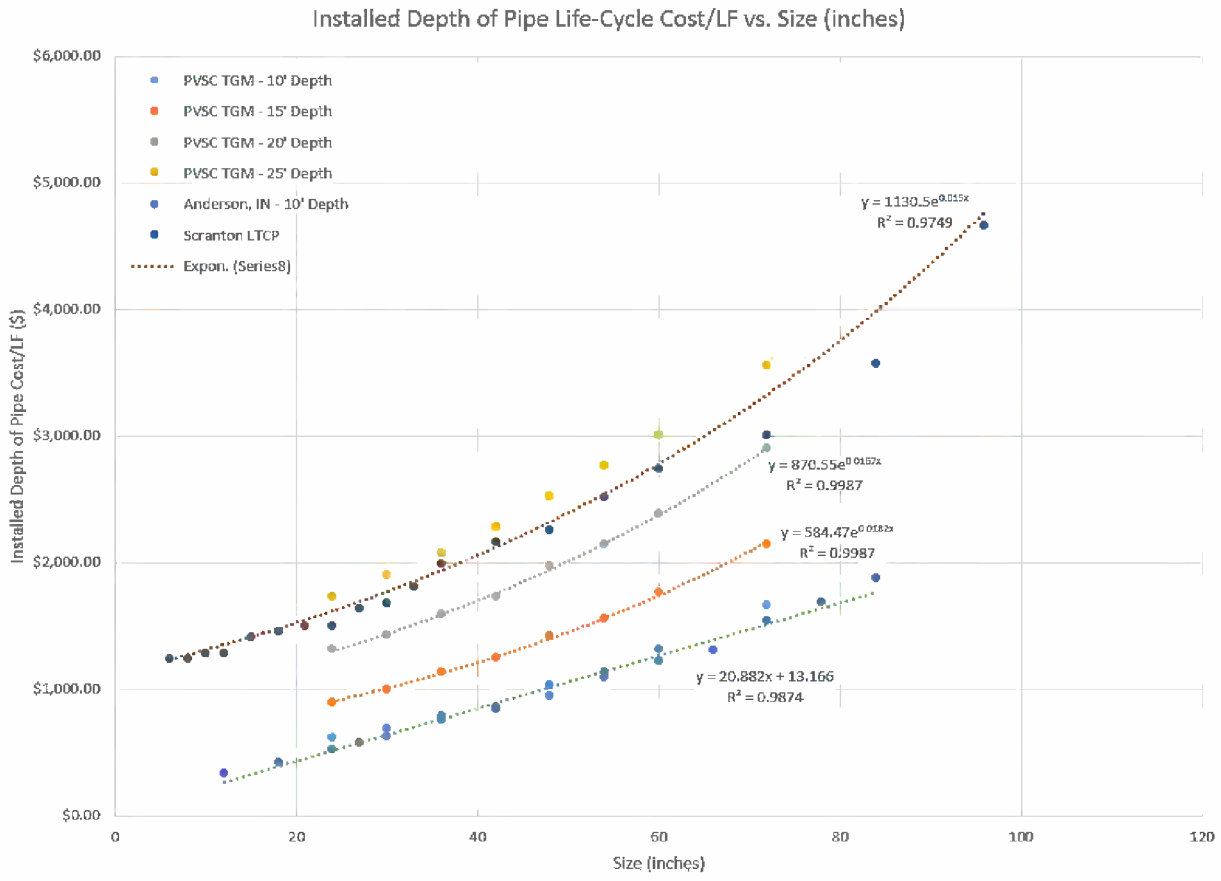
Where Y equals pipe cost per linear foot and x equals the size of pipe in inches.

The resulting capital cost curve for installed pipe at 25-ft depth is the following:

Y=1130.5*e^0.015*x

The trendline equations for the above show very high R^2 correlation values.

Figure 18: Installed Depth of Pipe Life-Cycle Cost/Linear Foot vs. Size (inches)



Wet Weather Blending

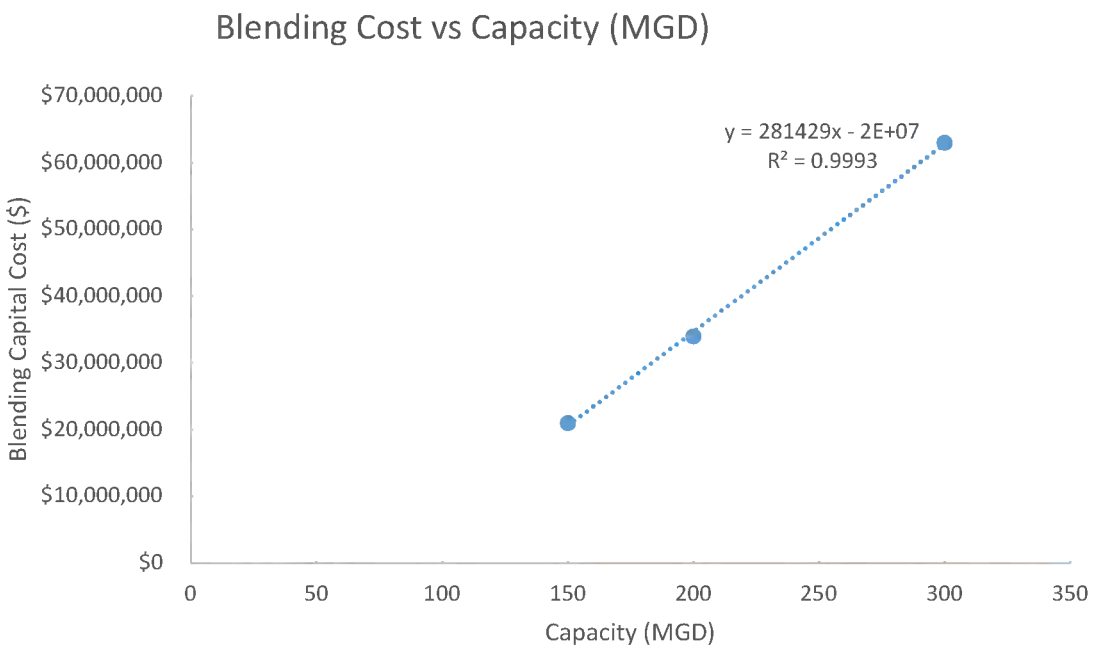
In the wet weather blending option, the additional wet weather flow undergoes the preliminary and primary treatment and then is directly conveyed to the disinfection process. The blended additional wet weather flow with the fully treated and disinfected flow is then discharged. The Wet Weather Blending option alone may not be able to meet the effluent quality standards and will achieve 78% TSS and 56% CBOD removal.

For estimation of the probable costs, 3 flow scenarios of 150, 200 and 300 MGD were considered for expansion of the plant's wet weather treatment capacity. Data sources for the budgetary capital cost estimate of 200 and 300 MGD scenarios include DELCORA Long-Term CSO Control Plan – Weston Solutions. The same costs have been adjusted for the 150 MGD flow scenario. The total capital cost used for cost curve construction does not include the chemical cost for chemically enhanced primary treatment, CEPT. The resulting capital cost curve for blending is the following:

Y = 281429x – 2E+07

Where Y equals the total cost in million dollars and x equals treatment capacity in MGD. This trendline equation can be seen in Figure 19 below, and shows a high R^2 correlation value.

Figure 19. Blending Capital Cost vs Capacity



BIOACTIFLO

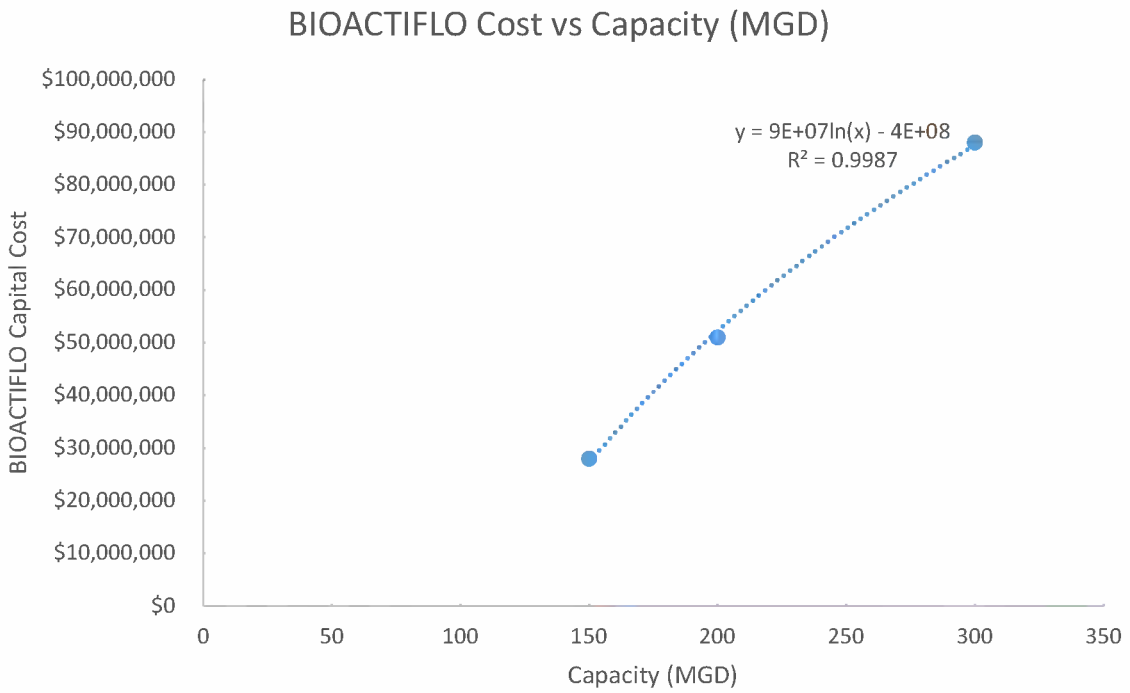
The BIOACTIFLO is a modified version of blending and provides enhanced treatment of additional wet weather flow through the combination of high rate biological treatment as well as high rate ballasted settling to meet the regulatory effluent standards. The additional wet weather flow that does not receive biological treatment in the plant's activated sludge process is treated by temporarily routing return activate sludge to a small aeration tank that is a part of the BIOACTIFLO process to achieve high rate biological treatment. The estimated effluent CBOD and TSS concentrations for BIOACTIFLO option are ≤ 25 mg/L and ≤ 30 mg/L respectively

Again, for the estimation of the probable costs, 3 flow scenarios of 150, 200 and 300 MGD were considered for expansion of the plant's wet weather treatment capacity to draw a comparison between the BIOACTIFLO and Blending option. Data sources for the budgetary capital cost estimate of 200 and 300 MGD flow scenarios include DELCORA Long-Term CSO Control Plan – Weston Solutions. The same costs have been adjusted to get the cost for 150 MGD scenario. The resulting capital cost curve for BIOACTIFLO is the following:

Y = 395714x – 3E+07

Where Y equals the total cost in million dollars and x equals treatment capacity in MGD. This trendline equation can be seen in Figure 20, and shows a high R^2 correlation value.

Figure 20: BIOACTIFLO Capital Cost vs Capacity



For any plant expansion costs, equivalent piping and pump additions or improvements to convey the proposed improvements must also be added for each alternative.

High Rate Clarification System (Actiflo)

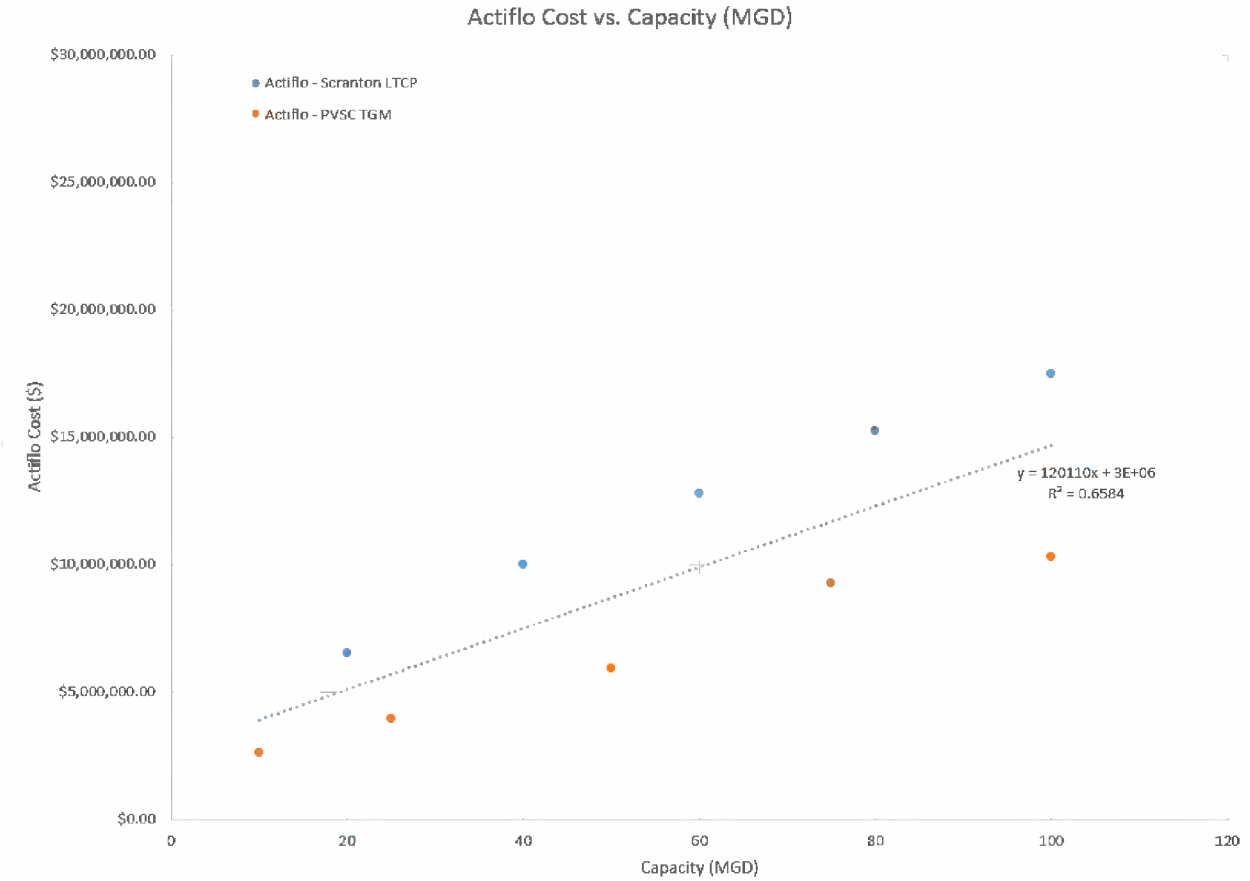
High rate clarification systems are to be used in the event primary treatment is needed at storage areas. These systems provide treatment at a quicker rate than conventional treatment systems along with having a decreased footprint. More specifically, a ballasted flocculation system increases the settling velocity of solids with the use of fine sands, polymer and coagulants. Actiflo® is a manufacturer of ballasted flocculation systems in particular. Data sources include cost curve information from PVSC TGM and Scranton LTCP with information from previous projects and actual installed costs being part of this data compilation. The resulting capital cost curve equation for high rate clarification systems is:

Y=120,110*x + 3E+06

Where Y equals the total Actiflo cost and x equals capacity in MGD.

The trendline equation for the above shows medium R^2 correlation.

Figure 21: Actiflo Capital Cost vs. Capacity (MGD)



The resulting life-cycle cost curve equation for high rate clarification systems is:

Y=344,354*x + 8E+06

Where Y equals the total Actiflo cost and x equals capacity in MGD.

The trendline equation for the above shows medium R^2 correlation.

Regulator Modification

Regulator modification is a lower-cost option for existing regulators to passively reduce CSO overflow and maximize flow to the existing interceptors. Each CSO regulator is modified in different ways to achieve this goal, but the different modifications used in this report are increasing overflow weir height, increasing the regulator gate opening, increasing the orifice plate opening, and increasing the outflow pipe diameter to the connecting interceptor. The weir height increase allows the regulator to utilize the existing upstream pipe as temporary storage, while also utilizing the connecting interceptor's flow capacity better during storm events. Waterware is currently replacing or modifying the existing regulators for DELCORA, and was contacted for cost estimates on the regulator modifications listed above. The modifications focused on improving the regulator itself, and excluded external items which could vary greatly depending on each structure, including outflow pipe replacement, permitting, traffic control, asphalt paving, access cover replacement, and labor associated with these items. Since the greatest cost involves the regulator gate modification, three inclusive costs were given based on the size of standard gate sizes:

12" x 12" = $175,000
15" x 15" = $180,000
18" x 18" = $215,000

Waterware gave a high-end cost for access covers at $2,000, and labor costs for a general purpose laborer with a Superintendent supervising the work is $4,750 per week. Assuming each regulator takes a week or work to modify, the cost is rounded up to $10,000 to account for traffic control, asphalt paving, and scaffolding for the access covers, all of which can vary depending on the location and depth of each CSO and decrease with scale. Installed pipe costs were used to estimate the outflow pipe replacement.

The increase in flow to the receiving interceptors will increase flow to the WRTP, and so wet weather treatment costs may also be incorporated into the regulator modification costs for each alternative as needed. The actual need for plant expansion may be mitigated by additional CSO control technologies, however, and a study during post-construction monitoring should be conducted to determine the actual needs of the WRTP.

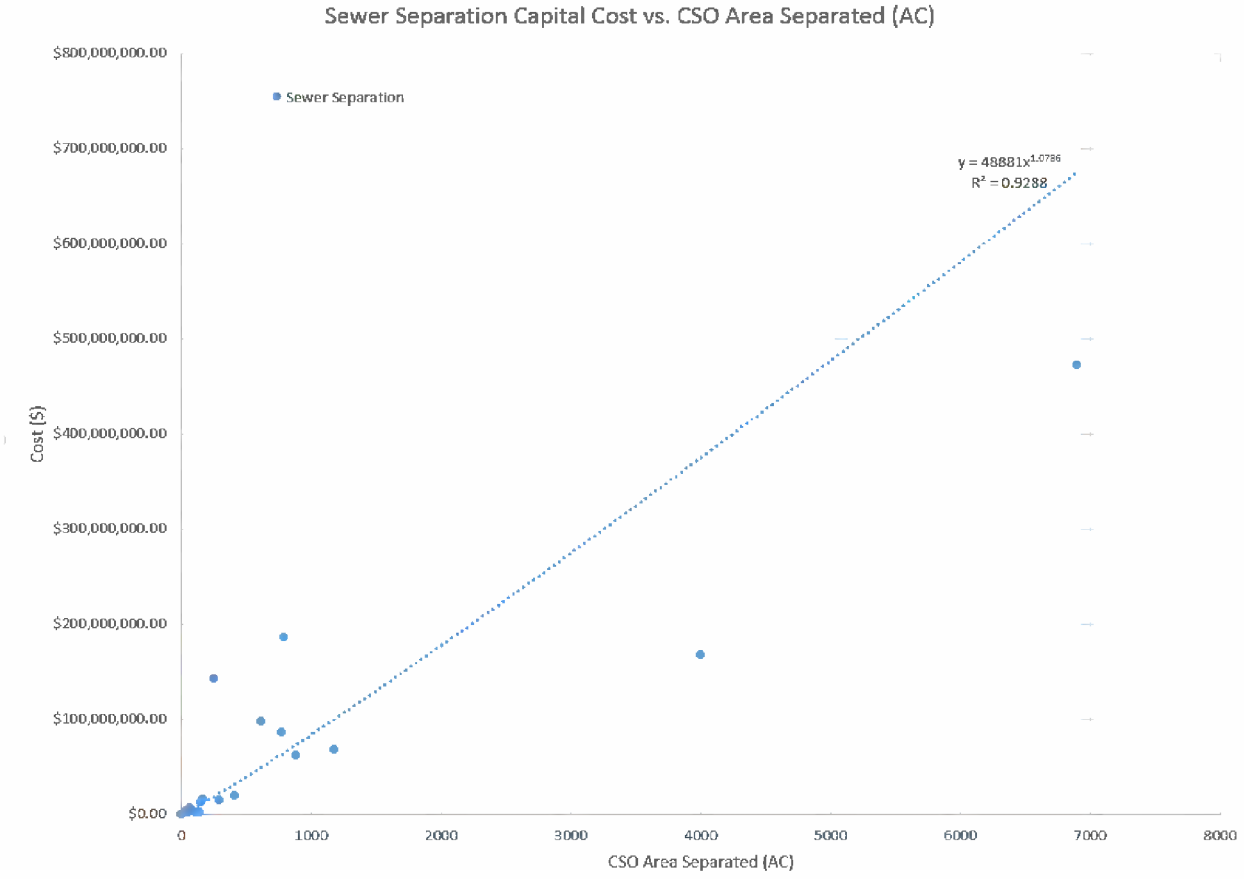
Sewer Separation

Sewer separation is utilized in combined sewer systems to ultimately reduce the amount of flow reaching the WRTP by eliminating stormwater from discharging into the system. This is usually done by installing new storm sewer pipe instead of sanitary pipe as sanitary pipe is usually deeper than storm sewer, thus causing it to cost more. In this specific analysis, the sewer separation cost curve is utilized for the Consent Decree analysis. A previous cost estimate was prepared to separate CSO 5, however this just involved installing a storm sewer along a strategic location to intercept stormwater flow as opposed to separating an entire area. The sewer separation cost curve uses construction cost estimates and bids from Elkhart, Indiana. The resulting capital cost curve for sewer separation is the following:

Y=48,881*x^1.0786

Where Y equals sewer separation cost and x equals the total area being separated. The trendline equation can be seen in Figure X below, showing a high R^2 correlation value.
Figure 23: Sewer Separation Capital Cost vs CSO Area Separated (AC)

Figure 23: Sewer Separation Capital Cost vs. CSO Area Separated (AC)

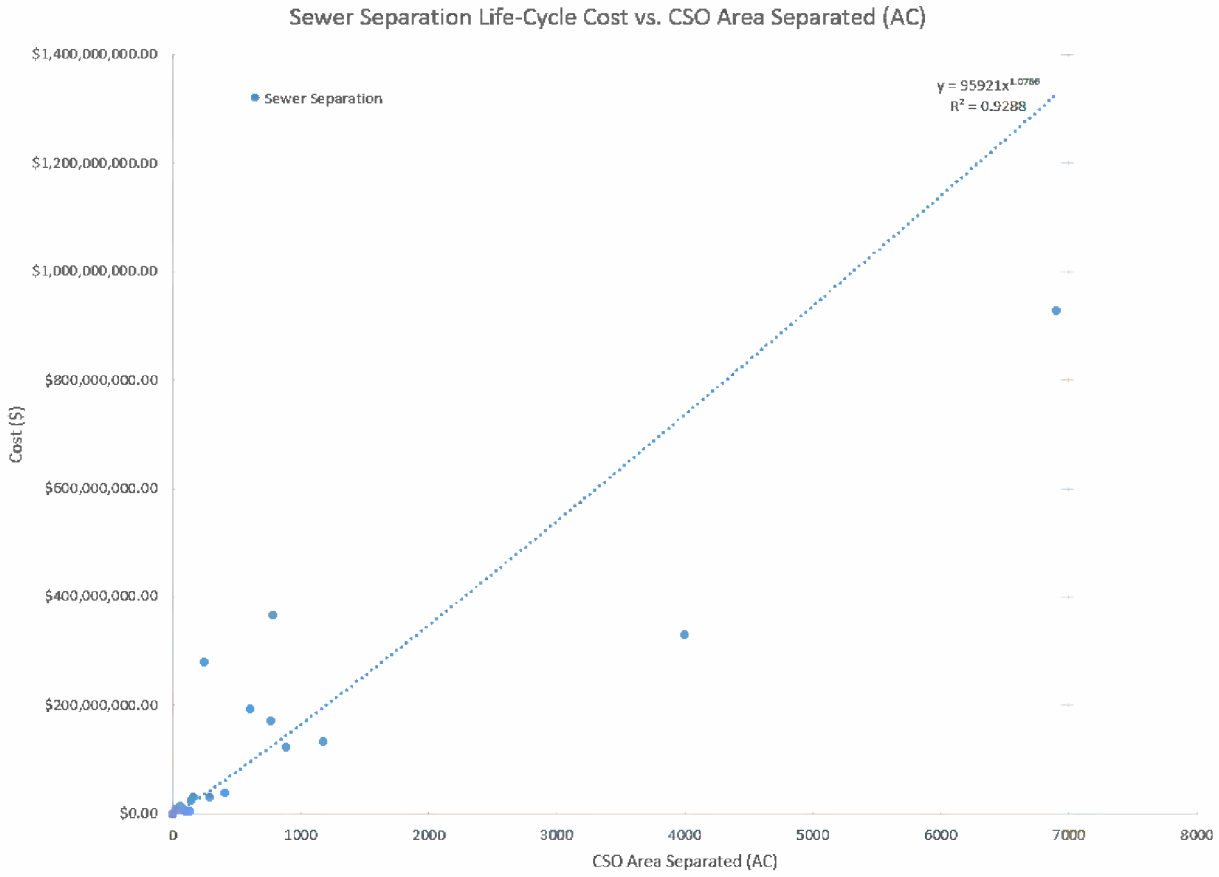


The resulting life-cycle cost curve for sewer separation is the following:

Y=95,921*x^1.0786

Where Y equals sewer separation cost and x equals the total area being separated in acres. The trendline equation can be seen in Figure X below, showing a high R^2 correlation value.

Figure 24: Sewer Separation Life-Cycle Cost vs CSO Area Separated (AC)



For the partial sewer separation in the regulator 5 CSS, Remington & Vernick provided two preliminary project estimates. We utilized the higher estimate, and added bonding and insurance, mobilization, and permitting costs to reach $4,400,000 for the project.

1. INTRODUCTION

This report presents an evaluation of the Delaware County Regional Water Quality Control Authority (DELCORA) Western Regional Treatment Plant (WRTP). DELCORA has requested that WESTON prepare an evaluation of the treatment process and hydraulic capacity of the WRTP.

1.1 BACKGROUND

In February 2000, DELCORA completed a Process Improvement Project (PIP) evaluation for its Western Regional Treatment Plant (WRTP) (WESTON 2000). The PIP evaluated the forward flow processes at the WRTP to identify process and operational efficiencies, determine the limiting hydraulic capacity of the plant, and evaluate the treatment capabilities of each unit process.

The results of the PIP evaluation showed the maximum hydraulic capacity of the WRTP was limited by the Aeration Basins, at a peak flow of at 137.4 MGD, with all basins in operation. If one basin is out of service, the hydraulic capacity is reduced to 102.1 MGD. The PIP also concluded that the biological treatment capacity of the WRTP was limited by the secondary clarifiers at 44.1 MGD (average flow) and the aeration basins at 45.5 MGD. The secondary clarifier limitation identified in the PIP was based on exceeding certain Pennsylvania Department of Environmental Protection (PADEP) design guidelines at peak flow, corresponding to average or rated flows above 44.1 MGD.

Since the completion of the PIP report, improvements to the aeration system have been implemented, resulting in increased treatment capacity to 50 MGD for the activated sludge components at the previously projected loadings.

In February 2003, WESTON prepared a report titled "Western Regional Treatment Plant Re-Rate to 50 MGD, Report on PADEP Guidelines" (WESTON, 2003). This report demonstrated that the performance of the aeration basins and clarifiers was not adversely impacted even while certain PADEP guidelines were not met, and that alternative loading factors may be more appropriate for design and operation of the system. This justification was further supported by

actual tested performance of the clarifiers under peak loading conditions. As a result of this study, PADEP has approved the re-rate of the WRTP to 50 MGD.

1.2 SCOPE OF EVALUATION

DELCORA is now pursuing additional flow for the WRTP through both strategic planning in the existing Western Region Service Area and potentially increasing the WRTP service area. Therefore, DELCORA desires to further evaluate the forward flow and solids handling processes at the WRTP for the purpose of identifying treatment capacity limitations. This evaluation will assume a target average daily flow of 60 MGD and utilize the most current loading data.

This report evaluates each unit process in the WRTP in order to estimate each unit's ultimate treatment capacity and its ability to accommodate the target 60 MGD (average flow). The end result of this evaluation is an assessment of whether the plant can accommodate 60 MGD and, if not, what upgrades are needed to meet that target. The assessment has been conducted utilizing recent influent loading data and, where appropriate, assumed loading values for the additional future flows. While the previous PIP evaluated forward flow processes, this evaluation includes thickening and dewatering processes as well. An evaluation of the incinerator system has not been included in this scope.

As compared to the PIP, and as discussed in the sections that follow, there are three main factors that may affect the capacity of the existing WRTP component.

1. The intended increase in average flow to 60 MGD.
2. An increase in wastewater strength since the time the PIP was completed. For example the PIP was based on a raw wastewater BOD_5 of approximately 127 mg/L at the then-rated capacity of 44 MGD. By comparison, data for the years 2006-2009, summarized in Section 2.1, shows an average influent BOD_5 of 199 mg/L. Allowing for future contributions (discussed in Section 2.1) this study is based on a projected influent BOD_5 of 208 mg/L.
3. An anticipated requirement for future nitrification, as discussed in Section 2.2. Nitrification requires lower loadings on the aeration basin and secondary clarifiers and therefore the capacity of these units at lower required loading is reduced.

A fourth factor that has an effect on these calculations is that the short-term peak factors were higher than were used in the PIP.

1.3 CURRENT FACILITIES

1.3.1 Description

The DELCORA Western Regional Treatment Plant (WRTP) has a permitted treatment capacity of 50 million gallons per day (MGD). The treatment process is commonly described as "Activated Sludge Treatment." The overall process includes pre-treatment, primary treatment, secondary treatment, and final treatment steps (Figure 1-1).

Municipal and industrial wastewater enters the WRTP and proceeds to the pre-treatment step. Pre-treatment consists of aerated grit removal and pre-aeration tanks. During pre-treatment inorganic solids (sand, gravel, etc.) are removed from the wastewater for disposal and air is introduced to the wastewater to aid in the biologic treatment of the waste.

During the primary treatment step, the wastewater passes through eight parallel primary settling tanks where organic and inorganic settleable solids (sludge) are removed and disposed. Oil, grease, and other floatables are skimmed off of the tanks and also removed for disposal.

Effluent from the primary settling tanks is directed to the four aeration tanks in the secondary treatment step. Here air is introduced to the wastewater to add oxygen and provide mixing to maintain bacteria and organic material in suspension (mixed liquor). As a result, dissolved and suspended organic material is synthesized into new biomass (activated sludge). The mixed liquor is then conveyed to the five secondary clarifiers. Settled activated sludge is continuously removed from the secondary clarifiers and returned to the aeration tanks to support the treatment process or, if not needed, it is "wasted" and sent to sludge holding tanks for subsequent treatment and disposal.

The final treatment step is composed of chlorination tanks where the water is disinfected prior to discharge to the Delaware River.

2. BASIS OF EVALUATION

2.1 INFLUENT CHARACTERISTICS

An understanding of current performance data (influent and effluent characteristics) and operating conditions (i.e., MLSS/MLVSS, aeration rates, RAS/WAS data and similar) is needed to evaluate the performance of the existing WRTP systems relative to conventional benchmarks and to help assess the potential effects of additional loads on that performance. In addition, the influent flow and wastewater characteristics for the evaluation must be estimated to calculate unit process capacities. The WRTP receives a mixture of domestic and industrial/commercial wastewaters (Figure 2-1). The peak flow factors and characteristics of the wastewater in the future will be affected by whether the incremental future flow is primarily domestic or industrial.

To accomplish this task, WESTON reviewed operating data for the period January 2007 through November 2009 to understand current flow conditions at the WRTP. For the incremental flow up to the target values, WESTON reviewed with DELCORA the possible sources of the flow and developed estimates of waste characteristics from those sources. The following contributions were projected.

- DELCORA's current flow from its existing service area is, on average, 36.65 MGD.
- The Southwest Delaware County Municipal Authority (SWDCMA) may close its wastewater treatment plant with DELCORA assuming its flow. The SWDCMA plant is rated at 6 MGD average flow, and it is assumed that all flow would be routed to the WRTP.
- The remaining flow up to the target 60 MGD (17.35 MGD) is assumed to come from additional but as yet not defined sources and is assumed to consist of typical medium strength domestic sanitary wastewater.

A combination of DELCORA data, limited data from SWDCMA and literature characteristics for sanitary wastewater was used to develop a weighted average characteristic for this evaluation. The calculations are summarized in Appendix A. Table 2-1 summarizes the results of this estimate.

Table 2-1
Estimated Wastewater Characteristics
for Capacity Evaluation

Parameter	Influent Characteristics
Flow, MGD	60
BOD_5, mg/L	208
COD, mg/L	484
TSS, mg/L	250
Total Nitrogen, mg/L	28
Ammonia Nitrogen, mg/L	16
Oil and Grease, mg/L	48
Alkalinity, as CaCO3, mg/L	100

Table 2-2 summarizes daily peak factors based on DELCORA's current data.

Table 2-2
Estimated Daily Peak Load Factors
Based on DELCORA Influent Data, 2007-2009
(All Factors are the Ratio of the
Indicated Value to the Average Value)

Parameter	Flow	BOD_5 Load	TSS Load	Total Nitrogen Load
Maximum	2.35	3.05	3.15	1.89
99^{th} Percentile	1.74	2.05	2.28	1.88
95^{th} Percentile	1.33	1.53	1.61	1.35

Based on these data, this evaluation assumes a maximum daily flow of 104.5 MGD corresponding to the upper 99^{th} percentile daily peak flow. Process calculations are also based on the upper 99^{th} percentile BOD_5, TSS and Nitrogen loadings where appropriate. This is considered to provide a conservative basis for estimating capacity without overdesign for extreme events.

An analysis of hourly flow data (which affects hydraulic sizing of certain process units) for the period of January 2007 to November 2009 would suggest an hourly peak factor of approximately 2.4 (based on an upper 99th percentile hourly flow of 88.5 MGD and the long term average flow of 36.65 MGD.) Extending this peak factor to the target flow of 60 MGD would indicate a peak

currently limited by influent pumping capacity to approximately 110 MGD, based on historically observed flow values. This would imply a mechanically limited peak factor at 60 MGD of approximately 1.84. However, since the mechanical limitation could be resolved in the future, DELCORA has directed that this limit not be used as the estimate for peak flow. Therefore, this evaluation assumes the 1.74 (upper 99th percentile) daily flow peak factor (Table 2-2) applies to daily flow up to 60 MGD and an hourly peak flow of 144 MGD (2.4 peaking factor based on upper 99th percentile value.)

PADEP design guidelines also use maximum monthly flow for some parameters. An estimate of maximum monthly average flow was calculated from 30 day averages of the daily flow data as provided by DELCORA. This estimated maximum monthly average flow for the period January 2007- November 2009 was 48.4 MGD. This corresponds to a maximum month to average peak factor of 1.33 and a maximum monthly flow of 80 MGD at the target 60 MGD average flow.

These peak values are considered to be relatively conservative. In general, pecking factors tend to decline at higher flow and it is possible that the peaking factors at the target for of 60 MGD may be somewhat lower than at the current average flow. In addition the peaking factors used in this report are based on upper 99th percentile values of the historic data. Because of these factors, the capacities estimated in this report are generally considered to be somewhat conservative.

2.2 EFFLUENT LIMITATIONS

Projected effluent limitations were evaluated to establish the performance standard the WRTP must meet under future conditions. In principle, this could be based on one of several assumed scenarios for the future, including:

- The continuation of existing mass based NPDES permit limits on BOD_5: This scenario would result in progressively lower concentration-based effluent limits as flows increase. (It should be noted however, that based on discussions between DELCORA and DRBC, DELCORA anticipates the current BOD_5 limit will be changed to a $CBOD_5$ limit during the next NPDES permit renewal.)
- The assumption that additional mass allocations can be obtained, such that the current concentration based limits would remain in effect.

- Nutrient (nitrogen and phosphorus) removal requirements. Nutrient limits have not historically applied on the main stem of the Delaware River. However at DELCORA's direction, WESTON has previously evaluated these options for DELCORA with respect to expanding the WRTP, constructing a new WWTP for Eastern Delaware County, and for certain potential satellite plants that could be constructed on smaller streams within the County, for which nutrient limitations may be applied in the near future.

- The potential for toxic Water Quality Based Effluent Limits (WQBELs) in the future could be considered. DELCORA does not at present have such limits imposed in the NPDES permit. If they were likely to be imposed in the future, several options may need to be considered including

    - Revision of local limits to more specifically control industrial inputs

    - Possible additional (tertiary) treatment, or,

    - Since many WQBELs allow for a mixing zone in the river as part of a compliance strategy, outfall modifications is a way to provide necessary dilution.

    It should be noted that DELCORA is currently designing an outfall extension into the Delaware River to address effluent mixing requirements based upon discussions with the DRBC, The new outfall will provide increase mixing and may affect the likelihood of WQBELS in the future.

Based on discussion with DELCORA the following determinations were made with respect to these options:

- With respect to BOD_5 limitation, WESTON, at DELCORA's direction, contacted the Delaware River Basin commission to determine whether an additional allocation would be obtained when DELCORA took over the Southwest Delaware County treatment plant. A record of this conversation is provided as Appendix B. Based on that discussion, it is assumed for this study that no additional allocation would be provided. Applying the existing mass allocation to the future flow of 60 mg/L would require an effluent BOD_5 concentration of 14 mg/L

- DELCORA anticipates an ammonia limit in the futures. For purposes of this evaluation an ammonia limit of 8 mg/L ammonia-nitrogen (NH_3-N) was adopted. DELCORA does not at present see a corresponding limit on phosphorus as a nutrient in the future.

- WQBELS will not be considered in this evaluation, but now may be placed in the NPDES permit with the pending rerate to 50 MGD.

3. HYDRAULIC EVALUATION

Section 4 of this report identifies the limiting element(s) for each unit process involving the forward flow of the treatment process In addition the capacity of the return activated sludge (RAS) and waste activated sludge (WAS) piping has been estimated. Information regarding equipment type and size was taken from as-built drawings provided by DELCORA.

3.1 FORWARD FLOW

3.1.1 Approach

Forward flow through the pre-aeration, primary clarification, activated sludge secondary clarification and disinfection processes was estimated based on gravity flow from one unit process to the next, accounting for head losses in the system (i.e. piping losses). Figure 3-1 depicts the hydraulic profile of the forward flow processes with the main points of analysis annotated.

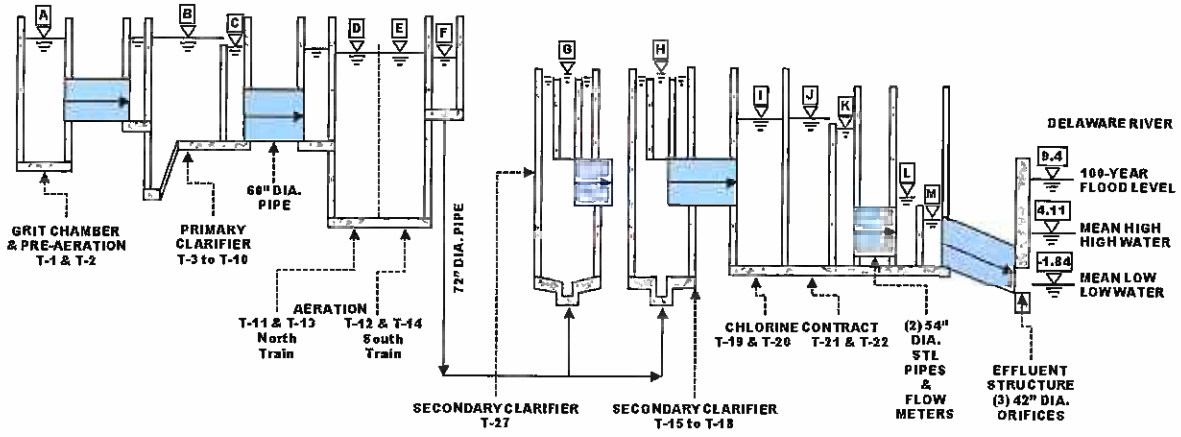

Figure 3-1 Hydraulic Profile of the Wastewater Processes

In general, the criterion adopted for this evaluation was to assume, at a minimum, free fall over weirs and outlet structures between unit process tanks. Piping losses are based on the data for piping and fittings as summarized in the PIP report and verified from record drawings.

3.1.2 Maximum Forward Flow Analysis (Individual Treatment Processes)

This analysis estimates the maximum forward flow for the pre-aeration, primary clarification, activated sludge secondary clarification and disinfection processes independently. Forward flow

through each process was increased until the effluent water elevation reached the top of its v-notch weirs (where applicable) or the influent water elevation reached 1 inch below the effluent weir of the preceding process. This analysis maintained the assumption of freefall over weirs and outlet structures as described in Section 3.1.1. Results of the individual process analysis are summarized in Table 3-2 and discussed further in the following four sections.

Maximum forward flow on an individual process basis is not limited by the capacity of downstream process flow capacities. Therefore the maximum forward flow through the entire treatment works differs from this analysis because it is controlled by the most flow limited process. Analysis of the treatment works as a whole is presented in Section 3.1.3.

Table 3-1
Maximum Forward Flow Analysis (Individual Treatment Processes)

PROCESS	MAXIMUM FORWARD FLOW, (MGD)	
Pre-aeration Tank and Primary Clarifier	169.3	
Aeration Basin	95.5[1]	108.6[2]
Secondary Clarifiers[3]	135.5[1]	118.2[2]
Chlorine Contact Tanks	131.1	

1. Maximum aeration basin effluent weir setting (EL. 20.30ft)
2. Minimum aeration basin effluent weir setting (EL. 19.32ft)
3. Maximum water surface elevation so backwater does not exceed 1" below aeration basin effluent weir setting.

3.1.2.1 Pre-aeration Tank and Primary Clarifier

The water level in the primary settling tanks (T-3 through T-10) is set by the 2.5 inch 90° v-notch weirs with a bottom elevation of 24.64 ft (point B). Maximum flow through the primary settling tanks is assumed to occur at the top of the v-notch weir (EL. 24.85 ft). At this elevation, each of the 5,288 notches flows at 22.23 gpm for a total maximum flow of 169.3 MGD. Head loss through the grit and pre-aeration tanks (T-1 & T-2) is estimated at 0.1 ft for 169.3 MGD forward flow. This results in a water surface elevation of 24.95 ft in the grit and pre-aeration tanks (point A). The calculations of maximum forward flow through individual unit processes are included in Appendix C.

Flow over the primary effluent weirs can be influenced by the water elevation in the primary effluent channel. Flow over the weir will be reduced if the water in the effluent channel

approaches the weir bottom; therefore it is assumed that the maximum water elevation in the primary effluent channel is 1 inch below the bottom of the v-notch weir or elevation 24.56 ft (point C).

3.1.2.2 Aeration Basin

The current configuration directs flow from the primary effluent channel through a 60 inch diameter steel influent pipe and into two parallel trains of aeration basins (T-11 to T-13 and T-12 to T14). The water levels in the aeration basins (points D and E) are set by eight 12 foot adjustable weirs with a maximum crest elevation of 20.30 ft and minimum elevation of 19.32 ft. Assuming a sludge recycle ratio of 0.53 and that the effluent weir is set at its maximum elevation, 95.5 MGD of forward flow will pass through the aeration basins without exceeding the maximum water elevation in the primary effluent channel of 24.56 ft (point C).

When the effluent weir is set at its minimum elevation, 108.6 MGD will pass through the aeration basins without exceeding the maximum water elevation in the primary effluent channel. The calculations of maximum forward flow through individual unit processes are included in Appendix C.

3.1.2.3 Secondary Clarifiers

The max flow through the secondary settling tanks is assumed to occur at the top of the 2.5 inch 90° v-notch weir. The maximum forward flow apportioned by weir capacity alone is 46.3 MGD for T-15 through T-18 and 44.5 MGD for T-27. This flow however is not proportional to the clarifier area as required for process optimization. Control valves are required to balance the flow by clarifier area to 31.2% for T-27 and 17.2% through each of the four remaining clarifiers.

Assuming a recycle ratio of 0.53 and that maximum flow occurs at the top of the v-notch weir, the maximum area apportioned forward flow is 142.6 MGD; however this exceeds the maximum water elevation (point F) of 1 inch below the aeration basin effluent weir at its maximum setting. A flow of 135.5 MGD can pass through the secondary clarifiers without exceeding the maximum crest elevation of the aeration basin effluent weir (EL. 20.30 ft) and a flow of 118.2 MGD can pass through the secondary clarifiers without exceeding the minimum weir setting (EL. 19.32 ft).

Depending on the position of the aeration basin effluent weir the aeration basins and secondary clarifiers are the hydraulically limiting segments and therefore control the maximum forward flow of the entire treatment works. The calculations of maximum forward flow through individual unit processes are included in Appendix C. The forward flow analysis of the entire treatment works is presented in Section 3.1.3. This analysis assumes that the aeration basin effluent weir is set at its highest position (EL. 20.30 ft).

3.1.2.4 Chlorine Contact Tanks

The maximum flow through the chlorine contact tanks was calculated based on three criteria: (1) the influent water elevation at the outfall structure was limited to 1 inch below the crest of the magnetic flowmeter weir (point M); (2) the water elevation in the chlorine contact tank effluent channel was limited to 1 inch below the crest of the chlorine contact tank effluent weirs (point K); and (3) the water elevation in the secondary clarifier effluent channel was limited to 1 inch below the secondary clarifier effluent weirs (points G_{out} and H_{out}). This analysis includes all piping losses and a high tide river elevation of 3.2 ft. To maximize contact time, the adjustable chlorine contact tank effluent weirs were assumed to be in the highest position (EL. 12.65 ft)

A flow of 131.1 MGD was found to meet all three criteria. Maximum flow was limited by the water elevation in the chlorine contact tank effluent channel due to the constriction of flow through the single 54 inch magnetic flowmeter. At this flow the influent water elevations in the secondary clarifier effluent channel and at the outfall structure were more than an inch below the maximum elevations. The calculations of maximum forward flow through individual unit processes are included in Appendix C.

3.1.3 Maximum Forward Flow Analysis (Entire Treatment Works)

This analysis estimates the maximum forward flow of the entire treatment works as a whole. When the aeration basin effluent weir is set at its highest position (EL. 20.30 ft), the aeration basins are the hydraulically limiting segment with a maximum forward flow of 95.5 MGD. When the aeration basin effluent weir is set at its lowest position (EL. 19.32 ft), the aeration basins are still the hydraulically limiting segment with a maximum forward flow of 108.6 MGD. These flows maintain the assumption of freefall over all weirs and outlet structures as described in Section 3.1.1. These results are discussed further in the following sections.

Figure 3-2 shows the water elevations in each treatment process at 95.5 MGD and 108.6 MGD as well as water elevations at the target flow of 60 MGD, the maximum monthly flow of 80 MGD, the maximum daily flow of 104 MGD and the maximum hourly flow of 144 MGD. The calculations of forward flow through the entire treatment works are included in Appendix C.

3.1.3.1 Pre-aeration Tank and Primary Clarifier

At a flow of 95.5 MGD, the water surface elevation within the primary clarifier is 24.81 ft which is below the top of the v-notch weir (point B). The water surface elevation in the grit and pre-aeration tanks is 25.23 ft (point A). At a flow of 108.6 MGD, the water surface elevation within the primary clarifier is 24.81 ft which is below the top of the v-notch weir (point B). The water surface elevation in the grit and pre-aeration tanks is 25.36 ft (point A).

3.1.3.2 Aeration Basin

At a flow of 95.5 MGD, the water elevation in the primary effluent channel is 24.56 ft (point C) which is at the maximum elevation of 24.56 ft. At a flow of 108.6 MGD, the water elevation in the primary effluent channel is 24.56 ft (point C) which is at the maximum elevation of 24.56 ft.

3.1.3.3 Secondary Clarifiers

At a flow of 95.5 MGD and a recycle ratio of 0.53, the water elevation in the aeration basin effluent channel (18.09 ft) is more than 1 inch below the bottom of the aeration basin effluent weir (point F). At a flow of 108.6 MGD and a recycle ratio of 0.53, the water elevation in the aeration basin effluent channel (18.72 ft) is more than 1 inch below the bottom of the aeration basin effluent weir (point F).

3.1.3.4 Chlorine Contact Tanks

At a flow of 95.5 MGD, the water elevation in the secondary clarifier effluent channels (14.42 ft and 14.29 ft), the contact tank effluent channel (10.59 ft), and the outfall structure (3.83 ft) are all more than 1 inch below the maximum water elevation (points G_{out}, H_{out}, K, and M). At a flow of 108.6 MGD, the water elevation in the secondary clarifier effluent channels (14.47 ft and 14.33 ft), the contact tank effluent channel (10.68 ft), and the outfall structure (3.85 ft) are all more than 1 inch below the maximum water elevation (points G_{out}, H_{out}, K, and M).

3.1.4 60, 80, 104 and 144MGD Forward Flow Analyses (Entire Treatment Works)

Maximum forward flow through the entire treatment works is limited to 95.5 MGD by the assumption of freefall over weirs and outlet structures. Therefore the freefall assumption also holds for the target flow of 60 MGD, the maximum monthly flow of 80 MGD, the maximum daily flow of 104 MGD, and the maximum hourly flow of 144 MGD.

At a maximum hourly flow of 144 MGD, however, water elevations would back up in the system and flood over the top of wall (EL. 27.0 ft) of the grit chamber and primary clarifiers. Similarly, the aeration basin effluent weirs (point F) would be flooded by almost 3 inches, the secondary clarifier effluent weirs (points G_{out} and H_{out}) would be flooded by 5 inches, and the chlorine contact tank effluent weirs (point K) would be flooded by over 9 inches.

The walls of the grit chamber and primary clarifiers would have to be raised by 31.6 inches to avoid flooding at 144 MGD. The highest forward flow that would not overflow the grit chamber and primary clarifiers is 119 MGD. Lowering the aeration basin effluent weirs to their minimum position would allow 128.5 MGD forward flow before overtopping these tanks. However the maximum forward flow in the secondary clarifiers under these conditions is 118.2 (Table 3-1) which makes the secondary clarifiers the hydraulically limiting segment.

3.2 RETURN FLOWS

3.2.1 Approach

Return activated sludge (RAS) and waste activated sludge (WAS) are pumped to the aeration basins and the DAF system respectively. The capacity of the RAS and WAS systems was evaluated assuming a typical flow velocity of 5 feet per second (which generally represent reasonable head losses). Higher velocities, if needed, may be achievable at higher losses.

3.2.2 Return Activated Sludge

RAS is collected from secondary clarifiers T-15 to T-18 and pumped via RAS pumps P-11 and P-12 (in Pump Station PS-3) to aeration basins T-11 to T-14. RAS from secondary clarifier T-27 is pumped via RAS pump P-63 and P-64 (in PS-5) into the common RAS line with between PS-3 and aeration basins T-11 to T-14.

FIGURE 3-2

WRTP HYDRAULIC PROFILE

This page is intentionally blank.

Conventional design guidelines (PADEP, Ten States Standards) recommend a return activated sludge flow between 100% to 150% of the forward flow based on the type of treatment (Table 3-2). Assuming the target flow of 60 MGD and the maximum monthly flow of 80 MGD, this would indicate a return sludge capacity of up to 80 MGD to meet design guidelines for BOD_5 removal and 120 MGD for nitrification.

Table 3-2
Return Activated Sludge Guidelines

Parameter	Guideline		
	1 PADEP	2 Ten States	
	Conventional Biol. Treatment:	Conventional Biol. Treatment:	Single Stage Nitrification:
Recommended Return Activated Sludge Flow	100% Maximum Monthly Flow	100% Forward Flow	150% Forward Flow

Assuming a maximum RAS pipe flow velocity of 5 feet per second for long pipe runs, the single 36 inch diameter RAS line between PS-3 and the common RAS line limits the maximum total flow from secondary clarifiers T-15 through T-18 to 22.8 MGD. At a maximum velocity of 5 feet per second, the single 24 inch diameter RAS collection line under T-27 limits the maximum flow from secondary clarifier T-27 to 10.2 MGD. Similarly, the single 42 inch diameter common RAS line conveying flow from all secondary clarifiers limits maximum total flow to 31.1 MGD at 5 feet per second. Assuming a sludge recycle ratio of 0.53, the maximum forward flow through the plant is limited to 58.5 MGD by the single 42 inch common RAS line. Figure 3-3 shows flow velocities at several points in the RAS lines for flows of 60 MGD, 80 MGD, 104 MGD and 144 MGD. Evaluation of the PS-3 and PS-5 pump curves and the PAS system curves indicated that there is adequate pumping capacity up to the maximum daily forward flow of 104 MGD.

The analysis in the previous paragraph is based on the existing process configuration. As discussed in Section 4, additional aeration basins and an additional secondary clarifier will be required to meet the 60 MGD objective. In this case additional RAS lines would be needed.

Addition of a new secondary clarifier (T-28) and new RAS lines from clarifiers T-27 and T-28 to a new aeration basin reduces the flow velocities in the RAS lines and increases the maximum

forward flow through the plant. Figure 3-4 shows flow velocities at several points in the existing and proposed RAS lines for flows of 60 MGD, 80 MGD, 104 MGD, and 144 MGD.

3.2.3 Waste Activated Sludge

Waste activated sludge is collected from secondary clarifiers T-15 to T-18 and pumped via WAS pumps in Pump Station PS-3 to dissolved air flotation DAF thickener tanks T-23 to T-26. WAS is collected from secondary clarifier T-27 and pumped via the pump in Pump Station PS-5 into the common WAS line with between PS-3 and the DAF thickener tanks.

Assuming a maximum pipe flow velocity of 5 feet per second for long pipe runs, the two 10 inch diameter WAS pump discharge lines in PS-3 have the smallest pipe diameters and therefore limit maximum total WAS flow from secondary clarifiers T-15 through T-18 to 3.5 MGD. At a maximum velocity of 5 feet per second, the single 12 inch diameter WAS line in PS-5 limits the maximum WAS flow from secondary clarifier T-27 to 2.5 MGD. Assuming a sludge waste rate of 0.017, the maximum forward flow through the plant is limited to 150 MGD by the single 12 inch common WAS line. Figure 3-5 shows flow velocities at several points in the WAS lines for flows of 60 MGD, 80 MGD, 104 MGD, and 144 MGD.

4. PROCESS EVALUATION

4.1 APPROACH

WESTON used the data presented in Section 2 to support process calculations to estimate the capacity of individual unit processes and the WRTP as a whole. As a starting point, these calculations have been compared to existing conventional design criteria and guideline documents:

1. Pennsylvania Department of Environmental Protection (PADEP), Bureau of Water Quality Protection, *Domestic Wastewater Facilities Manual, a Guide for the Preparation of Applications, Reports and Plans*, PADEP 362-0300-001, 1997.

2. Great Lakes-Upper Mississippi River Board of State and Provincial Public Health and Environmental Managers. *Recommended Standards for Wastewater Facilities*, 2004 Edition, ("Ten States")

3. Water Environment Federation (WEF) *Design of Municipal Wastewater Treatment Plants, Manual of Practice 8 (MOP-8)*, 1992

4. Metcalf and Eddy, *Wastewater Engineering, Treatment, Disposal, Reuse*, Fourth Edition 2003, ("M&E").

While the above sources provide baseline design criteria, it is also recognized that they are, for the most part, relatively conservative and that in some cases varying from those guidelines may be appropriate. For example, the WRTP's re-rate to 50 MGD is based in part upon a demonstration that the WRTP's clarifiers could operate successfully at flow values exceeding PADEP design guidelines.

WESTON evaluated the unit processes that could potentially limit the forward-flow processing rate at the WRTP. These processes include:

- Aerated Grit and Pre-aeration System
- Primary Clarifiers
- Aeration Tanks
- Secondary Clarifiers
- Disinfection System
  - Chlorine Contact Tanks
  - Chlorine Evaporators and Chlorinators

The following biosolids handling processes were considered:

- Sludge thickening by Dissolved Air Flotation (DAF)

- Sludge dewatering by Belt Filter Presses (BFP)

4.2 GRIT SYSTEM

4.2.1 Existing System Description

The WRTP has two aerated grit and pre-aeration tanks at the WRTP. These tanks are divided into a grit chamber (approximately one third of each tank) and a pre-aeration chamber (approximately two thirds of each tank). The grit chamber tanks are each 31.6 feet long and 30 feet wide, and have a side water depth of 15.75 feet.

4.2.2 Design Guidelines

Design criteria for grit chambers are typically based on hydraulic detention time (HRT).

4.2.3 Evaluation

Table 4-1 provides estimated values of design parameters for the WRTP grit chambers in comparison to design criteria.

Table 4-1
Grit System

Parameter	Guideline				WRTP at 60 MGD
	1 PADEP	2 Ten States	3 WEF MOP 8	4 M&E	
Peak Flow minimum HRT (minutes) [2]	Note 1	3-5	3 (typ.)	3 (typ.)	2.23

Notes:
1. To be based on particle size to be removed.
2. Peak hourly flow.

Based on these results the peak flow HRT in the grit system falls below most guidelines, although as noted PADEP allows for the tank to be sized based on the actual particle size distribution. HRT at average flow is 5.4 minutes. The effect of short retention time at peak flow would suggest some carryover of additional grit to the primary clarifiers particularly at peak flows. However, these calculations are based on that portion of the grit/pre-aeration tanks that are actually designed and equipped for grit separation (and which have a grit removal mechanism) (i.e. approximately 1/3 of the total grit/pre-aeration volume). It is likely that grit

would continue to separate in the remaining volume as well. This would likely reduce the grit carryover to the primary tanks. The principal concern with this is that, without grit removal equipment in these portions of the pre-aeration tanks, removal of the settled grit to maintain performance and provide for grit disposal would be more difficult.

Another option to reduce grit loading of the WRTP would be to improve grit removal at the pump stations serving the WRTP or at other remote locations.

4.3 PRIMARY CLARIFICATION

4.3.1 Existing System Description

There are eight primary clarifiers at the WRTP. Each primary clarifier tank is rectangular in shape, with a length of 155.5 feet, a width of 41.5 feet, and a side water depth averaging 9.50 feet. Each settling tank has a total weir length of 350 feet.

This evaluation assumes all eight primary clarifier tanks are operated in parallel, with influent flow split evenly among all tanks.

4.3.2 Current Performance

Primary clarifiers treating municipal wastewater can typically remove 50 to 70% of the suspended solids and 25 to 40% of the BOD_5 (M&E). The primary clarifier system performs very well at current flows (average 36.65 MGD) and loading conditions. Key performance parameters are summarized in Table 4-2.

Table 4-2
Summary of Primary Clarifier System Performance
January 2007 - November 2009
(Average Flow 36.65 MGD)

Parameter	Influent, mg/L	Effluent, mg/L	Removal Efficiency (%)
BOD_5	199	122	38
TSS	252	97	59

4.3.3 Design Guidelines

Design criteria for primary clarifiers are based on surface overflow rate, weir overflow rate and hydraulic retention time.

4.3.4 Evaluation

Table 4-3 provides estimated values of design parameters for the WRTP primary clarifiers in comparison to design criteria.

Table 4-3
Primary Clarifier System

Parameter		Guideline				WRTP at 60 MGD, 2.4 hourly peak factor
		1 PADEP	2 Ten States	3 WEF MOP 8[1]	4 M&E	
Surface Overflow Rate, gpd/sf	Average	1,000	1,000	NS[2]	800-1200 (1000 typical)	1,162
	Peak hourly	2,500	1,500-2,000	NS	2,000-3,000 (2,500 typical)	2,789
Weir Loading Rate, gpd/ft	Average	15,000[3]	NS	NS	10,000-40,000 (20,000 typical)	21,430 (average) 28,570 (max. monthly
	Peak hourly	NS	30,000	15,000 (typ.)	NS	51,430
Hydraulic Retention Time, hours	Average	NS	NS	NS	1.5-2.5 (2.0 typical)	1.47
	Peak hourly	NS	NS	NS	ND	0.61

Notes:
NS: Not specified.
1. In many cases MOP 8 does not provide criteria but refers to other literature values.
2. At maximum monthly flow rate.

The primary clarifier system is at the upper end of conventional design parameters at 60 MGD design average flow based on the surface overflow rates, and does not meet PADEP design criteria for WLR.

Among these design criteria the surface overflow rate is the more critical performance parameter. The surface overflow rate (SOR) is an upward flow velocity and particles having a settling velocity greater that the SOR will, in theory, be removed. Therefore maintaining SOR values within conventional ranges is the more critical factor in ensuring adequate removal of solids prior to the aeration basins.

By contrast weir overflow rate is related to the approach velocity of the water to the weirs; too high a velocity could tend to entrain some solids and carry them over the weir. However as noted in previous reports (WESTON 2003) weir overflow rate is generally considered of relatively minor importance in the performance of settling tanks and WEF MOP 8 notes that

"...weir rates have little effect on the performance of primary clarifiers especially with side wall depths in excess of 12 feet." (The WRTP clarifiers are 8.75 to 10.25 feet deep).

The primary clarifier system essentially meets typical criteria for HRT at 60 MGD average flow.

The Report on DEP Guidelines (WESTON 2003) summarized data from August 1999 when half of the clarifiers were out of service for maintenance and the remaining clarifiers consequently operated at high loadings (see Table 6, WESTON 2003). These results indicated that at maximum daily flows of almost 54 MGD and peak flow rates on the maximum day of 96 MGD the performance of the primary clarifier system was excellent at effective SOR values of 1,256 gpd/sf and WLRs as high as 23,164 gpd/ft. These values are slightly higher than the estimated values at the target flow of 60 MGD as noted in Table 4-3 and suggest that the primary clarifiers may operate at those conditions with little negative effect on performance.

At 60 MGD, however, the primary clarifier system will approach the upper range of typical practice and some decrease in efficiency may be expected. To provide a conservative basis for evaluation of the activated sludge system, it is assumed that at the target flow of 60 MGD the removal efficiency of the primary clarifier system is slightly lower than at the current flow, (50% for TSS and 30% for BOD_5).

DELCORA evaluated Chemically Enhanced Primary Treatment (CEPT) by addition of chemical coagulant to the primacy clarifier system, for two reasons:

1. As a possible means of addressing process upsets that interfere with primary settling. This might be done on either a short term (i.e. temporary) basis or by the installation of a permanent system.
2. Recent recommendations from an energy study by AECOM that DELCORA consider CEPT to increase primary BOD_5 removal and thus potentially reduce aeration power requirements.

While it is expected that CEPT could in fact increase BOD_5 and TSS removal in the primary system and assist with these goals, a preliminary evaluation of cost indicated that it would not be cost effective to do so on a continuous basis.

4.4 ACTIVATED SLUDGE SYSTEM

The activated sludge system includes the aeration basins and the aeration system blowers and diffusers.

4.4.1 Aeration Basins

4.4.1.1 Existing System Description

There are four aeration tanks at the WRTP. These tanks are square in shape, with a length of 136 feet, a width of 136 feet, and a side water depth of 18.1 feet. Various flow combinations are possible with the four tanks including a complete mix configuration. Typical operation uses two trains of two tanks each, providing essentially a complete mix activated sludge (CMAS) configuration.

Conventional design and operating criteria for aeration basins are based on hydraulic retention time, organic loading rate, food to microorganism ratio (F:M) and mixed liquor suspended solids MLSS levels. Current operating parameters for the system are summarized in Table 4-4.

Table 4-4
Summary of Aeration Basin Operating Parameters
January 2007 - November 2009
(Average Flow 36.65 MGD)

Parameter		Value
MLSS, mg/L		3,383
F:M, lb BOD_5/lb MLVSS		0.165
HRT, hours		6.6
SRT [(1)], days, MLVSS basis		10.5
Waste Activated Sludge (WAS)	Flow, MGD	0.263
	Concentration, mg/L	10,776
Return Activated Sludge (RAS)	Flow, MGD	19.27
	Concentration, mg/L	10,776
	Recycle Ratio, α	0.53

Notes:
1. Solids retention time.

A previous process model by Envitreat (Envitreat 2009) estimated a SRT of 15.4 days at 36.8 MGD average flow and an F:M value of 0.122 (VSS basis) using operating data from November 2006 to October 2008. According to the Envitreat report MLSS during the period averaged 3608 mg/L as compared to 3383 during the current evaluation.

A denitrification evaluation by Gannett Fleming (Gannett Fleming 2009) estimated a sludge age of 11 days at 38.21 MGD at an MLSS value of 3,565 mg/L, based on data from 2006-2008. The Gannet Fleming report indicated the SRT was based on MLSS rather than MLVSS. Assuming 80% VSS, the calculated 11 day SRT (MLSS basis) corresponds to approximately 8.8 days (MLVSS basis).The Gannet Fleming report did not include an estimated F:M value. However, based on data provided in Tables 4 and 5 and allowing for a VSS fraction of 0.8, an F:M value of 0.134 would be estimated.

This process evaluation considers the four aeration basins to be operating as a complete mix activated sludge system. The previous PIP evaluated multiple flow configurations for the activated sludge process, including so-called "reverse" flow wherein the influent would be directed to the second tank in each train (tanks T-12 and T-14 respectively) and back through the first tank in each train (tanks T-11 and T-13 respectively). This scenario is considered unlikely and therefore it will not be evaluated in this analysis.

While this section considers process capacity, it should be noted that the hydraulic capacity is between 95.5 MGD and 108.6 MGD depending on the effluent weir setting (see Table 3-1), the aeration basins cannot accommodate the estimated peak hourly flow of 144 MGD (60 MGD with a 2.4 peak factor.). This is relevant in that any option to increase process capacity in the existing tanks would still face this hydraulic limitation. This may effectively limit options for increasing activated sludge capacity to those which rely on new aeration basins.

4.4.1.2 Comparison to Standard Design Criteria

4.4.1.2.1 Design Guidelines

As noted above, conventional design and operating criteria for aeration basins are based on hydraulic retention time, organic loading rate, food to microorganism ratio (F:M) and mixed liquor suspended solids (MLSS) levels.

4.4.1.2.2 Evaluation under Conventional Design Guidelines

Table 4-5 provides estimated values of design parameters for the WRTP aeration system chambers in comparison to design criteria. Operation at 60 MGD will exceed all conventional criteria for nitrification and be at the upper limits of criteria for BOD_5 removal. Operation at 50

MGD average flow will continue to be above PADEP guidelines but is within other conventional design criteria for BOD5 removal. The Process Improvement Project Report (WESTON 2000) also concluded that treatment at 50 MGD would exceed certain PADEP guidelines. As noted below these guidelines are generally conservative. Typical criteria for nitrification would be exceeded at 50 MGD average flow.

Table 4-5
Existing Aeration Basin System

Parameter		Guideline				WRTP at 50 MGD	WRTP at 60 MGD
		1 PADEP	2 Ten States	3 WEF MOP 8	4 M&E		
Hydraulic Retention Time	BOD_5 Removal[1]	6[2]	NS	NS	3-5	3.62	3.02 [2]
	Nitrification [3]	12	NS	NS	6-15

	Nitrification[3]		NS	5-15	8-20		
Maximum Organic Loading Rate lb/ BOD_5/1,000 cf/day	BOD_5 Removal[1]	40[4]	40	NS	50-120	93.1	112[5]
	Nitrification [3]	20[4]	15	NS	5-20		
F:M, lb BOD_5/lb MLVSS/day	BOD_5 Removal[1]	0.2- 0.5	0.2-0.5	0.2-0.4	0.2-0.6	0.55	0.66[5]
	Nitrification [3]	0.08-0.16	0.05-0.1	NS	0.1-0.25		
MLSS, mg/L	BOD_5 Removal[1]	1,000-3,000	1,000-3,000	1,500-3,000	1,500-4,000	~3,400[5]	~3,400[5]
	Nitrification [3]	2,000-5,000	3,000-5,000	NS	1,500-3,500		

Notes:
NS: Not specified
1. Complete mix activated sludge, using air for aeration (vs. pure oxygen).
2. At maximum monthly flow.
3. Combined carbon oxidation – nitrification.
4. Based on maximum daily BOD_5 load to the aeration tank.
5. At upper 99th permit daily BOD_5 peak, 30% primary BOD_5 removal, 3,400 mg/L MLSS and 0.8 volatile fraction.
6. Typical value under current operating conditions.
7. In many cases MOP 8 does not provide criteria but refers to other literature values.

4.4.1.3 Process Design Calculations

As noted previously, design guidelines in standard references are generally conservative. In order to refine the estimated capacity of the aeration basin and adequately consider the particular properties of DELCORA wastewater, a process design calculation was performed using

conventional design models (USEPA 1975, M&E 1991) which are based on nitrification kinetics.

4.4.1.3.1 Assumptions

Input parameters for the model are based on the influent data presented in Table 2-1. Kinetic coefficients for the nitrification process were based on literature values.

The nitrification process is significantly affected by water temperature. For this analysis it was assumed that the future ammonia-nitrogen limit would be applied year round (rather than being seasonally adjusted as was commonly done in the past.) DELCORA reports wintertime minimum temperatures under current conditions as above 60 degrees F (15.6 degrees C) due in part to warm water input from industrial sources, and anticipates that even with a somewhat higher future contribution of cooler municipal wastewaters, the winter temperature is likely to remain above 60 degrees F. Therefore the design calculation was performed at 60 degrees F (15.6 degrees C) winter water temperature as the most conservative case.

4.4.1.3.2 Results

The design calculations indicated that a solids residence time (SRT) of approximately 11 days would be suitable. At current MLSS levels this results in a design hydraulic residence time of approximately 8.5 hours. At the target flow of 60 MGD a total aeration basin volume of approximately 21 MG would be needed under these conditions.

Comparison to Table 4-4shows that the current operation provides an SRT of 10-11 days at 36.65 MGD average flow. Under these conditions the plant typically nitrifies reasonably well.

The process model used conservative assumptions and additional modeling might be used to refine the final estimate. However, the essential conclusion is that the existing aeration basins are well short of providing adequate capacity for the 60 MGD nitrification scenario.

Furthermore, the design calculations indicate that the intended SRT would be achieved at a mixed liquor (MLSS) level of approximately 3,400 mg/L in the indicated reactor volume. Assuming the biomass continues to settle similar to current conditions, such that the recycle concentration can be maintained at approximately 10,000 mg/L, this would require a recycle

ratio (Q_R/Q) of approximately 0.51, (i.e. a recycle rate approximately 51% of the forward flow rate). This value is well below the general design guidelines of 100 to 150%.

4.4.1.4 Options

The most critical design parameter for nitrification is the solids residence time. In this regard a higher throughput could possibly be achieved in the fixed aeration volume by operating at significantly higher MLVSS levels. The WRTP currently operates at a MLSS level of approximately 3,400 mg/L (estimated to provide 2,270 mg/L MLVSS). The ability to significantly increase MLSS (and MLVSS) in the current configuration (e.g., by increasing recycle) is likely limited. Based on historical data (Gannett Fleming, 2009, Envitreat 2009), MLSS levels in the range of 3,600 mg/L were maintained at flows of approximately 36-38 MGD. Even if this value could be maintained at 60 MGD, it would likely not be sufficient to provide the desired operating conditions for nitrification. Options for doing this within the existing aeration basins may include (1) conversion to an integrated fixed film activated sludge (IFAS) process and (2) conversion to a membrane bioreactor (MBR) process.

However as noted above the existing basins also have a hydraulic limitation. At the future peak hourly flow (144 MGD) the water level in the primary effluent channel would approach the bottom of the weir, which was established in the hydraulic analysis as the limiting case. If additional basins are needed to address this hydraulic limitation, conversion to IFAS or MBR may be less favorable than adding new conventional activated sludge basins. Furthermore if additional basins are provided other activated sludge process options, such as step feed and plug flow configurations, could possibly be considered to optimize the aeration volume.

The hydraulic analysis (Section 3) indicates that the flow split between the two trains with all sluice gate valves open is not equal, with approximately 59% of the flow passing through the south train (Tanks T-13 and T-14) and 41% through the north train (T-11 and T-12). At maximum loadings particularly it will be important to balance the flow between the trains. This would presumably be done by adjusting the sluice gate valves on the south train to divert more flow to the north train. It should be noted that throttling the two gates to the south train may have some effect on upstream hydraulics. Since the upstream criterion in the hydraulic analysis was free fall over the primary clarifier weirs (a maximum elevation in the clarifier effluent channel

below the weir v-notch) it is possible that throttling the south train may result in peak flow levels exceeding this criterion.

4.4.2 Aeration System

4.4.2.1 Existing System Description

DELCORA replaced its surface aerators with a submerged diffuser aeration system. The system consists of submerged aeration diffusers and piping grid, centrifugal blowers, dissolved oxygen (DO) control system, interconnection ductwork, electrical controls and blower building. The submerged diffusers are high efficiency flat panel membrane diffusers manufactured by Parkson Corporation. The Parkson panels operate at a low air flux rate and have large floor coverage. The centrifugal blowers have a high efficiency rating and are manufactured by Turblex Corporation. The dissolved oxygen control system modulates the quantity of air and the main header air pressure in response to changing DO concentrations in the aeration basin and is also manufactured by Turblex Corporation. The aeration system was designed to reduce the electricity consumption and operating costs as compared to the surface aerators. Provisions were included in the design for future flow expansion at the WRTP to an influent flow of 50 MGD at then-projected loadings. Also included in the design was the provision for the addition of a fourth blower if needed for flow expansion above 50 MGD. To accommodate the fourth blower, the interconnecting ducting was sized for the increased compressed air flow rate, space was reserved in the blower and electrical rooms for the blower and its motor starter, and the electrical substation was sized for a fourth blower motor.

4.4.2.1.1 Blowers

The design air requirement was 10,200 scfm at average flow and 20,200 scfm at peak load. Average and peak design conditions were based on current operating data at that time.

The blower configuration uses two operating blowers and one installed spare blower. The proposed blowers are sized at 11,000 scfm each for a total capacity of 22,000 scfm (with one unit in reserve.)

4.4.2.1.2 Diffusers

Each basin contains 175 Parkson aeration panels arranged in groups of 25 for a total of 700 panels. The diffuser system was designed for the 50 MGD design basis. They are designed to pass a total of 10,350 scfm at average conditions and 20,200 scfm for the maximum condition (at the 50 MGD design basis.)

In addition there are provisions to place additional panels in each basin without revision to air piping if necessary to accommodate potential future flows above 50 MGD.

The basins were considered complete mix reactors. To provide homogeneous conditions in the tank, the aeration panels were spaced throughout the tank. However, toward the influent side of the tanks, additional panels were placed.

The Parkson diffuser panels are 4 ft by 12 ft long. The diffuser membrane is polyurethane. The airflow flux rate varies from 0.31 scfm/sf at the average flow rate to 0.72 scfm/sf at the maximum flow rate.

4.4.2.2 Comparison to Standard Design Criteria

4.4.2.2.1 Design Guidelines

PADEP and 10 States Standards guidelines for the design of aeration systems include the following narrative criteria:

- Aeration equipment should be capable of supplying 1.1 pounds of oxygen per pound of BOD_5 removed at maximum BOD_5 loadings (PADEP guidelines specify maximum daily BOD_5 while 10 States Standards refer to peak hourly BOD_5 loads). These references further recommend 4.6 pounds of oxygen per pound of TKN removed at maximum loads.
- Dissolved oxygen should be maintained at a minimum of 2.0 mg/l.
- The blowers shall be provided in multiple units, so arranged and in such capacities as to meet the maximum air demand with the single largest unit out of service. The design shall also provide for varying the volume of air delivered in proportion to the load demand of the plant.

4.4.2.2.2 Evaluation

As noted above the existing aeration system was designed for BOD_5 removal at 50 MGD (with provisions for expansion).

This evaluation considers both BOD_5 removal at current and projected influent conditions and the anticipated requirement for nitrification. The nitrification process exerts a significant oxygen demand, typically estimated at 4.57 lb of oxygen per lb of nitrogen, (as compared to 1.1 lb oxygen per lb BOD_5 removed). Note that the theoretical 4.57 lb O_2 value is rounded to 4.6 lb in the design guidelines.

Table 4-6 summarizes the average and peak oxygen requirements for BOD_5 removal alone (i.e. without nitrification). Also provided for comparison are the total oxygen requirements used for the design of the existing aeration system (WESTON 2003b). These values assume 100% BOD_5 and TKN removal at average conditions and 95% removal at peak load conditions. In addition, these calculations assume a minimum DO in the aeration basins of 2.0 mg/L.

Table 4-6
Oxygen Requirements for BOD_5 Removal

	Aeration System Design Basis 50 MGD Average Flow		Current Loadings 60 MGD Average Flow	
	BOD_5 Load removed lb/day	**Oxygen Requirement, lb./day**	**BOD_5 Load removed lb/day**	**Oxygen Requirement, lb./day**
Average	41,300[1]	45,430[2]	72,830[1]	80,115[2]
Peak day	68,780[3]	75,658[2]	141,840[3]	156,080[3]

Notes:
1. Assumes 100% BOD_5 and TKN removal at average load conditions.
2. Assumes 1.1 lb oxygen per lb BOD_5.
3. Assumes 95% BOD_5 and TKN removal at 99th percentile peak load condition.

The significant increase in total oxygen demand for BOD_5 removal results from both the increase in flow (from 50 MGD to 60 MGD) and the substantial increase in waste strength since the time of the previous evaluations. The PIP report and the aeration design were based on a raw wastewater strength in the range of 160 mg/L BOD_5. The recent historical DELCORA waste strength is approximately 199 mg/L BOD_5 (Table 1-1) and the projected waste strength allowing for future contributions is 208 mg/L BOD_5 (Table 2-1).

The total oxygen demand for a combined carbon oxidation/nitrification system can be estimated from the following equation:

$$O_2, \text{ lb/day} = Q(kSo + 4.57\ TKN) \times 8.34$$

where
- Q = flow, MGD
- k = conversion factor, lb O_2/lb BOD_5
- So = BOD_5, mg/L
- TKN = Total Kjeldahl Nitrogen, mg/L

The total oxygen demand for BOD_5 removal and combined BOD_5 removal./nitrification are summarized in Table 4-7.

Table 4-7
Oxygen Requirements for Combined
BOD_5 Removal and Nitrification at 60 MGD

	Total Oxygen Demand, lb/day		
	BOD_5 Removal	**Nitrification**	**Total**
Average Daily Load	80,115	56,885	137,000
Peak Daily Load	156,080	101,550	257,630

The aeration requirements to satisfy this demand is based on the design criteria with respect to water temperature and DO level, and the oxygen transfer characteristics of the aeration equipment. Oxygen transfer characteristics are based on data from Parkson. It is understood that the original aeration panels are being replaced with ones of a modified design. Parkson was consulted to determine whether the oxygen transfer characteristics of the new panel will differ from the original used for the design. Parkson responded that while testing is proceeding, the characteristics of the new panels are expected to be the same as the origin. Therefore data presented in the design report were used for this evaluation.

Table 4-8 summarizes the air supply requirement to meet the demand shown in Table 4-7.

Table 4-8
Aeration Requirements at 60 MGD

	Total Air Requirement, scfm		
	BOD_5 Removal	Nitrification	Total
Average Daily Load	21,270	15,090	36,360
Peak Daily Load [1]	41,420	26,950	68,370

Notes:
1. Assumes 95% BOD5 and TKN removal at 99th percentile peak load condition

Table 4-8 demonstrates that the existing system would not provide adequate capacity even with the fourth blower installed, With the fourth blower installed the maximum aeration provided would be ~33,000 scfm with one unit offline per PADEP guidelines.

Under current average flow conditions, (i.e. approximately 36.65 MGD), two blowers are adequate for nitrification at average flow conditions 18,300 scfm required). Calculated airflow rates indicate a shortfall at the 99th percentile peak loading condition (36,360 scfm required)

BOD5 removal alone (consistent with the current NPDES permit) would of course require significantly less air. However unless process operating conditions (primarily solids retention time) were modified to prevent nitrification, the nitrification demand will consume oxygen.

As noted in Section 4.4.2.1.2, the diffuser system was designed for a maximum flux rate of 0.72 scfm/ft^2 of diffuser area, assuming two blowers in operation at the required peak airflow rate of 20,200 scfm. If the third existing blower were operating (a maximum air flow rate of approximately 33,000 scfm), the flux rate would increase to approximately 1.18 scfm/ft^2 with the existing panels. If, as noted, in Section 4.4.2.1.2, 25 additional panels were installed in each basin using the existing piping, the maximum flux rate with three existing blowers, would be approximately 1.03 scfm/ft^2. Flux rates at peak nitrification conditions, assuming additional blower capacity were provided, may exceed the capacity of the panels. (At the time of publication flux rate curves were not available from the manufacturer. Actual flux rates and performance should be confirmed with the manufacturer.)

As noted in Section 4.4.1, it would be necessary to add aeration basins to meet nitrification requirements. With all eight basins (existing and new) using panel diffusers the peak air flow rate of 68,370 scfm would result in a peak flux rate of approximately 0.92 scfm/ft^2 (assuming the

additional panels are not installed in the existing basins and comparable floor coverage in the new basins). As noted above, at the time of publication flux rate curves were not available from the manufacturer. Since transfer efficiency is affected by flux rate, the actual oxygen transfer efficiency of the new panels, when available from the manufacturer, should be reviewed to confirm performance. If oxygen transfer drops significantly at these higher flux rates, additional blower capacity beyond that estimated above would be needed.

It should be noted that the above values are based on maximum daily loads as calculated from DELCORA data. As noted above, some guidelines recommend aeration to meet maximum hourly loads. Based on standard references, hourly peak load factors may be higher than the daily factors shown in Table 2-2. However data to assess hourly BOD_5 and nitrogen loads (i.e. diurnal fluctuations in influent BOD_5 and TKN) are not normally collected.

4.5 SECONDARY CLARIFICATION

4.5.1 Description

There are five secondary clarifiers at the WRTP. Four clarifiers (Tanks T-15, T-16, T-17, and T-18) have a 130-foot diameter and one clarifier (Tank T-27) has a diameter of 175-feet.

The four smaller clarifiers were included in the original design of the plant while the fifth larger clarifier was added in 1994. Return sludge from the four smaller units is drawn from the bottom well of each clarifier while the larger clarifier uses a suction pipe withdrawal mechanism.

Flow is distributed among the five clarifiers using control valves. Optimally, the flow to each clarifier should be proportioned according to surface area of the tank. As discussed in the PIP report (WESTON 2000), this was not possible with the original weir configuration for Tank T-27 (Clarifier 5). Of the total clarifier surface area, tank T-27 represents 31 percent of the total surface area and clarifiers T-15 to T-18 represent 17 percent of the total surface area each. However using the original weir configuration, tank T-27 had a maximum flow capacity of 24.9 MGD and each of the four smaller clarifiers has a maximum capacity of 25.9 MGD. The analysis of the flow distribution to the secondary clarifiers from the PIP report indicated that the flow would be distributed rather evenly without throttling the control valves to the tans. Under these conditions Tank T-27 would receive 21 percent of the total flow, tanks T-16 and T-18

would receive 19 percent of the total flow each, and tanks T-15 and T-17 would receive 20.5 percent of the total peak flow each.

In 2004 a study was conducted to analyze the flow split among the five final clarifiers and develop recommendations for flow balancing. Since that time DELCORA has implemented adjustments to the weir settings and it is estimated, based on flow meter data, that the intended area proportioned flow spilt can now be obtained. The tables that follow provide the estimated capacity both at the area proportioned split and at the original flow split to illustrate that impact of this difference. Since the secondary clarifiers are likely to be a limiting point in the effort to achieve the 60 MGD target flow it will be appropriate to reconfirm the ability to split flow as necessary.

4.5.2 Design Guidelines

Design criteria for secondary clarifiers are based on SOR, weir overflow rate and solids loading rate. For purposes of this evaluation, Table 4-9 provides the relevant characteristics of the five clarifiers.

Table 4-9
Secondary Clarifier Dimensions

Clarifier	Diameter, ft	Surface Area, sf	Weir Length, ft	Volume, gallons
T-15	130	13,279	728	1,489,856
T-16	130	13,279	728	1,489,856
T-17	130	13,279	728	1,489,856
T-18	130	13,279	728	1,489,856
T-27	175	24,063	1,438	3,671,745
Total		**77,177**	**4,350**	**9,631,169**

4.5.3 Evaluation

Table 4-10 summarizes design guidelines for secondary clarifiers. Table 4-11 provides estimated values of design parameters for the WRTP secondary clarifiers in comparison to design criteria, assuming that the flow is split proportionally among the five clarifiers based on their surface area (in this case the SOR and WLR). Table 4-12 summarizes the operating values at 60 MGD for each tank based on the estimated actual flow split from the hydraulic analysis.

Table 4-10
Secondary Clarifier Design Criteria

Parameter		Guideline			
		1 PADEP	2 Ten States	3 WEF MOP 8 [6]	4 M&E
Surface Overflow Rate, gpd/sf[1]	Average	800	NS[7]	400-700	400-700
	Peak	1,200[2]	1,200	1,000-1,600	1,000-1,600
Weir Loading Rate, gpd/ft	Average	15,000[3]	NS	NS	NS
	Peak		30,000	NS	30,000
Solids Loading Rate, lb/day/sf	Average	30[4]	NS	NS	20-30
	Peak	50[2,4]	35[3,5]	NS	48

Notes:
NS: Not Specified
1. Based on influent flow only.
2. At peak hourly flow.
3. At maximum monthly flow.
4. Based on mixed liquor flow (wastewater + return flow).
5. Peak loading rate for single stage nitrification.
6. In many cases MOP 8 does not provide criteria but refers to other literature values.

Table 4-11
Secondary Clarifier System
Area Proportioned Flow Split

		T-15	T-16	T-17	T-18	T-27
Flow Fraction		0.172	0.172	0.172	0.172	0.312
Surface Overflow Rate, gpd/sf	Average	777	777	777	777	777
	Peak	1,866	1,866	1,866	1,866	1,866
Weir Loading Rate, gpd/ft	Average	15,470	15,470	15,470	15,470	15,470
	Peak	37,123	37,123	37,123	37,123	37,123
Solids loading rate, lb/day/sf[2]	Average	34	34	34	34	34
	Peak	81	81	81	81	81

Notes:
1. assumes 60 MGD design average flow and 144 MGD peak hourly flow.
2. assumes 3,400 mg/l MLSS.

Table 4-12
Secondary Clarifier System
Flow Split Based on PIP Hydraulic Analysis

		T-15	T-16	T-17	T-18	T-27
Flow Fraction		0.205	0.19	0.205	0.19	0.21
Surface Overflow Rate, gpd/sf	Average	926	859	926	859	524
	Peak	2,220	2,060	2,220	2,060	1260
Weir Loading Rate, gpd/ft	Average	16,887	15,651	16,887	15,651	8,761
	Peak	40,540	37,560	40,530	37,560	21,030
Solids Loading rate, lb/day/sf [(2)]	Average	40	37	40	37	20
	Peak	96	90	96	90	55

Notes:
1. assumes 60 MGD design average flow and 144 MGD peak hourly flow.
2. assumes 3,400 mg/L MLSS.

Comparison of Table 4-8 and Table 4-9 indicates the following:

- At the target 60 MGD, the surface overflow rate exceeds design guidelines under either flow split scenario
- However if the flow is not balanced to split proportionally (i.e., if the flow split identified by the hydraulic analysis exists at 60 MGD), the SOR values for the smaller clarifiers are further above typical performance criteria (the larger clarifier, T-27 is within design guidelines under both cases since it is receives a smaller proportion of flow relative to its size).
- The effect of not balancing the clarifiers may result in reduced performance of the smaller four clarifiers at the target flow of 60 MGD.

As noted in Section 3.1.2.2 the current estimated peak hydraulic flow capacity of the aeration basins is 108.7 MGD. If the aeration basin hydraulic limitations were addressed without adding additional clarifiers the situation above would apply.

4.5.4 Options

The secondary clarifier system will exceed conventional design guidelines at the target flow of 60 MGD. An obvious method to resolve this would be to add additional clarifier capacity. However an alternate approach would be to evaluate the potential for optimizing the performance of the existing clarifier system, prior to incurring the capital cost of additional clarifiers. There may be two basic components to this process:

1. Determining the true settling characteristics of the sludge to determine whether higher than typical design parameters can be used. This could be done by field testing for sludge settleability characteristics ("solids flux" testing) and/or by clarifier stress testing (some of which has already been done as noted below).

2. Correcting any hydraulic limitations in the clarifiers, to ensure the full settling characteristics of the sludge can be exploited.

4.5.4.1 Sludge Settling and Thickening

Surface overflow rates and solids loading rates are determined by the settling characteristics of the sludge. Typical clarifier design criteria are based on typical sludge settling rates. For a good settling sludge, higher than typical design values may be used. There are already several lines of evidence suggesting that WRTP sludge characteristics may support higher than normal settling rates (and as noted below some of these data were used to support the re-rate of 50 MGD).

1. The 2003 "Report on DEP Guidelines" (WESTON 2003a) discussed historical data regarding effluent TSS during high loading periods and concluded that good performance was achieved at higher than normal overflow rates. Solids loading rate was within design guidelines so no such determination was necessary).

2. Stress Testing. Clarifier stress testing was conducted by DELCORA in November 2009 by directing additional flow to clarifiers T-16 and T-18. Solids removal remained good at flow rates up to approximately 22 MGD. When flow was increased to approximately 27.5 MGD effluent TSS began to increase and the sludge blanket level rose. These results indicate that on a short term basis peak loading rates in the range of 1600 gpd/sf may be acceptable. The Sludge Volume Index (SVI) on the day of testing was reported at 72. This indicates good settling characteristics (typically SVI values less than 100 are considered good.) Preliminary stress testing was also conducted in T-16 and T-8 on September 12, 206 and on T-27 on October 21, 2008. Results from these tests were variable and may have been affected by operating conditions during the test.

Additional testing to establish the actual operating range of the clarifiers could include (1) additional, and possibly longer term, stress testing and (2) solids flux testing. A procedure for

the latter is termed "State Point Analysis" and consists of bench scale solids flux rate testing. Solids flux rates are interpreted graphically in terms of overflow and underflow (RAS/WAS) rates to establish the range of acceptable loading rates for the clarifiers.

One possible limit on the use of the State Point Analysis procedure is the possibility that settling characteristics at 60 MGD (with a somewhat different wastewater composition) may differ from the current conditions and therefore the result of testing on the current sludge may not be fully representative. State Point Analysis is a procedure to evaluate clarifier performance in terms of its hydraulic operation (overflow and under flow rates) and the site specific settling characteristics of the sludge. It is conducted by performing site specific settling velocity tests at varying solids concentrations to establish a solids flux rate curve for the plant under various conditions. The flux rate relationship is graphically superimposed on the overflow and underflow rate curves to indicate whether the clarifier operating point (the "state point") is within acceptable ranges for the measured flux rate(s). These data may be used to adjust operating parameters or to determine the need for additional clarifiers.

4.5.4.2 Hydraulic Conditions

Hydraulic limitations in clarifiers may affect performance. While some hydraulic limitations may be inherent in the design of the clarifier tank, others could be possible be addressed by retrofits to existing clarifiers (it should be noted that at present there are no definitive data to indicate that the DELCORA clarifiers currently have such limitations).

One such modification is the use of density current baffles (one version of which is the Stamford Baffle, currently installed on DELCORA clarifier T-16. Such baffles have been demonstrated in a number of cases to substantially improve the performance of primary and secondary clarifiers. These are intended to address upward density currents along the clarifier wall carrying solids to the weir. They consist of baffle plates installed in the tank to intercept and redirect upward currents away from the weir and back into the center of the clarifier. As noted above clarifier T-16 has baffles installed. Long-term testing could be considered to evaluate whether its performance differs from the other clarifiers, although at the current low loadings the differences may not be apparent. Side by side comparison during the stress test did not indicate a clear effect of the baffles; in fact the effluent TSS values for T-16 were somewhat more variable than

those for T-18 at intermediate flow rates up to ~26 MGD but somewhat better at flow over 27 MGD. It is possible but not yet known that the decline in clarifier T-18 performance above 27 MGD was attributable at least in part to currents and, if so, baffles may assist in addressing this limitation.

Additional modifications that could be considered if warranted by testing could include Energy dissipating inlets and modifications to the sludge collection and withdrawal system.

These modifications could assist in taking full advantage of the settling characteristics of the sludge but would not provide an inherent improvement in those characteristics.

At present there are no definitive data to indicate whether such modifications would be of value at the DELCORA WRTP. Additional testing, such as dye testing in conjunction with stress testing to evaluate currents, could be considered to investigate this possibility.

Discussion with DELCORA during this project did however identify one potential concern. It was reported that the recycle sludge pumps in T-27 sometimes draw the feed well dry, inferring that the sludge withdraw piping on the clarifier cannot keep up with the intended RAS rate; specifically it was inferred that additional sludge withdrawal pipes may be needed; the range of RAS flow over which this occurs and the depths of the sludge blanket has not been investigated for this study. However the manufacturer of the T-27 clarifier mechanism (EIMCO) was contacted by WESTON regarding this possibility. The manufacturer indicated that the reported condition could occur because the withdrawal piping capacity is in fact low or because the withdrawal pipes are mounted too close to the bottom of the tank. Potential corrective actions could be, (1) to install additional withdrawal pipes, (2) to install larger withdrawal pipes and (3) to ensure that the pipes are mounted at the appropriate distance from the floor. EIMCO also advised that a previous evaluation had been conducted for T-27. WESTON has requested EIMCO to provide additional information on the approach to investigating and resolving this issue.

As a follow-up, WESTON again contacted the equipment manufacturer Ovivo (formerly EIMCO) on February 23, 2011 to request any documentation on the previous evaluation. On March 4, 2011, Ovivo advised that the only available documentation from the test were headloss

calculations and that the possibility of vortexing of the sludge collection box had been discussed. No additional information is available from the manufacturer on this test.

4.6 POST AERATION TANKS

There are two post-aeration tanks at the WRTP. The tanks are square with a length of 48.5 feet, width of 48.5 feet, and side water depth of 11.5 feet.

These tanks are not currently needed for aeration because the current NPDES permit does not specify a minimum dissolved oxygen level in the effluent (effluent DO is not a regulated parameter). In addition, turbulence over the chlorine contact tank weir and in the effluent chamber introduces dissolved oxygen to the effluent.

It should be noted that PADEP guidelines specify that post aeration to meet DO requirements (if such are imposed in the future) should be done after the chorine contact tank. The current WRTP configuration, however, places the post aeration tanks prior to the chlorine contact chambers. Under current permit conditions this is not an issue but modifications could be required if DO limits are imposed in the future.

4.7 DISINFECTION

4.7.1 Chlorine Contact System

4.7.1.1 Description

There are two chlorine contact tanks at the WRTP. The tanks are rectangular with a length of 116 feet, width of 36 feet, and side water depth of 12.5 feet. The tanks are baffled to provide a long flow path and prevent short circuiting, to help in providing adequate contact time. There are also two post-aeration tanks at the WRTP as noted above.

Based on the results of the PIP report, it was determined that it was desirable to operate one of the post-aeration tanks as a chlorine contact chamber to process a maximum peak flow rate of 94.0 MGD.

4.7.1.2 Design Guidelines

The effectiveness of chlorination is a function of chlorine dosage and contact time. As a guideline, however, PADEP specifies a minimum contact time of 15 minutes at peak hourly flow or 30 minutes at maximum monthly average flow, assuming adequate mixing. Other standard references (M&E, 1991) indicate that 15 minutes at peak flow is a commonly accepted value. As discussed below contact time and chlorine dosage should be considered together.

4.7.1.3 Evaluation

Table 4-13 shows the contact time at (1) peak hourly flow and (2) maximum monthly average flow using all four tanks (two chlorine contact tanks and two post aeration tanks) for chlorine contact chambers.

Table 4-13
Chlorine Contact Time as Compared to PADEP Guidelines

	Peak Hourly Flow		Maximum Monthly Flow	
	Required	Provided	Required	Provided
Hydraulic Retention Time, minutes	15	11.8	30	16.4

As shown in Table 4-13 chlorine contact time at the target flow of 60 MGD, at the estimated peaking factors, does not meet PADEP Guidelines.

4.7.2 Chlorine Feed System

4.7.2.1 Description

DELCORA uses a gas chlorination system. One ton chlorine cylinders located in the chlorine storage room within Building B-3 supply chlorine to a chlorine evaporator/feed system. The evaporator/chlorinator room currently has four Wallace and Tiernan (W&T) series 50-200 evaporative units and four W&T V-2000, V-NOTCH chlorinators. The V-2000 series has a range of capacities. The particular units at the WRTP include two units at 5,000 lb/day each and two units at 2,000 lb/day each.

4.7.2.2 Design Guidelines

Typical design guidelines for applied chlorine dosage are provided in Table 4-14.

Table 4-14
Design Criteria
Chlorine Feed Systems

Parameter	Guideline			
	1 PADEP[1]	2 Ten States	3 WEF MOP 8[2]	4 M&E
Chlorine Dosage, mg/L	8	8	NS	2-8

Notes:
1. Minimum dosing capacity.
2. MOP-8 refers to Ten States and M&E, as well as the Chlorine Handbook which provides a range of 6-9 mg/L.

More specifically PADEP guidelines specify that disinfection capacity "shall be adequate to produce an effluent that will meet the fecal coliform limits specified by the Department for that installation. Required disinfection capacity will vary, depending on the uses and points of application of the disinfection chemical. For domestic wastewater, the following minimum dosing capacity may be used as a guide in sizing chlorination facilities."

Table 4-15
Minimum Chlorine Dosing Capacity

Type of Treatment	Chlorine Dosage mg/L
Trickling Filter and Rotating Biological Contactor Effluent	12
Waste Stabilization Pond Effluent	12
Activated Sludge Plant Effluent	8
Tertiary Filtration Effluent	6
Nitrified Effluent	6

PADEP Guidelines do not specify the flow at which these guideline dosages apply. PADEP also specifies that standby equipment of sufficient capacity should be available to replace the largest unit during shutdowns.

4.7.2.3 Evaluation

Table 4-16 summarizes the chlorine feed required for average and peak flow conditions at the target flow of 60 MGD. Assuming one of the larger (5,000 lb/day) feed units is out of service (per PADEP guidelines) the total chlorination capacity is 9,000 lb/day. Based on the values in

Table 4-16, the chlorination feed system has adequate capacity to meet PADEP dosage guidance at average and maximum monthly demands with the largest unit out of service but cannot meet the peak hourly demand.

Table 4-16
Chlorine Feed Requirements

Flow		Chlorine Feed Requirement, lb/day
Condition	Value, MGD	
Average	60	4002
Maximum Monthly	80	5336
Peak Hourly	144	9604

4.7.3 Summary

The existing chlorine feed system has adequate capacity to meet PADEP dosage guidelines at average conditions at the target 60 MGD flow scenario but not for the peak hourly flow. The chlorine contract tank does not meet criteria for chlorine contact time.

If the PADEP design guideline for chlorine feed capacity is to be met an additional chlorine evaporator and chlorinator would be required. However as summarized above PADEP guidelines require disinfection adequate to meet permit requirements. The WRTP typically uses a dosage well below state guidelines with satisfactory performance. This is achieved at a contact time of 38.6 minutes at average flow (16 minutes at peak hourly flow) if all four tanks are used. It is possible therefore that adequate performance could be achieved at a dosage lower than 8 mg/L in the future as well. However the interrelationships between dosage and contact time must be considered.

Disinfection is a function of chlorine dosage and contact time. It might be possible to use a higher chlorine dosage to maintain disinfection efficiency. The maximum applied dosage that could be achieved from the existing system with one unit out of service, (9,000 lb/day total capacity) is approximately 7.5 mg/L at peak hourly flow. While not meeting PADEP guidelines this value is within the range of typical dosages provided by other data and, given the WRTP's past performance, it may be sufficient to provide disinfection *if adequate contact time can be provided.* Since the actual dosage needed depends also on the characteristics of the wastewater,

testing would be warranted to determine whether this dosage provides adequate disinfection performance.

An additional factor to be considered, however, is the WRTP's effluent limit on chlorine residual (0.5 mg/L monthly average, 1.0 mg/L instantaneous maximum). If the higher applied dosage results in an exceedance of the current (and assumed future) TRC limit a dechlorination step would be needed to meet the TRC limit.

4.8 SOLIDS HANDLING

4.8.1 Solids Quantities

Evaluation of solids handling (thickening and dewatering) requires first an estimate of total solids produced in the system.

A typical value for total sludge production from a municipal WWTP is on the order of 1950 pounds of dry solids per day per million gallons of flow, (based upon 1250 lb/MG of primary solids and 700 lb/MG of waste activated sludge (WAS) (M&E, Table 12-7).) This is 0.975 tons dry solids per million gallons of flow (dt/MG).

The following provide estimates of total sludge at the WRTP:

- Waste activated sludge is estimated at 21450 lb/day (based on DELCORA data for WAS sludge pumped from PS-3 and PS-5).
- There are currently two ways to estimate primary solids:
    - Based on data provided by DELCORA for the years 2007 through November 2009, the daily primary sludge production would be estimated at approximately 47,400 lb/day (assuming 36.65 MGD influent flow at 252 mg/L TSS and 59% primary removal efficiency).
    - However primary sludge pumping data indicates a total primary sludge volume of approximately 70,500 /lb/day (169,000 gpd at 5% total solids)

The total sludge quantity is approximately 66,950- lb/day or 0.91 dt/MG at the current average flow using the primary performance data and 91,950 lb/day, (45.98 dt/day) or approximately 1.25 dt/MG of influent flow, using the sludge pumping data

DELCORA's data for sludge fed to the incinerators indicates an average value of 44.2 dt/day for the period Jan 2007-mid November 2009. This would be an apparent value on the order of 1.21 dt/MG and is in reasonable agreement with the total value based on primary sludge pumping data. (Note that this value would also include trucked-in sludge and would normally be slightly higher than the WRTP-generated quantity.) It is assumed that the trucked in sludge quantities will remain approximately the same in the future, and their effect on the total sludge will diminish.

The observed production is based on current influent conditions. As shown in Table 1-2, the future BOD_5 loading is projected to be slightly (5%) higher. This will increase the WAS quantity slightly.

For purpose of this evaluation therefore an overall future sludge generation rate of 1.25 dt/MG is assumed.

Since the thickeners are only used for WAS, this does not affect the DAF analysis.

4.8.2 Thickening

4.8.2.1 Description

The WRTP uses dissolved air flotation (DAF) for thickening the waste activated sludge (WAS) prior to dewatering and thickening. (According to Catania Engineering Associates Drawing 80700-001, sheet 102, primary sludge could be diverted to the DAFs or to the holding tanks; but the DAFs are not used for the primary sludge.)

The system includes four DAF tanks (T-23, T-24, T-25, and T-26) located in Building B-4, each 20 ft wide and 64.5 ft long (in the flotation zone) with a maximum water depth of approximately 10.6 ft. Each DAF tank has its own pressure retention tank; two compressors are provided for the system. Recycle/utility water is fed to the pressure retention tanks; the pressurized water/dissolved air mixture is mixed with influent sludge just prior to entry to the DAF tanks where separation takes place in the flotation zone. Chemical addition (polymer) is used to assist in thickening. The floated solids are removed by a skimmer system. The DAF system dates to the early 1970's.

DELCORA reports that only two of the four DAF tanks can be used for sludge thickening capacity. One cannot be used as a DAF unit because its pressure retention tank no longer meets code requirements for a pressure vessel. This tank is used, with atmospheric air, to separate grease (essentially air flotation, vs. DAF operation.). Of the remaining three DAF tanks, DELCORA reports that, typically, one is out of service and often used to provide repair parts to the other two. Therefore this evaluation assumes that two duty DAF tanks are available for WAS thickening.

4.8.2.2 Current Performance

DAF units typically produce thickened sludge with concentrations up to 4% (40,000 mg/L). Data provided by DELCORA indicates an average of 26,600 gallons per day of "biosolids" pumped from building B-4. Assuming 4% thickened solids, this volume would constitute approximately 8,870 lb/day of solids, which is too low to account for the daily WAS value (~ 21454 lb/day). Capture of the daily WAS in the pumped value would suggest a very high DAF float concentration. Additional evaluation of these values could be of use to confirm existing performance. However DELCORA is in the process of evaluating options for modifying or replacing the thickening system due to the above-noted age and mechanical issues. Therefore this evaluation considers the potential capacity of the DAFs at conventional design values.

4.8.2.3 Design Criteria

General design criteria for DAF units used to thicken WWTP sludge are based primarily on solids loading and hydraulic loading per square foot of tank area. Typical values are provided in Table 4-17.

Table 4-17
Design Criteria
DAF Systems

Parameter		Guideline			
		1 PADEP	2 Ten States	3 WEF MOP 8	4 M&E
Solids loading rate, lb/day/sf	without chemical addition	20	NS	9.6-24	14-30
	with chemical addition	40	NS	"50-100% increase	Up to 45
Hydraulic loading rate, gpm/sf		0.8	NS	0.5-2	0.2-4

Notes:
NS: Not Specified

4.8.2.4 Evaluation

Based upon current data and at the target flow of 60 MGD and the influent conditions in Table 1-2 the estimated WAS loading to the DAF would be approximately 38,400 lb/day of slides and 460,600 gpd of WAS. Peak loads would be approximately 75,000 lb/day and 899,600 gpd. Table 4-18 provides estimated operating values for solids loading rate and hydraulic loading rate at the target value of 60 MGD.

Table 4-18
Estimated DAF Operating Loadings at 60 MGD

Parameter	Value at average loading	Value at peak loading
Solids Loading Rate, lb/day/sf	14.9	29
Hydraulic loading rate, gpm/sf [1]	0.13	0.25

Notes:
1. assumes estimated WAS at 60 MGD settles to 10,000 mg/L.

4.8.3 Sludge Holding Tanks

The WRTP has four (4) tanks (ET-1, ET-2, ET-3, and ET-4) currently used for sludge holding (note these tanks were originally designed as digesters prior to construction of the incinerator. Based upon the design drawings (Catania Engineering Associates, Dwg. 80700-101) each tank is 52 ft in diameter with a 18.5 ft wall height and 16 ft SWD and a 6 ft cone bottom. The estimated

liquid volume for each tank is approximately 250,000 gallons and the combined liquid capacity is approximately 1,000,000 gallons.

The primary sludge is pumped from the primary clarifiers and stored in one of the four sludge storage tanks. The waste activated sludge (WAS) is thickened in the dissolved air flotation (DAF) system. The trucked in grease is also separated in one of the DAF tanks (as noted above, under atmospheric conditions). The WAS and thickened grease are then combined and stored in tank ET-2. This system was recently modified to allow the WAS/grease to be metered into the incinerator feed to help control localized hotspot resulting from the high-BTU value grease in the system. The trucked in sludge is also directed to one of the holding tanks.

4.8.4 Dewatering

4.8.4.1 Description

The WRTP uses belt filter presses (BFPs) for dewatering primary, secondary and trucked-in sludge. There are three (3) Ashbrook 2-meter BFPs installed in building B-3 with space allotted for a fourth BFP.

4.8.4.2 Current Performance

The sludge is pumped from the sludge storage tanks to any one or more of three belt filter presses. Sludge cake from the belt presses have ranged generally from 21% to 26% solids. This indicates good dewatering characteristics of the sludge and good performance by the belt filter presses.

4.8.4.3 Design Criteria

Typical operating values for BFPs, depending on sludge type and feed concentrations are summarized in Table 4-19.

Table 4-19
Loading Criteria
BFP Systems

Parameter	Guideline			
	1 PADEP	2 Ten States	3 WEF MOP 8	4 M&E
Solids loading rate, lb/meter/hour	NS	NS	396-704	200-1,500
Hydraulic throughput, gal/meter/min	NS	NS	20.6-50.7	25-100

NS: Not Specified

Note that PADEP design guidelines do not specify loading rates but do state that the number of mechanical dewatering units "should be sufficient to dewater the sludge produced with one unit out of service. If standby dewatering facilities are not available, adequate storage facilities equivalent to a three-month sludge production, or other means of sludge disposal shall be provided." Even if all sludge was thickened prior to storage the existing WRTP storage tank system does not provide the specified three month capacity.

4.8.4.4 Evaluation

At the conservatively projected sludge generation rate of 1.25 dt/MG the estimated sludge load is summarized in Table 4-20. The peak value is based on the peak day data since short term peaks (i.e. hourly peaks) will not have a major effect on sludge quantity and could be accommodated in the storage system.

Table 4-20
Estimated Sludge Quantity

	Daily Sludge	
	Dt/day	Gallons per day (1)
Average	75	449,800
Peak Daily	165(2)	992,400

Notes:
1. Assumes thickened sludge at 4% total solids.
2. Assumes peak sludge load is determined by peak BOD_5 and TSS loading factors.

Table 4-21 summarizes BFP solids loading rates for average and maximum conditions. Table 4-22 summarizes hydraulic loading rates.

Table 4-21
Belt Filter Press Solids Loading Rates

Condition	Solids Loading Rate, lb/m/day		
	Two Operating 24 hours per day, One Standby[1]	Three Operating 24 hours per day, One Standby [2]	Four Operating 24 hours per day (peak only)
Average	1,560	1,040	--
Peak Daily	3,450	2,300	1,730

Notes:
1. Current condition with three installed BFP.
2. Assumes fourth BFP is installed.

Table 4-22
Belt Filter Press Hydraulic Loading Rates

Condition	Hydraulic Loading Rate, gal/m/min		
	Two Operating 24 hours per day, One Standby[1]	Three Operating 24 hours per day, One standby [2]	Four Operating 24 hours per day (peak only)
Average	78	52	NA[3]
Peak Daily	172	114	86

Notes:
1. Current condition with three installed BFP.
2. Assumes fourth BFP is installed.
3. Not applicable; a spare press is intended at average conditions.

Overall these data indicate that the three existing presses would not be adequate at the target flow of 60 MGD. If a fourth press is added loading rates for three operating presses are within normal ranges. Even with the fourth press operating on peak days, the loading rate is high. However it is possible a combination of four operating presses and optimal use of storage could be used to accommodate this peak day.

This page is intentionally blank.

5. SUMMARY

5.1 SUMMARY OF CAPACITY

Based upon the process evaluation, the WRTP does not have sufficient capacity to meet the target conditions (60 MGD capacity). While some of the limitation is based on the increased flow (and the increased wastewater strength over the past several years) an additional and significant constraint is the possible need to nitrify in the future. The effect of the nitrification requirement most directly impacts the aeration basins, the aeration system and the secondary clarifier capacity, where significantly additional capacity is required for nitrification as compared to BOD_5 removal.

5.2 RECOMMENDED UPGRADES TO PROVIDE 60 MGD AVERAGE CAPACITY

The following process upgrades would be needed to provide 60 MGD capacity under the conditions summarized in Section 2 of this report:

- Additional activated sludge capacity
  - Aeration basins
  - Aeration system
- Secondary clarification system
- Disinfection system
- Dewatering system

A conceptual block flow diagram is shown in Figure 5-1. The following sections outline the nature of these upgrades and provide an estimate of their cost. Figure 5-2 and Figure 5-3 provide conceptual layouts for these upgrades.

5.2.1 Activated Sludge System

Additional activated sludge capacity is needed to provide for BOD_5 removal and nitrification at 60 MGD average flow. This would include both additional aeration basin capacity and additional aeration (blowers).

Restoring Resource Efficiency

FIGURE 5-3

WRTP CONCEPTUAL LAYOUT AERIAL

This page is intentionally blank.

Based upon preliminary process calculations, a total aeration volume of approximately 21 million gallons would be needed at operating conditions (MLSS, SRT) comparable to those currently used (which are providing for nitrification). As noted in Section 4, conversion to MBR or IFAS configurations could be considered; however this evaluation assumes expansion with a conventional activated sludge system.

Four new aeration basins would be constructed to the north of the existing system in the area occupied by the former ash lagoon. The new tanks would be pile-supported concrete structures. The foot print would be slightly larger than the existing to provide 11 million gallons of capacity as compared to 10 MG in the existing. As shown on Figure 5-2 and Figure 5-3, this upgrade, along with others, would likely require expansion to the property to the north of the current site. In an effort to reduce this impact the basins could be rectangular as compared to the current square configuration. However space constraints are also present to the east and west (including the need for additional clarification).

5.2.1.1 Aeration Capacity

The total aeration capacity required for nitrification at the 99th percentile peak loads is estimated at approximately 53,900 scfm. This would require additional aeration capacity. Adding four (4) additional blowers in addition to the existing three blowers at 11,000 scfm each would provide a total capacity of 66,000 scfm, slightly less than the calculated value. However, these estimates are based upon preliminary information and the final sizing will need to be determined during preliminary design. It is possible to use slightly larger blowers for the new units with appropriate controls to balance total air flow among the eight aeration basins. For purposes of this budgetary estimate, it is assumed that the four new blowers of the same configuration as the existing would be used. In order to provide for full aeration capacity with one unit offline, per PADEP guidelines, a sixth blower would be needed.

Therefore this upgrade would include three new blowers; a new blower building, similar to the existing, would be constructed. The new aeration basins would use the same panel diffusers as the existing. The building would be a pile-supported foundation with precast panel walls. Another option would be to expand the existing Aeration Blower Building (B-6) and provide an overhead duct to the new aeration basins. Depending upon the space requirements of the

additional blowers, the relocation of other facilities (e.g., Maintenance Office) may be required to accommodate an expansion of B-6.

5.2.1.2 Cost

An order of magnitude estimate for cost for the upgraded activated sludge system is provided in Table 5-1.

Table 5-1
Order of Magnitude Estimate of Cost
Activated Sludge System

Item	Total Cost
Aeration Basins Tankage	$11,700,000
Aeration Basin Pilings	$1,200,000
Blower Control Building, including foundations and pilings	$850,800
Blowers, Installed	$2,163,100
Diffused Aeration System, in basin	$1,765,000
Aeration Header Piping	$645,000
Influent Pipe	$300,000
Influent Pipe Support Pilings	$90,000
Tank Inlet Sluice Gates	$100,000
Subtotal	**$18,813,900**
Power Distribution @ 15%	$2,822,085
Electrical and Controls @2%	$376,378
Total Construction Cost (rounded)	**$22,012,263**

5.2.2 Secondary Clarifier System

5.2.2.1 Description

One additional clarifier would be provided making a total of six units. In order to reduce loading rates for the system the new clarifier would be 200 ft in diameter. For purposes of this evaluation it is assumed the clarifier type would be the overall configuration as T-27.

The new clarifier would be constructed to the west of clarifier T-27 and would tie into pump station PS-5. The new tank would be a pile-supported concrete structure. The feed to the six clarifiers would be modifies to allow the correct area-proportioned flow split among the units and the return from the six clarifiers together would be modified as necessary to provide the necessary RAS split between the old and new aeration basins. As shown on Figure 5-2 and

Figure 5-3 the new clarifier would also require an expansion of the site to the north of the current WRTP property.

5.2.2.2 Cost

An order of magnitude estimate for cost for the upgraded activated sludge system is provided in Table 5-2.

Table 5-2
Order of Magnitude Estimate of Cost
Secondary Clarifier System

Item	Total Cost
Clarifier Tankage	$2,990,000
Clarifier Pilings	$480,000
Clarifier Equipment	$542,000
Piping (Influent, Effluent, RAS, WAS)	$1,410,000
Pipe Support Pilings (Influent, Effluent, RAS, WAS)	$630,000
Pumps (WAS, RAS)	$600,000
Subtotal	**$6,652,000**
Power Distribution[1]	--
Instrumentation and Controls @2%	$133,040
Total Construction Cost (rounded)	**$6,785,000**

Notes:
1. Assumed existing.

5.2.3 Disinfection System

5.2.3.1 Description

The expanded chlorination system would include additional chlorine contact tanks to provide the required contract time and one additional chlorine evaporator/chlorinator.

The new chlorine contact tanks would be constructed on the south side of the post aeration tanks (Figure 5-2 and Figure 5-3) and the system would be modified to allow flow from the new tanks then through the existing. Some demolition in the area south of the post aeration tanks would be needed construct the new tanks. Baffles would be installed in the post aeration tanks to better provide the flow path desired for chlorination and minimize short circuiting. The new tanks would be pile-supported concrete structures.

As shown on Figure 5-2 and Figure 5-3, space in this area for construction is limited, and construction near the existing bulkhead would be complicated.

The new chlorine evaporators and chlorinator would be installed in the chlorine room (in Building B-3).

5.2.3.2 Cost

An order of magnitude estimate for cost for the upgraded activated sludge system is provided in Table 5-3.

Table 5-3
Order of Magnitude Estimate of Cost
Disinfection System

Item	Total Cost
Demolition	$50,000
Chlorine Contact Tank	$1,100,000
Chlorine Contact Tank Pilings	$80,000
Chlorine Evaporator	$14,000
Chlorinator	$8,000
Chlorine Feed Piping	$200,000
Subtotal	**$1,452,000**
Power Distribution[1]	
Electrical and Controls, ls	$10,000
Total Construction Cost (rounded)	**$1,462,000**

Notes:
1. Assumed existing.

5.2.4 Dewatering System

5.2.4.1 Description

To provide the required dewatering capacity with one unit off line, a fourth 2-meter belt filter press would be installed in the filter press room in Building B-3. Space was allotted in this room for a fourth filter press and modifications to the building are therefore not required for this addition.

5.2.4.2 Cost

An order of magnitude estimate for cost for the upgraded activated sludge system is provided in Table 5-4.

Table 5-4
Order of Magnitude Estimate of Cost
Dewatering System

Item	Total Cost
Belt Filter Press, Installed	$335,000
Total Installed Cost (rounded)	**$335,000**

5.2.5 Summary of Upgrades

Table 5-5 provides a summary of the total estimated cost for all process upgrades to provide the target 60 MGD capacity.

Table 5-5
Order of Magnitude Estimate of Cost
Combined Upgrades

Item		Total Cost
Activated Sludge System		$21,496,500
Secondary Clarifier System		$6,785,000
Disinfection System		$1,462,000
Dewatering System		$335,000
Subtotal		**$30,078,200**
Engineering and Legal	20%	$6,015,700
Contingency	25%	$7,519,625
Total (rounded)		**$43,614,000**

5.3 NEW OUTFALL DIFFUSER

5.3.1 Description

In addition the process upgrades discussed above DELCORA is investigating the possible need for an outfall diffuser system. Effluent from the WRTP is currently discharged through three 42-inch diameter openings essentially at the property bulkhead. A new outfall pipe and diffuser would be used to extend the discharge further into the river and better mix the discharge into the stream flow. This would be useful to help address possible future effluent limits that would be based on in-stream quality criteria (primarily Water Quality Based Effluent Limitations (WQBEL's) which may in the future be required to meet DRBC Water Quality Criteria. This section prices an order or magnitude cost for an outfall diffuser system. It should be noted that the degree of mixing required for any particular WQBEL parameter has not been established.

Once the mixing objectives are quantified the design of the diffuser to provide that mixing would be based on, generally by dilution modeling using, for example, the Tidal Cormix model.

5.3.2 Cost

For purposes of this preliminary evaluation it is assumed that a new outfall would be constructed approximately 455 ft into the river, roughly perpendicular to the bulkhead. The outfall would be a pile supported pipe to control settling into the anticipated soft river bottom in the area.

Based upon these assumed design parameters, an order of magnitude estimate for cost for the upgraded activated sludge system is provided in Table 5-6.

Table 5-6
Order of Magnitude Estimate of Cost
Outfall Diffuser System

Item	Total Cost
New Outfall and Diffuser	$2,330,000
Admin / Legal (2%)	$46,600
Contingency (15%)	$349,500
Bond / Insurance (4%)	$93,200
Total Installed Cost (rounded)	**$2,819,300**

APPENDIX A

PROJECTED WASTEWATER CHARACTERISTICS

This page is intentionally blank.

Table A-1 summarizes the data for the capacity evaluation. This estimate uses a weighted average approach to estimate the combined characteristics at 60 MGD from the three main anticipated wastewater sources: DELCORA's existing sources, the Southwest Delaware County Municipal Authority (SWDCMA) and other future flows.

Table A-1
Estimated Wastewater Characteristics for Capacity Evaluation

Parameter	Source			Weighted Average Characteristics (rounded)
	DELCORA	SWDCMA	Other Future Sources [1]	
Flow, MGD	36.65	6	17.35	
BOD_5, mg/L	199	317	190	208
COD, mg/L	471	718	430	484
TSS, mg/L	252	351	210	250
Total Nitrogen, mg/L	19.7	40	40	28
Ammonia Nitrogen, mg/L	10.7	25	25	16
Oil and Grease, mg/L	21.6	90	90	48
Alkalinity, as $CaCO_3$, mg/L	90	90	90	90

Notes:
1. Parameter values from M&E, Fourth Edition, 2003, Table 3-15.

Wastewater Flow

Average daily waste water flows included:

- Existing DELCORA flow, approximately 36.65 MGD average based on January 2007-November 2009 data.
- Anticipated SWDCMA flow using the full rated capacity of 6 MGD. Based on the Chapter 94 Report, the projected 2013 flow is 5.8 MGD. It is assumed DELCORA would take over the full rated capacity of 6 MGD.
- Remaining flow from other sources up to a maximum of 60 MGD daily average.

Wastewater Characteristics;

The following estimates were used:

- For those parameters for which DELCORA has influent data (BOD_5, COD, Total Nitrogen, Ammonia, Oil and Grease), the values in Table A-1 are the averages based on 2007-2009 data.
- For the SWDCMA plant, the BOD_5 value is based upon the projected 2013 BOD_5 loading (15,346 lb/day) and the projected 2013 flow of 5.8 MGD. It is assumed the concentration will remain the same as the flow increases to the rated 6 MGD.
- For all other flow, this evaluation uses typical medium strength wastewater characteristic values from Metcalf and Eddy, Wastewater Engineering, Fourth Edition 2003, Table 3-15. Note that PADEP's Municipal WWTP guidance and Recommended Standards for Wastewater Facilities, 2004 Edition ("Ten States Standards") do not provide constituent data to be used for planning. (PADEP guidance for BOD_5 only provides loads on a per capita basis.) Ten States Standards references M&E Fourth Edition waste strength data in Appendix A (related to septage handling and treatment).
- The those parameters for DELCORA for which data are not available have been estimated from the M&E data using the ratio of DELCORA's BOD_5 (199 mg/L) to the M&E value (220 mg/L), assuming that the other parameters would vary in proportion to the BOD_5 levels. The same procedure was used for SWDCMA data except for nitrogen and O& G levels for which, at DELCORA's recommendation the M&E values were used.

Assumed alkalinity values are provided because the nitrification evaluation would need to consider whether there is adequate alkalinity in the system.

Subj: Possible transfer of DRBC $CBOD_{20}$ Waste Load Allocation to WRTP

I spoke with Steve Walsh of DRBC regarding whether, if one plant closes and connects to another, the closing facility's $CBOD_{20}$ Waste Load Allocation (WLA) would be transferred to the receiving facility. I did not identify the specific situation or the plants involved. Since the answer to the question depends in part on where the plants are, I indicated only that the facilities would be in Zones 4 or 5 of the estuary (DELCORA's WRTP is in Zone 4).

As a point of clarification the $CBOD_{20}$ WLAs are applied only to plants discharging to the estuary, i.e. the Delaware River or the tidal portions of its tributaries. For plants located on the non-tidal portions of tributaries, the BOD_5 limits are based on DRBC's Water Quality Criteria for those tributaries.

SCENARIO 1: Assuming both plants discharge to the estuary and therefore have WLAs:

- In general the receiving plant would get some or all of the allocation from the closing plant.
- How much of a closing plant's allocation would be transferred to the receiving plant depends where the plants are located.
    - If they are located in the same Zone and if that Zone has capacity remaining, the receiving plant could get all or most of the closing plant's allocation. (This is the case for Zone 4 where DELCORA is located and may have been the situation when, for example, the Muckinapates and Darby Creek Plants were closed in 1977).
    - By contrast, in Zone 2, which is already over-allocated, the receiving plant would probably not get the allocation.
- If both plants discharge to the estuary but in different Zones, the transfer of allocation would not likely be linear, since the available capacity in the two Zones may differ.

SCENARIO 2: Assuming the closing plant does not discharge to a tidal tributary:

- If the closing plant discharges to a non tidal tributary, such that it doesn't have an allocation, then whether the receiving plant's allocation is adjusted for taking the new load would be case-specific.

In general if the receiving plant has room in its existing allocation to accommodate the closing plant, they probably won't increase the allocation. Basically this situation would require them to review the case to make a determination.
Based upon my review of the existing Waste Load Allocation document (revision dated 1 October 2000) it does not appear that the Southwest plant has an allocation. I infer it does not discharge to a tidal portion of a tributary. If this is the case then I think Scenario 2 above would apply.

As a matter of information DRBC also advises that they are working on a revision to the waste load allocation document and it will likely be promulgated in 2010.

APPENDIX C
HYDRAULIC CALCULATIONS
