In re: Docket No. A-2019-3015173
Application of Aqua Pennsylvania Wastewater, Inc. pursuant to Sections 1102, 1329 and 507 of the Public Utility Code for Approval of its Acquisition of the Wastewater System Assets of the Delaware County Regional Water Quality Control Authority

Dear Secretary Chiavetta:

We are counsel to Aqua Pennsylvania Wastewater, Inc. ("Aqua" or "Company") in connection with its above referenced Application, filed with the Public Utility Commission ("Commission") on March 3, 2020, pursuant to Sections 1102, 1329 and 507 of the Public Utility Code, for approval of the acquisition of the wastewater system assets of the Delaware County Regional Water Quality Control Authority. The Bureau of Technical Utility Services is reviewing the Application and has asked that we address certain requests for additional information. We addressed several requests in a letter filed with you on May 6, 2020. Additional requests are addressed hereinafter. Requests not addressed in this letter and the May 6 letter will be addressed in a later submission.

INFORMATION REQUEST 18:
Checklist Item No. 20.f. – The Application's Page 11 indicates DELCORA recently updated its Long-Term Control Plan (LTCP) for the City of Chester's combined sewer system and submitted it for review. Please provide an electronic copy of DELCORA's LTCP and provide a list of the current actions DELCORA has planned or completed in its implementation of the LTCP.

RESPONSE:
An electronic copy of the LTCP is provided with this letter. An Implementation Schedule, which includes Project Milestones, is included in Section 10.3.6 of the LTCP.

INFORMATION REQUEST 20:
Checklist Item No. 22.a – The requested service territory depicted on the Application's Exhibit A3 does not appear to match the Springhill Farms service area depicted in Appendix II, Map 1 of the Update to Chadds Ford Township's Sewage Facilities Management (Act 537) Plan provided as part of the Application's Exhibit P3. Please explain this discrepancy.

RESPONSE:
Appendix II, Map 1 of the Update to Chadds Ford Township Act 537 Plan included as Application Exhibit P3, shows all areas of Chadds Ford Township that would have their default connection into Springhill Farms system. The areas delineated as Spring Hill Farms Service Area in the Chadds Ford Act 537 Plan that were not included in Aqua's proposed service territory in Application Exhibit A3 are not currently connected to the Springhill Farms system and are connected to on-lot septic. In the future if those residents of Chadds Ford Township had failing septic systems they would connect to the Springhill Farms system and Aqua would revise its service territory accordingly through a service territory expansion application.

INFORMATION REQUEST 28:
Checklist Item No. 25 – The Application's Exhibit F4, Supplemental Agreement dated November 26, 1952, is missing pages 1, 3, 5, 7, 9, 11 and 13. Please provide a complete copy of this agreement that includes the noted missing pages.

RESPONSE:
Aqua has submitted a Right-to-Know Request to Ridley Park Borough for a complete copy of the Agreement and will file the Agreement with the Commission after receiving the complete copy in response to its Request. A copy of the Right-to-Know Request is included with this letter.

INFORMATION REQUEST 31:
Checklist Item No. 25 – The copy of the Sanitary Sewer Improvements Agreement, dated March 2016, By and Among DELCORA and Brookhaven Acquisition LP, provided as the Application's Exhibit F67 is not complete or fully executed by all parties, as it does not include all required signatures and its Exhibits A through E are blank. Please provide a complete and fully executed version of this agreement.

RESPONSE:
A complete copy of the Agreement is included with this letter.

INFORMATION REQUEST 32:
Checklist Item No. 25 – The Application's Exhibit F101 is missing Exhibits A, B and C. Please provide copies of these exhibits.

RESPONSE:
Aqua has submitted a Right-to-Know Request to Rose Valley Borough for a complete copy of the Agreement and will file the Agreement with the Commission after receiving the

complete copy in response to its Request. A copy of the Right-to-Know Request is included with this letter.

INFORMATION REQUEST 33:
Checklist Item No. 25 – The Application's Exhibit F103 is missing its copy of its Exhibit A map area and boundary description. Please provide a copy of this exhibit.

RESPONSE:
Aqua has submitted a Right-to-Know Request to Rose Valley Borough for a complete copy of the Agreement and will file the Agreement with the Commission after receiving the complete copy in response to its Request. A copy of the Right-to-Know Request is included with this letter.

INFORMATION REQUEST 35:
Checklist Item No. 25 – The Application does not contain a list of "other" DELCORA contracts with associated dollar values as required in Checklist Item No. 25 that Aqua intends to continue after the completion of the acquisition. Please provide a comprehensive list of all other contracts, based as a revenue or expense, APW intends to maintain due to contractual obligations or for the continued operation of the wastewater assets.

RESPONSE:
The dollar values associated with DELCORA contracts is considered CONFIDENTIAL. A PUBLIC version, with CONFIDENTIAL information redacted, of the contracts that Aqua plans to maintain presently for the continued operation of the system is included with this letter. A CONFIDENTIAL version of the list is being provided to the Secretary of the Commission by email correspondence. Aqua will continue to review the contracts to determine which ones are necessary for operation of the system post-closing.

Please contact me with any questions about the foregoing.

Very truly yours,

THOMAS, NIESEN & THOMAS, LLC

APPENDICES

This Long Term Control Plan Update was developed as a series of technical reports submitted to the USEPA and/or PADEP for their review and comment. Although these documents served as the basis for the final LTCPU, specific aspects of the final LTCPU Report have changed since the original technical memoranda were written. As such, these reference documents included as appendices here can be used to gain a deeper understanding of the methodologies used in developing the final LTCPU Report

Appendix A - Alternatives Evaluation Approach Report (Final), April 2016
Appendix B - Applicable Water Quality Standards Master Table
Appendix C - Identification of Sensitive Areas and Pollutants of Concern Report, May 2016
Appendix D - Hydrologic and Hydraulic Model Update and Calibration Plan (Final), October 2015
Appendix E - Typical Hydrologic Period Report (Final), Updated April 2016
Appendix F - Sewer System Hydrologic and Hydraulic Model Report, June 2017 with revised Appendix C updated March 1, 2018 to address USEPA comments
Appendix G - Rainfall and Flow Monitoring Quarterly Reports:

Appendix T – Updated Model Calibration and Validation Results for Sewer System Hydrologic and Hydraulic Model Report and Existing Service Area Characterization Report, dated July 2018

Foreword

This Long Term Control Plan Update (LTCPU) has evaluated the Delaware County Regional Water Quality Control Authority's (DELCORA's) sewer systems according to United States Environmental Protection Agency (USEPA) requirements and guidance. The final plan addresses all aspects of the Consent Decree issued to DELCORA by USEPA. Although monitoring and modeling studies show DELCORA is not causing Water Quality Standards to be exceeded, the plan includes further investment to reduce Combined Sewer Overflow (CSO) discharges and improve water quality. The investments include improvements to the collection system, the treatment plant and the implementation of green infrastructure that will provide multiple benefits to DELCORA customers. These improvements increase the level of system wide annual average wet weather flow capture to over 90% of the total wet weather flow. This level of capture exceeds Federal Clean Water Act requirements under USEPA's "Presumption" approach.

Prior to this LTCPU, DELCORA has expended approximately $150 M in capital improvements to address CSOs as planned in the original 1999 Long Term Control Plan. This update adds over $120 M in life cycle costs to the prior and ongoing investment within an accelerated 10 year schedule. This additional investment is affordable if other program costs do not increase significantly.

DELCORA Monitoring and Modeling required by the DELCORA/USEPA/Pennsylvania Department of Environmental Protection Consent Decree has shown that high wet weather flows in the separate sewered areas result in Sanitary Sewer Overflows (SSOs) and contribute to increased CSO discharges. Projects planned under the LTCPU address the impact of CSO discharges as required by the Clean Water Act. However, while SSOs are reduced under the plan, the DELCORA/USEPA consent decree requires the elimination of SSOs. To address the Consent Decree, DELCORA will continue to monitor and model the hydraulically connected system to evaluate SSOs and identify additional areas where remediation is needed. While some of these areas in need of remediation are likely to be in a DELCORA owned system, it is known that there are significant areas in non-DELCORA owned satellite systems that will require investment to address SSOs and remain cost effective.

THIS PAGE INTENTIONALLY LEFT BLANK

Executive Summary

The Delaware County Regional Water Quality Control Authority (DELCORA) has prepared this report to describe the development and selection of the Combined Sewer Overflow (CSO) Long-Term Control Plan Update (LTCPU). Based on water quality monitoring and modeling, DELCORA's collection system is not the reason the receiving waters are not achieving the requisite water quality standards. Therefore, DELCORA's plan to meet the Presumptive Approach requirements of 85% wet weather volume capture is through improvements in the CSO community portion of the collection system. The evaluation of this LTCPU included the development of a hydraulic and hydrologic model which has concluded that separate storm sewer areas in the DELCORA collection system contribute significantly to the discharge of CSOs in the combined system. This plan addresses these issues in affordable manner as long as:

- Upstream communities' excessive Infiltration and Inflow (I/I) into downstream sewer infrastructure is affordably addressed;
- DELCORA's Eastern Service Area costs do not upset the City of Chester's financial capability to implement its share of these wet weather controls;
- Excess flow wet weather treatment as recommended at DELCORA's Western Regional Treatment Plant (WRTP) to obtain over 90%, is approved by Pennsylvania Department of Environmental Protection (PADEP) and/or United States Environmental Protection Agency (USEPA).

The LTCPU has been conducted in accordance with each item described in the Consent Decree to produce a detailed analysis, discussion, and proposed schedules, deadlines, and timetables for implementing each component of the LTCPU. The selected CSO controls set forth by DELCORA in this LTCPU are designed to meet the following overarching goals:

- Bringing all CSO discharge points into full compliance with the technology-based and water quality-based requirements of the Clean Water Act (CWA); and
- Minimizing the impacts of CSOs on water quality, aquatic biota, and human health.

The submission of this document to the USEPA and/or PADEP demonstrates DELCORA's readiness to begin implementing the proposed technologies in this document to meet the above goals.

The development of the LTCPU involves the completion, submission, and incorporation of a number of specific reports to the USEPA and/or PADEP required by the Consent Decree in paragraphs V.A.10 through V.A.22. The required reports scheduled by the Consent Decree have been submitted and approved by the USEPA and/or PADEP to date or have been submitted and are under review by USEPA and/or PADEP and awaiting comments or final approval.

DELCORA's Public Participation Plan (PPP) was developed to employ an on-going public participation process that actively involves the public by informing and soliciting input from stakeholders, including the public, customer communities and regulatory agencies as the LTCPU is developed and implemented and to meet the requirements of the USEPA's CSO Policy and DELCORA's Consent Decree. To encourage feedback and present the progress of the LTCPU, four public meetings were held in various locations throughout the DELCORA service area. After the presentation, the public could ask questions at the meeting hall, or submit a feedback form for DELCORA to incorporate their comments into the LTCPU. Presentation materials and feedback forms for each public meeting are posted to DELCORA's website for anyone who was not able to attend.

DELCORA has also maintained a working relationship with the municipalities and authorities in its service and has made efforts to coordinate any improvements to the LTCPU with them. Most notably is the City of Chester, where the Combined Sewer System (CSS) CSO outfalls are located. Chester City wanted to do more regarding stormwater runoff and developed the Stormwater Authority of Chester to coordinate these efforts with DELCORA, especially in the combined sewer areas. Chester City also hired a sub consultant, Corvias, to develop green infrastructure in the areas of the city where DELCORA could use the technology most.

The support of the serviced communities is instrumental to implementing the LTCPU, as DELCORA does not own all conveyance piping or pump stations within serviced area. The DELCORA service area comprises two distinct areas. The first is the "DELCORA owned" area, where DELCORA owns and operates all sewer infrastructure. The second is the "DELCORA Contracted" area where the satellite communities served continue to own and/or operate their sewer collection and conveyance infrastructure while delivering flows to DELCORA for treatment.

Flows in DELCORA's Eastern Service Area are still treated at the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWD-SWWPCP). While not a part of this long-term control plan, DELCORA and the municipal authorities it serves face significant challenges with its Eastern Service Area. The cost of providing service to this area has the potential to rise significantly in the near future. All other DELCORA service areas send flow through Chester to the DELCORA Western Regional Treatment Plant located in Chester, Pennsylvania. Most of the DELCORA service area has separate storm and sanitary sewers. There is a relatively small area where stormflows and sanitary wastewater are collected in the same combined sanitary and stormwater conveyance sewer. There are 25 permitted combined sewer overflow locations in Chester where combined stormwater and sanitary wastewater can discharge into Ridley Creek, Chester Creek and the Delaware River during wet weather, also referred to as CSOs. The combined flow shares conveyance piping to the treatment plant with the upstream separate sanitary areas, and restrictions into this shared conveyance piping contribute to CSOs. In a typical year, these CSOs average about 36 discharges a year, with half of the CSO outfalls activating more than 43 times a year. In addition, during less frequent, relatively large rainfall events, there are overflow locations in the separate sewer areas where the collection system can be overwhelmed with a combination of sanitary wastewater and stormwater that has leaked into the separate sewer system.

During certain moderate and large rainstorms, CSOs are more likely to occur in the 1,486 acre combined sewer area due to the wet weather flow of the approximately 50,000 acre collection system. In large storms, flows from the separate areas completely fill the conveyance system in the CSO area, and may on occasion fully utilize or exceed the capacity of the wastewater treatment plant. Under these conditions, the combined area flow delivered to the DELCORA treatment plant is greatly reduced or stopped by CSO regulator devices that restrict flow. The combined area flow rates to the conveyance system are controlled to allow most of the separate area flows to be delivered for treatment. However, even with these CSO regulator controls limiting the combined flow entering the system, some separate area flows escape the system, causing unauthorized releases.

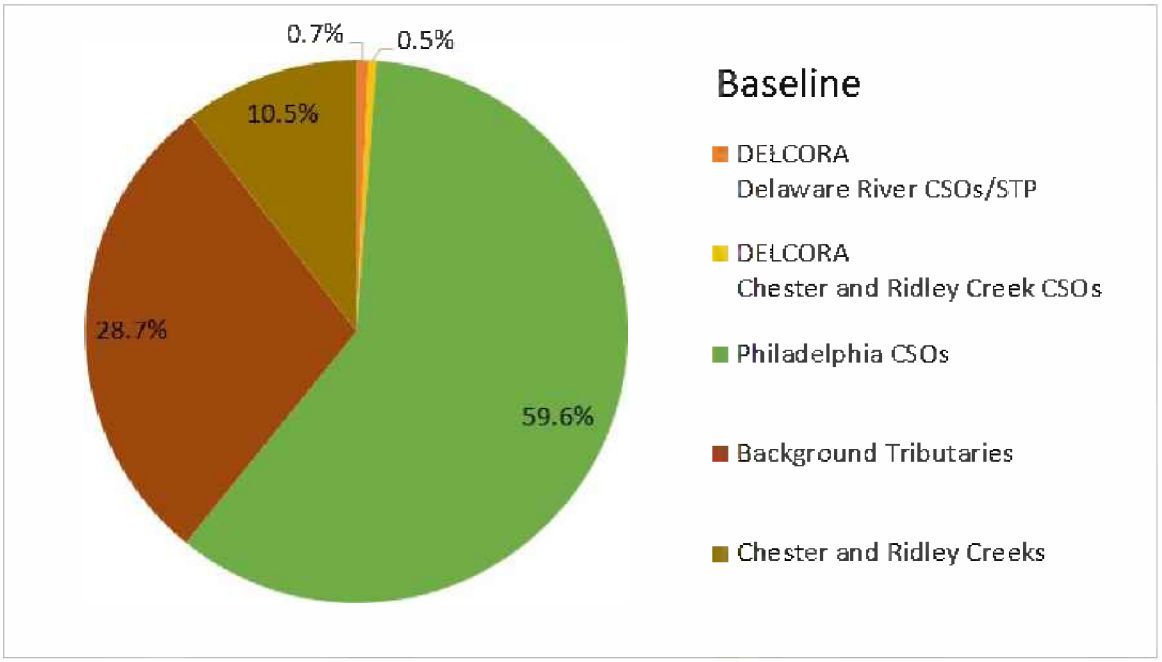
Monitoring and modeling of Ridley and Chester Creeks indicate that these creeks often do not meet water quality standards for recreation. Monitoring and modeling also show that the Delaware River meets recreational standards most of the time. The vast majority of the contamination in the creeks and Delaware River in the service area comes from sources outside of DELCORA's CSOs. The DELCORA CSO loads are small compared to the upstream and background bacteria loads entering the DELCORA

project area (see **Figure ES-1-1** for Enterococcus source loading in the Delaware River). These waters would not meet standards even if the DELCORA CSOs were completely removed. The CSOs by themselves do not prevent (preclude) meeting water quality standards. However, even though controlling CSOs alone will not fully address the problem, DELCORA is moving forward to address overflows from both the combined and separate areas to reduce pollution and prepare for a time in the future when the other pollution loads are better controlled.

DELCORA developed a long-term control program to address CSOs in 1999, which was approved by PADEP. Since that time, approximately $150M in capital investment has been made to the system because of the control program and its operating expenses to increase the amount of combined and separate area flow treated by DELCORA. These projects have included upgrades to the collection and conveyance system pipes, repair of damaged pipes to prevent additional water from leaking into the system, expanded and new pump stations, and increased capacity at the DELCORA wastewater treatment plant. After the installation of the first CSO regulator Tide Gate Monitoring System, DELCORA determined that the monitoring system improves system operation and significantly reduces dry-weather overflows by notifying operators at the WRTP that flow is passing over the diversion weir. DELCORA has since installed the monitoring system on all CSO regulators even though it was not required until the CSO regulator was replaced. DELCORA continues to use this system and it provides critical information to maintain proper operation of the CSO regulators.

DELCORA has conducted extensive flow monitoring and water quality receiving stream monitoring throughout the DELCORA service area, both in the DELCORA Satellite and DELCORA Owned areas. Based on this monitoring, it has been determined that there are collection system improvements that are needed in the separate areas in addition to what is recommended to address the CSOs in Chester.

Figure ES-1-1: Summary of Delaware River Enterococcus Loads by Source Type



In addition to the capital improvements for wet weather control, DELCORA continues to comply with requirements to invest and implement the Nine Minimum Controls (NMCs), which are best management practices designed to reduce CSOs and their effects on receiving water quality. One example of an implemented NMC was the investment in a 10-year inlet replacement program to help screen debris and prevent it from entering the collection system. DELCORA provided $75,000 a year for 10 years to the City of Chester (since discontinued), which in turn installed this control. Another example is DELCORA's implementation of public outreach, which includes periodic mail notifications.

The term "Sensitive Areas" is specifically defined under federal law as areas including Designated Outstanding National Resource Waters, National Marine Sanctuaries, waters with threatened or endangered species and their habitat, waters with primary contact recreation, public drinking water intakes or their designated protected areas, and shellfish beds. After study and evaluation, it has been determined that no sensitive areas as defined by federal law need to be addressed by the DELCORA plans in the Chester and Ridley Creeks or in the Delaware River. However, DELCORA conducted public outreach and three prior public meetings during the development of this plan that identified areas of special concern to the public which comprises the Chester Riverfront and specifically the boat ramp at Flower Street. The DELCORA recommended plan makes this area a high priority for CSO control.

DELCORA conducted a comprehensive alternatives analysis to identify and evaluate a wide range of options for applicability to local conditions. This included the type of control provided, cost, impact on the community, ancillary benefits, and more.

DELCORA evaluated over 50 traditional and innovative sewer overflow control technologies including:

- Source Control/Green Infrastructure
- Sewer Separation
- Conveyance to the Treatment Plant
- Storage in the System
- System Control Improvements

DELCORA developed and examined 15 alternative plans that utilized all five categories of the technologies described above. One alternative examined the use of subsurface tanks. These tanks would store combined flows that would otherwise discharge to the surface waters and release it back to the combined sewer system when the pipes can handle additional flow. Another alternative examined using deep underground tunnels. These two alternatives were examined further by incorporating green infrastructure to reduce tank sizes. Making improvements to the treatment plant and maximizing the combined flow conveyance was another alternative, as was complete sewer separation for the entire combined sewer system.

The remaining 9 alternatives all use system control improvements called regulator modifications, with the added technologies described above located in strategically targeted areas. Regulator modifications are meant to move water into available spaces in the sewer system instead of discharging to surface waters. Regulator modifications can be adjusted to find the appropriate increase in flow to the treatment plant without overwhelming the pipe system.

The alternatives were evaluated in a cost vs. performance comparison called a "Knee-of-the-Curve" graph, where the alternative Life Cycle Cost (initial construction cost with 20 years of operation and maintenance) is plotted for each CSO capture percentage. This method allows for identification of the

alternative beyond which each dollar spent has less improvement than the previous dollars. In other words, the point where spending more money provides less benefit for the additional investment.

The minimum-cost alternative where 88.8% of wet weather is captured exceeds the control required under Federal CSO policy's Presumption Approach (85%). Increasing to the next level of wet weather control, 89.9% capture, is slightly less cost effective, requiring more investment, but providing slightly higher CSO capture. This trend of slightly lower cost-effectiveness continues as the level of control increases to 91.2% and to 94%, but there is a significant increase in cost after the alternative providing 94% capture. Going beyond 94% provides much less capture for the increased cost. While not as cost effective as the 88.8% control, the 94% alternative still provides good public benefits for the additional investment. However, further increases in capture beyond the 94% alternative come with sharply increased costs, and the additional capture gained is not as justified.

Thus to make certain the 88.8% capture level of control, DELCORA will establish as its regulatory performance measure the achievement of 90% system wide wet weather capture during the design year. DELCORA's recommended plan comprises of the three elements incorporating the 88.8% and 94% control alternatives: Regulator Control Improvements, Targeted Overflow Reduction, and Adaptive Management.

DELCORA identified 19 locations in the existing collection system where modifying CSO regulator weirs, orifices, gates, and outflow pipes pushes more water into the conveyance piping, while also utilizing upstream pipes as temporary storage. These improvements increase the level of system wide annual average wet weather flow capture to 88.8%. This level of capture exceeds Federal Clean Water Act requirements under USEPA's "Presumption" approach.

While the regulator control improvements, in addition to the previous investments noted above, meet the presumption approach requirements, monitoring and modeling indicate that the frequency and volume of CSOs are exacerbated by excessive peak flows from the separate sewer areas. These separate area flows can be addressed cost-effectively by adding to the following additional controls to the prior improvements:

- Multiple locations for green infrastructure, with currently identified areas in Widener University's campus, between Providence Ave and Upland Street, on Edgmont Avenue north of I-95, Crozer Street, and other viable areas[1].
- Partial sewer separation of the neighborhood downstream of Veterans Memorial Park.
- Improving flow to bottlenecks in conveyance piping along the Delaware River by adding to, extending, and rehabilitating the existing piping.
- Installing storage tanks in the vicinity of the Taylor Arboretum, providing relief sewers in Upland Borough, and providing I/I sewer rehabilitation in the Rose Valley Service Area[2].
- Public outreach to inform the general public about the status of the DELCORA system.

[1] In addition to the specific Green Infrastructure Project in the (CSO 18 & CSO 19) Neighborhoods, DELCORA anticipates funding additional Green Projects where such projects contribute to the cost-effective reduction of overflows.
[2] The location of these facilities have not been determined and will be open to public comment after more study is completed and before implementation

Each of these CSO control technology projects have specifically targeted effects to further reduce overflows in the DELCORA service area. For example, the removal of the noted sewer bottlenecks significantly increases the peak wet weather flows that can be delivered to the wastewater plant. These controls will also significantly reduce the discharges in the vicinity of Flower Street Chester City Boat Ramp. Addressing interceptor bottlenecks will help to address unauthorized releases in the DELCORA system. In addition, each project will be optimized using adaptive management as the LTCP implementation proceeds.

As a result of delivering greater peak wet weather flows to the treatment plant through the regulator control improvements and these targeted overflow reduction projects, the current capacity of the treatment plant (88 MGD) would be exceeded about 3 times in the design year. While these flows could be discharged out the combined system, real-time controls will be evaluated during a post-construction monitoring period. It will be necessary to study the peak wet weather flows and determine if real-time motor operated valves and controls in the regulators and conveyance system are necessary. The evaluation will provide confidence that any increased flows do not back up into homes or deliver excessive flow to the treatment plant without losing hydraulic and process control. After the flows are evaluated, additional improvements to the WRTP will be addressed. Excess flow wet weather treatment will include screening to remove trash and grit settling, (settling of solids and removal of floatables). This treated excess wet weather flow will then be discharged out the existing CSO located adjacent to the plant. While not achieving full treatment of these excess CSO flows, DELCORA will reduce pollutant loadings before recombining these flows with untreated CSO volumes for discharge. This approach will simply capture more flow for partial treatment, whereas the flow would otherwise be discharged out of a CSO outfall without any treatment. Assuming that it is actually determined to be feasible and warranted and that PADEP will authorize this additional treatment approach, DELCORA is willing to include it in the LTCP.

The previous two elements address the CWA Requirements for CSOs by attaining a CSO annual average system wide wet weather capture of 90% or higher. In addition, the average occurrence across all 25 CSOs is reduced from 36 to less than 15 in the design year with some having more and most having fewer. The expected results meet the necessary requirements, but additional monitoring is still planned by DELCORA, especially in locations with CSOs that may continue at a higher frequency.

Adaptive management provides an opportunity for DELCORA to conduct post construction monitoring, after partially implementing the first two elements to re-assess the implementation schedule. These projects will be monitored to determine if they are operating as intended, and the Clean Water Act and community goals are met. If this post construction monitoring indicates more investment or actions are needed, those investments and actions will be evaluated, and a supplemental control plan will be developed for review and approval by the PADEP. This control plan will also incorporate any new technologies or group similar projects to reduce costs, pending regulatory approval and other anticipated factors. Minimizing community impacts is one of the cornerstones and key benefits of the Recommended Plan. However, DELCORA's plan will likely trigger some public and private impacts from construction/implementation activities. There will be some re-purposing of public land, a need for rights of way, and potentially the need for some land now in private ownership. Nevertheless, these impacts are expected to be relatively minor in comparison to other similar programs.

Special attention to locations with higher frequencies of activation will be evaluated during this post construction monitoring period, and based on results, DELCORA will continue to examine sewer system optimization through additional monitoring and potentially using real time control to further reduce the

frequency at these overflow points. Further measures will be implemented to the modeled area as necessary, depending on the technologies' performance, and will include a schedule that takes into the account the modeled area's financial capability at that time.

With regulatory approval to this LTCPU, the Regulator Control Improvements can proceed with the current and anticipated finances available to DELCORA. Targeted Overflow Reduction implementation is dependent on a number of factors including the following:

- Upstream communities' excessive infiltration and inflow into leaking pipes can be affordably addressed;
- DELCORA's Eastern Service Area costs do not upset Chester's financial capability to implement its share of these wet weather controls;
- Excess flow wet weather treatment as recommended at the DELCORA treatment plant to obtain over 90% capture, is approved by PADEP and/or USEPA.

If the above factors can be addressed, it is anticipated that the Regulator Control Improvements can begin implementation immediately and the Targeted Overflow Reduction projects can be fully implemented in approximately 10 years.

All Elements of the program will be evaluated as the program progresses in an adaptive management approach where the program may be adjusted as monitoring and modeling show cost-effectiveness. Initial life-cycle costs of the program are in **Table ES-1-1**. The implementation schedule will be examined as an on-going part of the adaptive management program. The initial iteration of this schedule is in **Table ES-1-2**. The timeline for all reports proposed by this plan can be found in **Table ES-3-1**. The O&M Plans will be updated 60 days after the full implementation of the Taylor Arboretum storage tank and again after the WRTP modifications are first placed in operation.

While not a direct component of the CSO Long-Term Control Plan, Federal and State law also require DELCORA to address peak excess flows in the sanitary systems. Such flows can cause sanitary sewer overflows, local sewer surcharging, and impact downstream users of the sewer system. Consistent with PADEP and USEPA requirements, DELCORA will continue to identify such peak excess flows, share that information with the communities and support ongoing control efforts by the tributary sanitary sewer systems.

DELCORA's plans involve actions within two areas:

- Addressing CSO controls in its owned and contracted service areas
- Addressing the cost of the Eastern Service Area treatment provided by Philadelphia Water

Given the localized nature of the peak wet weather flow issues and control measures proposed along with State delegation and oversight of program implementation, State oversight of our program implementation makes the most sense. DELCORA plans to propose a State implementation mechanism to both PADEP and/or USEPA in the near future for their consideration. Streamlined State implementation oversight is particularly warranted because EPA/DEP program approval will substantively control other State planning mechanisms, such as Act 537 plan updates. It will be important for PADEP to assist DELCORA to timely secure any actions required by DELCORA's satellite customers, such as the requirement that they update their Act 537 plans to reflect the EPA/PADEP-approved program, in order to maintain the approved implementation schedule.

Table ES-1-1: Estimated Capital & Life Cycle Costs of the Proposed Improvement Projects

Regulator Control Improvements	Capital Cost ($M)	Life Cycle Cost ($M)
Regulator Modifications	$ 5.1	$ 14.2
Targeted Overflow Reduction		
Parallel Delaware River Interceptor	$ 3.5	$ 3.6
WE Interceptor Rehab & Extension	$ 2.4	$ 2.5
CSO-5 Partial Sewer Separation	$ 4.4	$ 4.5
CSO 18 & 19 Green Infrastructure	$ 10.1	$ 11.7
RCI Arboretum Modifications	$ 7.2	$ 17.0
Upland Relief Sewer Line	$ 0.8	$ 1.0
Rose Valley I/I Controls	$ 3.0	$ 3.0
Monitoring and Modeling	$ 5.0	$ 5.0
Public Outreach	$ 3.0	$ 3.0
WRTP Plant Expansion/Upgrade	$ 15.2	$ 27.4
Visual CSO Public Notification System	$ 0.3	$ 1.4
Real Time Control	$ 0.4	$ 1.0
Crum Creek Diversion Pipeline	$ 8.6	$ 8.6
Adaptive Management		
Adaptive Management	$ 13.0	$ 13.0
Project Management	$ 5.0	$ 5.0
Total	$ 86.9	$ 121.9

Table ES-1-2: Proposed Project Milestone Deadlines

Project Milestone Deadlines[1]	
Project	**Placement in Operation**
6 Regulator Modifications Completed	December 31, 2020
Upland Relief Sewer Line	December 31, 2020
6 Additional Regulator Modifications Completed	December 31, 2021
RCI Regulator Manhole Modifications	December 31, 2021
CSO-5 Partial Separation	December 31, 2022
Green Stormwater Infrastructure	December 31, 2022
Rose Valley Infiltration & Inflow Improvements	December 31, 2022
Crum Creek Diversion Pipeline	December 31, 2024
Visual CSO Public Notification System	December 31, 2024
6 Additional Regulator Modifications Completed	December 31, 2025
West End Interceptor Rehab & Extension	December 31, 2026
Parallel Delaware River Interceptor	December 31, 2028
Western Regional Treatment Plant Modifications	TBD

Section 1 Introduction, Overview and Historical Review

1.1 Introduction

The Delaware County Regional Water Quality Control Authority (DELCORA) is a municipal wastewater authority that owns, operates and maintains collection systems that serve approximately a half-million people in southeastern Pennsylvania, including 45 municipalities in Delaware and Chester Counties, and is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA owns and operates a combined sewer system (CSS) that is comprised of sewer sections that accept both stormwater runoff and sanitary wastewater that is treated at DELCORA's Western Regional Treatment Plant (WRTP), both of which are located in the City of Chester, Pennsylvania.

Combined sewer systems are remnants of the country's early wastewater infrastructure when communities built sewer systems to collect both stormwater and sanitary sewage in the same piping system. During dry weather periods, CSSs transport all of the wastewater directly to a wastewater treatment plant (WWTP) for proper treatment. However, during periods of heavy rainfall or snowmelt, stormwater is combined with the sanitary sewage and the volume of wastewater can sometimes exceed the capacity of the CSS or WWTP. When this occurs, regulator chambers in the CSS allow the excess volume of wastewater to discharge into nearby streams, rivers and other waterbodies.

Under its National Pollutant Discharge Elimination System (NPDES) Permit No. PA0027103, issued and administered by the PADEP, DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four storm water outfalls at the WRTP (#028-#031) and from 26 CSO regulators (#002-#005, #007-#026, #032 and #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek. There are a total of 26 combined sewer overflow regulators listed with 25 discharge points in DELCORA's existing NPDES Permit; Regulators #009 and #010 both discharge at Outfall #009.

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated Combined Sewer Overflow (CSO) Long-Term Control Plan (LTCP) to the United States Environmental Protection Agency (USEPA or EPA) and/or the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. This Long-Term Control Plan Update (LTCPU) Report has been developed for controlling discharges from DELCORA's CSOs to the receiving waters in satisfaction of the requirements of the Consent Decree and NPDES permit, and in accordance with the Federal Clean Water Act (CWA) and the 1994 Federal Combined Sewer Overflow Control Policy.

DELCORA has made considerable progress on mitigating CSOs over the last decade, including, but not limited to, improvements to their regulators and other early action items such as the upgrade of Pump Station 1 (EPS-1) to convey more flow to the WRTP. The design and construction of a Regulator Monitoring System, and the replacement of Regulator #s 002, 003, 004, 005, 010, 012, 013, 014, 015, 016, 023, 024 and 026 has already been completed. The upgrade of EPS-1 is competed and the new pump station is called "PS-6".

The progress DELCORA has made on mitigating CSOs to date is not withstanding the financial challenges of the City of Chester, as evidenced by 37% of Chester's citizens living under the poverty line and the median household income being stagnant. Additionally, the City of Chester is a financially distressed municipality as defined by Pennsylvania's 1987 Financially Distressed Municipalities Act 47 and appears destined to remain in the Act 47 program for the indefinite future.

1.1.1 Purpose of CSO LTCP Update

DELCORA has prepared this LTCPU Report to update its April 1999 LTCP and the July 2008 addendum to the LTCP.

The primary purposes of the CSO Long-Term Control Plan Update are as follows:

- To develop a long-term strategy to minimize the impacts of DELCORA's CSOs on the water quality of the receiving waters. Such strategy must be both technically viable and financially feasible and will result in compliance with water quality standards.
- To document the success of existing CSO control projects in achieving water quality and CSO control goals.
- To re-assess the remaining original CSO control projects using the latest data, information and control technologies.
- To evaluate alternative CSO control technologies and make recommendations for the most optimal CSO control projects to be implemented.

1.2 Regulatory Requirements

1.2.1 CSO Control Policy Requirements

The USEPA issued a national policy statement entitled *Combined Sewer Overflow (CSO) Control Policy* in April 1994 that established a consistent national approach for controlling discharges from CSOs to the Nation's waters through the National Pollutant Discharge Elimination System (NPDES) permit program. In 2000, the CSO Control Policy was incorporated into the Clean Water Act (CWA) by reference. This policy provides guidance to permittees with CSOs and other parties on coordinating the planning, selection, and implementation of CSO controls that meet the requirements of the CWA and allow for public involvement during the decision making process.

The USEPA's *Combined Sewer Overflows Guidance for Long-Term Control Plan* document from September 1995 provides guidance to CSO communities to assist them in developing appropriate, site-specific programs to control CSOs in compliance with documented NPDES permit program and Clean Water Act requirements. Among other things, this guidance identifies the following nine essential elements of LTCPs:

1. **Characterization, monitoring and modeling** activities as the basis for selection and design of effective CSO controls
2. A **public participation** process that actively involves the affected public in the decision-making to select long-term CSO controls
3. Consideration of **sensitive areas** as the highest priority for controlling overflows

4. **Evaluation of alternatives** that will enable the permittee, in consultation with the NPDES permitting authority, Water Quality Standard (WQS) authority, and the public, to select CSO controls that will meet CWA requirements
5. **Cost/performance considerations** to demonstrate the relationships among a comprehensive set of reasonable control alternatives
6. **Operational plan** revisions to include agreed-upon long-term CSO controls
7. **Maximization of treatment at the existing POTW treatment** plant for wet weather flows
8. An **implementation schedule** for CSO controls
9. A **post-construction compliance monitoring program** adequate to verify compliance with water quality-based CWA requirements and ascertain the effectiveness of CSO controls.

The CSO Control Policy contains four key principles to ensure that CSO controls are cost-effective and meet the requirements of the CWA:

- Provide clear levels of control that would be presumed to meet appropriate health and environmental objectives
- Provide sufficient flexibility to municipalities, especially those that are financially disadvantaged, to consider the site-specific nature of CSOs and to determine the most cost-effective means of reducing pollutants and meeting CWA objectives and requirements
- Allow a phased approach for implementation of CSO controls considering a community's financial capability
- Review and revise, as appropriate, WQS and their implementation procedures when developing long-term CSO control plans to reflect the site-specific wet weather impacts of CSOs.

These key principals were incorporated during the development of this LTCP Update report.

1.2.2 Long Term Control Plan Approach

The USEPA's CSO Control Policy expects that a CSO Control Plan will develop a "reasonable range" of alternatives and should adopt one of the following approaches: the "Presumption" approach, or the "Demonstration" approach. DELCORA will utilize the Presumption approach for the LTCP Update.

- Under the "Presumption" approach a CSO LTCP is presumed to meet water quality provided one of the three following criteria is satisfied: (1) no more than an average of four overflow events per year; (2) eliminate or capture for treatment 85% of the annual combined sewage volume; (3) eliminate or remove the mass of pollutants for the volume eliminated or captured for treatment.
- The "Demonstration" approach states that a CSO LTCP is adequate if it meets the current state and local WQS of the receiving waters. With this approach there are no specific limits on CSO events, flow or pollutant loading.

It is to be noted that DELCORA had originally planned to utilize the Demonstration approach for each of its receiving water, as was documented in its *Alternatives Evaluation Approach Report* that was approved by the USEPA on October 13, 2016. This document can be found in **Appendix A**. The Demonstration approach relies on data collection and model simulation to demonstrate that the proposed LTCPU will meet applicable water quality standards and designated uses, and it provides a reliable tool to identify, evaluate and compare the selection and recommendation of the CSO control measures to be installed.

However, after the water quality model was developed, two major observations were made from the water quality modeling application results. One is that background sources dominate the modeled Pollutant of Concern (POC) concentrations, and by extension, DELCORA's CSO loads are small (modeled at 1.3% percent – See **Figure ES-1-1** and **Figure 5-4**) compared to background loads), and the second is that the DELCORA CSOs by themselves do not cause non-attainment, or preclude the attainment, of WQS. Moreover, the modeling results show that regardless of additional CSO controls, even complete separation, water quality standards would still be exceeded under current conditions because background sources typically prevent compliance with WQS. The water quality modeling results are supported by the water quality data results from the wet weather sampling program, which show that wet weather concentrations at the most upstream monitoring locations (located upstream of CSO influence) in Chester Creek and Ridley Creek (and to a lesser extent in the Delaware River) often exceed the monthly geometric mean and standard threshold value (STV) WQS concentration for the three bacteria POCs. These monitoring and modeling data taken together indicate the upstream bacteria loads prevent the attainment of Water Quality Standards in the tidal waters through CSO control.

While the Consent Decree addresses the issue of background sources by requiring CSO controls to also be assessed, assuming that background sources are reduced to 75% of the applicable WQS, using the results of such a scenario in decision making is arbitrary and irrational. There is no current plan for reducing background loads in the Chester and Ridley Creeks, and the planned reductions in the Delaware River will still result in DELCORA's Enterococcus loads being less than 1% of the total load as shown in **Figure 1-1**. The CSO Policy states that "*where WQS and designated uses are not met in part because of natural background conditions or pollution sources other than CSOs, a total maximum daily load, including a wasteload allocation and a load allocation, or other means should be used to apportion pollutant loads*". Such apportionment of loads does not currently exist for the Ridley and Chester Creeks for bacteria.

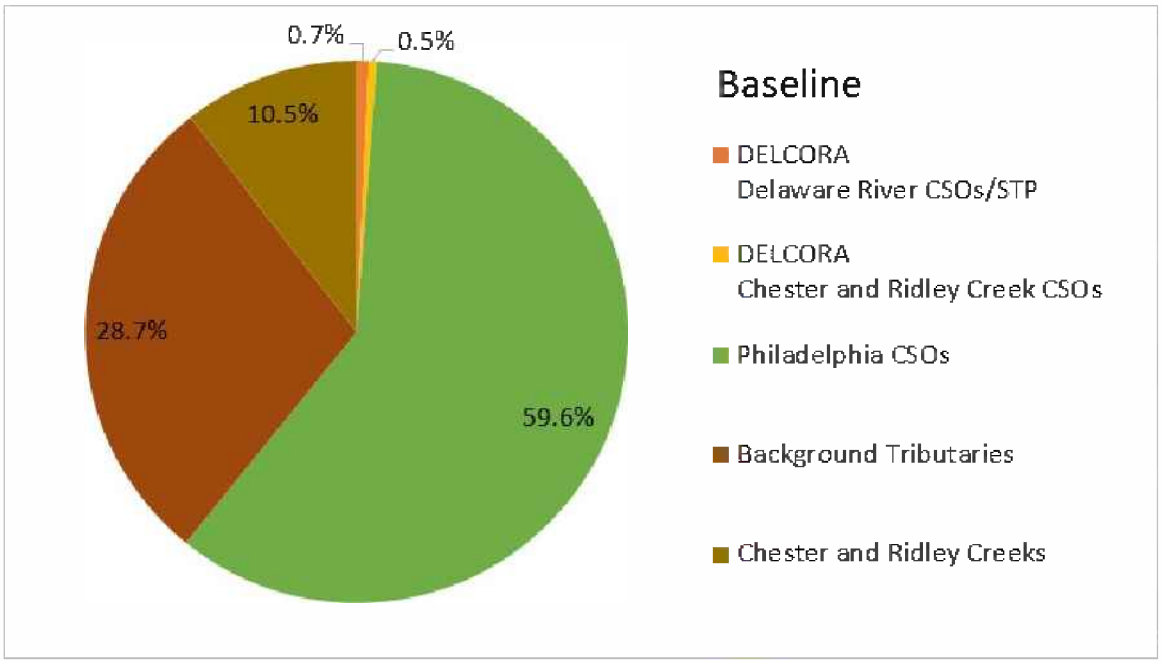
As stated previously, the intended use of the water quality modeling framework is to evaluate CSO control alternatives with respect to applicable water quality standards and demonstrate that alternatives selected for the LTCPU program will meet the water quality-based requirements of the Clean Water Act and Consent Decree. As discussed in the Final Water Quality Modeling Report that was submitted to the USEPA and PADEP on February 27, 2018 and approved on April 17, 2018:

> *"The water quality model is adequate to assess Presumption levels of control to show that the CSOs after controls are in place do or do not preclude the attainment of water quality standards…As such, DELCORA will utilize the Presumption approach, which is shown…to be reasonable in light of the data and analysis as called for in the National CSO Policy."*

The model framework can also be used to assess the Demonstration approach. Currently, the modeling shows that CSOs alone do not cause WQS violations, do not preclude the attainment of WQS, and background loads are currently causing WQS violations upstream of the CSOs and the CSO influence.

Given these in-stream realities and the need for DELCORA to develop the LTCP Update, DELCORA will utilize the Presumption approach instead. This conclusion was documented in the Water Quality Model Report and determined to be appropriate in light of the monitoring data and modeling analysis as called for in the National CSO Policy.

Figure 1-1: Baseline Summary of Delaware River Enterococcus Loads by Source Type



The Presumptive approach requires that one of three criteria be met for compliance to be presumed:

- No more than an average of 4-6 overflow events per year;
- The elimination or the capture for treatment of no less than 85% by volume; or
- The elimination or removal of no less than the mass of the pollutants identified as causing water quality impairment equivalent to the 85% capture by volume.

The Presumption approach criteria selected for this LTCPU is to achieve a minimum 85% system-wide capture by volume on an annual average (typical year) basis.

Use of the Presumption approach is reasonable because the water quality modeling demonstrates that the CSOs alone are a very small source of bacteria to the receiving waters and the CSO discharges themselves do not cause any exceedances of applicable bacterial water quality standards. Thus, the presumption is appropriate in that 85% capture of the Chester CSO flows will be consistent with water quality requirements. Notably, this is the same conclusion that PADEP and USEPA reached with regard to the City of Philadelphia's CSO program. It is also the most appropriate approach for DELCORA to take unless and until there is a realistic plan to control the other sources that dominate bacteria loadings to the receiving streams.

1.2.3 Consent Decree Requirements

The objectives of the Consent Decree are for DELCORA to take the steps necessary to achieve full compliance with the Clean Water Act, the Clean Stream Laws and with all of the terms and conditions of its NPDES permit.

Paragraph V.A.9 of the Consent Decree requires the development of an Updated Long-Term Control Plan no later than three and one half years (42 months) after the Date of Lodging of the Consent Decree. The Consent Decree states that the LTCPU shall include, at a minimum, a detailed analysis and discussion of each item described in Paragraphs V.A.10 through V.A.22 for the entire Model Area and shall include proposed schedules, deadlines and timetables for implementing each component of the LTCPU. The Consent Decree states that the LTCPU shall conform to the requirements of the USEPA's CSO Control Policy and Guidance for Long-Term Control Plan, and that the selected CSO controls set forth in the LTCPU shall be designed to meet the following overarching goals:

a. Bringing all CSO discharge points into full compliance with the technology-based and water quality-based requirements of the CWA; and

b. Minimizing the impacts of CSOs on water quality, aquatic biota, and human health

Paragraph V.A.14.b of the Consent Decree describes the "Model Area" as follows:

> *… all areas tributary to the entire Collection System, as well as all areas tributary to all municipal wastewater collection and transmission systems that are, as of the date the LTCP is submitted, hydraulically connected to, or that directly or indirectly influence flow to, the CSOs and/or the WRTP, regardless of who owns or operates the system(s), including but not limited to the entire "Western Service Area" and "Eastern Service Area" depicted on Figure 1-2 of the Long-Term Control Plan submitted by DELCORA in April 2012, and attached as Appendix A hereto (collectively, the "Model Area").*

DELCORA's service area is divided into the Western Service Area and the Eastern Service Area. The Western Service Area discharges to DELCORA's WRTP and is therefore included in the Model Area. The Eastern Service Area is served by three pumps stations: the Central Delaware Pump Station, the Muckinipates Pump Station and the Darby Creek Pump Station. Up to 20 MGD (which includes both dry and wet weather flows) from the Central Delaware Pump Station can be pumped to, and thus is hydraulically connected to, DELCORA's WRTP. Therefore, municipalities connected to the Central Delaware Pump Station are considered part of the Model Area. Sewage from the Muckinipates Pump Station and the Darby Creek Pump Station flows to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWD-SWWPCP) rather than to the WRTP. Therefore, municipalities connected to these pump stations are not hydraulically connected to the WRTP and do not directly or indirectly influence CSOs or flow to the WRTP, and, therefore, are not considered part of the Model Area. In summary, the Model Area (or project area/study area) includes the municipalities in the Western Service Area plus those municipalities in the Eastern Service Area that are connected to the Central Delaware Pump Station.

1.2.4 Report Submissions

The development of the LTCPU involves the completion, submission and incorporation of a number of specific reports to the USEPA and PADEP required by the Consent Decree in Paragraphs V.A.10 through V.A.22. **Table 1-1** lists the required reports have been submitted and approved by the USEPA to date. **Table 1-2** lists required reports that have been submitted and that are under review by USEPA and awaiting comments or final approval.

Table 1-1: Required Reports Submitted and Approved by USEPA to Date

Consent Decree Reference	Report	USEPA / PADEP Approval Date / Status
V.A.11	Identification of Sensitive Areas and Pollutants of Concern	Approved October 13, 2016
V.A.12	Typical Hydrologic Period Report	Approved May 23, 2016
V.A.13	Alternatives Evaluation Approach Report	Approved October 13, 2016
V.A.14	Hydrologic and Hydraulic (H&H) Model and Calibration Plan	Approved March 1, 2016
V.A.17	Public Participation Program Plan	Approved April 28, 2016
V.A.18	Draft Financial Capability Assessment Report (FCA)	Submitted 2nd revision 4/21/17, (Pending see below)
VII	Semi-Annual Reports 1, 2, 3, 4, 5, and 6	Submitted 2015, 2016 and 2017, 2018 No Comments received. Assumed Approved.
V.A.14.e	Rainfall and Flow Monitoring Quarterly Reports 1, 2, 3 and 4	Submitted 2016 and 2017, No Comments
V.A.15.a	Updated Water Quality Monitoring and Modeling Work Plan and Quality Assurance Project Plan (QAPP)	Submitted January 11, 2017 Submitted update July 31, 2017 Approved April 16, 2018
V.A.16	Existing Service Area Characterization Report	Submitted August 15, 2017 Approved April 16, 2018
V.A.14.f	Sewer System H&H Model Report	Submitted June 30, 2017 Resubmitted Appendix C - 3/1/18 Approved April 17, 2018
V.A.15.b	Water Quality Modeling Report	Report was submitted to USEPA on February 27, 2018 meeting Consent Order deadline. Approved April 17, 2018

Table 1-2: Required Reports Submitted and Under Review by USEPA

Consent Decree Reference	Report	Submittal / Status
V.A.18	Third round of USEPA comments were received for the Draft Financial Capability Assessment Report (FCA).	Submitted April 28, 2016 Submitted 2nd revision 4/21/17 and response to comments. Submitted FCA Supplement August 17, 2017. Submitted responses to USEPA and PADEP comments on October 31, 2017. No further comments received to date.
VII	Semi-Annual Report 7	Submitted December 28, 2018 to meet Consent Order Date of January 1, 2019.

1.2.5 Nine Minimum Controls

Paragraph V.B.25 of the Consent Decree requires that concurrently with the submission of the LTCPU, DELCORA shall submit to USEPA and/or PADEP for review and approval a revised and updated Nine Minimum Controls (NMCs) Plan. The Consent Decree states that "The NMC Plan shall evaluate and document the current level of implementation of the NMCs within the Combined Sewer System and shall identify actions necessary for achieving compliance with the CSO Control Policy for all NMCs and include an implementation schedule for completing those actions". For this reason, the details of the current level of implementation of the NMCs within DELCORA's CSS are not specifically addressed in this LTCP Update as they are addressed in the NMC Plan.

1.2.6 Early Action CSO Control Measures

Paragraph V.B.26 of the Consent Decree requires DELCORA to place in operation a new EPS-1 Pump Station to reduce discharges from CSO Outfalls #002, #003, #004, #005 and #007 by December 31, 2018. The construction of the new pump station "PS-6" is complete; it has been in operation since November 3, 2018 and located adjacent to the now-abandoned EPS-1.

DELCORA has also made progress on a range of other CSO control measures including the design and construction of a Regulator Monitoring System, and the replacement of Regulator #s 002, 003, 004, 005, 010, 012, 013, 014, 015, 016, 023, 024 and 026. Pipe grouting and other miscellaneous repairs have been made to the Ridley Creek Interceptor. The Chester East and Chester West Interceptors have also had grouting work performed on their pipe joints. Additionally, property has been purchased to expand the available area for future projects relating to the LTCPU. Additional details of the work DELCORA has done to implement the Original LTCP are included in Subsection 1.5.

1.3 Water Quality Standards

1.3.1 Receiving Water Use Designations and General Water Quality Standards

Information about the applicable water quality standards and designated uses for the three receiving water bodies impacted by DELCORA's CSOs were obtained from the PADEP's 2014 Integrated Water Quality Monitoring and Assessment Report (or "303(d) list"), the Pennsylvania Code, the Delaware River Basin Commission's (DRBC's) Water Quality Regulations (WQRs) and from the DRBC's 2014 Delaware River and Bay Water Quality Assessment.

For the Delaware River and the tidal portions of its tributaries, the DRBC's Water Quality Regulations are the prime source for the water quality standards, and the PA Code Chapter 93 WQS for the designated use serves as a secondary source. The DRBC's regulations have primacy over the PA Code for the Delaware River and the tidal portions of its tributaries. For the non-tidal portions of the Chester Creek and Ridley Creek, the specific designated use for the water body in the PA Code serves as the prime source of the WQS. If a parameter is not listed in the DRBC's Water Quality Regulations or in the PA Code, then there is not a WQS for that parameter that applies to the Delaware River, Chester Creek or Ridley Creeks.

A conservative approach was taken in the identification of the applicable WQS, such that the more stringent standard was used where the standards from the DRBC's Water Quality Regulations and the PA Code overlapped. The methodology for identifying the applicable WQS was complicated by the fact that the

WQS vary for the three receiving water bodies and can also vary within the same water body depending on where the sample was taken.

General descriptions of the information sources used for the determination of the applicable water quality standards for the Delaware River, Chester Creek and Ridley Creek are presented in the following subsections. The details for the determination of the applicable water quality standards are presented in the Identification of Sensitive Areas and Pollutants of Concern Report in **Appendix C.** The Applicable Water Quality Standards Master Table that was developed to identify the specific WQS for each of the three receiving water bodies is presented in **Appendix B**.

1.3.2 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report (303(d) list)

The primary source of information about the causes of impairment, and the Total Maximum Daily Load (TMDL) status of the water bodies (if any) is the 2014 PA Integrated Water Quality Monitoring and Assessment Report (PA Integrated Report), which satisfies Pennsylvania's requirement of both Section 303(d) and 305(b) of the Clean Water Act. The PA Integrated Report lists all impaired surface waters within Pennsylvania that are not attaining designated and existing uses, even after appropriate and required pollution control technologies have been applied. A TMDL is designed to reduce pollutant loads to impaired waters and enable these waters to meet water quality standards.

1.3.3 PA Code Chapter 25 §93.9g

The primary source of information for the Critical Use Designation for each section of the three receiving water bodies is Chapter 25 §93.9g – Drainage List from the Pennsylvania Code. The relevant Critical Use Designations for DELCORA's receiving water bodies include Warm Water Fishes (WWF), Migratory Fishes (MF), Trout Stocking (TSF), and Water Contact Sports/Recreation (WC).

Critical Use Designations for the Delaware River:
All stretches of the Delaware River in the area impacted by DELCORA's CSOs are designated as Warm Water Fishes (WWF) (maintenance only) and Migratory Fishes (MF) (passage only). Additionally, the Delaware River has a Water Contact (WC) designation downstream of River Mile 81.8, which is located directly adjacent to the City of Chester between CSO #009 and #011.

Critical Use Designations for the Chester Creek:
All stretches of the non-tidal portions of the Chester Creek in the area impacted by DELCORA's CSOs are designated as Warm Water Fishes (WWF) (maintenance only) and Migratory Fishes (MF) (passage only). The DRBC's water quality standards apply to the tidal portions of the Chester Creek.

Critical Use Designations for the Ridley Creek:
All stretches of the non-tidal portions of the Ridley Creek in the area impacted by DELCORA's CSOs are designated as Warm Water Fishes (WWF) (maintenance only), Migratory Fishes (MF) (passage only), or Trout Stocking (TSF). The TSF stretch only applies in the sections of the Ridley Creek upstream of the Chestnut Street bridge crossing. The DRBC's water quality standards apply to the tidal portions of the Ridley Creek.

1.3.4 DRBC's Water Quality Regulations and PA Code Chapter 25 §93.7

The applicable water quality standards for the three receiving water bodies were found in the Delaware River Basin Commission's Water Quality Regulations, and in Water Quality Criteria lists found in Chapter 25 §93.7 and §93.8c of the Pennsylvania Code. For the Delaware River, the water quality standards are dictated by the DRBC's WQRs that have primacy over the standards in the PA Code. The water quality standards in the PA Code apply to the non-tidal portions of the Chester Creek and Ridley Creek, and to the Delaware River if there is no standard listed for a particular parameter in the DRBC's WQRs.

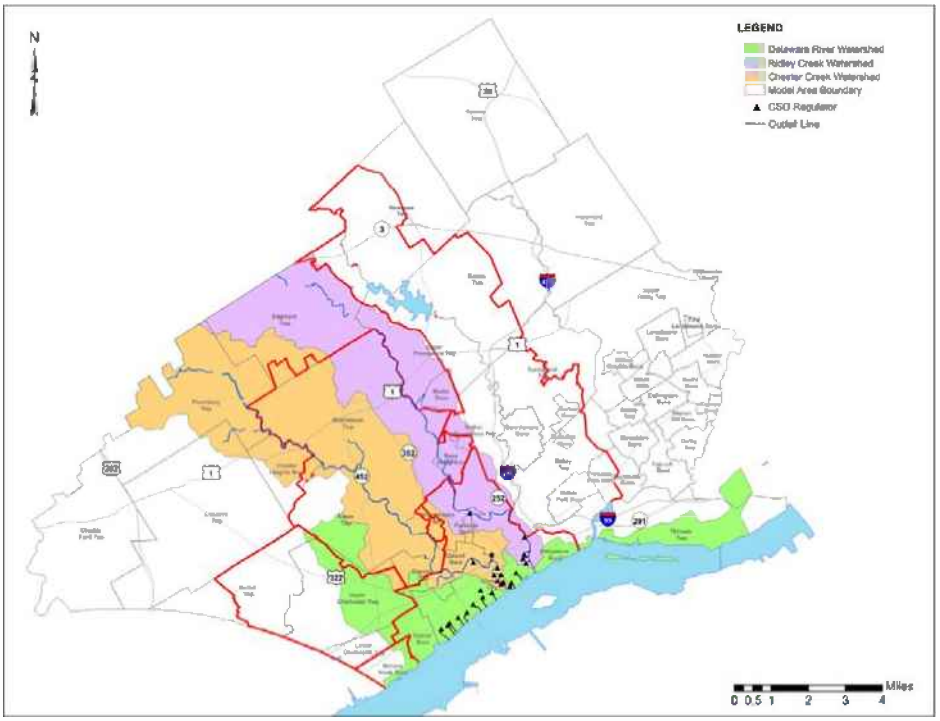
1.3.5 DRBC's 2014 Delaware River and Bay Water Quality Assessment

The DRBC's 2014 Delaware River and Bay Water Quality Assessment (2014 Assessment) reports the extent to which waters of the Delaware River and Bay are attaining designated uses in accordance with Delaware River Basin Commission's Water Quality Regulations for the period October 1, 2008 through September 30, 2013. The 2014 Assessment involves the comparison of key water quality parameters with the applicable DRBC water quality regulations. The states of Pennsylvania, New Jersey, Delaware and New York consider the DRBC's Assessment report as part of their determinations as to whether sections of the Delaware River should be listed on the state 303(d) list for a certain pollutant.

1.4 Watersheds

The watersheds of concern that are impacted by DELCORA's CSS include portions of the Delaware River, Chester Creek and Ridley Creek watersheds. **Figure 1-2** illustrates the watershed boundaries along with the boundaries of the Model Area.

Figure 1-2: Watershed Boundaries



1.5 Overview of DELCORA's Facilities

DELCORA owns and operates an extensive conveyance system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in **Figure 1-3**. The total service area served by DELCORA, as shown on **Figure 1-4** is approximately 76,439 acres and illustrates that DELCORA serves a significant and widespread portion of Delaware County. The acreage division of the ownership and serviced areas within the service area can be found on **Table 1-3**. Note that DELCORA owns conveyance facilities in less than 6% of the collection system area.

To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers and over 14 miles of large-diameter (>24-inch) force mains. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-six (26) combined sewer regulators that discharge to twenty-five (25) combined sewer outfalls, as CSO Regulators #009 and #010 both discharge to CSO Outfall #009. The combined sewer area simulated in DELCORA's Hydrologic and Hydraulic (H&H) model is located within the City of Chester and consists of a drainage area of approximately 1,486 acres. It comprises approximately half of Chester City's serviced area. The location of Chester City's service area is illustrated on **Figure 1-4**.

In addition to the DELCORA owned and operated facilities, additional facilities are owned by satellite authorities and municipalities that are contracted with DELCORA to utilize the DELCORA owned system. These authorities and municipalities are listed along the top of **Figure 1-3**.

DELCORA has characterized its service areas as "Eastern" and "Western". Historically, the Eastern service area has discharged to the Philadelphia Water Department's Southwest Water Pollution Control Plant while the Western Service Area discharged to DELCORA's Western Regional Treatment Plant.

Figure 1-3 and **Figure 1-4** show the interconnections in DELCORA's system. The left side of the figures indicates the Western Service Area and the right side indicates the Eastern Service Area. This interconnectivity coupled with the legal agreements DELCORA maintains with the municipalities and conveyance authorities in Delaware County creates the complicated legal/financial framework under which DELCORA operates.

1.5.1 City of Chester CSO System

As noted previously, the combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's serviced area. The combined wastewater/stormwater system in the City of Chester is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, and CSO regulators and CSO outfalls. The inlets, stormwater-only sewers that connect to the combined sewer system, and stormwater-only outfalls are owned by the City and maintained by the Stormwater Authority of Chester (SAC). The SAC is responsible for the maintenance of the stormwater system, street sweeping, enforcement of storm water regulations and standards, public information and education, and planning, zoning, and development of capital storm water facilities.

Figure 1-3: DELCORA's Conveyance System

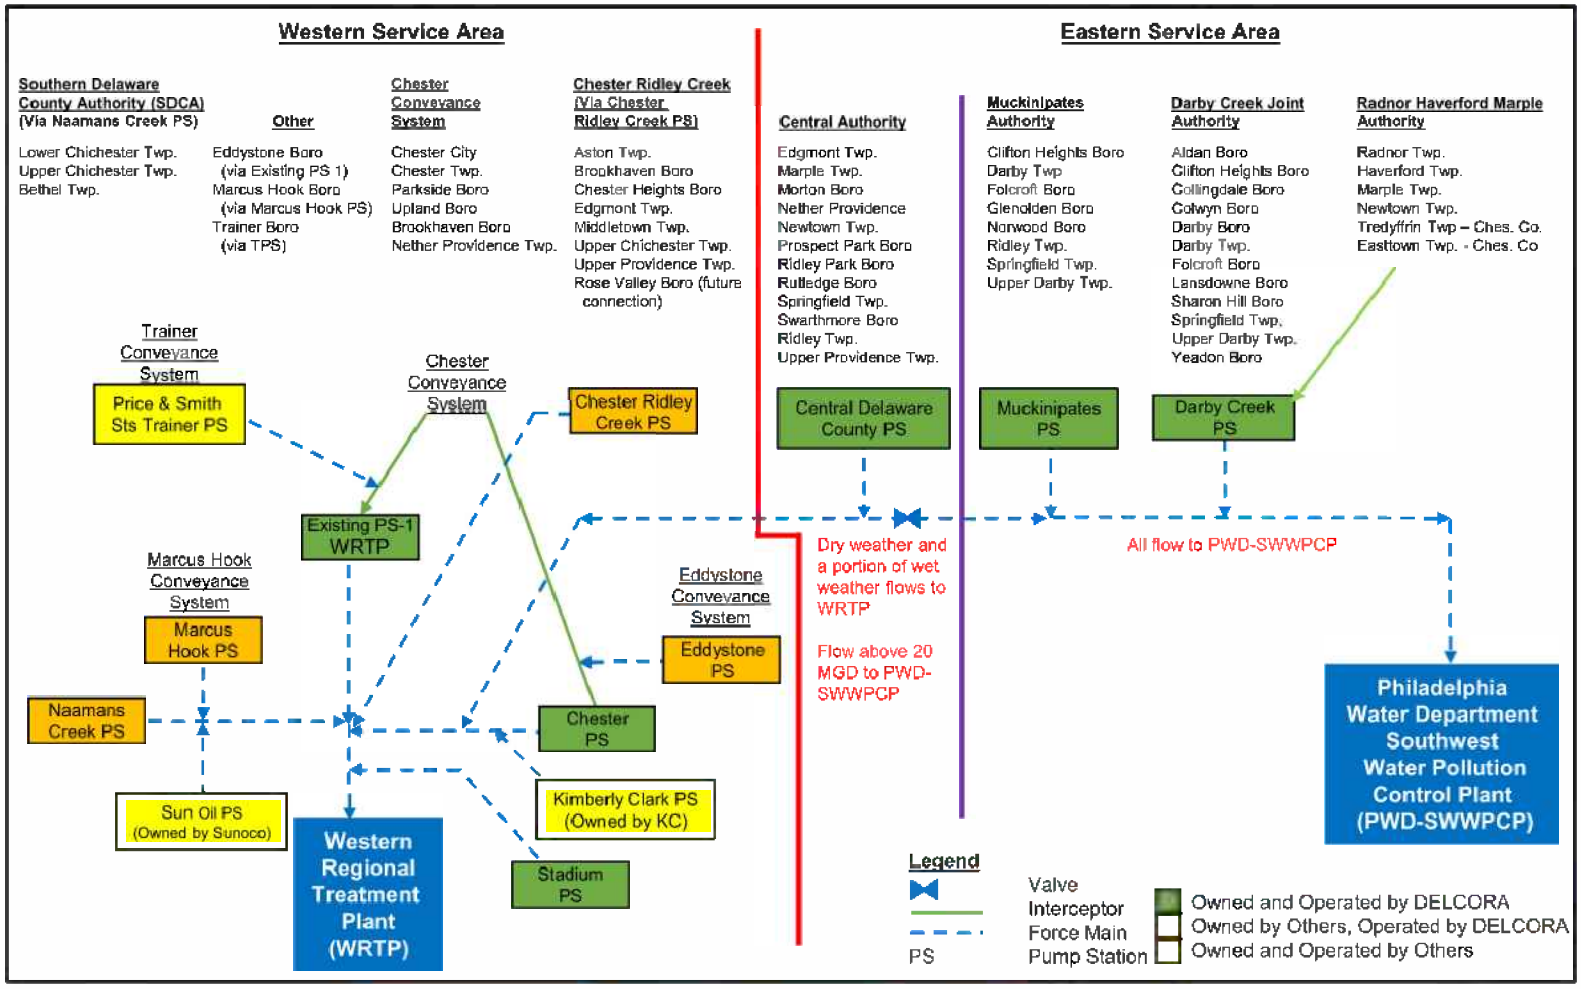


Figure 1-4: DELCORA's Service Areas

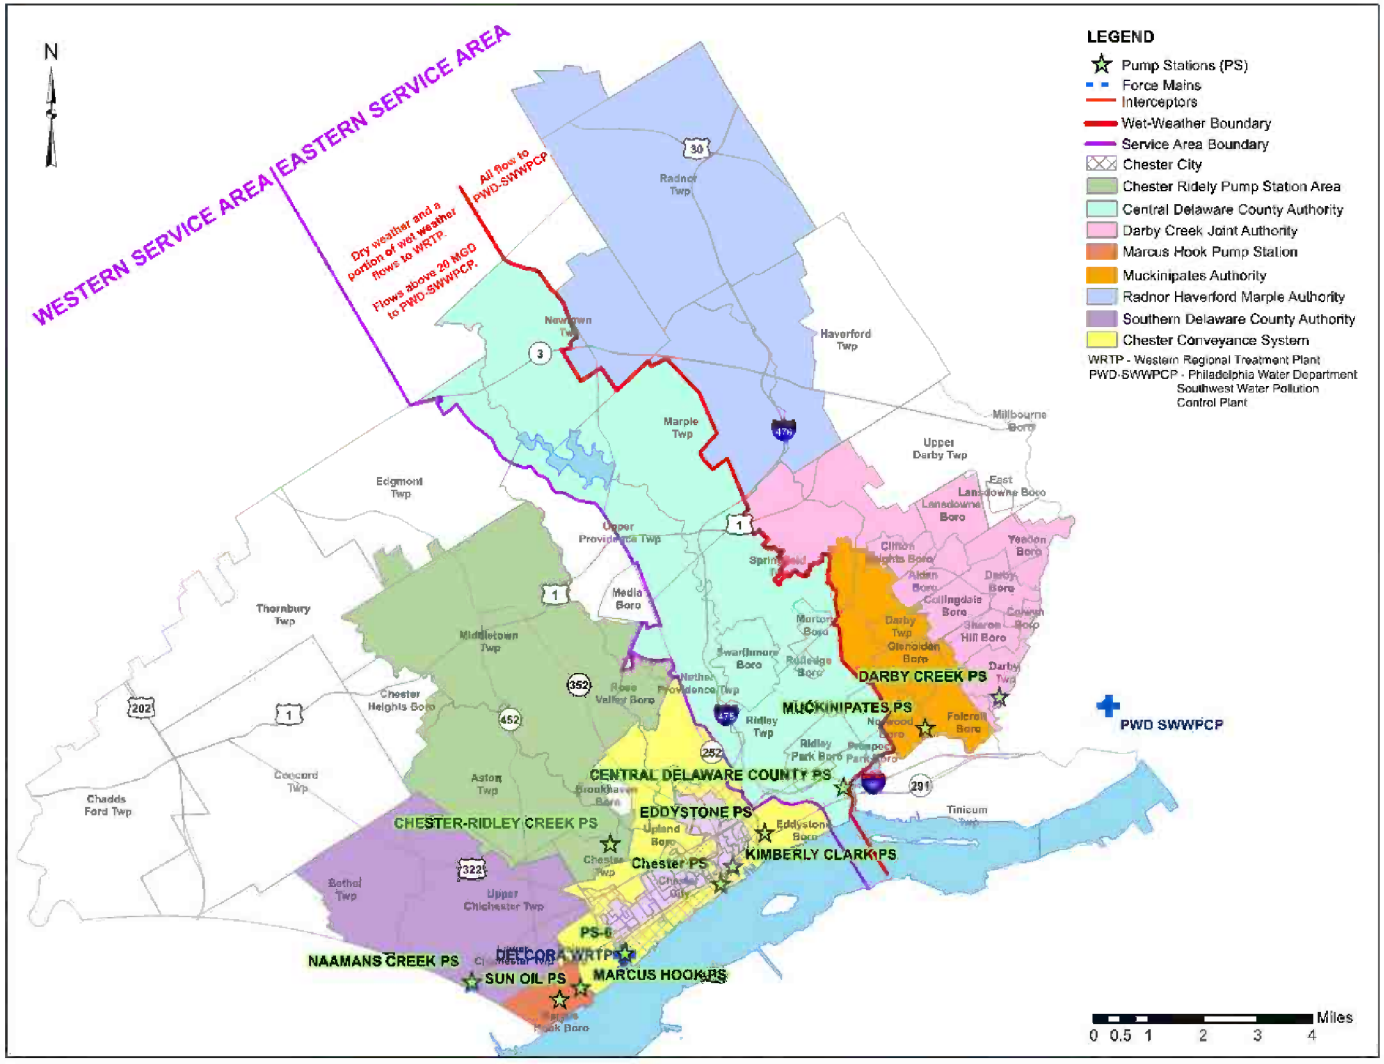

Table 1-3: DELCORA Service Area Distribution

Service	Area (Ac)
Owned and Serviced by DELCORA	5,598
Serviced by DELCORA	23,655
Serviced by DELCORA and PWD	18,806
Eastern Service Area (Serviced by PWD)	28,379

The Chester CSO system contains 26 permitted DELCORA outfalls as listed in **Table 1-4**, and they discharge to three receiving water bodies: the Delaware River, Chester Creek, and Ridley Creek. However, there are only 25 CSO discharge locations, as CSO #010 discharges to the Delaware River through CSO #009. **Figure 1-5** depicts the locations of CSO regulators and outfalls that are DELCORA's responsibility.

Figure 1-5 also provides a sewer system characterization and illustrates the breakdown of each outfall and how each drainage area has combined sewers and separate sewers. **Figure 1-6** is a schematic of the Chester CSO system and shows the outfalls and the interceptors that are connected to each CSO.

1.5.2 DELCORA's Treatment Facilities

DELCORA's primary treatment facility is the WRTP located at 3201 W. Front Street in Chester, PA. The WRTP was built in 1974 and it is an activated sludge treatment plant. A process schematic of the plant is shown in **Figure 1-7**. Based on data obtained for the period March 18, 2016 to May 1, 2017, the annual average dry weather flow to the WRTP is approximately 28 MGD. Due to record rainfall, recent flows have been higher. This facility treats all wastewater from the Model Area which includes all flow from the Western Service Area as well as up to 20 MGD from the Central Delaware County Authority. The WRTP was originally designed to treat 44 MGD. As is typical, the WRTP was designed to treat peak flow of 2-times the average design flow (of 44 MGD), or 88 MGD. The PADEP and the Delaware River Basin Commission have approved a re-rate of the WRTP to 50 MGD. DELCORA is currently working to extend the WRTP discharge outfall into the Delaware River to meet DRBC regulatory requirements for a re-rate to 50 MGD.

After the 1999 LTCP was approved, NMCs were implemented in the DELCORA sewer system, including the maximization of flow to the WRTP treatment. The purpose of this practice is to decrease CSOs in the collection system. Reducing CSOs in this manner sends more flow to the WRTP for short periods of time. At the WRTP, once wet weather flows exceed 88 MGD, there is an incremental reduction in hydraulic and process controls. Under most conditions, short periods of wet weather flows above 88 MGD can be processed through the treatment facility. The WRTP has demonstrated treatment capacity up to and above 104 MGD, while meeting discharge requirements. However, if operating conditions are not idea (such as the plant biomass not settling well) and the high flows continue too long, a wash out of biomass from the WRTP's secondary treatment system and severe property damage can occur. Typically, operating the plant above 88 MGD is acceptable if operating conditions are normal and settling, as indicated by the SVI, is not an upset condition. However, with the implementation of the LTCP and more wet weather flows being delivered to the plant, the current plant operations will not provide the best practice to address unusual operating conditions. Other means of addressing high sustained wet weather flows will be

Table 1-4: Permitted CSOs in the City of Chester

Name of Receiving Stream	CSO Outfall	Interceptor/CSO Regulator Location	Latitude	Longitude
Delaware River	002	Front and Booth	39°49'30"N	75°23'31"W
Delaware River	003	Front and Highland	39°49'34"N	75°23'11"W

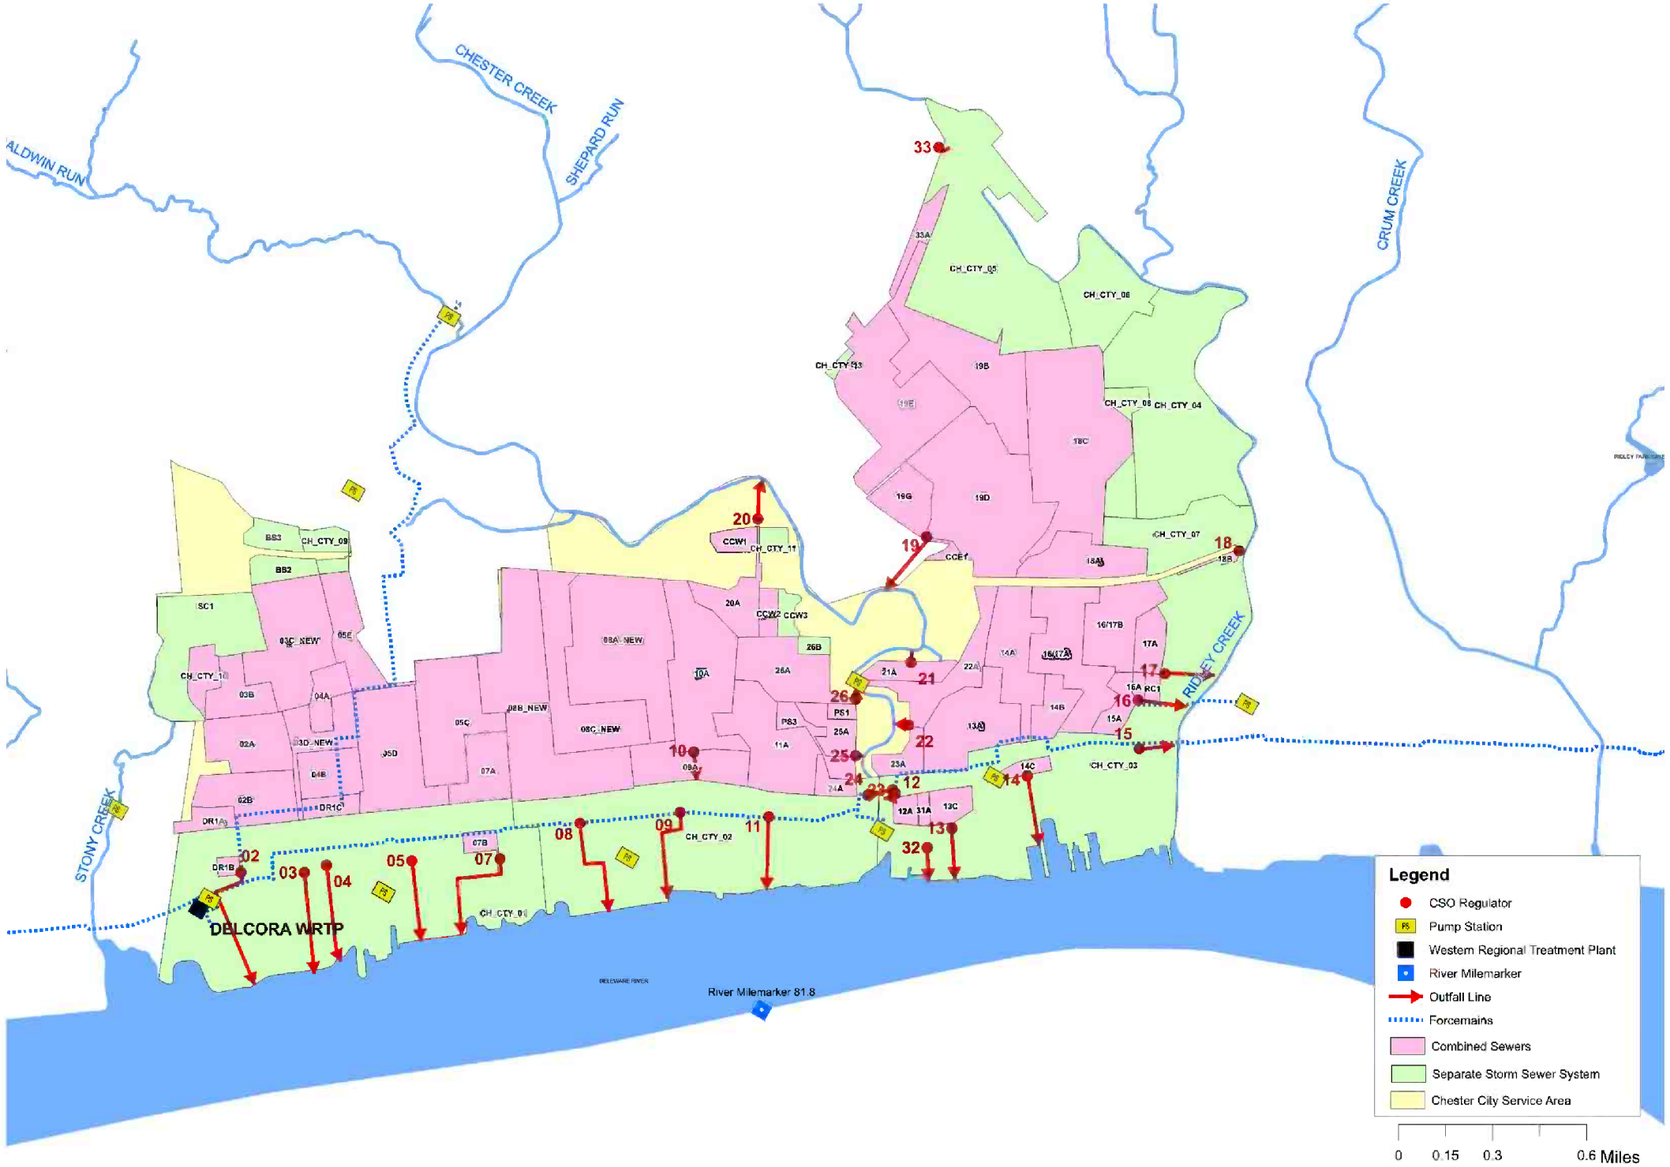

Figure 1-6: Schematic of Chester CSO System

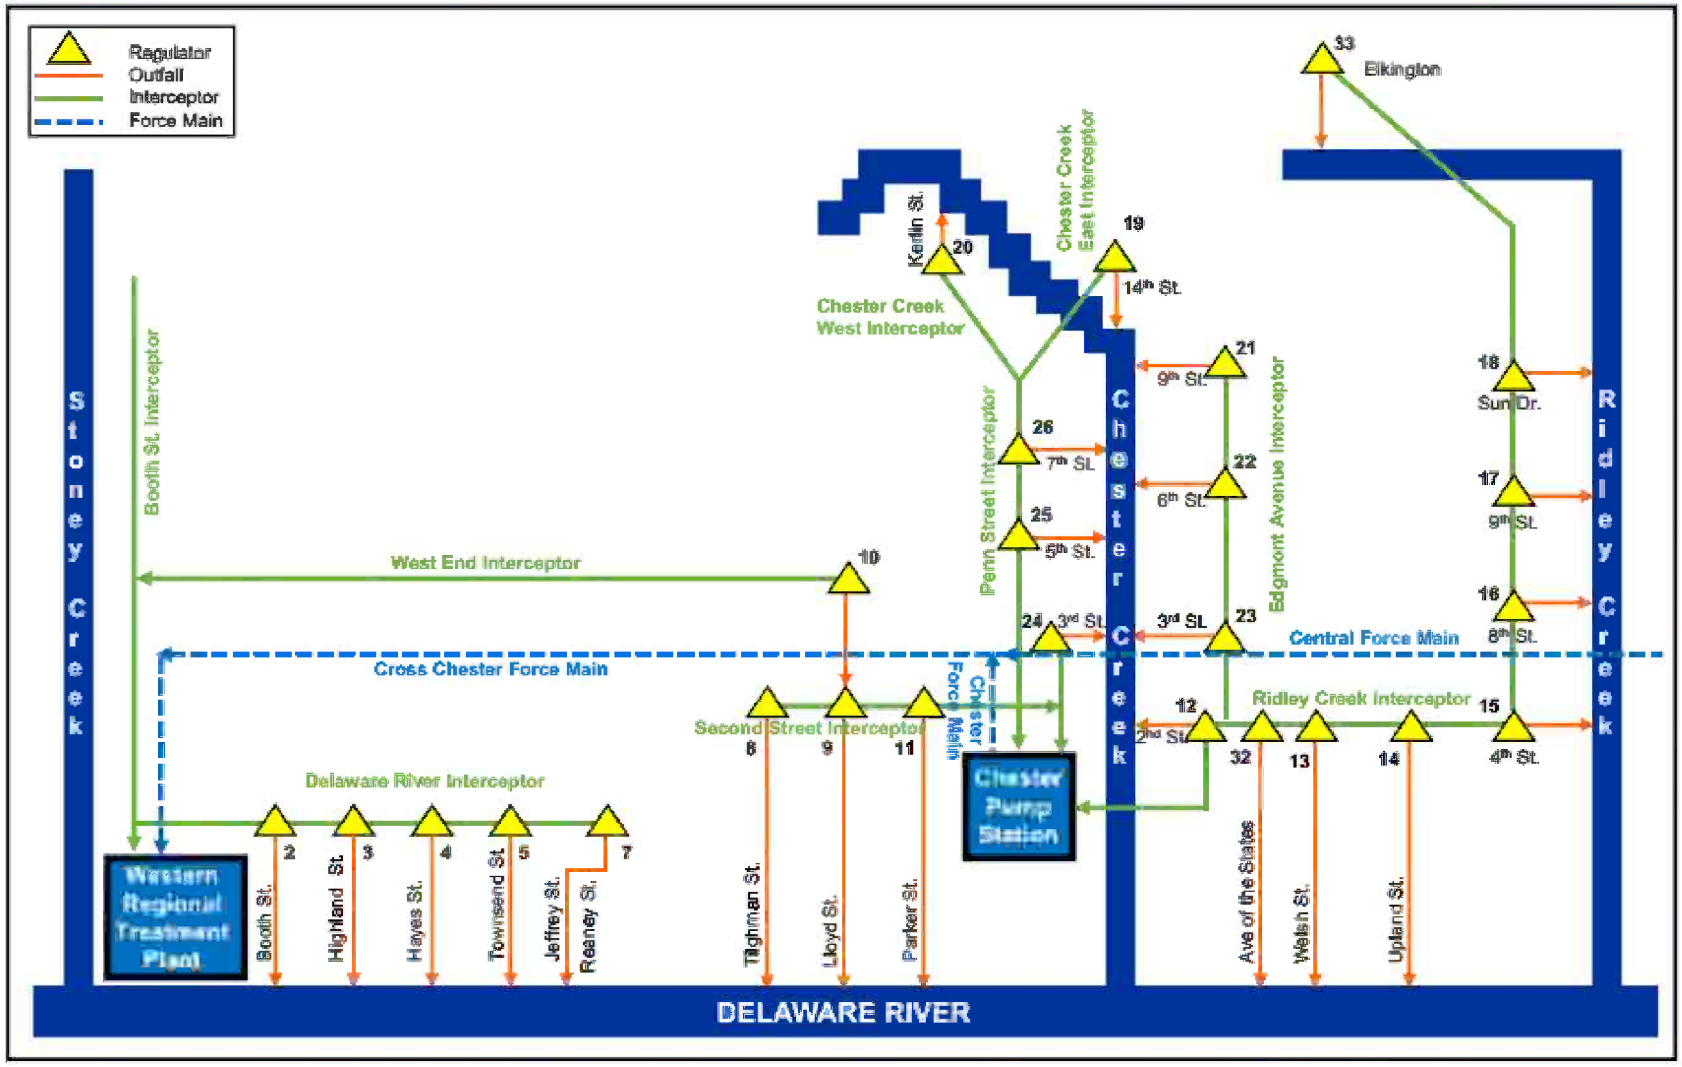

Figure 1-7: Western Regional Treatment Plant Schematic

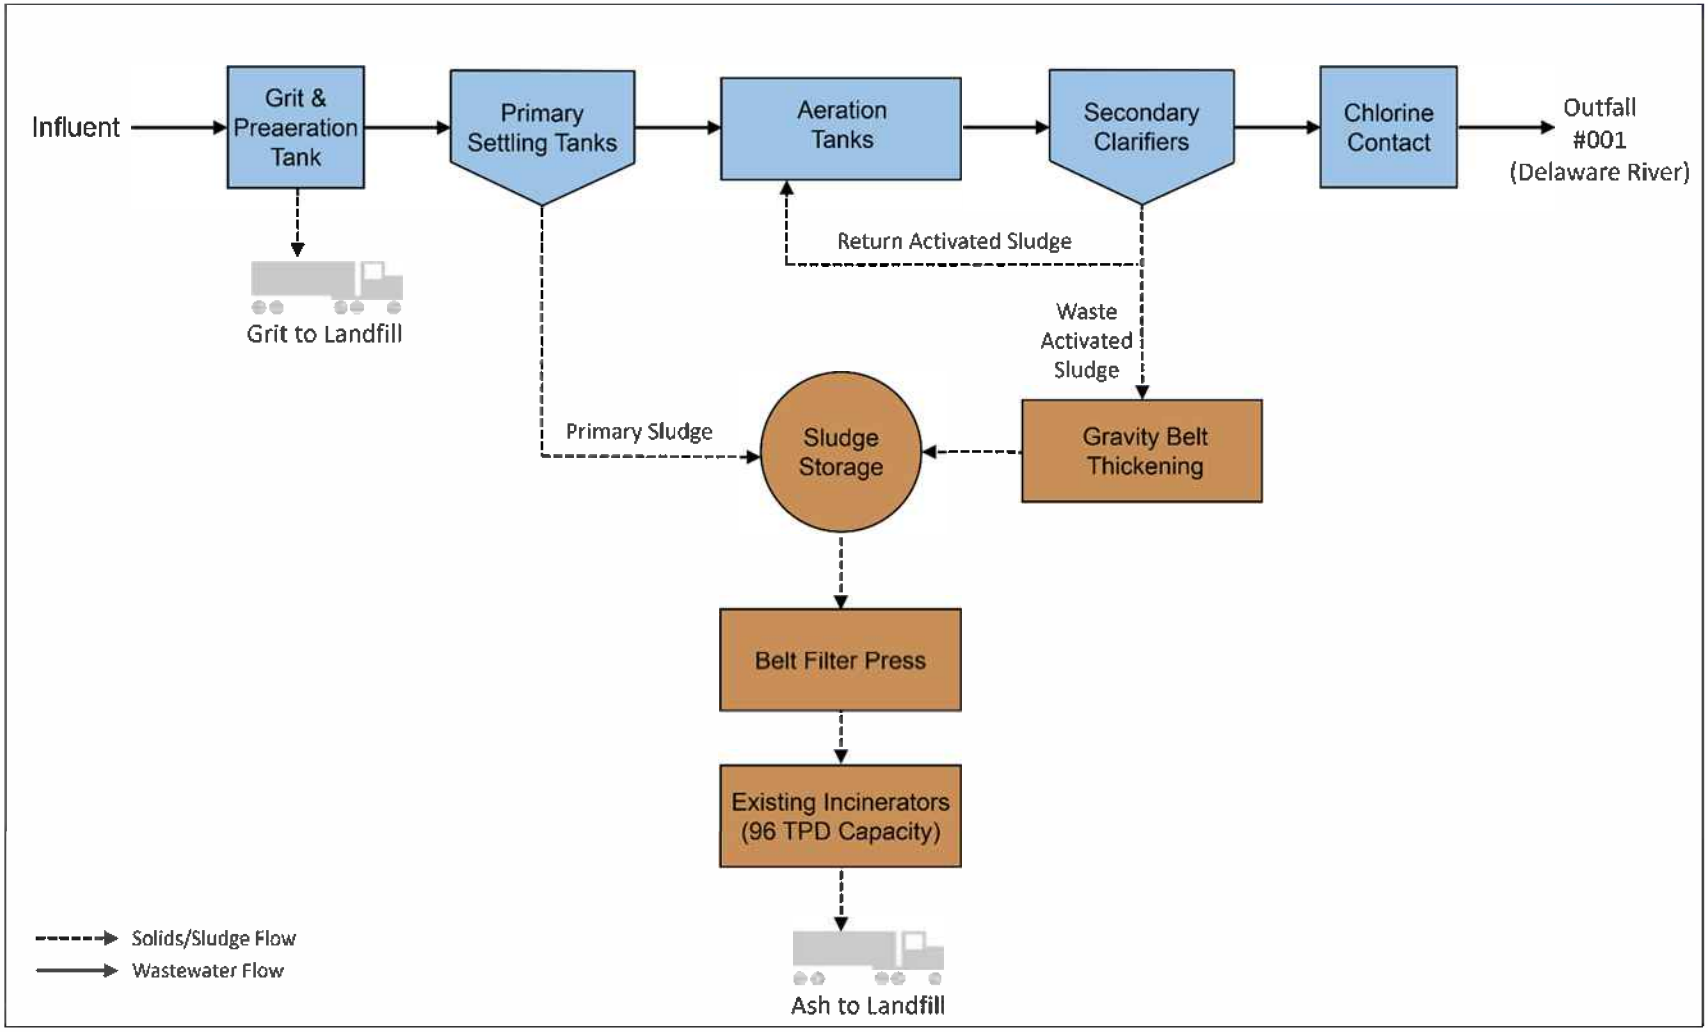

needed. The WRTP operations procedures will address the need to maximize treatment of wet weather flows, while not risking permit non-compliance or the loss of treatment.

All wastewater from the Muckinipates Authority, Darby Creek Joint Authority, and the Radnor Haverford Marple Authority are transported to the PWD-SWWPCP for treatment and disposal. The Central Delaware Pump Station can direct flow to the WRTP via the Central Diversion Force Main or to the PWD-SWWPCP. DELCORA has an agreement with the City of Philadelphia for the disposal of wastewater. This agreement specifies DELCORA's flow thresholds to the PWD-SWWPCP not exceed an annual average of 50 MGD, a daily maximum of 75 MGD (24 consecutive hours), and an instantaneous peak flow of 100 MGD (5 consecutive minutes). Flows above these thresholds are subject to exceedance charges.

DELCORA also purchased the Rose Valley Treatment Plant in 2009; it is currently no longer in operation and the WRTP receives its flow. The Rose Valley Treatment Plant was permitted at 0.13 MGD and located in Delaware County. On March 1, 2010, DELCORA purchased the Riverside Treatment Plant in Pocopson Township, Chester County. It is permitted at 0.045 MGD.

1.6 Overview of DELCORA's Service Areas

As mentioned previously and depicted in **Figure 1-4**, DELCORA serves a significant and widespread portion of Delaware County and has characterized its service areas as the "Eastern" and "Western." The Western Service Area discharges to the Western Regional Treatment Plant. The Eastern Service Area discharges to the Philadelphia Southwest Water Pollution Control Plant.

In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Western Service Area's Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority in the Eastern Service Area now discharges to the WRTP while only those CDPS flows above 20 MGD are to be directed to the PWD-SWWPCP.

1.6.1 Eastern Service Area

The Eastern Service Area is composed of four subareas that are served by conveyance authorities. These areas are the Radnor Haverford Marple (RHM) Authority, Darby Creek Joint Authority (DCJA), Muckinipates Authority (MA), and Central Delaware County Authority (CDCA) and are delineated in **Figure 1-4**. Each of these authorities has a legal agreement with their member municipalities to dispose of their wastewater. In turn, DELCORA has legal agreements with each of the authorities, except RHM, to receive and dispose of the collected wastewater. RHM discharges to the DCJA.

DELCORA owns and operates three large pump stations that serve DELCORA's Eastern Service Area; they are the Central Delaware County Pump Station, the Muckinipates Pump Station, and the Darby Creek Pump Station. These pump stations are designed to pump the wastewater from DELCORA's Eastern Service Area to the Philadelphia Southwest Water Pollution Control Plant for treatment. Originally constructed in the 1970s, the Central Delaware Pump Station (serving CDCA) is rated for 40 MGD. As originally designed, the Central Delaware Pump Station discharges though a 1.9-mile, 36-inch-diameter pre-stressed concrete cylinder pipe (PCCP) force main that runs northeast toward the Muckinipates Pump Station. The next pump station is the 24-MGD Muckinipates Pump Station (serving

MA). Here the force main increases to 48 inches in diameter and continues approximately 1.65 miles northeast to the Darby Creek Pump Station. Upon reaching the 60-MGD Darby Creek Pump Station (serving DCJA and RHM), the force main increases in diameter to 66 inches and continues approximately 2.5 miles on to the PWD-SWWPCP.

As noted previously, the operation of the Central Delaware Pump Station was modified in 2002 to allow for flow from the CDPS to be discharged to the WRTP. Currently, wastewater flows up to 20 MGD are discharged to WRTP and the wastewater flows in excess of 20 MGD are conveyed to the PWD-SWWPCP.

1.6.2 Western Service Area

DELCORA's Western Service Area is also shown in **Figure 1-4**. All wastewater flows from the Western Service Area are treated at DELCORA's WRTP. DELCORA owns and operates the collection system in the following communities in the Western Service Area:

- Chester City
- Chester Township[3]
- Marcus Hook Borough
- Parkside Borough
- Rose Valley Borough[4]
- Upland Borough
- Trainer Borough

DELCORA does not own or operate the collection system in the following communities in the Western Service Area:

- Brookhaven Borough
- Lower Chichester Township
- Nether Providence Township
- Eddystone Borough

[3] DELCORA owns only a portion of the collection system in Chester Township.
[4] Rose Valley Borough collection system discharges to its own treatment plant and a portion is discharged to the WRTP via Nether Providence's collection system.

1.7 Implementation of the Original LTCP

DELCORA has worked in a diligent manner to implement its April 1999 LTCP and the July 2008 addendum to the LTCP until the Long-Term Control Plan Update is approved. DELCORA is required to implement Phases I and II of the existing LTCP as outlined below:

A. Phase I - Implementation of the Nine Minimum Controls
Implementation of the NMCs is currently underway and is continuing in accordance with DELCORA's NMC Plan "*Delaware County Regional Water Quality Control Authority (DELCORA) Western Regional Treatment Plant (WRTP) Nine (9) Minimum Controls (NMC) for Correction of Combined Sewer Overflows (CSO)*" dated July 1995, and revised February 2019.

B. Phase II - Completion of Capital Improvements Projects
DELCORA's implementation of the required Capital Improvements Projects has met or exceeded the original LTCP schedule, including the required Regulator Replacements and installation of the Tide Gate Monitoring Systems. The CSO LTCP projects DELCORA has completed since the original LTCP was approved are as listed in **Table 1-5**.

It is to be noted that after the installation of the first CSO regulator Tide Gate Monitoring System, DELCORA determined that the monitoring system improves system operation and significantly reduces dry-weather overflows by notifying operators at the WRTP that flow is passing over the diversion weir. DELCORA has since installed the monitoring system on all CSO regulators even though it was not required until the CSO regulator was replaced. DELCORA continues to use this system and it provides critical information to maintain proper operation of the CSO regulators.

Table 1-5: Completed CSO LTCP Projects

CSO Regulator No.	CSO Regulator Location	CSO Receiving Water	CSO Regulator Type	Regulator Replacement Status
002	Front & Booth	Delaware River	Brown & Brown	Replaced
003	Front & Highland	Delaware River	Brown & Brown	Replaced
004	Front & Hayes	Delaware River	Brown & Brown	Replaced
005	Front & Townsend	Delaware River	Brown & Brown	Replaced
007**	Delaware & Reaney	Delaware River	Brown & Brown	Replaced

025	5th & Penn	Chester Creek	Brown & Brown	Replaced
026	7th & Penn	Chester Creek	Brown & Brown	Replaced
032	2nd & Avenue of the States	Delaware River	Weir Structure	Removed Mechanisms
033	Elkington Blvd. and Ridley Creek	Ridley Creek	Weir Structure	See Notes***

Notes:
* CSO Regulator 010 discharges at Outfall 009.
** CSO Regulators 006 ad 007 have been disconnected from CSS and removed from NPDES permit
*** CSO Regulator 033 has been disconnected from the CSS but had not been removed from NPDES permit at the date of this Report.

Section 2 Identification of Sensitive Areas and Pollutants of Concern

2.1 Background

Paragraph V.A.11 of DELCORA's Consent Decree (Identification of Sensitive Areas and Pollutants of Concern) requires that within six (6) months after the Date of Lodging, DELCORA shall submit a report to the USEPA and/or PADEP that identifies all Sensitive Areas and Pollutants of Concern that are impacted by CSOs and that are within the Model Area for each of its receiving waters. DELCORA met this submission deadline, and the Identification of Sensitive Areas and Pollutants of Concern Report was delivered to the USEPA and PADEP on May 20, 2016 and approved on October 13, 2016. This Section of the LTCP Update summarizes information that was presented in that report. The full version of the approved Identification of Sensitive Areas and Pollutants of Concern Report is included in **Appendix C**.

2.2 Regulatory Requirements

2.2.1 Consent Decree Requirements

For the Identification of Sensitive Areas, Paragraph V.A.11 of the Consent Decree specifically states:

> *"For each of its Receiving Waters, DELCORA shall contact appropriate agencies, access available data sources, and collect additional data as necessary to identify Sensitive Areas. DELCORA shall fully document all such contacts and the associated responses, and all additional investigations carried out to identify Sensitive Areas. DELCORA shall also identify any additional areas that, while not Sensitive Areas, have been identified by DELCORA as being appropriate for prioritization ("Priority Areas")."*
>
> Additionally, *"For each of its Receiving Waters, DELCORA shall conduct community outreach and appropriate studies to determine whether and to what extent primary contact recreation is occurring in each Receiving Water, and shall fully document its outreach and study methods, and its findings."*

For the Identification of Pollutants of Concern, Paragraph V.A.11 of the Consent Decree specifically states:

> *"For each of its Receiving Waters, DELCORA shall review existing water quality data and recent PADEP CWA § 303(d) listings to identify POCs. Even if a water body has not been formally listed as out of compliance with its water quality standards and designated uses, if available data indicate such impairment exists and such impairment involves pollutants associated with CSOs, DELCORA shall consider the related pollutants to be POCs."*

2.2.2 Requirements of the USEPA's CSO Control Policy and Sensitive Areas Definition

The USEPA's CSO Control Policy (Federal Register 59 [April 19, 1994]: 18688-18698) "expects a permittee's long-term CSO control plan to give the highest priority to controlling overflows to sensitive areas" (Section II.C.3). The CSO Control Policy states the six (6) criteria for defining an area as a "Sensitive Area" include:

1. Designated Outstanding National Resource Waters
2. National Marine Sanctuaries
3. Waters with threatened or endangered species and their habitat
4. Waters with primary contact recreation
5. Public drinking water intakes or their designated protected areas
6. Shellfish beds

The CSO Control Policy states that if Sensitive Areas are present and impacted, the LTCP should include provisions to:

- Prohibit new or significantly increased overflows
- Eliminate or relocate overflows wherever physically possible and economically achievable
- Treat overflows where necessary
- Where elimination or treatment is not achievable, reassess impacts each permit cycle

Sensitive Areas should be considered prior to the evaluation of CSO control alternatives. This allows a CSO community to identify and estimate costs for controls that could eliminate or relocate CSOs from Sensitive Areas where pollutant loadings pose a high environmental or public health risk and where control efforts should be focused.

After study and evaluation, it has been determined that no sensitive areas as defined by federal law need to be addressed by the DELCORA plans in the Chester and Ridley Creeks or in the Delaware River.

2.2.3 Priority Areas Definition

The term "Priority Areas" is not specifically defined by the USEPA in the Consent Decree nor in the CSO Control Policy or Guidance Document. For the purposes of this report, the term "Priority Areas" is defined as follows:

> *"Areas having some environmental significance but not to the level of "sensitive areas" as defined in the federal CSO Control Policy. These priority areas may include: public access areas (i.e., near marinas, schools, playgrounds, parks, or athletic fields); or use of shallow streams for recreational activity, with something less than full contact (i.e., wading)".*

In compliance with the Consent Decree, DELCORA conducted community outreach in order to determine whether and to what extent primary contact recreation is occurring in each Receiving Water. In order to cover DELCORA's large service area, a public survey was deemed to be the most comprehensive method to actively solicit community outreach. The public survey results are provided in **Appendix M**. Multiple regulatory agencies and environmental organizations were also contacted.

DELCORA conducted public outreach and held four public meetings during the development of this plan to identify areas of special concern to the public. The boat ramp at Flower Street along the Chester Riverfront was identified and, as discussed below, the DELCORA recommended plan makes this area a high priority for CSO control.

2.3 Summary of Sensitive Areas and Priority Areas

As documented in the Identification of Sensitive Areas and Pollutants of Concern Report (Final) dated May 2016, a comprehensive review of online databases, correspondences with regulatory agencies and local environmental organizations, and a review of responses to the public survey was conducted to identify potential Sensitive Areas and Priority Areas within the combined sewer system portion of the collection system. The further details and discussion about the identified areas can be found in the Identification of Sensitive Areas and Pollutants of Concern in **Appendix C**, and the public survey results in **Appendix M.**

2.4 Regulatory Requirements for the Identification of Pollutants of Concern

2.4.1 Sources of Information

The primary source of information about the causes of impairment, and the Total Maximum Daily Load status of the water bodies (if any) is the 2014 PA Integrated Water Quality Monitoring and Assessment Report (PA Integrated Report), which satisfies Pennsylvania's requirement of both Section 303(d) and 305(b) of the Clean Water Act (CWA). The PA Integrated Report lists all impaired surface waters within Pennsylvania that are not attaining designated and existing uses, even after appropriate and required pollution control technologies have been applied. A TMDL is designed to reduce pollutant loads to impaired waters and enable these waters to meet water quality standards.

The PA Integrated Report uses a five-part categorization (lists) of water according to their use attainment status. The categories represent varying levels of use attainment, ranging from Category 1, where all designated water uses are met to Category 5, where impairment by pollutants required the development of a TMDL to correct. Each segment of the waterbody is placed into one of these five categories. "Impairment" of a receiving water body is indicated to exist for a particular parameter if the parameter appears in Categories 4A and 5, as they indicate the need for a TMDL in the receiving water body and the limiting of additional loadings for those parameters. The Category 5 list constitutes the Section 303(d) list that the USEPA will approve or disapprove under the CWA. For the purposes of the determination of Pollutants of Concern, Categories 4A and 5 are the relevant categories as they indicate the need for a TMDL in the receiving water body and the limiting of additional loadings for those parameters. For DELCORA's drainage area, the HUC for the Lower Delaware River (02040202) was used for searching the data in the PA Integrated Report for all three of DELCORA's receiving water bodies.

The primary source of information for the Critical Use Designation for each section of the three receiving water bodies is 25 Pa. Code §93.9g – Drainage List. The relevant Critical Use Designations for DELCORA's receiving water bodies include Warm Water Fishes (WWF), Migratory Fishes (MF), Trout Stocking (TSF), and Water Contact Sports/Recreation (WC).

The applicable water quality standards for DELCORA's three receiving water bodies are found in the Delaware River Basin Commission's Water Quality Regulations, and in Water Quality Criteria lists found

in 25 Pa. Code §93.7 and §93.8c. For the Delaware River, the water quality standards are dictated by the DRBC's WQRs that have primacy over the standards in the PA Code. The water quality standards in the PA Code apply to the non-tidal portions of the Chester Creek and Ridley Creek, and to the Delaware River if there is no standard listed for a particular parameter in the DRBC's WQRs.

The DRBC's 2014 Delaware River and Bay Water Quality Assessment (DRBC, 2014) reports the extent to which waters of the Delaware River and Bay are attaining designated uses in accordance with Delaware River Basin Commissions' Water Quality Regulations for the period October 1, 2008 through September 30, 2013. The 2014 Assessment involves the comparison of key water quality parameters with the applicable DRBC water quality regulations. The states of Pennsylvania, New Jersey, Delaware and New York consider the DRBC's Assessment report as part of their determinations as to whether sections of the Delaware River should be listed on the state 303(d) list for a certain pollutant.

2.4.2 Delaware River Regulatory Requirements

2.4.2.1 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) list)

The 2014 PA Integrated Water Quality and Assessment Report ("the 303(d) List") lists a 61.02 mile segment of the Lower Delaware River in Category 4A as having an approved TMDL for polychlorinated biphenyls (PCBs) from an unknown source related to its fish consumption use. The USEPA approved a TMDL for PCBs for Zone 2 through Zones 5 in 2003, and a second PCB TMDL was approved for Zone 6 in 2006. The TMDLs for PCBs encompass the Delaware River Estuary and stretch from the mouth of the Delaware River upstream to the Trenton, NJ /Morrisville, PA Bridge. The segment of the Delaware River having an approved TMDL for PCBs is shown in yellow in the map in **Figure 2-1**, which was derived from the PADEP's eMapPA website.

As noted in **Subsection 2.5.2.1**, while the Delaware River is impaired from PCBs the PCBs are not normally associated with CSOs. Additionally, PCB impairment begins well upstream of DELCORA's service area and additional CSO sampling results from November/December 2015 showed all samples below the Reporting Detection Limit (RDL). For these reasons it was determined that PCBs are not associated with DELCORA's CSO discharges and are not considered a Pollutant of Concern.

2.4.2.2 Designated Critical Uses and Specific Water Quality Criteria from PA Code

The Critical Uses for the Delaware River in the area of DELCORA's CSO discharges are designated as WWF (maintenance only) and MF (passage only). Additionally, the Delaware River has a WC designation downstream of River Mile 81.8, which is located directly adjacent to the City of Chester between CSO #009 and #011.

For WC-designated waters, 25 Pa. Code §93.7 establishes the following as the water quality criterion for fecal coliform bacteria:

- Fecal Coliform – A geometric mean of 200 colonies/100 mL from May 1 - September 30 based on a minimum of five samples collected during a 30-day period. For the remainder of the year, the maximum fecal coliform level is a geometric mean of 2,000 colonies/100 mL based on a minimum of five samples collected during a 30-day period. There are no fecal coliform bacteria

Figure 2-1: Non-Attaining Streams and TMDL Streams within DELCORA's Service Area

- criteria for the Delaware River or tributaries that are not designated as Water Contact or Public Water Supply (PWS) waters.

For WWF and MF waters, the WWF designation is the more restrictive of the two and 25 Pa. Code §93.7 establishes the following additional standards for WWF waters:

- Dissolved Oxygen: Minimum above 5.0 mg/L, with the 7-day average value above 5.5 mg/L
- Alkalinity: A minimum of 20 mg/L as CaCO3, except where natural conditions are less
- Ammonia Nitrogen – the maximum total ammonia nitrogen concentration (in mg/L) shall be the numerical value given by un-ionized ammonia nitrogen (NH3-N) x (log-1[pKT-pH] + 1)
- Iron: 30-day average 1.5 mg/L as total recoverable
- pH: From 6.0 to 9.0 inclusive
- Temperature: A table is included within 25 Pa. Code §93.7 for maximum water temperatures in the receiving water body at various times of the year
- Total Residual Chlorine: Four-day average 0.011 mg/L; 1-hour average 0.019 mg/L

2.4.2.3 Designated Zone and Water Quality Regulations from the DRBC

Chapter 25 Pa. Code §93.9 lists the DRBC regulations for Water Quality Zone 4 as exceptions to PA Code's specific water quality criteria. The DRBC's water quality regulations have primacy over the standards in the PA Code for the Delaware River.

The segment of the Delaware River directly impacted by DELCORA's CSO discharges is referred to as Zone 4" by the DRBC. The DRBC defines Zone 4 as that part of the Delaware River extending from R.M. 78.8 to R.M. 95.0, the Pennsylvania-Delaware state boundary line to the upstream side of the Philadelphia Navy Yard, including the tidal portions of the tributaries thereof. The extent of Zone 4 is represented in **Figure 6-6.** The DRBC states that the quality of Zone 4 waters shall be maintained in a safe and satisfactory condition for the following uses:

- Industrial water supplies after reasonable treatment
- Maintenance of resident fish and other aquatic life
- Passage of anadromous fish
- Wildlife
- Recreation - secondary contact above R.M. 81.8
- Recreation (all water-contact sports) below R.M. 81.8
- Navigation

The DRBC's Stream Quality Objectives for Zone 4 are as follows:

1. Dissolved Oxygen
   - 24-hour average concentration shall not be less than 3.5 mg/L.
   - During the periods from April 1 to June 15, and September 16 to December 31, the DO shall not have a seasonal average less than 6.5 mg/L.

2. Temperature shall not exceed:
   - 5°F (2.8°C) above the average 24-hour temperature gradient displayed during the 1961-66 period, or
   - A maximum of 86°F (30.0°C), whichever is less.

3. pH between 6.5 and 8.5 inclusive, unless outside this range due to natural conditions

4. Phenols maximum 0.02 mg/l, unless exceeded due to natural conditions

5. Threshold Odor Number not to exceed 24 at 60°C

6. Synthetic Detergents. (M.B.A.S.). Maximum 30- day average 1.0 mg/L

7. Radioactivity
   - Alpha emitters - maximum 3 pc/L (picocuries per liter);
   - Beta emitters - maximum 1,000 pc/L.

8. Bacteria
   - Fecal Coliform
     - Above R.M. 81.8: maximum geometric average 770 per 100 milliliters
     - Below R.M. 81.8: maximum geometric average 200 per 100 milliliters
   - Enterococcus
     - Above R.M. 81.8: maximum geometric average 88 per 100 milliliters
     - Below R.M. 81.8: maximum geometric average 33 per 100 milliliters

9. Total Dissolved Solids not to exceed 133% of background
   (NOTE: The background TDS concentration is at present undefined, according to the DRBC's 2014 Delaware River and Bay Water Quality Assessment.)

10. Turbidity unless exceeded due to natural conditions
    - Maximum 30-day average 40 units (NTU)
    - Maximum 150 NTU

11. Alkalinity between 20 and 120 mg/L

12. Toxic Pollutants
    - Applicable criteria to protect the taste and odor of ingested water and fish are presented in the DRBC's WQRs Table 4.
    - Applicable freshwater stream quality objectives for the protection of aquatic life are presented in the DRBC's WQRs Table 5.
    - Applicable freshwater stream quality objectives for the protection of human health are presented in the DRBC's WQRs Tables 6 and 7.

2.4.2.4 DRBC Evaluation of Use Attainment Status

Table 2-1 presents a summary of Table 23 from the DRBC's 2014 Delaware River and Bay Water Quality Assessment for Zone 4 of the Delaware River.

Table 2-1: 2014 DRBC Integrated Assessment for Zone 4 of the Delaware River

Zone	Designated Use			
	Aquatic Life	Drinking Water	Recreation	Fish Consumption
4	NS	N/A	S	NS

Notes:
N/A - Not applicable
NS - The Designated Use is not supported
S - The Designated Use is supported

Table 2-1 shows whether or not the designated use is being attained for the Delaware River in Zone 4. According to the table, the designated use for Water Contact Recreation is being attained but the designated use for Aquatic Life and Fish Consumption are not being attained. The DRBC's Assessment Report (DRBC, 2014) states, "*the composite aquatic life assessment for 2014 yields a result of "Not Supporting" for all assessment units* (or zones). *It is important to note, however, that this result is largely driven by the requirement to categorize as not meeting criteria any assessment unit* (or zone) *with 1 exceedance plus 1 confirmatory exceedance.*" The DRBC's Assessment Report also states: "*Data showed multiple exceedances of aluminum acute and chronic freshwater objectives for the support of aquatic life in Zone 4. Of 35 surface water samples tested for aluminum in Zone 4 during the assessment period, 34 exceeded the chronic criterion and 8 exceeded the acute criterion at 21PA_WQX-WQN0182 near Marcus Hook, PA. No exceedances of aluminum were reported in Zones 2, 3, 5 and 6.*" As part of the Recommendations for Future Action at the end of the report, the DRBC states that the "*exceedances of aluminum criteria in Zone 4 warrant further attention*".

The Fish Consumption designated use is not being attained. The Assessment Report states that their assessment criterion for fish consumption is based on the presence of fish consumption advisories from the four Basin states for the main stem of the Delaware River. If a fish consumption advisory is present, this resulted in the DRBC making an assessment of "not supporting the designated use". Violation criteria for PCBs also supported this assessment, with the presence of measureable concentrations of PCBs in the river that exceeded the surface water quality standard. The 2016 Commonwealth of Pennsylvania Fish Consumption Advisories for Zones 2, 3, and 4 of the Delaware River (Trenton, NJ/Morrisville, PA Bridge to PA/DE border) are as shown below in **Table 2-2**. These advisories identify PCBs as a pollutant of concern in fish tissue.

Table 2-2: PA Fish Consumption Advisory Summary for PCBs in the Delaware River

Fish Species	Meal Frequency	Contaminant
White Perch	1 meal/month	PCB
Flathead Catfish	1 meal/month	PCB
Channel Catfish	1 meal/month	PCB
Striped Bass: over 28 inches in length	1 meal/month	PCB
Carp	6 meals/year	PCB
American Eel	Do Not Eat	PCB

2.4.3 Chester Creek Regulatory Requirements

2.4.3.1 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) list)

Chester Creek is listed in Category 5 of the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report as not meeting its recreational use due to pathogens, and for not meeting its aquatic life use due to siltation. "Pathogens" were listed in 2006 for three segments totaling 0.94 miles, and a TMDL is anticipated in 2019. The source for the pathogens is listed as "unknown", and these three stream segments are all well upstream of DELCORA's service area. Therefore, it appears that the noted impairment of the Chester Creek due to pathogens is not related to DELCORA's CSO discharges.

"Siltation" was listed in 2014 for four segments of the creek totaling 18.41 miles, and a TMDL is anticipated in 2027. The source for the siltation was identified as "urban runoff/storm sewers". The majority of Chester Creek is not attaining its designated use for aquatic life due to siltation, and the vast majority of these impaired segments are located upstream of DELCORA's service area and are shown in red in the map in **Figure 2-2**. However, one of DELCORA's CSO outfalls does discharge to the furthest downstream segment of the Chester Creek that is impaired by siltation, which is Outfall #020 near Kerlin Street and Finland Drive.

The impairment of Chester Creek by siltation primarily occurs upstream of DELCORA's service area as shown in **Figure 2-1**. The term "Siltation" is not defined in the 2014 PA Integrated Water Quality & Assessment Report, but through various sources can be defined as:

> *"the pollution of water by fine particulate terrestrial clastic material, with a particle size dominated by silt or clay. It refers both to the increased concentration of suspended sediments, and to the increased accumulation (temporary or permanent) of fine sediments on bottoms where they are undesirable. Siltation is most often caused by soil erosion or sediment spill."*

There is not a water quality standard for "siltation", however, siltation can be considered as closely related to the widely used water quality parameter of "Turbidity", which is associated with CSO discharges. For this reason, "Turbidity" was reviewed further as a surrogate for siltation to determine if it might be considered as a POC. As noted in **Subsection 2.5.2.1**, per available USEPA Storage and Retrieval (STORET) data the Turbidity concentrations on the Chester Creek were found to be below the WQS and therefore siltation was screened-out as not being a POC.

Category 4A lists a 0.81-mile segment of Chester Creek at its mouth that does not meet its designated use for fish consumption due to PCBs from an unknown source, and for which a TMDL for PCBs was issued in 2006. This is shown in yellow in the map in **Figure 2-1** and is related to the TMDL for PCBs in the Delaware River Estuary.

2.4.3.2 Designated Critical Uses and Water Quality Criteria from PA Code

The Critical Uses for the Chester Creek in the area of DELCORA's CSO discharges are designated in 25 Pa. Code §93.9. All stretches of the Chester Creek in this area are designated as WWF (maintenance only) and MF (passage only). The same specific water quality criteria apply to the WWF and MF Critical Use designations for Chester Creek as apply for the Delaware River.

2.4.4 Ridley Creek Regulatory Requirements

2.4.4.1 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) list)

Ridley Creek is listed in Category 5 of the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report as not meeting its aquatic life use due to siltation. The "Siltation" was listed in 2012 for five segments totaling 26.76 miles, and a TMDL is anticipated in 2025. The source for the siltation was identified as "unknown" or from "urban runoff/storm sewers".

In actuality, it appears that the majority of Ridley Creek is not attaining its designated use for aquatic life due to siltation, and the vast majority of these impaired segments are located well upstream of DELCORA's service area and are shown in red in the map in **Figure 2-1**. All of Ridley Creek within DELCORA's service area is shown as impaired for aquatic life due to siltation. As with the Chester Creek, the Ridley Creek is listed in the 2014 PA Integrated Water Quality & Assessment Report as impaired for Aquatic Life from siltation, with Urban Runoff/Storm Sewers identified as the source.

However as noted for the Chester Creek, there is not a water quality standard for "siltation" but it can be considered as closely related to the widely used water quality parameter of "Turbidity", which is associated with CSO discharges. As noted in **Subsection 2.5.2.1**, per available USEPA STORET data the Turbidity concentrations for the Ridley Creek were found to be below the WQS and therefore siltation was screened-out as not being a POC.

2.4.4.2 Designated Critical Uses and Water Quality Criteria from PA Code

The Critical Uses for the Ridley Creek in the area of DELCORA's CSO discharges are designated in 25 Pa. Code §93.9. All stretches of the Ridley Creek in this area are designated as WWF (maintenance only), MF (passage only), or TSF. The TSF stretch only applies in the sections of the Ridley Creek upstream of the Chestnut Street bridge crossing.

The same specific water quality criteria apply to the WWF and MF Critical Use designations for Ridley Creek as apply to the Chester Creek and Delaware River, except for the parameters of Dissolved Oxygen and Temperature – which are more stringent in the TSF stretch because of the high oxygen needs of trout.

Specifically, for TSF waters 25 Pa. Code §93.7 establishes the following additional standards:

- Dissolved Oxygen – For the period February 15 to July 31 of any year, the minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 6.0 mg/L. For the remainder of the year, the minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 5.5 mg/L.
- Temperature – A separate table is included within 25 Pa. Code §93.7 for maximum water temperatures in the receiving water body at various times of the year for TSF waters.

2.5 Assessment of Pollutants of Concern

A comprehensive review of existing receiving water quality data was conducted to identify the Pollutants of Concern and this review was performed in accordance with the requirements of the Consent Decree and the CSO Guidance Manual. This review included on-line USEPA STORET data from the years 2010-2015, results of sampling performed during the preparation of DELCORA's 1999 LTCP and additional CSO sampling.

2.5.1 Methodology for Identification of the Parameters Considered

For the identification of the POCs, DELCORA took an inclusive approach to determine that all relevant water quality parameters were appropriately considered and evaluated. The first step was to develop a comprehensive list of the overall "Parameters Considered", which was then further evaluated and refined to determine the list of the applicable POCs. Development of the list of Parameters Considered was meant to cast a wide net as the first step towards identifying any parameters that might possibly be of concern.

The initial list of the Parameters Considered was compiled from six (6) primary reference sources from the USEPA, PADEP and the DRBC. The Parameters Considered list initially consisted of those specific parameters listed in the USEPA's CSO Guidance Document. Additional parameters to consider were added from the parameters requiring sampling per DELCORA's NPDES permit, from the PA Code's specific water quality criteria for DELCORA's three receiving water bodies, from the DRBC's Water Quality Regulations for Zone 4 of the Delaware River, from the 2014 PA Integrated Water Quality Monitoring and Assessment Report (a.k.a. "303(d) List"), and from the DRBC's 2014 Delaware River and Bay Water Quality Assessment report. **Appendix C** provides a summary of the initial Parameters Considered list that was developed by compiling the parameters listed in each of the six primary reference sources.

Once the initial list of Parameters Considered was developed, additional parameters including Metals Nutrients, and Toxics were added onto the list if they had been detected during the historical sampling data of the influent to the WRTP, or in the existing CSO monitoring data. One year's worth of DELCORA's plant influent historical sampling data from September 1, 2014 through September 1, 2015 was collected and analyzed to identify additional Parameters Considered.

It is important to state that that the historical sampling data noted above for the influent to the WRTP also included industrial wastewater from DELCORA's forty-five (45) Significant Industrial Users (SIUs). The industrial wastewater from forty-three (43) of DELCORA's SIUs is trucked directly to the WRTP and is discharged downstream of all CSOs into the combined sewer flow prior to the plant's influent sampling location. Consequently, the historical sampling data for the influent to the plant detected

twenty-eight (28) industrial-type chemicals from these SIUs that are not normally associated with sanitary sewage or combined sewer overflows. Since the trucked-in industrial wastewater is discharged directly to the WRTP, it is not able to migrate back into the combined sewer system and, therefore, this industrial wastewater cannot be discharged from any of DELCORA's CSOs. However, as part of the due diligence to address all possible POCs, the 28 industrial chemicals that were detected in the historical sampling of the plant influent were added onto an expanded list of Parameters Considered.

To help eliminate from the expanded list of the Parameters Considered the industrial chemicals that were detected as a result of the SIUs discharging to the WRTP, it was determined that additional wet weather sampling at the CSOs was required. The purpose of the additional sampling was to verify and confirm that the industrial-type chemicals not normally associated with CSOs that were detected in the historical sampling of the plant influent were in fact actually from the trucked-in industrial wastewater and not a part of the normal flow within the CSS that might overflow at a CSO. The CSO sampling results were used to screen non-detected parameters from the list of the Parameters Considered. The additional sampling results more accurately reflect the actual characteristics of the wastewater discharged at the CSOs, than the historical data at the plant influent since the trucked-in industrial wastewater only goes into the plant and does not enter into the CSS. Therefore, if a parameter on the expanded Parameters Considered list was not detected in the November and December 2015 wet weather sampling of the CSOs, those parameters were not considered further as POCs.

2.5.2 Methodology for Identification of the Pollutants of Concern List

Once the Parameters Considered list was narrowed using the November/December 2015 additional sampling results at the CSOs, the parameters remaining on the narrowed list of Parameters Considered were further evaluated to determine if they are Pollutants of Concern, or Parameters of Potential Concern (POPC). A parameter is considered a "Pollutant of Concern" for a water body if more than 10% of the samples exceeded the applicable water quality standard. This criterion is based on guidance provided by the USEPA, which recommends a "greater than 10% exceedance percentage" for determining that waters only partially meet their designated use for aquatic life support. A parameter is considered a "Parameter of Potential Concern" if 2 – 10% of the samples exceeded the water quality standard.

Water quality data for the parameters on the narrowed Parameters Considered list were collected from the STORET data repository for the one-year period from September 1, 2014 to September 1, 2015 from the water quality monitoring stations on each of the three receiving water bodies.

The segments of the Delaware River, Chester Creek and Ridley Creek have unique water quality standards that apply to them depending on the regulating authority, their designated uses, and the specific location within the waterbody. The Water Quality Standards Master Table that was developed to identify the applicable WQS is presented in **Appendix B**. The maximum concentrations detected for each of the Parameters Considered were compared against the applicable surface water quality standards to determine which parameters were exceeding their standards. The Delaware River was evaluated in two sections; one for the Delaware River upstream of R.M 81.8 ("upper Delaware") and one for the Delaware River downstream of R.M 81.8 ("lower Delaware") based on the Water Contact Recreation designated use for the Delaware River below R.M. 81.8 and the more stringent requirements associated with primary contact. The receiving stream water quality data from the USEPA STORET data warehouse was compared against the applicable WQS to check for exceedances. Both the acute and chronic conditions

for the Parameters Considered were compared to the WQS, where applicable, to determine if there were exceedances.

A flowchart was created to help illustrate the decision-making methodology used for developing the Pollutants of Concern list. The flowchart represents the process used for answering five (5) screening questions about the Parameters Considered in order to determine if a parameter is to be considered a Pollutant of Concern, a Parameter of Potential Concern, or neither. **Figure 2-2** presents the Methodology Flowchart used for developing the list of POCs and POPCs, and the following subsection provides additional details about the methodology used to answer the 5 screening questions.

2.5.2.1 Screening of Parameters Using the Methodology Flowchart

The Methodology Flowchart for POC and POPC Determination in **Figure 2-2** shows that the first step is to determine if a Parameter Considered has an applicable PA State or DRBC water quality standard. If a parameter does not have an applicable water quality standard, there is no standard to exceed. Therefore, those parameters without a water quality standard are not considered further as a POC or a POPC. These include many of the Parameters Considered. Of the 76 Parameters Considered, 25 were removed from further consideration because they do not have an applicable water quality standard.

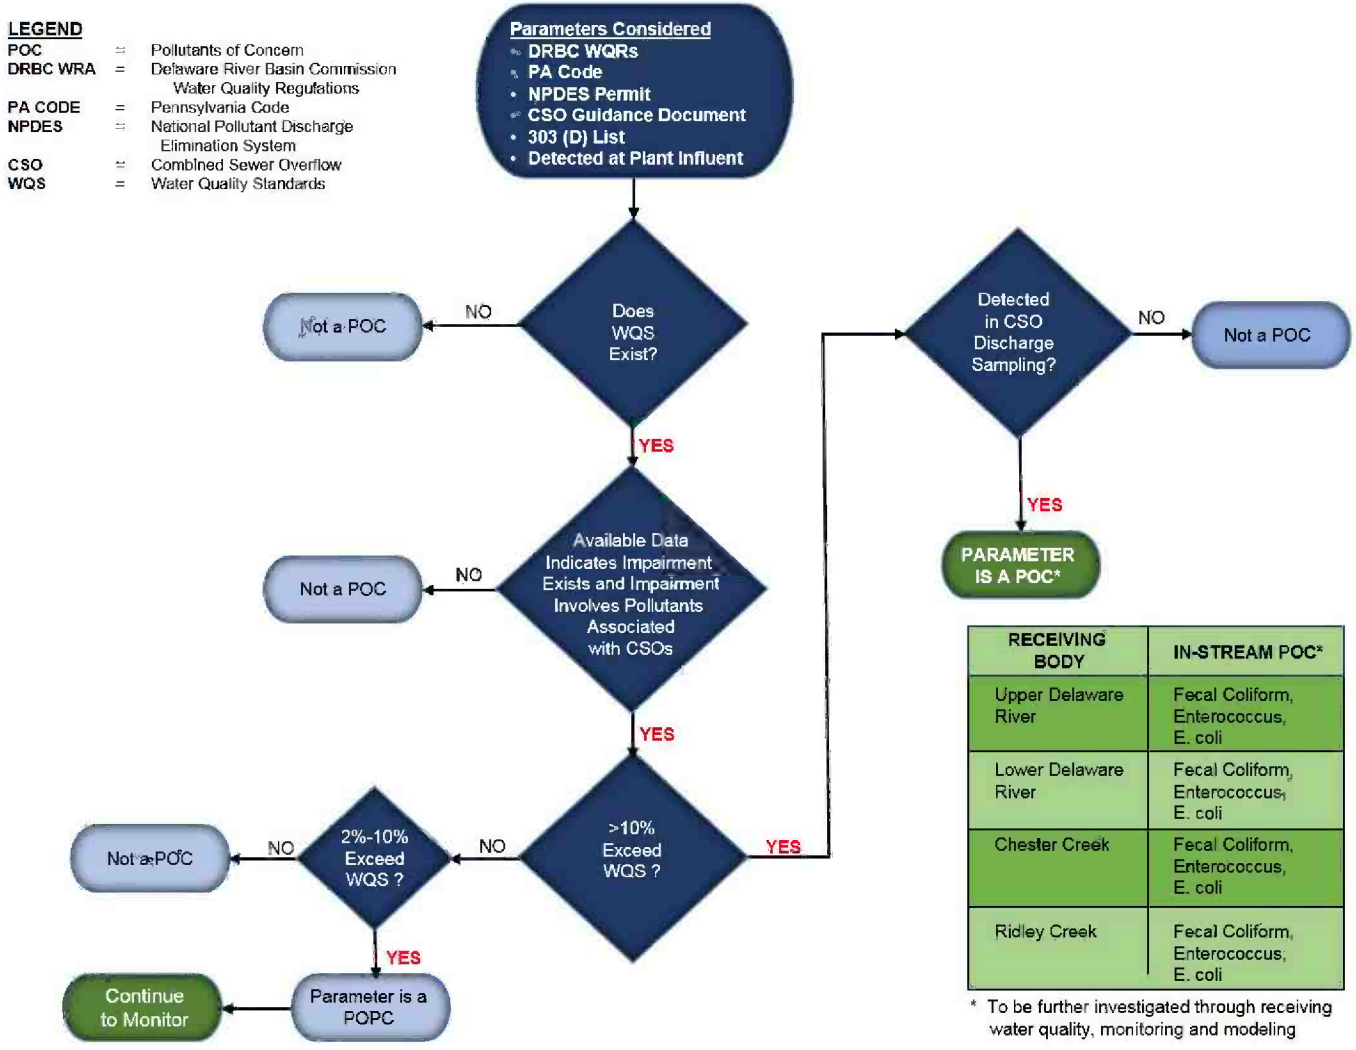
For the 51 Parameters Considered that do have an applicable water quality standard, the Methodology Flowchart shows that the second screening decision is to determine if existing water quality data indicate impairment of the receiving water bodies exists and the impairment involves pollutants associated with CSOs. The inclusion of this determination comes directly from the requirements of the Consent Decree.

"Impairment" of a receiving water body is "indicated" to exist in one of two ways. First, the receiving water body is considered impaired for a particular parameter if the parameter appears in the 2014 PA Integrated Water Quality & Assessment Report (303(d) List). The PA Integrated Report identifies surface water bodies that are not attaining their designated and existing uses as "impaired". Secondly, for the purpose of this report, a receiving water body is also considered impaired for a parameter if any of the available sampling data for that parameter in the water body shows that there had been an exceedance of the applicable water quality standard. Those parameters that showed exceedances of the WQS and that may be associated with CSOs were evaluated further to determine if they should be considered as a POC.

The 2014 PA Integrated Water Quality & Assessment Report shows the Delaware River to be impaired for Fish Consumption by PCBs from an unknown source, and there is a PCB TMDL on the Delaware River stretching far upstream to Trenton, NJ. While the Delaware River is impaired from PCBs, the PCBs are not normally associated with CSOs. Given this reason, and the fact that the PCB impairment begins well upstream of DELCORA's service area – PCBs were screened as not being a POC. Furthermore, the additional CSO sampling results from November/December 2015 show that PCBs were found to be at a lower concentration than the Reporting Detection Limit. For this additional reason it was determined that PCBs are not associated with DELCORA's CSO discharges.

For the Chester Creek and Ridley Creeks, the 2014 PA Integrated Water Quality & Assessment Report shows that both of the creeks are impaired for Aquatic Life from siltation, with Urban Runoff/Storm Sewers identified as the source. The impairment of the Chester Creek and Ridley Creek by siltation primarily occurs upstream of DELCORA's service area as shown in **Figure 2-2**. There is not a water quality standard for "siltation", however, siltation can be considered as closely related to the widely used water quality parameter of "Turbidity", which is associated with CSO discharges. Per available USEPA STORET data,

Figure 2-2: Methodology Flowchart for POC and POPC Determination



the Turbidity concentrations on all of the three receiving water bodies were found to be below the WQS and therefore siltation was screened-out as not being a POC.

The concentrations of those Parameters Considered that were detected within the receiving water bodies from USEPA's STORET data for the Years 2010 - 2015 were compared to the applicable water quality standards to determine if a Parameter Considered should be viewed as a Pollutant of Concern. If 10% or more of the total number of samples for a Parameter Considered exceeded the WQS, then the parameter was further evaluated to see if it was detected in the CSO discharges. If 2% - 10% of the total number of samples for a Parameter Considered exceeded the WQS, then the parameter was considered a Parameter of Potential Concern. The concentrations of the Parameters of Potential Concern will continue to be monitored over time, and re-evaluated should the monitoring show their concentrations to increase over time. Per the flowchart, if 2% - 10% of the total number of samples for a Parameter Considered do not exceed the WQS, then the parameter was not considered to be a POC or POPC.

The Methodology Flowchart shows that additional analysis is required for those parameters that exceeded the water quality standards for the receiving water bodies in more than 10% of the samples. For those parameters, the concentration of the parameter detected in the November/December 2015 sampling of the CSO discharges was reviewed.

If the parameter was "Not Detected (ND)" or was below the Reporting Detection Limit in the November/December 2015 CSO sampling results, it indicates that the parameter was not observed in DELCORA's CSO discharges. In this case, the parameter is not considered to be a POC. In this manner, the industrial-type chemicals that had been originally detected in the historic sampling results from the influent to the WRTP were able to be removed from further consideration as a POC or POPC.
If the parameter was detected within the November/December 2015 CSO sampling results, it indicates that the parameter was in DELCORA's CSO discharge. In these cases, the parameter is considered as a POC, and is to be further investigated through additional receiving water quality monitoring and modeling.

2.5.3 Discussion of the Pollutants of Concern and Parameters of Potential Concern

The following discussion of the individual parameters is focused only on those parameters that were shown to be either a POC or a POPC.

2.5.3.1 Fecal Coliform Bacteria

Fecal coliform bacteria are the most common microbiological contaminants of natural waters and are used to indicate contamination by human pathogens. Fecal coliform live in the digestive tracks of warm-blooded animals, including humans, and are excreted in the feces. The DRBC collects fecal coliform bacteria data at Stations 332049 and 892062 on the Delaware River. Additionally, DELCORA sampled the Chester and Ridley Creeks in 2010 for fecal coliform concentrations.
There are no PA Code, Chapter 93 fecal coliform bacteria water quality standards for streams designated WWF, MF or TSF with no other qualifiers. However, the DRBC's Delaware River Zone 4 has a Stream Quality Objective for fecal coliform of no more than 770 CFU/100 mL for the section upstream of R.M. 81.8, which includes the tidal portions of the Chester and Ridley Creeks, and 200 CFU/100 mL for the section of the river downstream of R.M. 81.8.

Of the six samples taken by DELCORA in 2010 on Ridley Creek, four show exceedances of the Stream Quality Objective for fecal coliform. These values indicate that Ridley Creek was not meeting the DRBC Stream Quality Objective. Of the six samples taken by DELCORA on Chester Creek, four show exceedances of the Stream Quality Objective for fecal coliform. These values indicate that Chester Creek was also not meeting the DRBC WQS at that time. More sampling was recommended to further confirm these results. The available data indicates that there were no exceedances observed of fecal coliform in the Delaware River.

Given the exceedances of fecal coliform WQS at both the Ridley and Chester Creeks, fecal coliform should be considered as a POC for the two creeks. However, although the existing data for the Delaware River has demonstrated that there were no exceedances observed of fecal coliform, since fecal coliform is a primary pollutant typically associated with CSO discharges it has been decided to also include it as a POC for the Delaware River in the interest of minimizing potential impacts to human health and the environment.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - Fecal Coliform considered to be a Pollutant of Concern.
- For the upper Delaware River (Upstream of R.M. 81.8)
  - Fecal Coliform considered to be a Pollutant of Concern.
- For the Chester Creek
  - Fecal Coliform considered to be a Pollutant of Concern.
- For the Ridley Creek
  - Fecal Coliform considered to be a Pollutant of Concern.

2.5.3.2 *Enterococcus* Bacteria

Enterococcus is a second bacteria genus that also resides in the digestive system of humans and animals, and that is used to indicate the presence of human pathogens. They have been long recognized as important human pathogens and are becoming increasingly so.

Unlike fecal coliform, the DRBC does not collect *Enterococcus* bacteria data at Stations 332049 and 892062 on the Delaware River, and DELCORA did not collect samples for *Enterococcus* bacteria in 2010 as it did for fecal coliform. *Enterococcus* are used as an indicator bacteria for marine waters.
As with fecal coliform, there are no PA Code, Chapter 93 water quality standards for *Enterococcus* bacteria for streams designated WWF, MF or TSF with no other qualifiers. However, the DRBC's Delaware River Zone 4 has a WQS for *Enterococcus* bacteria of no more than 88 CFU/100 mL for the section upstream of R.M. 81.8, which includes tidal portions of the Chester and Ridley Creeks, and 33 CFU/100 mL for the section of the river downstream of R.M. 81.8.

Very little existing data was available for *Enterococcus* bacteria concentrations in the Delaware River, Chester Creek and Ridley Creek in the area of DELCORA's CSO discharges. However, *Enterococcus* bacteria and fecal coliform bacteria are similar to each other, they are both produced in the human digestive tract, and are both considered to be parameters typically associated with CSOs. For this reason, it was decided to also include *Enterococcus* bacteria as a POC at the same locations identified for fecal coliform bacteria, which includes all three of DELCORA's receiving water bodies.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - *Enterococcus* considered to be a Pollutant of Concern.
- For the upper Delaware River (Upstream of R.M. 81.8)
  - *Enterococcus* considered to be a Pollutant of Concern.
- For the Chester Creek
  - *Enterococcus* considered to be a Pollutant of Concern.
- For the Ridley Creek
  - *Enterococcus* considered to be a Pollutant of Concern.

2.5.3.3 *Escherichia Coli* Bacteria

Escherichia coli (also known as *E. coli*) is a facultative anaerobic, rod-shaped bacterium of the genus Escherichia that is commonly found in the lower intestine of warm-blooded organisms. *E. coli* is expelled into the environment within fecal matter. Fecal material can enter the environment from many sources including wastewater treatment plants, CSO discharges, livestock or poultry manure, sanitary landfills, septic systems, sewage sludge, pets and wildlife.

E. coli was not listed as an initial Parameter Considered because it is not listed in the applicable reference sources from the PA Code or DRBC. However, in consultation with the PADEP it is understood that *Enterococcus* bacteria could be replaced with *E. coli* in future regulations (on the anticipation that national standards for *E. coli* will be adopted in Pennsylvania) and therefore *E. coli* is included as a POC for all the receiving water bodies.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - *E. coli* considered to be a Pollutant of Concern.
- For the upper Delaware River (Upstream of R.M. 81.8)
  - *E. coli* considered to be a Pollutant of Concern.
- For the Chester Creek
  - *E. coli* considered to be a Pollutant of Concern.
- For the Ridley Creek
  - *E. coli* considered to be a Pollutant of Concern.

2.5.3.4 Metals

None of the CSO receiving waters are listed as being impaired for metals. Because 43 of 45 significant industrial users of the DELCORA system truck their wastes to the plant, DELCORA's CSO discharges will have significantly lower industrial contributions of metals and other pollutants than other CSO communities. Moreover, these CSO discharges only occur during wet weather events when significant instream dilution is available. Therefore, the appropriate control measures to address metals from DELCORA's CSO discharges are the continued implementation of and compliance with the Nine Minimum Controls as required by DELCORA's NPDES permit.

The NPDES permit requires DELCORA to submit an annual report each year to the PADEP, with appropriate documentation demonstrating the continued implementation of and compliance with the NMCs required on a system wide basis.

For the removal of metals, the most applicable Nine Minimum Controls include the maximum use of the collection system for storage, the review and modification of pretreatment requirements to ensure that CSO impacts are minimized, maximization of flow to the POTW for treatment and pollution prevention programs (such as street sweeping) to reduce these contaminants in the CSOs.

For these reasons, like almost every other CSO community's LTCP, metals are not considered POCs.

2.6 Identified Pollutants of Concern

In the effort to identify Pollutants of Concerns related to its CSO discharges, DELCORA has reviewed the 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) List), the historic sampling data for the influent to the Western Regional Treatment Plant, the USEPA's STORET Data repository, historic water quality sampling data from the Chester and Ridley Creeks, and additional sampling results from the CSOs from November and December of 2015.

Three (3) POCs were determined as identified in Table 2-3. These include Fecal Coliform bacteria, *Enterococcus* bacteria and *E. coli* bacteria. These three POCs are parameters typically associated with CSO discharges. The concentrations of these identified POCs in the Delaware River, Chester Creek and Ridley Creek will be further investigated through receiving water quality monitoring and modeling.

No Parameters of Potential Concern were identified.

Table 2-3: List of Pollutants of Concern (POC)

No.	Upper Delaware River		Lower Delaware River		Chester Creek		Ridley Creek	
Pollutants of Concern (>10% of observed samples exceed WQS)								
1	Fecal Coliform[b]	100%	Fecal Coliform[b]	100%	Fecal Coliform[a],[b]	100%	Fecal Coliform[a],[b]	100%
2	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%
3	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%

[a] Based on historical sampling conducted in 2010 upstream and downstream of CSO outfalls only on Chester and Ridley Creeks.

[b] Fecal Coliform and Enterococcus are listed as POCs due to both being parameters typically associated with CSOs.

[c] DRBC regulations are available for Enterococcus and it is typically associated with CSOs and therefore it is included as a POC. However, in consultation with PADEP Enterococcus could be replaced with E. coli bacteria in the future (based on the anticipation that national standards on E. coli will be adopted in Pennsylvania) and therefore E.coli is also included as a POC.

Section 3 Typical Hydrologic Period

3.1 Introduction

3.1.1 DELCORA's Consent Decree

According to the Consent Decree between the USEPA, PADEP, and DELCORA, within ninety (90) days after the lodging date of August 17, 2015, DELCORA shall submit to Plaintiffs a report or technical memorandum describing DELCORA's statistical evaluation of long-term local rainfall patterns and the identification of an appropriate typical period for LTCPU development purposes. To satisfy this Consent Decree requirement, DELCORA submitted the Hydrologic and Hydraulic Model Update and Calibration Plan (**Appendix D**) in October 2015 and the Typical Hydrologic Period Report (**Appendix E**) on November 15, 2015, which was updated and re-submitted on April 22, 2016, and approved by PADEP and USEPA on May 23, 2016. The remainder of this Section is based on the approved Typical Hydrologic Period Report.

The statistical evaluation in the Typical Hydrologic Period Report utilizes local long-term rainfall record from the Philadelphia International Airport. It considers various appropriate rain year characteristics, including distributions of event rainfall totals, event durations, and peak and average rainfall intensities.

3.1.2 Typical Year for CSO LTCPU Development

Precipitation generates urban storm water, combined sewer overflows, and increased wet weather flows to the wastewater treatment plant. These will contribute bacteria and pollutants to the Delaware River and its tributaries. The effect of these contributors on the Delaware River mainly depends on the magnitude and duration of rainfall events and on the prevailing ambient river conditions controlling dilution and transport of the pollutants. This variability and complexity poses a significant challenge for assessing the performance of wet weather and CSO control alternatives.

In accordance with the USEPA CSO Control Policy, the CSO control alternatives should be assessed on a "system-wide, annual average basis". This is accomplished by continuous simulation using a typical hydrologic period for the combined sewer system and receiving water quality modeling applications. The CSO Policy supports continuous simulation modeling, i.e., using long-term rainfall records rather than records for individual storms. Long-term continuous rainfall records enable simulations to be based on a sequence of storms so that the additive effect of storms occurring close together can be examined. They also enable storms with a range of characteristics to be included.

In this study, a three-year period was evaluated to balance between manageable model simulation time and representation of various rainfall/river conditions. The representative three-year period was intended to contain a relatively wet year, a dry year and an average year. Hourly rainfall data from the Philadelphia International Airport was obtained from the National Oceanic and Atmospheric Administration from 1900 through 2013. This provided sufficient data to evaluate climate change impact in the area. In the past 114 years, annual rainfall ranged from 29.3 to 64.33 inches, with the wettest year in 2011. The 10-year rolling average rainfall indicates that precipitation in the area runs through various dry and wet cycles, however with more extreme conditions (both dry and wet) in recent years.

Considering the climate change impact, it was determined that the Typical Hydrologic Period for the LTCPU be selected based on statistical analysis of rainfall records from the most recent 30 years (i.e., 1984-2013).

3.1.3 Methodology of Typical Year Selection

The Typical Hydrologic Period is selected to provide representative and unbiased approximations of expected future conditions in terms of both averages and historical variability. Representativeness is assessed using objective criteria for each of the ambient factors (i.e., river flow and rainfall). As indicated in the previous subsection, the selection of the Typical Hydrologic Period was based on the historical records in the past 30 years from 1984 through 2013.

The following datasets were used for the analysis of the typical hydrologic period:

- Hourly precipitation data for the National Climate Data Center gauge at Philadelphia International Airport for 1984 - 2013.
- Daily Delaware River stream flow data from the U.S. Geological Survey gauge at Trenton, NJ (USGS 01463500) for 1984 - 2013. This is the closest USGS gauge with daily river flow available.

Key hydrologic parameters used in the evaluation were given a weighting factor to describe the individual importance on the normality of the analyzed time period. The parameters that are given the highest impact weighting included the following:

- The total annual rainfall depth, which drives the total runoff volume.
- The maximum peak intensity, which usually defines the biggest overflow event.
- The median Delaware River flow (the impact of sewer overflows on the water quality of the receiving water is dependent on the magnitude of the flows in river, and in the project area, intense local rainfall events are typically independent from watershed-wide high flow events).

3.2 Typical Year Selection for DELCORA

3.2.1 Annual Rainfall and River Flow Analysis

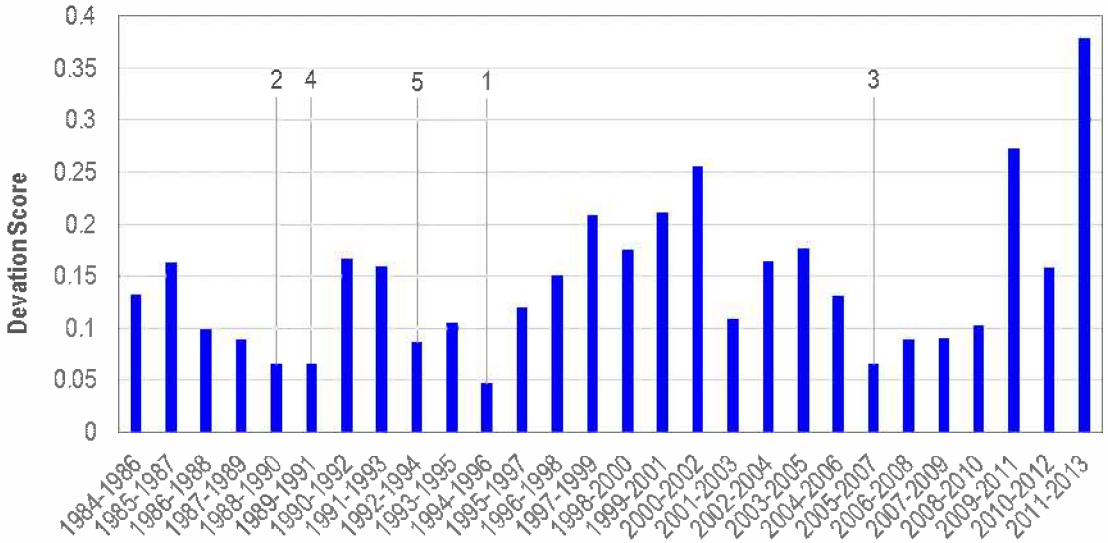
All rainfall events within the 30-year data period (1984 - 2013) were analyzed and evaluated for duration, inter-event duration, total rainfall amount, as well as maximum and average rainfall intensities. A total of 1,934 rainfall events were counted for the period of 1984 - 2013. Once annual rainfall and river flow statistics were determined for the 30-year period, three-year rainfall and river flow characteristics were developed based on an annual average of the three consecutive years. The goal of using a three-year analysis period was to find a period that had a relatively dry year, a relatively wet year, and a relatively average year. That way, any evaluations done using the typical hydrologic period have a more diverse spectrum of wet weather events and dry weather periods.

3.2.2 Ranking Analysis

From the weighting parameters listed in **Subsection 3.1.3**, a deviation score was developed for each individual period. The 3-year periods were then ranked based on the deviation score. The lower the

deviation score (Figure 3-1 Y-axis), the higher the rank for the hydrologic period (i.e., the closer it is to the average condition). **Figure 3-1** shows the ranking results of the 28 hydrologic periods, with a ranking of 1 being the highest and a ranking of 28 being the lowest ranked hydrologic period. Hydrologic period 1994-1996 is ranked No.1 because it has the lowest deviation score of 0.047.

Figure 3-1: Ranking Score of 3-year Periods, 1984-2013



3.2.3 Selected Hydrologic Period

The 3-year period 1994-1996 (Rank 1) was selected as the Typical Hydrologic Period for the CSO LTCPU. This period contains a wide range of storms and antecedent conditions. The hydrologic period of 1994-1996 was also evaluated for longer historical rainfall records up to 100 years. It is ranked No. 1 for the 50-year records and No. 2 for the 100-year records.

THIS PAGE INTENTIONALLY LEFT BLANK

Section 4 Sewer System Hydrologic and Hydraulic Model Update and Calibration

4.1 Introduction

The Sewer System Hydrologic and Hydraulic (H&H) Model Report was submitted to USEPA and PADEP on June 30, 2017, as was approved on April 17, 2018 after DELCORA responded to comments received on January 2, 2018. The approved report is included in **Appendix F**. It is to be noted that the H&H model was updated and recalibrated after the June 2017 submission as a result of receiving additional monitoring data, pump station operation data, and sewer system characteristics data. The H&H Model Calibration and Validation Results (updated July 2018) are provided in **Appendix T**.

4.1.1 Regulatory Requirements

Consent Decree Requirements

DELCORA's original Hydrologic and Hydraulic Model was updated to meet the requirements of Paragraph V.A.14 of the Consent Decree (Hydrologic and Hydraulic Model (H&H model) Update and Calibration Plan). Consent Decree Paragraphs V.A.14.a-f detail the specific requirements for the update and calibration of the H&H Model, which are listed in **Table 4-1**.

Table 4-1: Summary of Consent Decree Section V.A.14

Consent Decree Requirement
§V.A.14.a *"a. Not later than sixty (60) Days after the Date of Lodging of this Consent Decree, DELCORA shall submit a detailed plan to update, calibrate, and validate the H&H Model to Plaintiffs for review and approval pursuant to Section VI (Review and Approval of Submittals). The plan shall address:* *(i) Model Update Methodology.* *(ii) Hydrologic and Hydraulic Model Refinement.* *(iii) Flow Data Assessment, and additional Rainfall and Flow Monitoring to be Carried Out.* *(iv) Dry Weather Flow Calibration, including quantitative and qualitative calibration criteria.* *(v) Wet Weather Flow Calibration, including quantitative and qualitative calibration criteria.* *(vi) Model Validation; and* *(vii) Schedule for model development and implementation, including integration into LTCP development consistent with other dates required pursuant to this Consent Decree.",*
§V.A.14.b *"The updated H&H Model shall specifically include hydrologic representation of all areas tributary to the entire Collection System, as well as all areas tributary to all municipal wastewater collection and transmission systems that are, as of the date the LTCP is submitted, hydraulically connected to, or that directly or indirectly influence flow to, the CSOs and/or the WRTP, regardless of who owns or operates the system(s), including but not limited to the entire "Western Service Area" and "Eastern Service Area" depicted on Figure 1-2 of the Long-Term Control Plan submitted by DELCORA in April 2012, and attached as Appendix A hereto (collectively, the "Model Area")."*

Consent Decree Requirement
§V.A.14.c *"The H&H Model shall accurately represent the response of the Model Area to wet weather events, including the flows that result from wet weather events to and from DELCORA's CSOs and to the WRTP. To accomplish this, the model shall explicitly include all interceptors, diversion structures, CSOs, pump stations and major trunk sewers within the Collection System, as well as such pipes and appurtenances within the areas outside the Collection System that are needed to ensure adequate H&H Model accuracy. The H&H Model shall also include all sewers required for model continuity and/or that hydraulically impact or are downstream of known chronic unpermitted releases. DELCORA shall investigate and collect current system attribute information as necessary to update the H&H Model.",*
§V.A.14.d *"Rainfall and flow monitoring shall be carried out in accordance with current good industry practice for a period of at least twelve (12) months, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization of dry and wet weather flows from the entire Model Area, and the response of each CSO to wet weather flows.*
§V.A.14.e *"For all rainfall and flow monitoring carried out in support of efforts to update and calibrate the H&H Model, DELCORA shall prepare and submit to Plaintiffs for review and comment in accordance with the requirements of Section VI (Review and Approval of Submittals) quarterly technical memoranda documenting the results and quality of the rainfall and flow monitoring data.*
§V.A.14.f *"Within 30 Days after the H&H Model is revised, calibrated, and validated in accordance with the schedule set forth in the plan, DELCORA shall submit a Sewer System H&H Model Report to Plaintiffs for review and approval in accordance with the requirements of Section VI (Review and Approval of Submittals). The Sewer System H&H Model Report shall specifically address each item set forth in Subparagraphs 14(a)(i)-(vii) hereof."*

4.2 DELCORA's Facilities and Service Areas

A detailed overview of DELCORA's Facilities and its service areas is provided in **Subsections 1.3** and **1.4** of this report respectively.

4.3 Rainfall and Flow Monitoring

As per the Consent Decree, DELCORA was required to perform a Rainfall and Flow Monitoring program for at least 12 months and submit quarterly reports to document the findings of the program. This program started on March 18, 2016 and was completed on April 4, 2017. The rainfall and flow monitoring data were collected on a monthly basis. The network of rainfall and flow monitoring instrumentation, outline the monitoring program, and description of data collection and analysis of rainfall and flow monitoring data for use in the H&H Model calibration and validation is discussed in detail in **Appendix F**, with updated model calibration and validation results from July 2018 in **Appendix T**. The Rainfall and Flow Monitoring Reports can be found in **Appendix G**. The subcatchment names and the total areas associated with each metershed used in the H&H model are presented in **Table 4-2**.

4.3.1 Wet Weather Event Selection for Model Calibration and Validation Flow Analysis

Based on the rainfall and flow monitoring data analysis, the rainfall events shown in **Table 4-3** were selected for model calibration and validation. The events were selected to cover variations in terms of rainfall depth, intensity, duration and antecedent conditions. Event E4 was added as more monitoring data was received.

Table 4-3: Calibration and Validation Rainfall Events

Event	Start	End

4.4 Model Update

The original DELCORA H&H model was developed and calibrated for the 1999 LTCP. The model was updated and expanded over the years to account for changes in the CSO system, but it was not re-calibrated during the development of the 2012 LTCPU (Weston, 2012). The project team reviewed the 2012 version of the H&H model in order to:

- Assess adequacy of the original model for use in DELCORA's LTCPU,
- Identify gaps with the original model in meeting the requirements in the Consent Decree,
- Identify updates required to reflect current hydrologic and hydraulic conditions of DELCORA's collection system, and
- Determine refinements needed for the model update.

Results from the review of the 2012 H&H Model are presented in the **Appendix D**. (Greeley and Hansen, 2015).

4.4.1 Model Update Methodology

The purpose of this part of the Report is to describe the model update methodology and summarize the revisions incorporated into the updated H&H model.

4.4.1.1 Hydrologic Representation

Instead of including only the combined area for the subcatchments as in the 2012 H&H model, the updated model has added subcatchments for both the combined and separated service areas. All the areas that contribute dry weather flow and/or wet weather flow to DELCORA's CSOs and/or the WRTP were

included in the updated Model Area. Wet weather flows generated from surface runoff in the combined area and Rainfall dependent inflow and infiltration (RDII) parameters in the separated areas were simulated in the updated model.

4.4.1.2 Hydraulic Representation

The 2012 H&H model included only the combined sewer system area of DELCORA's collection system, which is located within the boundaries of the City of Chester. The CSS area is shown in **Figure 1-4**. The combined CSS area according to the 2012 H&H model is shown in **Figure 4-1**. Per the requirements of the Consent Decree, the H&H model was updated to include the entire Model Area. Pipe networks in the updated model were extended to the updated service areas for both the combined and separated areas. All hydraulic structures that control flows in the collection system, including pump stations, siphons, regulator orifices and weirs, and their operating rules, were simulated in the updated model.

4.4.2 Model Refinement

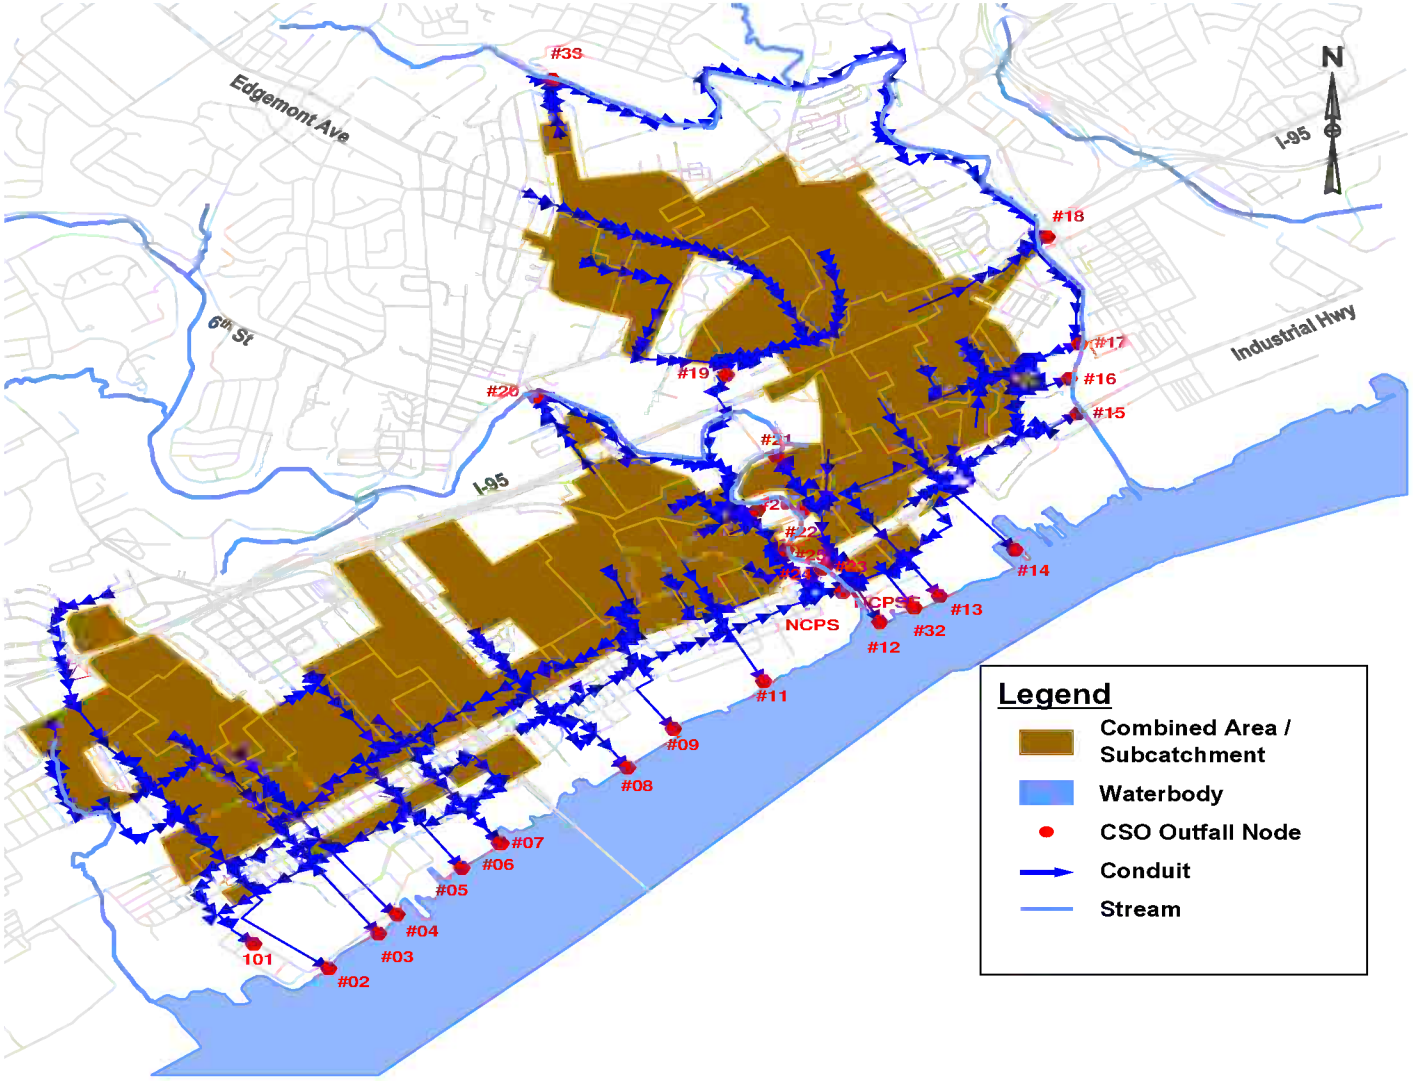
A number of hydraulic modeling software packages are available, including EPA SWMM, InfoSWMM, InfoWorks, Mike Urban and PCSWMM. For this H&H Model update, EPA SWMM, Version 5.1, and Innovyze InfoSWMM Version 14.6 were selected as the modeling software. EPA SWMM is a fully dynamic model and has been used extensively throughout the United States and abroad to assess CSO, flooding and water quality issues. It can be applied to simulate single events or long periods of time in a continuous mode. InfoSWMM uses the current EPA SWMM engine as its computational solution and is fully integrated with ArcGIS, which provides greater flexibility of importing the model network from the existing GIS database and preparing initial model inputs from existing datasheets. InfoSWMM was used during the model development and the calibration phase.

The model update is based on information obtained from a variety of sources including DELCORA's input, GIS, record drawings and field survey. Other documents pertaining to standard/actual operating procedures for CSO regulators, pump stations and the WRTP were also used to set up real time controls in the model. The model network consists of all major interceptors and force mains and extends to all active overflow points. The datum used for the model is NGVD 29.

4.4.2.1 Delineation of Model Area and Combined Area

DELCORA's latest GIS database, survey and record drawings were used to perform the desktop CSS delineation to verify the metershed boundaries. The total acreage of the model area is approximately 50,000 acres and the updated combined sewer area is approximately 1,486 acres as of July 2018.

Figure 4-1: CSS Area Delineation in the 2012 H&H Model



Metersheds were delineated for the purpose of dry weather flow allocation and model calibration. A metershed means the geographical area served by a system of sanitary drains, storm drains, private interceptor, main sewers, and public sewers that drain to a common monitoring point (flow meter location). Metershed delineation was performed based on the location of flow meter, sewer connectivity, and city contours. The listing of metersheds, their acreage and their associated subcatchments is presented **Table 4-2**.

Sewersheds (or "subcatchments") are delineated based on the drainage network, area characteristics, and flow monitor locations. Each sewershed has a dry weather and a wet weather flow input to the model network. The model network comprises 128 sewersheds (subcatchments), which includes 55 combined and 73 separated subcatchments.

Delineation of Model Area

The updated H&H model is used to evaluate the Model Area which is comprised of those areas hydraulically connected to the WRTP. As shown in **Figure 1-4**, the conveyance system is divided into the Western Service Area and the Eastern Service Area. The Western Service Area discharges to DELCORA's WRTP and is therefore included in the Model Area. The Eastern Service Area is served by three pumps stations: the Central Delaware Pump Station, the Muckinipates Pump Station and the Darby Creek Pump Station. Wastewater flows up to 20 MGD (which includes both dry and wet weather flows) from the Central Delaware Pump Station can be pumped to (and thus is hydraulically connected to) DELCORA's WRTP. Therefore, municipalities connected to the Central Delaware Pump Station are considered part of the Model Area. Sewage from the Muckinipates Pump Station and the Darby Creek Pump Station flows directly to the PWD-SWWPCP rather than to the WRTP. Therefore, municipalities connected to these two pump stations are not hydraulically connected to the WRTP and do not directly or indirectly influence CSOs or flow to the WRTP, and, therefore, are not considered part of the Model Area. The updated delineation of the Model Area is presented in **Figure 4-2**.

Eastern Service Area

Within the Eastern Service Area, only the municipalities in the Central Delaware County Authority contribute flows to the WRTP and therefore, only these municipalities are included in the Model Area. These municipalities include Marple Township, Morton Borough, Nether Providence Township, Newtown Township, Prospect Park Borough, Ridley Park Borough, Rutledge Borough, Springfield Township, Swarthmore Borough, Ridley Township, and Upper Providence Township. In October 2012, DELCORA signed an agreement with Edgmont Township to provide sewer service to the eastern portion of the Township. The sanitary sewage of Edgmont Township is now collected and transported using the Crum Creek Sewer District System through the CDCA collection and conveyance facilities to the DELCORA System for treatment at the WRTP and ultimate disposal and discharge.

Figure 4-2: Model Area Delineation

Western Service Area

DELCORA's Western Service Area (shown in **Figure 4-1)** contributes all of its flow to the WRTP and is therefore considered part of the Model Area. DELCORA owns and operates the collection system in the following communities in the Western Service Area.

- Chester City
- Chester Township (parts of[5])
- Marcus Hook Borough
- Parkside Borough
- Rose Valley Borough[6]
- Upland Borough
- Trainer Borough

DELCORA does not own or operate the collection system in the following communities in the Western Service Area, however, these communities will be included as part of the service areas in the updated H&H model because they contribute flows to the WRTP.

- Brookhaven Borough
- Lower Chichester Township
- Nether Providence Township[7]
- Eddystone Borough
- Chester Heights Borough
- Upper Providence Township
- Aston Township
- Middletown Township
- Edgmont Township[5]
- Upper Chichester Township
- Bethel Township

Model Area Summary

In summary, the Model Area includes the municipalities in the Western Service Area plus those municipalities in the Eastern Service Area that are connected to the Central Delaware Pump Station, as shown in **Table 4-4**. The entire Model Area is illustrated in **Figure 1-4** and **Figure 4-2**

[5] DELCORA owns only a portion of Chester Township's collection system, but all flow comes to the WRTP as some goes through the CRC PS service area.
[6] Rose Valley Borough collection system used to discharge to its own treatment plant. This portion now discharges to the CRC PS service area.
[7] Parts of these communities are in the Eastern Service Area.

Delineation of the Combined Sewer System Area

The entire combined sewer system area of DELCORA's collection system is located in the City of Chester and consists of a drainage area of approximately 1,486 acres. It comprises approximately half of Chester City's serviced area. The location of the CSS area is shown in **Figure 1-4**. An enlarged view of the CSS area according to the 2012 H&H model is shown in **Figure 4-1**.

The CSS area delineation was updated with separation projects completed in recent years. The latest GIS database, survey, and record drawings were used to perform the desktop combined sewer area check. Some areas have separated systems with trunk sewers that subsequently connect to the CSS. For this situation, these particular separate sewer system areas were included within the delineation of the CSS. The revised CSS delineation in the updated H&H Model is illustrated in **Figure 4-3.**

Figure 4-3: CSS Area Delineation in the Revised Model

4.4.2.2 Model Network Extension

The collection system network in the original model has been updated with the following:

- Extended sewers to the updated delineation of the combined and separated areas
- Included all pump stations that control flows in the DELCORA collection system, and
- Reflect actual configuration of the CSO regulators.

Since the approval of the first LTCP in 1999, DELCORA has under-taken a program to replace and/or rehabilitate CSO regulators and tide gates in the City of Chester CSO system. In some cases, regulators have been eliminated. The updated model includes twenty-six (26) CSO regulators, which were modeled as weirs and orifices. The configuration of CSO regulators was obtained from both record drawings and field surveys.

Regulators

As indicated in **Subsection 1.5**, the majority of the City's CSO regulators are Brown & Brown type regulators. The operation of the CSO regulators has been changed from being controlled by the level in the trunk sewer entering the CSO regulator chamber to being controlled by the level in the downstream interceptor. This change is being implemented as part of the CSO regulator replacement program. This ensures that the flow sent to the WRTP for treatment is maximized.

During dry-weather operations, the sewage flow levels entering the CSO regulator chamber are below the top of the diversion weir and will pass through the CSO regulator gate. Once through the CSO regulator gate, the flow typically passes through an orifice plate and then will be sent to the WRTP via the interceptors. During wet-weather events, the level in the combined sewer (Type A regulator) or in the interceptor (Type B regulator) will begin to rise thus raising the float assembly that will close the CSO regulator gate. For cases where the regulator float and gate have been removed, dry weather flow and some portion of the wet weather flow will pass through the opening previously covered by the now removed gate. Flow through this opening will be modeled as an orifice. When wet weather flow exceeds the capacity of the orifice, the level in the sewer will continue to rise until it is high enough for a portion of the flow to pass over the weir to be discharged through the associated outfall.

Regulator gates, diversion weirs, and operating rules are simulated in the updated model.

Pump Stations

Major pump stations in the Western Service Area and the Central Delaware Pump Station in the Eastern Service Area were added to the updated model, as well as force mains connecting the pump stations to the interceptor/WRTP. **Figure 1-3** shows the pump stations included in the updated model. The list of the pump stations in the model includes:

- Chester PS
- Existing PS-1 WRTP
- Marcus Hook PS
- Naamans Creek PS
- Eddystone PS
- Central Delaware PS
- Chester Ridley Creek PS
- Sun Oil PS (Owned by Sunoco)
- Kimberly Clark PS (Owned by Kimberly Clark Corporation)

The following pump stations were excluded from the H&H Model:

- Price & Smith Street Trainer PS
- Stadium PS

Flow from the Price & Smith Street Trainer PS discharges to the downstream Existing Pump Station (EPS-1) where it is re-pumped. The updated H&H model assumes that all flow from subcatchments associated with the Price and Smith Street Trainer PS can be treated as an input to EPS-1.

Flow from the Stadium PS is sanitary sewage only with no stormwater flow. The Stadium PS discharges flow only during events held at the stadium. Due to the limited flow, its sporadic nature and the lack of wet weather flow, the Stadium PS is expected to have negligible effect on the wet weather capacity of the CSS. Therefore, the Stadium PS was not included in the H&H Model.

DELCORA owns or operates a number of lift stations in the Western Service Area and whose flows are handled by the above list of pumps stations. It was determined that the behavior of these lift stations would not require modeling and that inflow to the lift station can be assumed to equal outflow to the downstream conduit.

4.4.2.3 Model Input

The model inputs include the following-

- Subcatchments
  - Area
  - Percent of Directly Connected Impervious Area
  - Width
  - Slope
  - Manning's roughness coefficient (n)
  - Depression Storage
  - Soil and Soil Infiltration Parameters
- Manholes
- Sewer Mains
- CSO Outfalls
- Flow Diversion Structures
  - Regulator Gates
  - Orifices
  - Weirs
- Pump Stations
- Rainfall Derived Inflow and Infiltration (RDII) – Modeling Separated Areas

The above model input parameters are discussed in detail in **Appendix F**.

4.4.3 Summary

The 2012 H&H model was updated as described in this section. A summary of the key revisions to the H&H Model are presented in **Table 4-5**. The detailed layout of the updated model is shown in **Figure 4-4** and **Figure 4-5**.

Table 4-5: Summary of Revised H&H Model

Review Item	2012 Model Review Observation	Updated Model
Model Software	- EPA SWMM 5.0	Innovyze InfoSWMM version 14.6
Vertical Datum	- NAVD 88	- NGVD29
General Sub Models	- EPASWMM for the runoff model - Horton Equation for the infiltration model - Hydrodynamic wave for the flow routing model	
Rain Gauge	- One (1) rain gage, located at the Western Regional Treatment Plant (WRTP)	- Seven (7) rain gauges, as shown in Section 2 - Additional GARR analysis performed
Service Area	- 67 subcatchments, all for combined area - One set of Horton infiltration parameters are applied to most of the subcatchments (66 out of 67 subcatchments) - The infiltration parameters applied in the model is equivalent to infiltration parameters for soil type C/D	- 128 subcatchments, 55 for combined area and 73 for separated areas - Combined area was modified to include newly separated areas. - Horton infiltration parameters applied to 55 out of 128 subcatchments - Horton infiltration parameters varied based on identified soil types
Sewer Manhole	- 736 storage nodes. - All sewer manholes are simulated as storage units in the model. - The majority of the storage units (732 out of the 736) have a diameter of 4-ft, and the rest (4 units) have a surface area of 100 square feet (sf.) (equivalent to 10'x10'). - All storage units are set-up with a ponding area of 9,999 sf. to allow excess water to collect atop of the nodes and be re-introduced into the system as conditions permit.	- 918 common junction nodes. - The majority of the common junction nodes have a diameter of 4-ft, and the rest (4 units) have a surface area of 100 square feet (sf.) (equivalent to 10'x10'). - There are 35 imaginary junctions created to receive flow from the subcatchments gravity network not included in the model network
CSO Outfall	- 29 outfall nodes - All CSO outfalls are free outfall	- 25 CSO outfall nodes - Tidal data is assigned to 25 outfalls using time series

Review Item	2012 Model Review Observation	Updated Model
Sewer Mains	- 735 conduit links. - Negative slopes at Nodes 73803 and 70709 not matching the GIS. - Pipe connectivity is not consistent with the GIS in Subcatchment EA1, 25A. - Pipe size and connectivity is not consistent with the GIS around Node: 5201242, 5201234. - Pipe size is not consistent with the GIS around Node: 52018-52015. - Pipe size is not consistent with the GIS around Node: 531-527, 522-517, 516-513, 510020301-5100202, 403-NCPS, 40801-40801A, 32405-32404, and 1110402-11103. - Pipe size and slope are not consistent with the GIS around Node: 422-4140. - NREG06 outfall pipe direction is opposite.	- 926 conduit links. - 30 imaginary conduit links created to receive flows from subcatchment gravity network not included in the model
CSO Regulators	- 34 orifice links. - All CSO regulators are simulated using orifices to intercept dry weather flows and partial wet weather flows to the collection system, and with elevated conduits to convey extra flows to the CSO outfalls. - Approximately 75% of the orifices (25 out of 34) are modeled with Real Time Control (RTC) to mimic regulator gate opening based on level. - None of the regulator diverting weir structures is simulated in the model.	- 44 orifice links. - CSO regulators are simulated using orifices and float-operated gates to intercept dry weather flows and partial wet weather flows to the collection system, and with conduits set a verified inverts to convey extra flows to the CSO outfalls. Exceptions occur at several regulators where orifices have been removed and at one regulator where the float and gate have been removed. - Approximately 55% of the orifices (24 out of 44) are modeled with Real Time Control (RTC) to mimic regulator gate opening based on level. - Regulator diverting weir structures added to the model. - All orifice opening dimensions were verified using record drawings
Pump Station	- No pump station is included in the model	- Pump stations added to model. - Related force mains added to model. - Pump Curves added to the model.

Review Item	2012 Model Review Observation	Updated Model
Dry Weather Flow	- 94 dry weather flow (DWF) inputs - Total DWF is 7.01 MGD - No diurnal curve - DWF does not include all the separated service areas that contribute to the DELCORA system	- 116 dry weather flow DWF inputs - Total DWF is 29.46 MGD - DWF analysis was performed on all flow meters in separated and combined areas as well as pump stations - Weekday and weekend diurnal curves were generated as well as overall, weekday, weekend and monthly DWF factors.
RDII	- No rainfall-derived infiltration/inflow (RDII) element was found in the model	- RDII was included in the model to estimate reasonable wet weather inflow from RDII

4.5 H&H Model Calibration and Validation

4.5.1 Model Calibration and Validation

Model credibility is developed through model calibration and validation. Model calibration involves application of the model to known external inputs (e.g., rainfall), evaluation of the model's ability to replicate monitored conditions (e.g., flow and volume), and adjustment of key model parameters as needed until an acceptable level of agreement is reached between the simulated and monitored conditions.

After the model is satisfactorily calibrated it must be validated by running known storms with known flow results and having the model replicate the known events. Storms used in model validation should be independent from the storms used in the model calibration.

4.5.1.1 Calibration/Validation Criteria

Dry Weather Flow Calibration Criteria

Dry weather flow analysis was based on the rainfall and flow monitoring results. DWF distribution in the collection system was based on land use data. Weekday, weekend and monthly diurnal factors from the DWF analysis were applied for each flow meter service area. Upstream meters in the system were calibrated first, then flows through the system to the pumps stations and to the WRTP were balanced. **Figure 4-6** presents a flowmeter schematic and shows the arrangement of the meters in the system and meter identification.

DWF calibration adheres to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be within 1 hour of the observed,
- The simulated peak flow will be within 10% of the observed flow, and
- The simulated flow volume over 24 hours will be within 10% of observed flow.

Figure 4-4: Updated H&H Model Layout

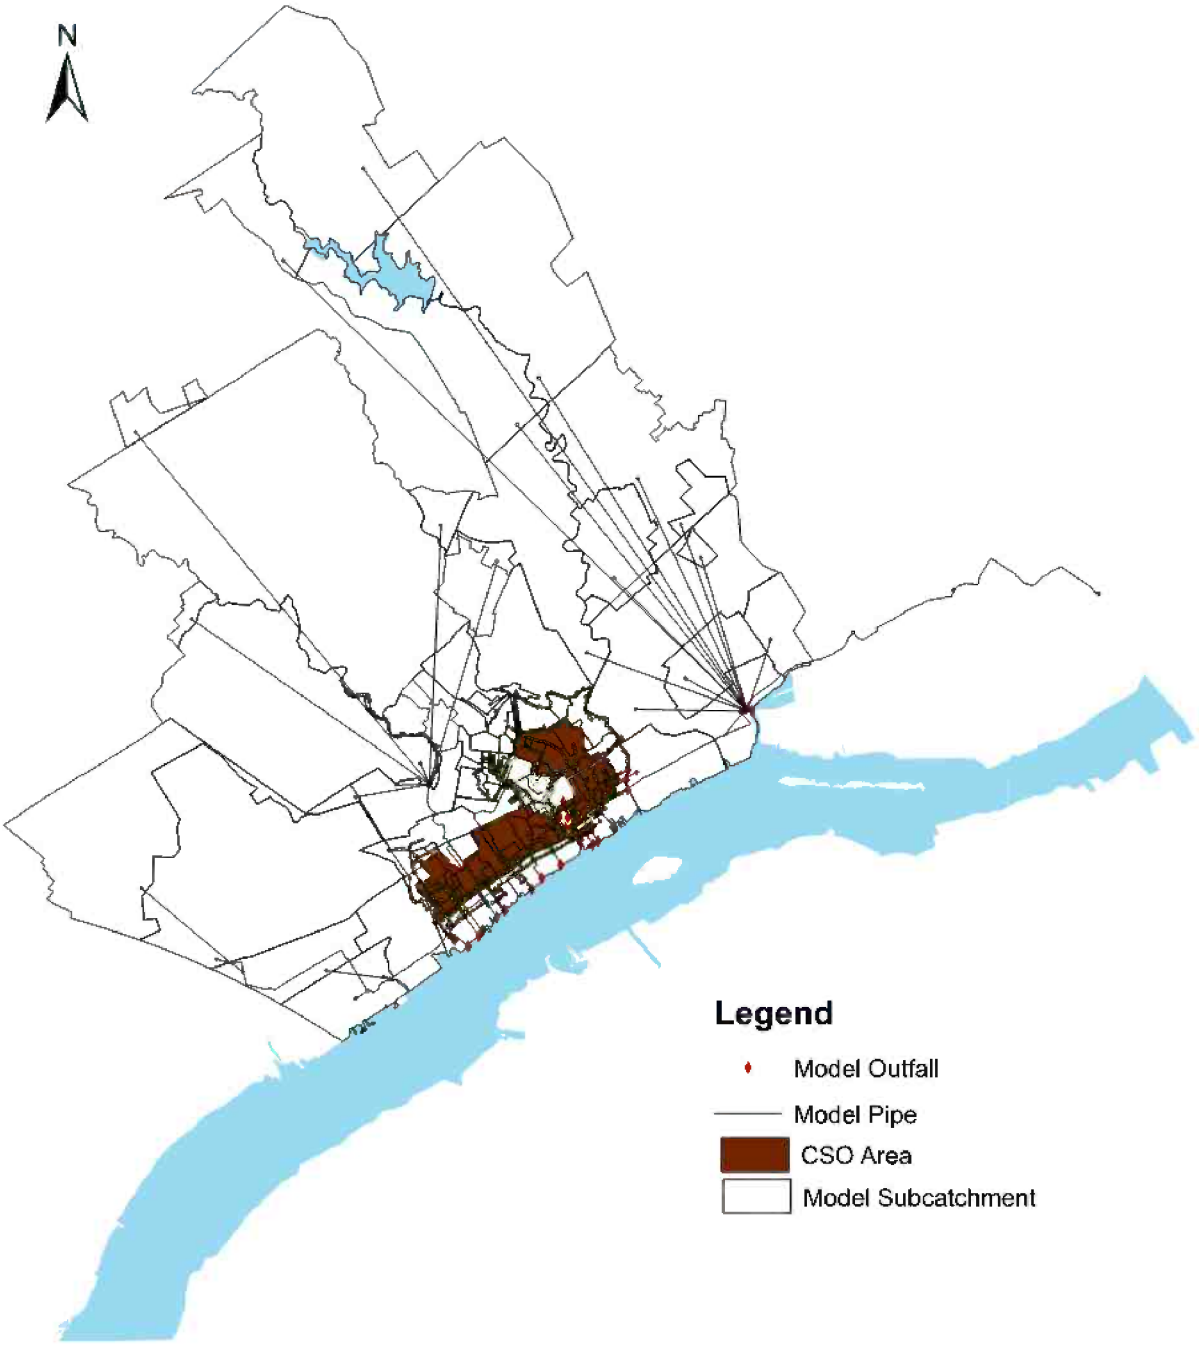

Figure 4-5: Updated H&H Model Layout – CSS Area

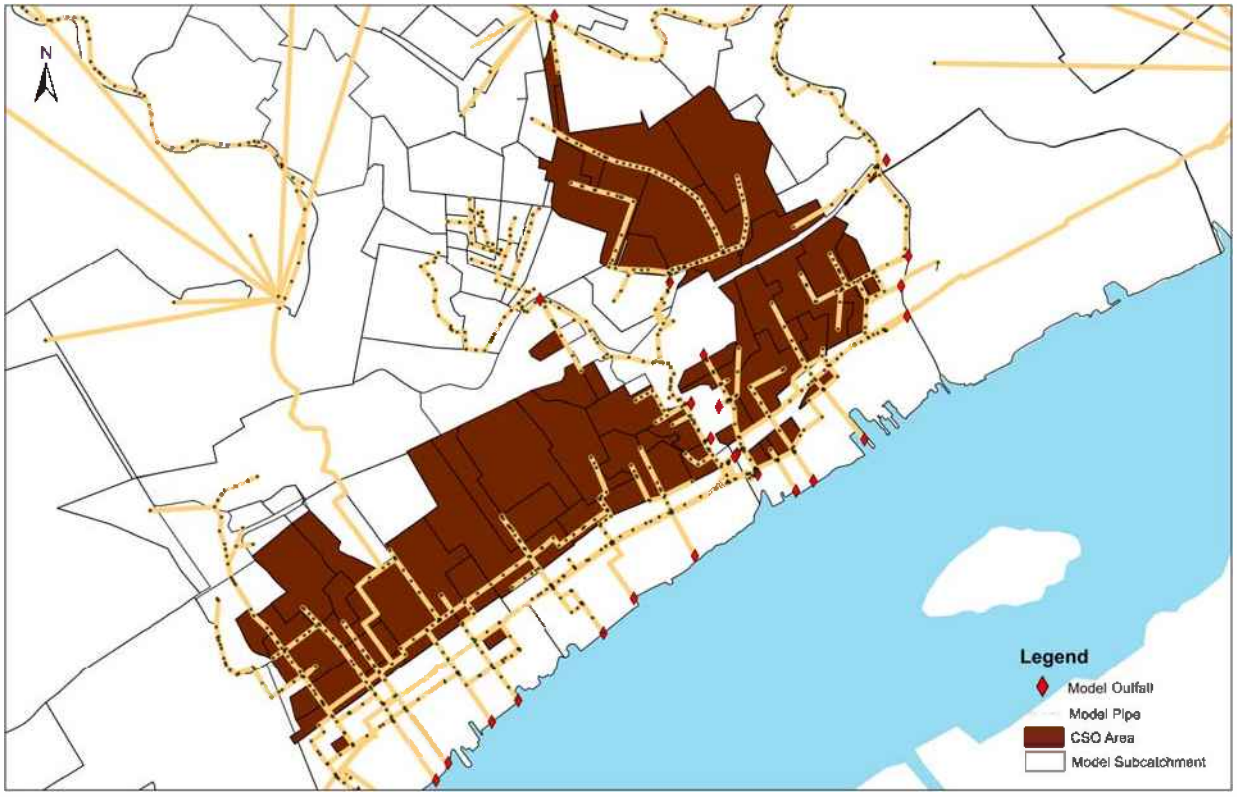


Wet Weather Flow Calibration Criteria

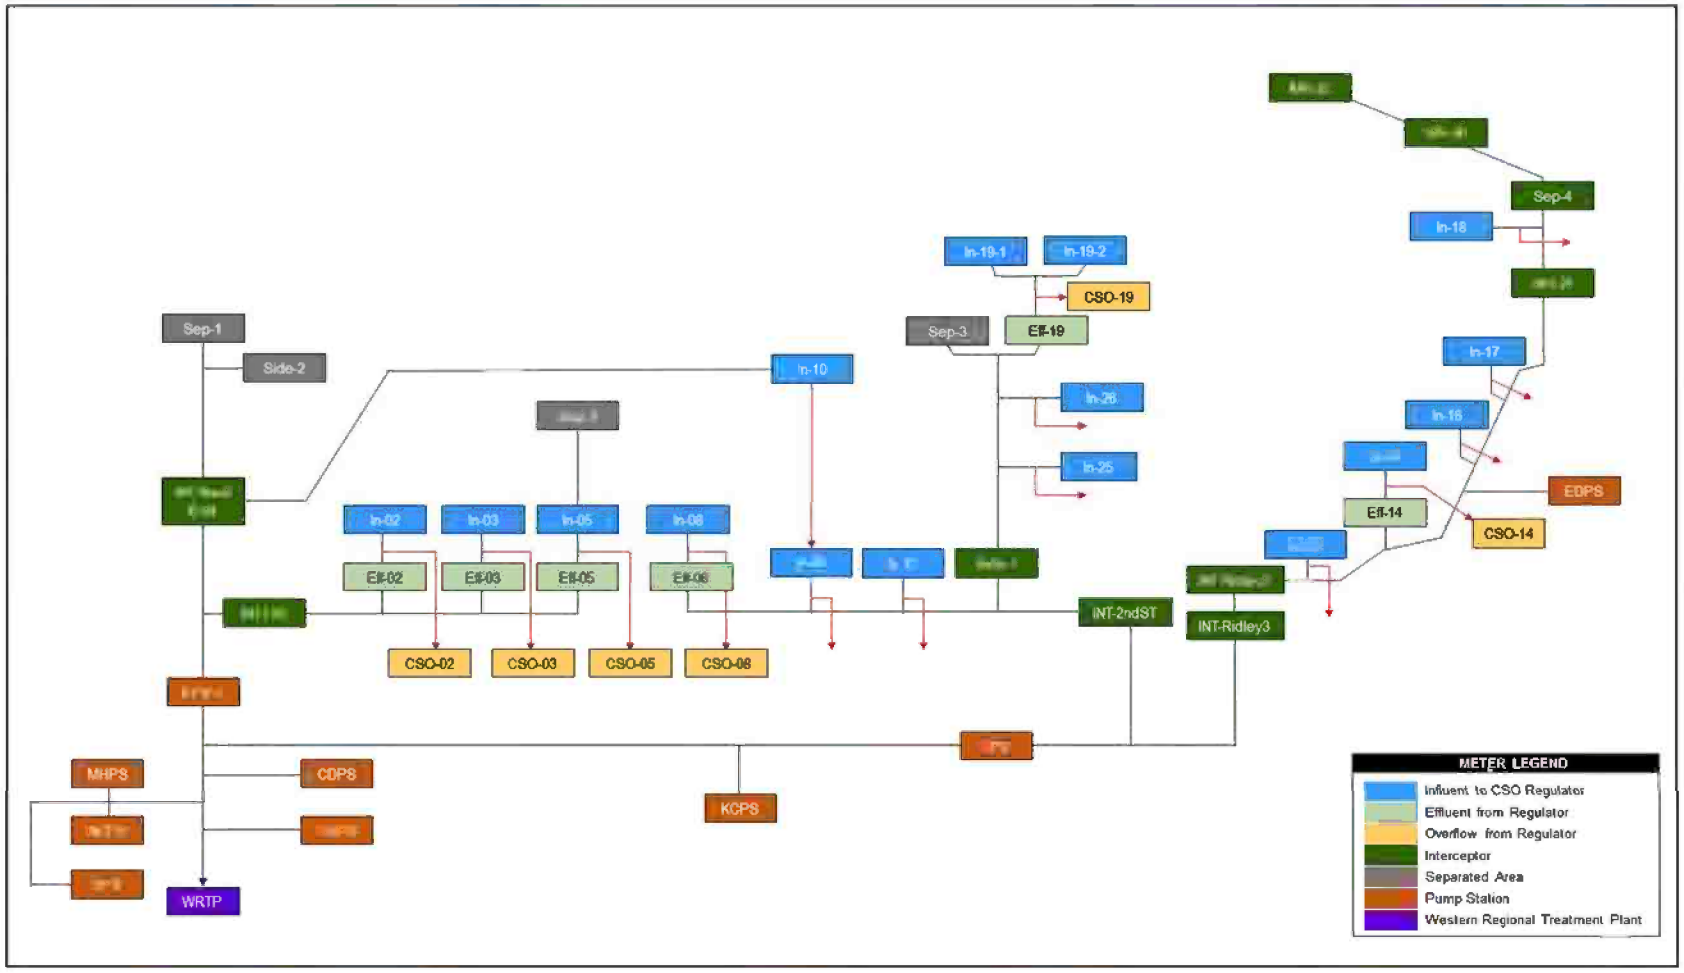
Wet weather flow (WWF) includes surface runoff from the combined area, RDII from the entire service area, and connected rooftops, if any, from the separated area. RDII parameters are developed based on the separated area, and surface runoff parameters are adjusted for the combined area to calibrate the system's response to the wet weather conditions.

Four (4) wet weather events were selected for wet weather calibration. Final selections include wet weather events with various rainfall intensities and volume.

WWF calibration adheres to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be similar having regard to the duration of the event,
- The simulated peak flow for significant peaks will be within the range of -15% to +25%,
- The simulated flow volume will be within the range of -10% to +20%,
- The depth of surcharge will be in the range of -0.1 m to +0.5 m, and
- At key points such as CSOs, the unsurcharged depth will be within ± 100 mm (± 0.33 ft.)

Figure 4-6: Flow Meter Schematic



4.5.1.2 Model Calibration Approach

The runoff calibration for the combined sewer area is achieved by primarily adjusting width and percent imperviousness. The RDII calibration for separated areas was achieved by adjusting RTK values. The calibration of hydraulic control structures (weirs and orifices) is achieved by adjustment the discharge coefficients. The conduit hydraulics calibration is achieved by adjusting Manning's "n" and head loss coefficients. Flow depth, as well as flow rate, is checked while calibrating the hydraulic model.

After calibration, a different set of flow monitoring data was used to validate the model calibration. Model calibration and validation is an iterative process.

The Model Calibration Approach has been discussed in detail in **Appendix F**.

4.5.1.3 Model Calibration Results

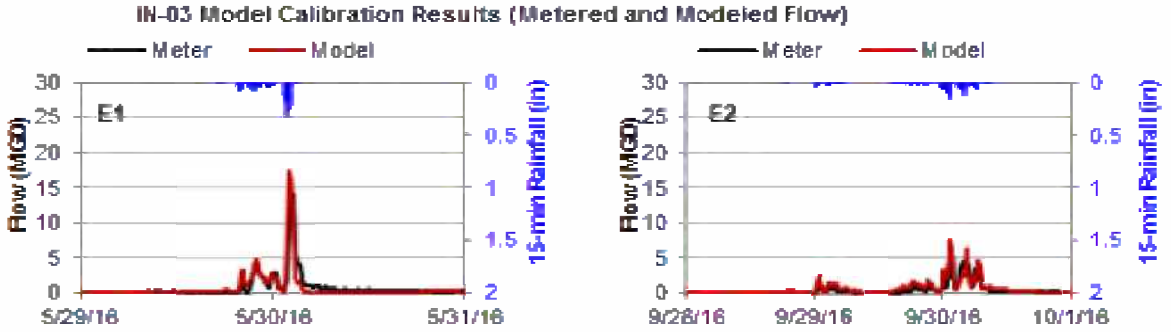
Successful calibration of the H&H Model is indicated by satisfying agreements between the model prediction and the flow monitoring data in terms of the shape of hydrograph, wet weather volume and peak flow. The calibration was performed and evaluated for various sizes of storms and different antecedent conditions so that the calibrated model can be reasonably applied for various hydrologic conditions. Wet weather events used for model calibration and validation are summarized in listed in **Table 4-6**. The larger storm events have more of a weighting factor in the calibration process because the large events are the ones that dominate the total overflow volume.

Table 4-6: Wet Weather Events Used for Model Calibration and Validation

Event ID	Start Time	Stop Time	Rainfall Depth* (inches)	Used in Calibration	Used in Validation
E1	5/29/16 19:00	5/30/16 5:00	1.82	C	
E2	9/28/16 12:00	9/30/16 10:00	2.36	C	
E3	11/29/16 7:00	11/29/16 20:00	1.08	C	
E4	3/30/17 21:00	4/1/17 3:00	1.83		V
E5	5/21/16 11:00	5/22/16 21:00	1.71		V
E6	7/28/16 15:00	7/29/16 9:00	1.26	C	
*At Chester PS rain gauge					

Examples of model calibration results are shown in
Figure 4-7. Additional figures for all meters installed at different locations, including meters installed at major trunk interceptor, overflow pipes, influent pipe to overflow control structure, intercepting pipes, previous CSO areas, separate sewer areas and boundaries can be found in **Appendix F** and **Appendix T**.

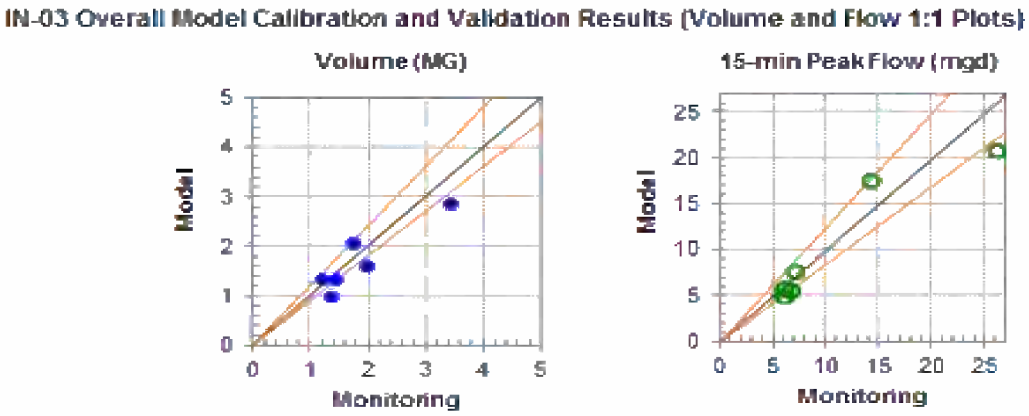
Figure 4-7: Model Calibration Hydrograph (Example Plot)



Comparisons of the predicted total volume against the monitoring total volume and predicted peak flow against monitoring peak flow were analyzed and shown in 1:1 ratio plots for all calibrated meters. This is to evaluate the overall calibration and validation from all the events. The event points in **Figure 4-8** are distributed close to the 1:1 ratio line, which means that the model predicted peak flow and wet weather event volumes are in good agreement with the metered data. Additional figures for all model calibration plots can be found in **Appendix F** and **Appendix T**.

The H&H model from the 2012 DELCORA LTCP Update was reviewed and updated as a part of the development of the LTCPU. Data from the rainfall and flow monitoring program was used to calibrate and validate the updated H&H model. The calibrated H&H model was used to assist DELCORA throughout the remaining steps in the CSO LTCP update process. The calibration and validation plots and a statistical evaluation of the model calibration are presented in **Appendix F** and **Appendix T**. The calibrated model was judged adequate for the purposes of the LTCPU and adheres to industry standards and criteria.

Figure 4-8: Model Calibration 1:1 Plots (Example Plot)



Section 5 Water Quality Monitoring and Modeling

5.1 Introduction

Water quality monitoring and modeling were conducted to support the development of the Long-Term Control Plan Update. The objective of the water quality modeling was to compute Pollutant of Concern concentrations in Chester Creek, Ridley Creek, and the Delaware River by accounting for all major POC sources within the Model Area. The objective of the water quality monitoring was to collect data that would allow for the characterization of the major POC sources, and to support calibration and validation of the receiving Water Quality Model under both dry and wet weather conditions. Another objective of the water quality model was to describe current water quality for the Typical Hydrologic Period, and predict future water quality for the proposed CSO control alternatives. The primary focus of the receiving water quality monitoring and modeling was on the local water conditions, including the tidal zones of Chester and Ridley Creeks, and the Delaware River from roughly river mile 80 near Marcus Hook to river mile 85 near Crum Creek.

5.1.1 Regulatory Requirements

Consent Decree Paragraph V.A.15 (Water Quality Model Plan) requires that within ninety (90) days after USEPA approval of the Alternatives Evaluation Approach, DELCORA shall submit to USEPA and PADEP a Water Quality Model Plan for review and approval. The Water Quality Modeling and Monitoring Work Plan was first submitted in January 11, 2017, a revision was submitted in July 31, 2017, and the Work Plan was approved by the USEPA on April 16, 2018.

The Consent Decree further specifies that within sixty (60) days after the approved Water Quality Model Plan is fully implemented according to the schedule included therein, DELCORA shall submit to USEPA and PADEP a Water Quality Model Report for review and approval pursuant to Section VI (Review and Approval of Submittals) to specifically address each item set forth in Paragraph 15(a)(i)-(vi). The Water Quality Model Report was submitted on February 27, 2018 and approved by the USEPA on April 17, 2018.

5.2 Water Quality Monitoring and Sampling

5.2.1 Water Quality Work Plan and Quality Assurance Project Plan Development

The Water Quality Modeling and Monitoring Work Plan was designed to support the development of the receiving water quality model (Water Quality Model) and described the collection of data that would be used to develop and calibrate the Watershed Model and the Water Quality Model. The water quality monitoring objectives were to 1) collect water quality data for the POCs during dry and wet weather event periods that were used to characterize the POC sources in the Delaware River, Chester Creek, and Ridley Creek, and in the vicinity of the City of Chester, and 2) to support calibration and validation of the Water Quality Model, consistent with the Consent Decree requirements in Paragraph V.A.15.a. Additional in situ parameters, such as salinity, temperature, and conductivity were also collected to inform the development of the Water Quality Model.

A Water Quality Monitoring and Modeling Quality Assurance Project Plan (QAPP) was also developed to meet the requirements of the DELCORA Consent Decree Paragraph Section V.A.15.a.(iv) which required detailed information regarding all additional data collection and water quality modeling

activities. The purpose of the QAPP was to document the necessary procedures required to ensure that the project was executed in a manner consistent with applicable USEPA guidance documents and with generally accepted and approved quality assurance objectives. The QAPP integrated quality control policies and project-specific work tasks to successfully conduct water quality monitoring and modeling to support the CSO Long -Term Control Plan Update. The overall intent of the QAPP was to provide professional guidelines for activities by all personnel on the project and to ensure that proper quality assurance/quality control (QA/QC) procedures were followed.

The Water Quality Monitoring and Modeling Work Plan and the Water Quality Monitoring and Modeling Quality Assurance Project Plan are included in **Appendix H** and **Appendix I**, respectively.

5.2.2 Sampling and Analysis Plan Overview

Water quality monitoring was undertaken at thirteen (13) in-stream locations (seven of which were Delaware River sampling locations), four (4) CSO locations in the DELCORA combined sewer system area, and two (2) stormwater sewer locations in the City of Chester municipal separate storm sewer system, as shown in **Figure 5-1**. Water quality monitoring and sampling were conducted as follows:

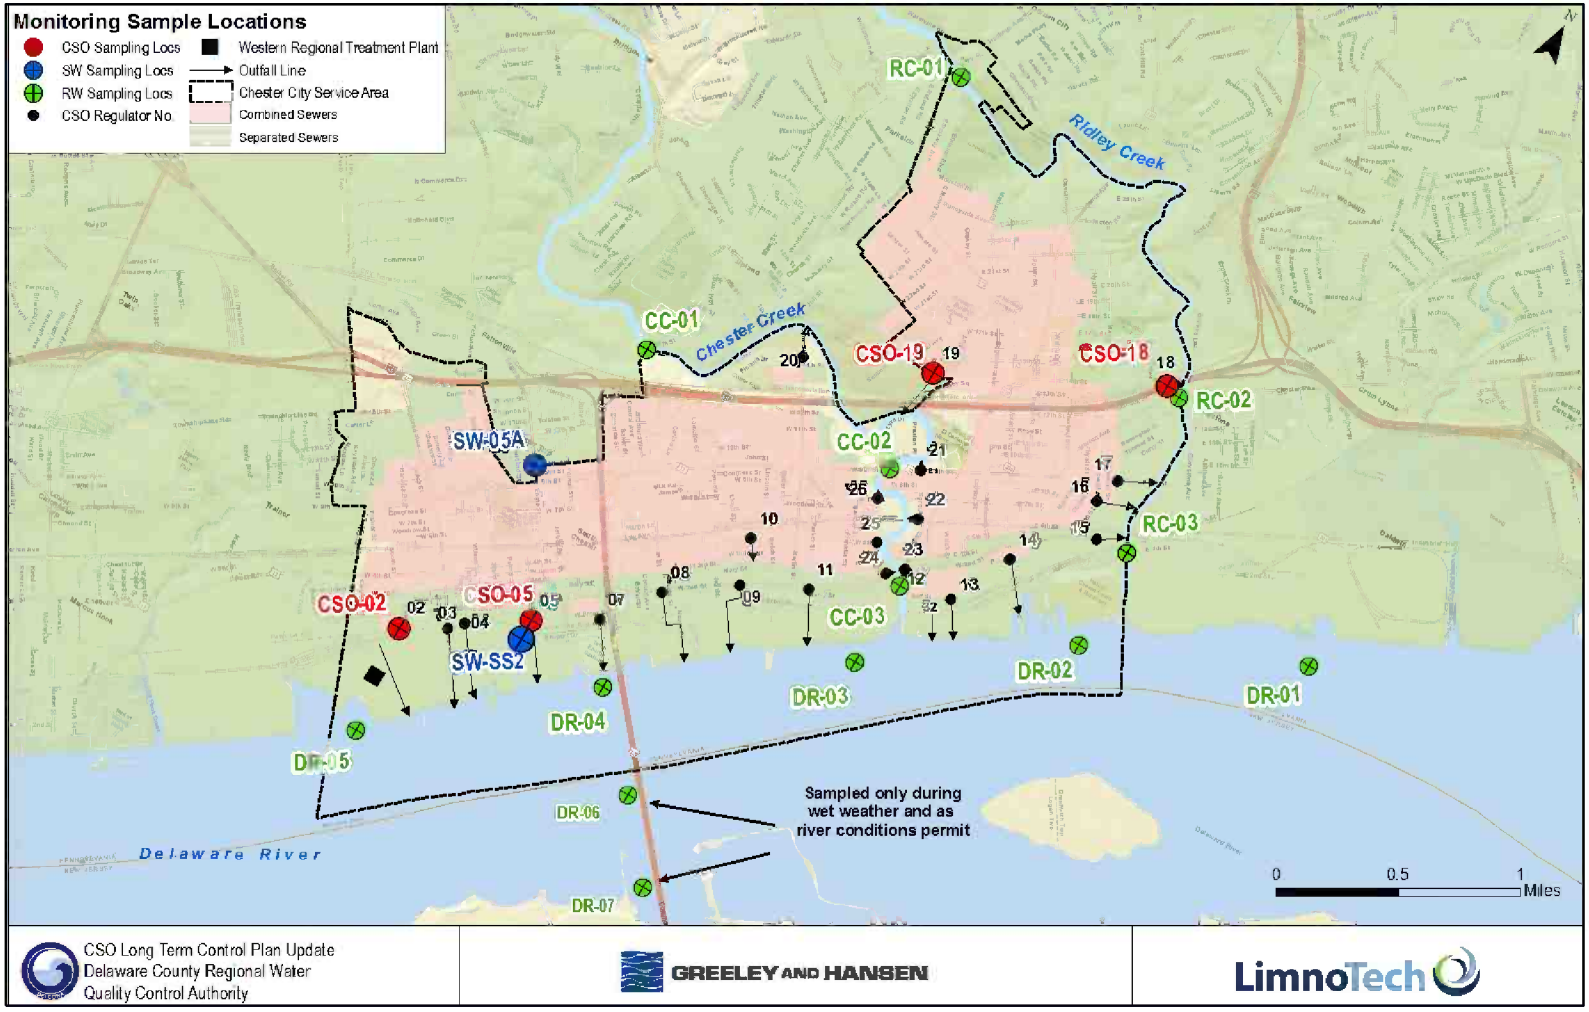
- Eleven (11) in-stream locations in the vicinity of the DELCORA CSO area were sampled for water quality for three (3) dry weather events; one of which was targeted for collection during a tributary low-flow period (less than 25th percentile flow). The mid-stream and far-shore Delaware River locations were not sampled during the dry weather surveys because the water quality in the river is found to be relatively uniform laterally due to the lack of active sources during dry weather. These dry weather events were distributed across the sampling season, which was from March through June of 2017. Grab samples and *in situ* measurements were collected at each location during each event.
- All thirteen in-stream locations were sampled for water quality using grab samples and *in situ* monitoring for three (3) discrete wet weather events, according to the surface water quality monitoring program protocols described in the Water Quality Monitoring and Modeling Work Plan;
- Up to four CSO and two stormwater outfall locations were sampled for water quality for the same three discrete wet weather events according to the outfall monitoring program protocols described in the Water Quality Monitoring and Modeling Work Plan. Samples for all outfalls were collected as grab samples.

The sampling events were distributed across the sampling season, which was from March through June 2017.

5.2.3 Sampling Locations

Monitoring locations were selected to characterize the watershed at a sub-watershed level, recognizing various political and hydrologic features, land uses and potential pollutant sources. Site selection and analytical parameters were designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. The sampling locations are shown in **Figure 5-1**.

Figure 5-1: Receiving Water, Combined Sewer Overflow (CSO), and Stormwater (SW) Monitoring Locations



The Chester Creek and Ridley Creek locations were selected to distinguish, to the extent possible, between upstream, stormwater, and DELCORA CSO pollutant loads. The Delaware River sampling locations characterized water quality entering the DELCORA CSO area from either tidal direction as well as water quality within the CSO discharge area. During wet weather, three samples were collected across the transect corresponding to the DR-03 sampling location to characterize lateral variability in the Delaware River during storm events.

The CSO sampling locations were selected based on their outfall discharge location, relatively high frequency and volume of overflow, and their accessibility. The stormwater sampling locations were selected to characterize the water quality associated with the predominant land uses (residential and commercial/industrial) in the Model Area. Each stormwater sampling location is in an area that is representative of the land use elsewhere in the City's stormwater area.

5.2.4 Analytical Parameters

All of the in-stream dry and wet weather samples were analyzed for the parameters shown in **Table 5-1**. The outfall samples were analyzed for *E. coli*, *Enterococcus* and Fecal coliform bacteria.

Table 5-1: Analytical and Field Parameters

Parameter	Description	Sampling Program	Type of Measurement
E. coli	*Escherichia coli*	Dry, Wet	Grab
Enterococcus	*Enterococcus sp.*	Dry, Wet	Grab
Fecal coliform	Fecal coliform	Dry, Wet	Grab
Temp	Water temperature	Dry, Wet, Receiving Water Only	In-situ
Cond	Conductivity	Dry, Wet, Receiving Water Only	In-situ
Salinity	Salinity	Dry, Wet, Receiving Water Only	In-situ

5.2.5 Sampling Results

The DELCORA Sampling Program was designed to fill data gaps and characterize sources and surface waters during dry and wet weather events to support the development of water quality models for use in the development of the CSO Long-Term Control Plan Update. The data was sufficient to characterize DELCORA's CSO and stormwater source loads for the Water Quality Model. The data also spanned a range of environmental conditions and provided an extensive dataset for demonstrating the robustness of the Water Quality Model. The Sampling Program fully achieved the objectives of collecting comprehensive and complete datasets needed to characterize pollutant sources, produce an appropriately calibrated watershed and water quality model, and successfully meet the quality objectives of the QAPP.

The Water Quality Model Report (**Appendix J**) includes the Water Quality Sampling Report that presents a detailed overview of the dry and wet weather datasets by individual event. The following observations were presented with respect to the data:

- The presence of an incoming versus an outgoing tide did not significantly influence bacteria concentrations during dry weather;
- Dry weather bacteria concentrations in the Delaware River tended to be well below numeric thresholds used for water quality standard criteria;
- An increase in POC concentrations from upstream to downstream was observed in each of the tributaries, suggesting there may be significant non-CSO bacteria sources impacting these tributaries during dry weather;
- Downstream locations show more spread in the distribution of concentrations within each event as compared to the farthest upstream locations. This is likely the result of higher mixing with the Delaware River and the tidal influence on water quality at the more downstream locations;
- Short-term wet weather bacteria concentrations in all of the waterbodies were significantly higher than during dry weather;
- Bacteria concentrations in CSOs are highly variable and a consistent first flush concentration was not observed for the POCs.
- Lateral POC gradients in the Delaware River were present but not at a significant level (e.g. orders of magnitude); and,
- The time series profiles in the Chester Creek and Ridley Creek waterbodies indicated that upstream or other wet-weather sources also contribute to high bacteria concentrations during wet weather events in addition to DELCORA's CSOs and Chester's MS4 discharges.

Additional data results are presented below in **Subsection 5.3** in the Water Quality Model calibration discussion.

5.3 Water Quality Model

The objective of the water quality modeling was to compute POC concentrations in the tidal portions of Chester Creek and Ridley Creek, and in the Delaware River, by accounting for all major POC sources within the region of interest. To meet this objective, the Water Quality Model was developed and calibrated based on site-specific data representing local hydrodynamic and water quality conditions. Flow-weighted Event Mean Concentration (EMC) values were calculated from the sampling data as a starting point for determining EMCs to use in the Water Quality Model.

The full description of the model development, calibration, application, results, and analysis can be found in the Water Quality Monitoring Report, included in **Appendix J**. A summary of the report is provided in the following subsections.

5.3.1 Model Description and Development

Three types of models, which comprise the modeling framework, were jointly applied to compute POC concentrations in the Chester and Ridley Creeks and in the Delaware River:

- A watershed model (Watershed Model) which simulates flows and POC loads from the Chester and Ridley Creek watersheds;
- CSS models (H&H Models) that simulate flows and POC loads from the DELCORA and Philadelphia Water Department combined sewer systems; and,
- A receiving water quality model (the Water Quality Model) that computes POC concentrations in the Chester and Ridley Creeks and in the Delaware River resulting from the various sources of POCs to the water bodies (primarily Philadelphia's CSOs, watershed runoff, and DELCORA's CSOs).

The watershed and CSS models were developed using the EPA Stormwater Management Model (SWMM) and the receiving water quality model was developed using the EPA Environmental Fluid Dynamics Code (EFDC) model.

Figure 5-2 illustrates the extents of the watershed, CSS, and receiving water quality models.

The model development process for DELCORA's water quality modeling framework included definition of:

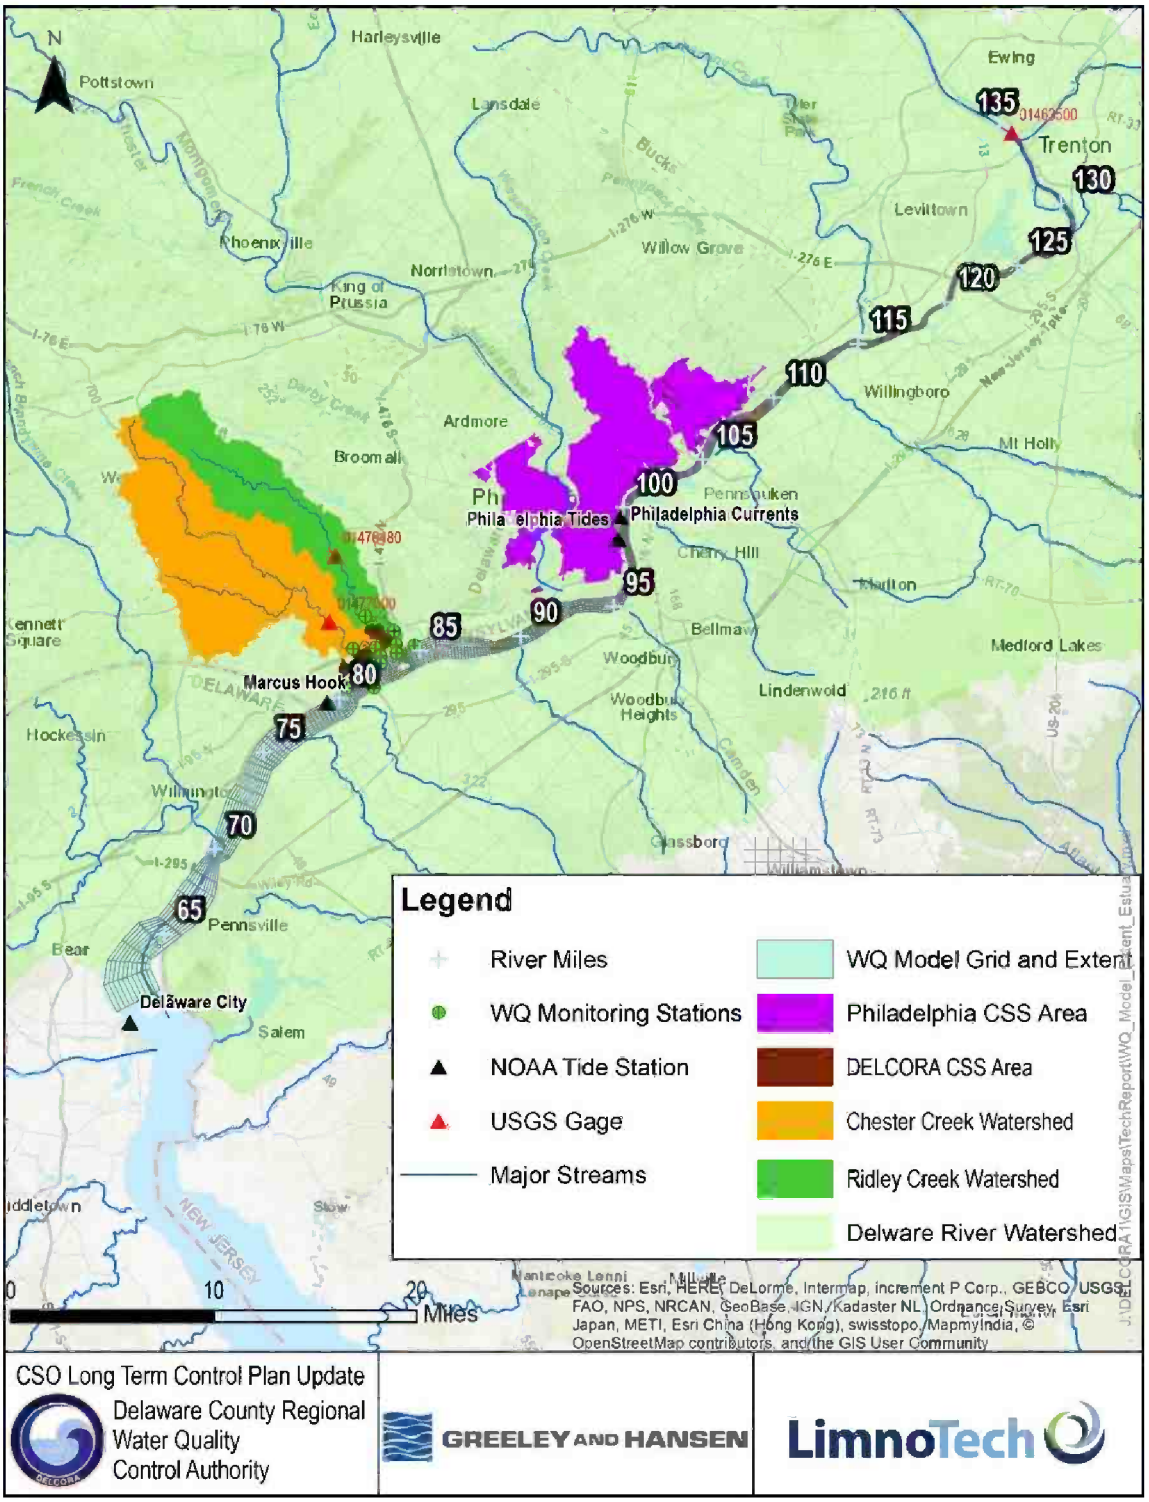
- Important physical and biological processes such as stormwater runoff and POC decay rates;
- Model inputs and assumptions influencing the modeled processes, such as water depths and stream flow rates;
- The spatial extent of model calculations; and,
- The time span of model calculations.

5.3.2 Model Calibration

Site specific data were used for calibrating the various models, including USGS flow data, NOAA tide data, wet and dry weather water quality data obtained by DELCORA, and ambient water quality data obtained from the Delaware River Basin Commission. The water quality data obtained by DELCORA proved particularly useful in calibration of the Water Quality Model, as it contained both wet and dry weather data at various locations within the study area, including both upstream and downstream of DELCORA's CSO discharges.

Calibration of the various models was evaluated using metrics such as total runoff volume, peak flow rates, timing of the flow response, frequency of discharge, water levels, water velocities, and in-stream water quality concentration. The calibration approach was to adjust model parameters and evaluate changes in model results against the entire calibration dataset, and identify the model input values that were most consistent with the central tendencies and distribution of the datasets by water body. Each model within the framework was developed and calibrated using the best available data. Calibration of the receiving water quality model served as a check on the reliability of the watershed and CSO models because the performance of the receiving water quality model was dependent on the quality of the other two models. Each model was found to be reasonably consistent with observed data and therefore reliable to be applied for the development of the Long-Term Control Plan Update.

Figure 5-2: Water Quality Model Extent and Related Features



5.3.3 Application of the WQ Model to support the LTCPU Development

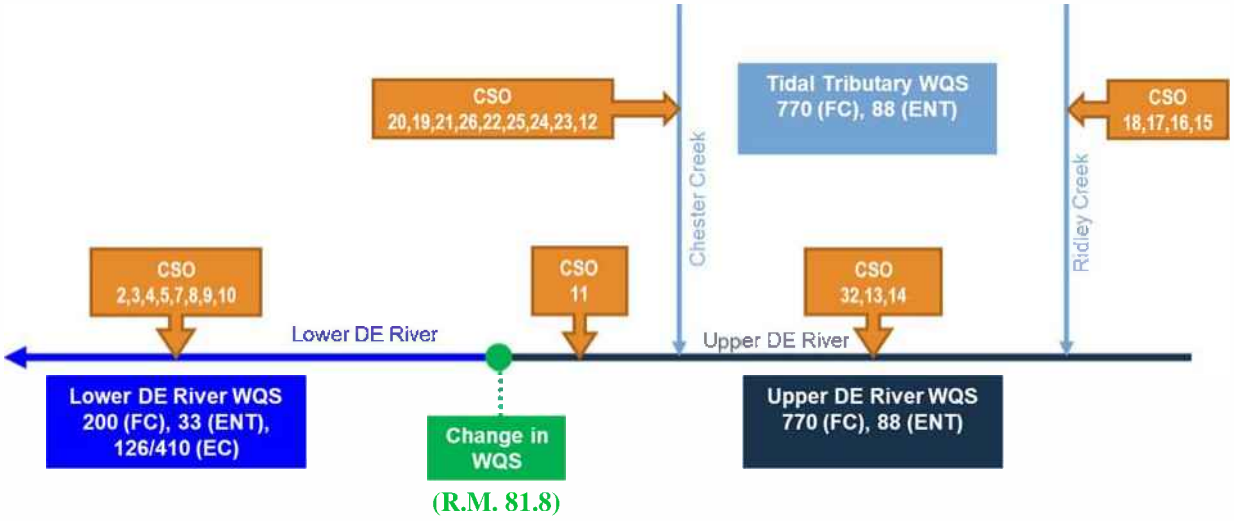
The Water Quality Model was applied for the typical year hydrologic period of 1994-1996, which includes one relatively dry year, a relatively wet year, and an average year (see **Section 3**). The modeled POC concentrations were compared to the currently applicable and potential future water quality standards, as shown in **Table 5-2**. The Upper Delaware River and the tidal zones of Chester and Ridley Creek currently have secondary contact water quality standards whereas the Lower Delaware River currently has primary contact water quality standards for fecal indicator bacteria. The boundary between the Upper and Lower Delaware River occurs at river mile 81.8, which is just downstream of Chester Creek and CSO-11 (see **Figure 5-3**).

Table 5-2: Water Quality Standards for Comparisons with Model Results

Segment	*Enterococcus* (#/100 mL)	Fecal Coliform (#/100 mL)	*E. coli*[1] (#/100 mL)
Upper Delaware River and Tidal Zones of Creeks	Monthly Geomean: 88 #/100 mL	Monthly Geomean: 770 #/100 mL	n/a
Lower Delaware River	Monthly Geomean: 33 #/100 mL	Monthly Geomean: 200 #/100 mL	Monthly Geomean: 126 #/100 mL Statistical Threshold Value: 410 #/100 mL

[1] It has been reported that *E. coli* (EC) standards are likely to be codified by PADEP in the near future and for this reason it was included as a parameter in the 2018 sampling. These criteria would apply to the non-tidal tributaries and to the Delaware River below R.M. 81.8, during recreational months only (May 1 - September 30).

Figure 5-3: Schematic of Applicable POC Water Quality Standards



5.3.4 Baseline Results

Model results were summarized over the stream reaches that receive CSO discharges, and that occur within Pennsylvania waters. Generally, the modeling indicated that the *Enterococcus* standards are the most stringent among the three POCs. Exceedances above the WQS are frequent in the two creeks and infrequent in the Delaware River. The exceedances are almost always due to background sources coming from upstream of the DELCORA CSO area. DELCORA's CSOs have a much smaller impact (less than 10%, on average) on the monthly geometric mean concentrations than do the upstream background sources.

Table 5-3 shows the number of months when water quality standards were exceeded for each of the three POCs in the Upper and Lower Delaware River and in the two creeks. Results are shown for all sources (background and CSOs) and for CSOs only. This table shows that DELCORA's CSOs by themselves do not cause water quality violations in the Upper or Lower Delaware River or in Chester and Ridley Creeks and are not precluding the attainment of WQS. DELCORA's CSOs have a relatively small impact (less than 10%, on average) on the monthly geometric mean concentrations than do the upstream background sources because they are intermittent discharges that are only active for short time periods within a monthly geometric mean evaluation period.

Table 5-3: Number of Months Exceeding the Monthly Geomean Water Quality Standard

	Enterococcus Monthly Geomean	Fecal Coliform Monthly Geomean	*E.coli*[1] Monthly Geomean	*E.coli*[1] STV
Ridley Creek				
All Sources	36/36	24/36	n/a	n/a
CSOs only	0/36	0/36	n/a	n/a
Chester Creek				
All Sources	21/36	1/36	n/a	n/a
CSOs only	0/36	0/36	n/a	n/a
Upper Delaware				
All Sources	1/36	0/36	n/a	n/a
CSOs only	0/36	0/36	n/a	n/a
Lower Delaware				
All Sources	6/36	1/36	2/36	13/36
CSOs only	0/36	0/36	0/36	0/36

[1] No *E.coli* standard currently exists or has been officially proposed for the tidal portions of Ridley and Chester Creeks or for the Upper Delaware River, therefore results for these segments are marked as "n/a" in this table. Water Quality Modeling results indicate the contribution of CSOs only to these waterbodies do not result in *E. coli* counts above 126#/100mL for a monthly geomean.

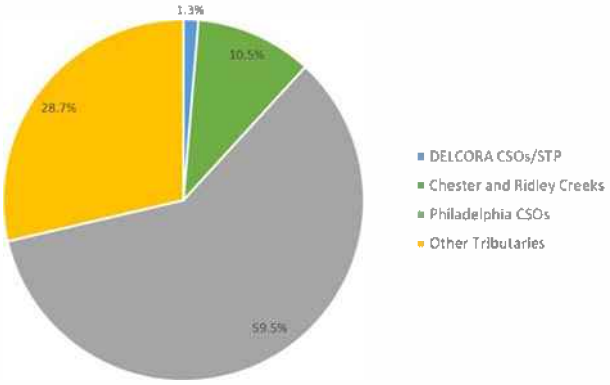
5.4 Water Quality Monitoring and Modeling Findings

The water quality sampling program and Water Quality Model were developed to compute POC concentrations in the Delaware River and in the tidal sections of Chester Creek and Ridley Creek. Major findings of the monitoring and modeling are as follows:

- The model is deemed adequate to assess the local water quality conditions in the DELCORA study area, including in the tidal portions of Chester and Ridley Creek and in the Delaware River from roughly river mile 80 near Marcus Hook Creek to river mile 85 near Crum Creek.
- Outputs of the Hydrologic and Hydraulic Model relative to volumes and loadings were adequate for utilization as inputs for the development of the Water Quality Model.
- The monitoring data shows that wet weather concentrations at the most upstream monitoring locations (located upstream of DELCORA's CSO influence) in Chester Creek and Ridley Creek often exceed the monthly geometric mean WQS concentration for the two POCs there. Wet weather exceedances are also observed in the most upstream monitoring location for the Delaware River, but less frequently as compared to the creeks. The *E.coli* statistical threshold value WQS[8] concentration (410 #/100 mL) was exceeded once under wet weather conditions during the sampling periods in the Delaware River.
- The modeling results show that when water quality standards are exceeded during wet weather events, upstream and background sources typically prevent the attainment of both the monthly geometric mean and statistical threshold value water quality standards.
- The modeling results show that CSOs by themselves do not cause water quality violations in any of the stream segments.
- Each model within the framework was developed and calibrated using the best available data, and found to be reasonably consistent with observed data and therefore reliable to be applied for the development of the LTCPU.

The DELCORA CSO loads are small compared to the upstream and background bacteria loads entering the DELCORA project area based off of the results of the Water Quality Model Report (see **Figure 5-4**, original source in **Appendix J**).

Figure 5-4: Percent of Bacteria Load by Source



[6] E.coli (EC) standards likely to be codified by PADEP 12-24 months from July 2017. These criteria would apply to the non-tidal tributaries and Delaware River below R.M. 81.8, during recreational months only (May 1 - September 30).

Two major observations can be made from the water quality modeling application results. One is that background sources dominate the modeled POC concentrations (and by extension, DELCORA's CSO loads are small compared to background loads), and the second is that the DELCORA's CSOs by themselves do not cause non-attainment, or preclude the attainment, of WQS. Moreover, the modeling results show that regardless of additional CSO controls, even complete sewer separation, water quality standards would still be exceeded under current conditions because background sources of bacteria typically prevent compliance with the WQS. The modeling results are supported by the water quality data results from the wet weather sampling program, which shows that wet weather concentrations at the most upstream monitoring locations (located upstream of CSO influence) in Chester Creek and Ridley Creek (and to a lesser extent in the Delaware River) often exceed the monthly geometric mean and STV WQS concentration for the three POCs. These monitoring and modeling data taken together indicate the upstream bacteria loads result in a practical impossibility of meeting water quality standards in the tidal waters through CSO control alone.

The Water Quality Model is deemed adequate to evaluate compliance with the WQS and the degree to which DELCORA's CSOs contribute to the non-attainment of WQS. The intended use of the water quality modeling framework is to evaluate CSO control alternatives with respect to applicable water quality standards and demonstrate that the alternatives selected for the LTCPU program will meet the water quality-based requirements of the Clean Water Act and Consent Decree. The Water Quality Model is adequate to assess the Presumption approach levels of control to show that the CSOs will or will not preclude the attainment of water quality standards after CSO control measures are implemented.

The Water Quality Model was used to help assess the water quality benefits of potential infrastructure projects considered for the LTCPU (i.e. CSO alternative scenarios). The selected CSO alternatives were simulated in the DELCORA H & H Model (i.e. CSS model) and then evaluated with the receiving Water Quality Model. Resulting changes to in-stream POC concentrations were compared to the applicable water quality standards as well as to the concentrations observed under the baseline conditions. These model results are described in **Section 10 - Implementation of the CSO LTCP Update**.

THIS PAGE INTENTIONALLY LEFT BLANK

Section 6 Existing Service Area Characterization

6.1 Background

The *Existing Service Area Characterization Report* was prepared to fulfill the requirements of Paragraph V.A.16 of the Consent Decree, and of the federal CSO Control Policy Section II.C.1 – Characterization, Monitoring and Modeling of the Combined Sewer System and was approved by the USEPA on April 16, 2018. This Section of the LTCP Update summarizes the information presented in that report to characterize, monitor and model DELCORA's combined sewer system, and incorporates the conclusions about Sensitive Areas that were previously determined in **Section 2** of this LTCPU report. The full version of the approved *Existing Service Area Characterization Report* is included in **Appendix K**, with updates to the model calibration and validation results in **Appendix T**.

6.2 Regulatory Requirements for the Existing Service Area Characterization

6.2.1 Consent Decree Requirements for the Existing Service Area Characterization

The primary requirements for the Existing Service Area Characterization Report are established in the Consent Decree. Specifically, Paragraph V.A.16 of the Consent Decree, Existing Service Area Characterization, states that:

> *"Not later than two years (24) months after the Date of Lodging of the Consent Decree, DELCORA shall submit a characterization of the Model Area that includes all of the information required by CSO Control Policy Section II.C.1 and associated guidance to Plaintiffs for review and approval in accordance with the requirements of Section VI (Review and Approval of Submittals). The characterization shall include, but not be limited to, the following:*
>
> *DELCORA shall use the updated, calibrated, and validated H&H Model to characterize the expected volume, frequency, and duration of CSO discharge events from each CSO during the Typical Year, based on an inter-event period of twelve (12) hours;*
>
> *DELCORA shall incorporate the results of its investigation of Sensitive Areas;*
>
> *DELCORA shall provide a characterization of current water quality in its Receiving Waters, based upon all available sampling data, and its efforts to identify POCs.*
>
> *The characterization submitted pursuant to this paragraph shall include the entire Model Area, including the hydrology (i.e., runoff) from and within the entire Model Area."*

Additionally, the Consent Decree requires Rainfall and Flow Monitoring in Paragraph V.A.14.d.:

> *"Rainfall and flow monitoring that shall be carried out in accordance with current good industry practice for a period of at least twelve (12) months, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization*

of dry and wet weather flows for the entire Model Area, and the response of each CSO to wet weather flows."

6.2.2 Requirements from the USEPA's CSO Control Policy

Additional requirements for the *Existing Service Area Characterization Report* are established in the USEPA's CSO Control Policy. Section II.C.1 of the CSO Control Policy "Characterization, Monitoring and Modeling of the Combined Sewer System" states:

> *"In order to design a CSO control plan to adequately meet the requirements of the CWA, a permittee should have a thorough understanding of its sewer system, the response of the system to various precipitation events, the characteristics of the overflows, and the water quality impacts that result from CSOs. The permittee should adequately characterize through monitoring, modelling, and other means as appropriate, for a range of storm events, the response of its sewer system to wet weather events including the number, location and frequency of CSOs volume, concentration and mass of pollutants discharged and the impacts of the CSOs on the receiving waters and their designated uses."*

The CSO Control Policy states that the major elements of a sewer system characterization include the following:

> ***Rainfall Records***
>
> *"The permittee should examine the complete rainfall record for the geographic area of its existing CSS using sound statistical procedures and best available data. The permittee should evaluate flow variations in the receiving water body to correlate between CSOs and receiving water conditions."*
>
> ***Combined Sewer System Characterization***
>
> *"The permittee should evaluate the nature and extent of its sewer system through evaluation of available sewer system records, field inspections and other activities necessary to understand the number, location and frequency of overflows and their location relative to sensitive areas and to pollution sources in the collection system, such as indirect significant industrial users."*
>
> ***CSO Monitoring***
>
> *"The permittee should develop a comprehensive, representative monitoring program that measures the frequency, duration, flow rate, volume and pollutant concentration of CSO discharges and assesses the impact of the CSOs on the receiving waters."*
>
> ***Modeling***
>
> *"Modeling of a sewer system is recognized as a valuable tool for predicting sewer system response to various wet weather events and assessing water quality impacts when evaluating different control strategies and alternatives. EPA supports the proper and effective use of models, where appropriate, in the evaluation of the nine minimum controls and the development of the long-term CSO control plan."*

6.3 Overview of DELCORA's Facilities

DELCORA owns and operates an extensive conveyance system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in **Figure 1-3**. An overview of DELCORA's facilities is presented in **Subsection 1.3** of this report.

6.4 Characteristics of the Model Area Sewer System

This subsection presents an investigation of the collection system to meet the requirements of Paragraph II.C.1.b, Combined Sewer System Characterization, of the USEPA's CSO Control Policy. Paragraph II.C.1.b requires DELCORA to evaluate the nature and extent of the sewer system through evaluation of available sewer records and inspections necessary to understand the number, location and frequency of overflows, and their locations relative to Sensitive Areas and to pollution sources in the collection system.

6.4.1 Sources of Collection System Data

The characteristics and attributes of DELCORA's collection system were determined through the collection, assessment, and evaluation of existing data and information, as part of the implementation of the *Hydrologic and Hydraulic Model Update and Calibration Plan* (Greeley and Hansen, 2015).

Data and information on the collection system were obtained from several sources including DELCORA's input, DELCORA's Geographic Information System, as-built record drawings, design drawings and field surveys.

6.4.2 Overview of Sewer System Characteristics

The wastewater collection system within the Model Area consists of separated storm and sanitary sewer piping in some areas and combined sewer system piping in other areas. The Model Area covers approximately 50,000 acres, with approximately 48,500 acres served by separated storm and sanitary systems while only 1,486 acres are served by a combined sewer system. The combined sewer system is located entirely within the City of Chester. However, the City of Chester also has areas that are served by separated storm and sanitary piping or are direct drainage. The remaining areas of the Model Area outside of the City of Chester are all served by separated storm and sanitary sewer piping.

In separated areas, the sanitary sewers convey wastewater to the WRTP/PWD-SWWPCP for treatment and stormwater runoff is collected through storm sewers and discharged directly to the receiving waters.

Within the City of Chester's combined sewer areas, however, sanitary and storm sewers are combined into the same pipe. During dry weather, the sanitary wastewater is conveyed to the WRTP. During large storms, the stormwater runoff causes the carrying capacity of these combined sewers to be exceeded, and part of this combined flow may discharge directly to the receiving waters without undergoing any treatment.

Sewersheds (subcatchments) are delineated based on the drainage network and area characteristics. Each sewershed has a dry weather and a wet weather flow input to the model network. The model network comprises 128 sewersheds (subcatchments), including 55 combined and 73 separated subcatchments.

6.4.3 Characteristics of Separated Sewer Areas

Sanitary sewers within the separated areas deliver flow to the WRTP through connections to DELCORA's sewers and through connections to DELCORA's pump station. In many cases, DELCORA does not own or operate the sanitary sewers in separated areas. Consequently, detailed information regarding the characteristics of sanitary sewers from the separated areas is not included in this Report. Key characteristics necessary for developing flow inputs include the delineation of subcatchment boundaries as shown in **Figure 4-2** and in **Table 6-1**.

6.4.4 Characteristics of Combined Sewer System

As noted in **Subsection 1.3** of this report, the combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's serviced area. The combined wastewater/stormwater system in the City is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, and CSO regulators and CSO outfalls. The City owns, operates and maintains the inlets, stormwater-only sewers that connect to the combined sewer system and any stormwater-only outfalls. The City is also responsible for the maintenance and cleaning of the streets, planning, zoning, and development controls.

The CSS system in the City of Chester has several key components that all impact how the system operates. These key components are the local street sewers, combined collector sewers, CSO regulators, interceptors, and outfalls. The system starts with local street sewers that take flow from houses and businesses as well as the stormwater inlets that drain the streets. These local street sewers typically range in size from 12" to 24" in diameter. The local street sewers discharge to combined collector sewers, which flow to the CSO regulators. The combined collector sewers are larger pipes that typically range in size from 18" to 72" in diameter and connect directly to the CSO regulators.

Generally, in the CSO drainage areas, flows from the separate sanitary sewers flow into the combined sewers. Flows from the combined sewers in the collection system flow to the regulator structures where dry weather flow and a portion of wet weather flow are diverted into the interceptors. The remainder of the wet weather flow that exceeds the capacity of the interceptors is discharged directly to the closest receiving water (Delaware River, Chester Creek or Ridley Creek) through the CSO outfalls.

6.4.5 Overall Configuration

A schematic of the CSS was developed to facilitate the development, calibration, and validation of the H&H Model. The schematic illustrates the relationship between all major regulators, interceptors, outfalls, pump stations, force mains and other major appurtenances. The schematic also includes the location of the flow meters, and provides and good understanding of the relationship between the flow meters. The schematic of the collection system components is shown in **Figure 1-6**.

Figure 4-3 in **Section 4** depicts the locations of DELCORA's CSO regulators and outfalls and also depicts the various drainage subcatchments that flow to the CSO regulators. Information about the 26 CSO drainage areas including their subcatchments, total acreage and combined sewer acreage are shown depicted in **Table 6-1**.

6.4.6 Sewer Mains

Sewer data was collected from DELCORA's GIS in support of the work to update and calibrate the H&H model. Most of the pipe input characteristics, including upstream and downstream nodes, dimension, shape, number of barrels, and flap gate information, were found or estimated from record drawings, design drawings and sewer gravity main GIS shapefiles. If sewer main information was not available, sewer length was estimated using GIS geometry measurement; sewer sizes were assumed based on upstream and downstream sewers; and sewer upstream and downstream offsets were estimated based on sewer connectivity assuming constant slope. Conduit ID was inherited from the 2012 H&H Model and new IDs were provided for the pipes not in the 2012 H&H Model.

Manhole information, including invert and rim elevations, were found or estimated from record drawings, design drawings, and the sewer manhole shape file. Manhole ID was inherited from the name of the manhole in the sewer GIS. Manhole input information was updated based on the latest available GIS information.

6.4.7 Flow Diversion Structures and CSO Regulators

The Chester CSO system contains 26 permitted CSO regulators as listed in **Table 6-2**. The CSO regulators and outfalls serve as combined sewer reliefs necessitated by stormwater entering the sewer system and exceeding the hydraulic capacity of the sewers and/or treatment plant. Wet weather flows in excess of the collection system's capacity are discharged to the Delaware River, Chester Creek or Ridley Creek. Although there are 26 regulators, there are only 25 CSO discharge locations, as CSO #010 discharges to the Delaware River through CSO #009. **Table 6-2** shows that eleven of the outfalls, CSO Outfalls #002, 003, 004, 005, 007, 008, 009, 011, 013, 014, and 032, discharge excess wet weather flows into the Delaware River. Nine of the outfalls, CSO Outfalls #012, 019, 020, 021, 022, 023, 024, 025 and 026, discharge excess wet weather flows into the Chester Creek. The remaining five designated outfalls, Outfall #015, 016, 017, 018 and 033, discharge excess wet weather flows into the Ridley Creek.

Since the approval of the first LTCP in 1999, DELCORA has under-taken a program to replace and/or rehabilitate CSO regulators and tide gates in the City of Chester CSO system. In some cases, regulators have been eliminated. The modifications DELCORA committed to in the 1999 LTCP include a complete replacement of the mechanism, installation of a monitoring system to determine if flow is passing over the CSO regulator diversion weir to the outfall, and conversion of the CSO regulators to Type A. After installation of the first CSO regulator monitoring systems, DELCORA determined that the monitoring system improves system operation and significantly reduces dry-weather overflows by notifying operators at the WRTP that flow is passing over the diversion weir. (If it is not raining, this notification is indication of a dry-weather overflow and DELCORA dispatches a maintenance crew to correct the situation.) After this determination, DELCORA installed the monitoring system on all CSO regulators even though it was not required until the CSO regulator was replaced. DELCORA continues to use this system and it provides critical information to maintain proper operation of the CSO regulators.

Table 6-2: CSO Regulator Information

CSO Regulator No.	CSO Regulator Location	CSO Receiving Water	Latitude	Longitude	CSO Regulator Type	Regulator Replacement Status
002	Front & Booth	Delaware River	39°49'30"N	75°23'31"W	Brown & Brown	Replaced

026	7th & Penn	Chester Creek	39°50'58"N	75°21'55"W	Brown & Brown	Replaced

CSO Regulator No.	CSO Regulator Location	CSO Receiving Water	Latitude	Longitude	CSO Regulator Type	Regulator Replacement Status
032	2nd & Avenue of the States	Delaware River	39°50'34"N	75°21'25"W	Weir Structure	Removed Mechanisms
033	Elkington Blvd. and Ridley Creek	Ridley Creek	39°52'22"N	75°22'29"W	Weir Structure	See Notes
Notes: - CSO Regulator 010 discharges at Outfall 009. - CSO Regulators 006 ad 007 have been disconnected from CSS and removed from NPDES permit - CSO Regulator 033 has been disconnected from the CSS but had not been removed from NPDES permit at the date of this Report						

As indicated in **Table 6-2**, the majority of the City's CSO regulators are Brown & Brown type regulators. The original CSO regulators were Type B regulators in which the regulator gate position is controlled by the level in the trunk sewer entering the CSO regulator chamber. As part of its regulator replacement program DELCORA is replacing the regulators with Type A regulators in which the gate position is controlled by the level in the interceptor. This allows for the interceptor to operate at full capacity thus maximizing the amount of flow being sent to the WRTP for treatment. Flow that cannot enter the interceptor because it is at capacity, passes over the CSO regulator diversion weir and into the outfall for release to the receiving water.

The updated H&H model includes twenty-six (26) CSO regulators, which were modeled as weirs and orifices. The configuration of CSO regulators was obtained from both record drawings and field surveys.

6.4.7.1 Flow Diversion Structure Components

The key components required for modeling these structures include float-operated gates, orifice plates and diversion weirs. **Table 6-2** lists basic information for each of DELCORA's 26 CSO regulators.

Regulator Gates

Characteristics of the regulator gates were obtained from as-built drawings and field surveys and are discussed in detail in **Appendix K**.

Orifices

Most of the regulators include an orifice between the regulator gate and the downstream interceptor. All orifices in the collection system are side orifice type, rectangular in shape and were assigned a discharge coefficient of 0.65. The dimensions are based on record drawings. The orifices in the updated H&H Model are discussed in Section 4 of this report.

Weirs

Characteristics for the diversion weirs were obtained from record drawings and were field verified as necessary. The characteristics of the weirs is discussed in Section 4 of this LTCPU Report.

6.4.8 Interceptors

The interceptors convey flow from the CSO regulators to the WRTP or to the Chester Pump Station, which discharges directly to the WRTP. The interceptors shown on **Figure 1-4** vary in size from 24" to 72" in diameter. Any flow entering the interceptor system will eventually reach the WRTP for treatment.

Figure 1-6 is a schematic of the Chester CSO system and shows the outfalls and the interceptors that are connected to each CSO. Specifically, as diagrammed in **Figure 1-6**, the relationship between DELCORA's interceptors and outfalls are as follows:

- The Delaware River Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 002, 003, 004, 005 and 007 into the Booth Street Interceptor that then leads to the WRTP.
- The Second Street Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 008, 009, 011 and 024 to the Chester Pump Station, which is then pumped to the WRTP.
- The West End Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Area 010 into the Booth Street Interceptor and then to the WRTP.
- The Ridley Creek Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 012, 013, 014, 015, 016, 017, 018, 032 and 033 to the Chester Pump Station, which pumps the flow to the WRTP.
- The Edgmont Avenue Interceptor conveys dry weather flow and a portion of wet weather flow from CSO Service Areas 021, 022 and 023 into the Ridley Creek Interceptor and from there to the Chester Pump Station and then to the WRTP.
- The Chester Creek East Interceptor and the Chester Creek West Interceptor respectively convey the dry weather flow and a portion of the wet weather flow from CSO Service Areas 019 and 020. These two interceptors then both flow into the Penn Street Interceptor that also conveys the dry weather flow and a portion of wet weather flow from CSO Service Areas 025 and 026 to the Chester Pump Station, which pumps the flow to the WRTP.

6.4.9 CSO Outfalls

Outfalls are the discharge points at the receiving streams. The outfalls can either be free outfalls without any boundary conditions or the outfalls can have a boundary condition that the head needs to overcome for outflow to occur. The outfalls in DELCORA's collection system are mostly in the tidal river reach. Therefore, appropriate tidal stages from NOAA data were used to set boundary conditions. Outfalls can have a flap gate or other backflow device at the end to prevent backflow. The CSO Outfalls are discussed in detail in **Section 4** of this report.

6.4.10 Drainage Areas and Subcatchments

Each of the 26 CSO regulators has a unique drainage area associated with it. A CSO drainage area is defined as the entire surface area contributing overland wet weather flow to a specific CSO. Subcatchments are smaller drainage basins located within the overall CSO drainage area. Subcatchments are more useful when developing a model, because the area is smaller and it becomes more site-specific. Subcatchment boundaries were determined from sewer system maps and local topography. GIS software was then used to estimate the acreage within a subcatchment boundary.

The subcatchment parameters - percent imperviousness, depression storage, and soil infiltration parameters are discussed in **Section 4** of this report.

6.5 Collection System Pump Stations

Major pump stations in the Western Service Area and the Central Delaware Pump Station in the Eastern Service Area were added to the updated model, as well as force mains connecting the pump stations to the WRTP. The pump stations included in the updated H&H Model are as follows:

- Chester PS (CPS)
- Existing PS-1 (EPS-1)
- Marcus Hook PS (MHPS)
- Naamans Creek PS (NCPS)
- Eddystone PS (EDPS)
- Central Delaware PS (CDPS)
- Chester Ridley Creek PS (CRPS)
- Sun Oil PS (Owned by Sunoco) (SPS)
- Kimberly Clark PS (Owned by KC) (KCPS)

The Pump Stations that were excluded from the H&H Model are discussed in **Section 4** of this report.

6.6 Force Mains

DELCORA's Model Area includes the numerous force mains that convey flow from the various pump stations to the WRTP.

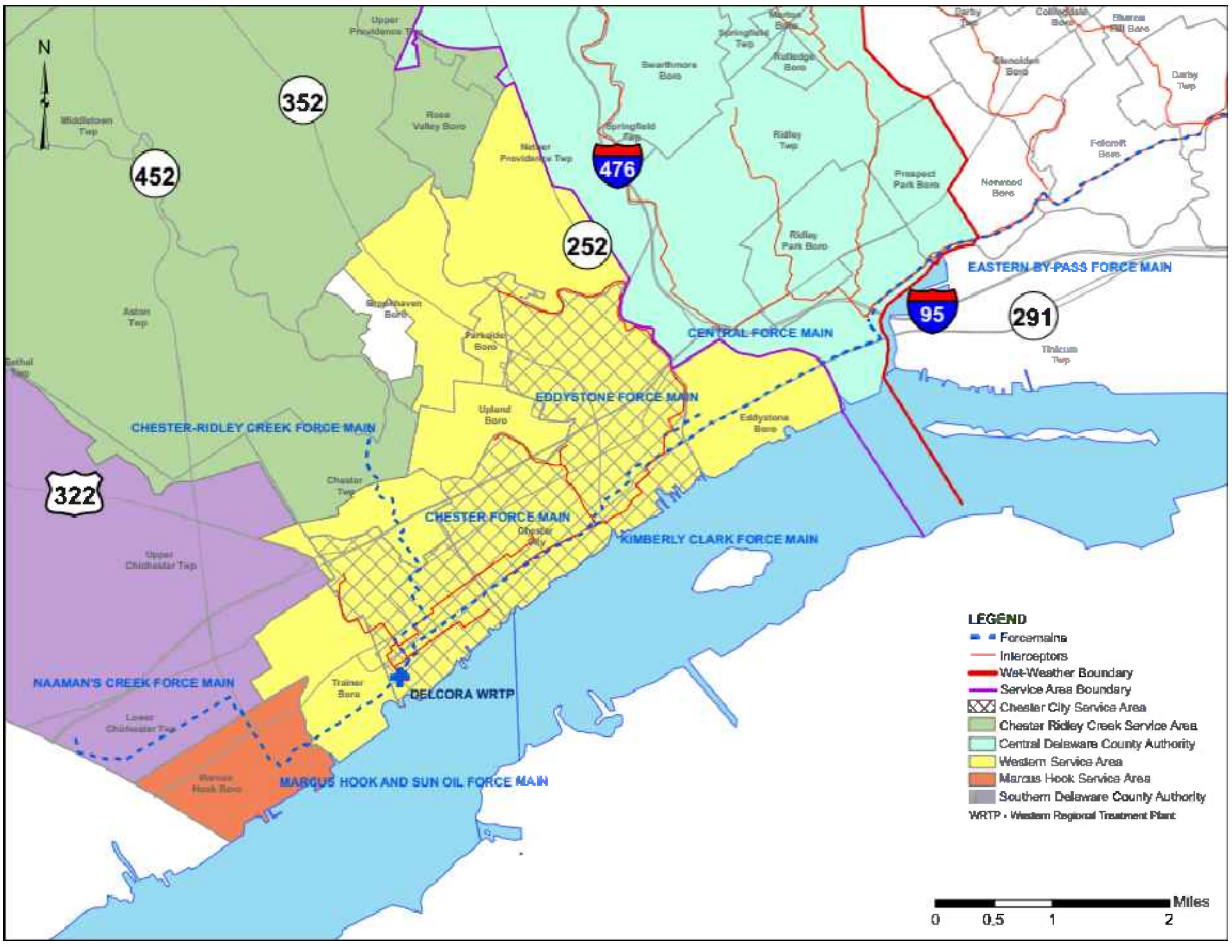
- Chester Force Main
- Central Force Main
- Chester-Ridley Creek Force Main
- Naaman's Creek Force Main
- Marcus Hook/Sun Oil Force Main
- Eddystone Force Main
- Kimberly Clark Force Main
- Existing Pump Station Force Main

The 40-MGD Chester Pump Station discharges to the Chester Force Main which then runs to the WRTP as a 54-inch diameter ductile iron force main.

The Central Delaware Pump Station discharges through two force mains, one of which connects to the Model Area and the WRTP while the other delivers flow to the PWD-SWWPCP. The force main to the Model Area is referred to as the Central Force Main and is a 3.4-mile, 24-inch ductile iron force main which subsequently connects to the Chester Force Main. This connection allows DELCORA to send up to 27 MGD of flow from the CDPS to the WRTP, however, DELCORA's operating policy limits this flow to 20 MGD, with flows above this point to be directed to PWD-SWWPCP. Only the force main connecting to the Model Area is included in the updated H&H model.

A schematic representation showing the force mains can be found in **Figure 1-6**. A map showing the location of the force mains is depicted in **Figure 6-1**.

Figure 6-1: Force Mains



6.7 Flow Monitoring Data Summary

Rainfall Monitoring and Analysis, Dry Weather Flow Analysis, and Wet Weather Flow Analysis can all be found in the Existing Service Area Characterization Report in **Appendix K** and **Appendix T**.

The majority of the flow meters measured flow, level and velocity data for each flow monitoring site at 5-minute interval; other flow meters measured the same parameters in 15 minute intervals. Metering data was analyzed for dry weather flows and wet weather flows for each monitoring site.

The DWF was ultimately used as inputs into the H&H model. Overall annual average DWFs, average monthly DWFs, and weekday and weekend diurnal patterns were input into the model for each flow meter in the combined area. The WWF were used to calibrate the model output. Model data was compared side by side with metered data for each wet weather event for each flow meter.

6.8 Collection of WRTP Operational Data

In addition to flow data collected from the flow meters located in the collection system, flow data from DELCORA's WRTP influent flow meter was obtained for the same time period. A summary of the plant flow data is shown in **Figure 6-2**, **Figure 6-3**, **Figure 6-4**, and **Figure 6-5**.

6.9 Characteristics of the Receiving Waters

6.9.1 Physical Characteristics

The CSS discharges to portions of the Delaware River and two of its tributaries, Chester Creek and Ridley Creek. These receiving waters are located in the tidal portion of the Delaware River Basin, which stretches from the mouth of the Delaware Bay (River Mile 0) to Trenton (River Mile 133.4). The segment of the Delaware River directly impacted by DELCORA's CSO discharges is Zone 4, which extends from River Mile 78.8 to River Mile 95.0 (see **Figure 6-6**). Chester Creek is located at River Mile 82.93 and Ridley Creek at River Mile 83.8. These creeks are tidally influenced tributaries to the Delaware River. For Chester Creek, the tidal portion extends from the mouth of the tributary at Delaware River upstream to Kerlin Street in Chester City while for Ridley Creek, the tidal portion extends from the mouth of the tributary at the Delaware River upstream to MacDade Boulevard in Chester City (Summary Book - 2017 Pennsylvania Fishing Laws & Regulations, http://www.pfbc.pa.gov/fishpub/summaryad/delaware.html) (PFBC, 2017).

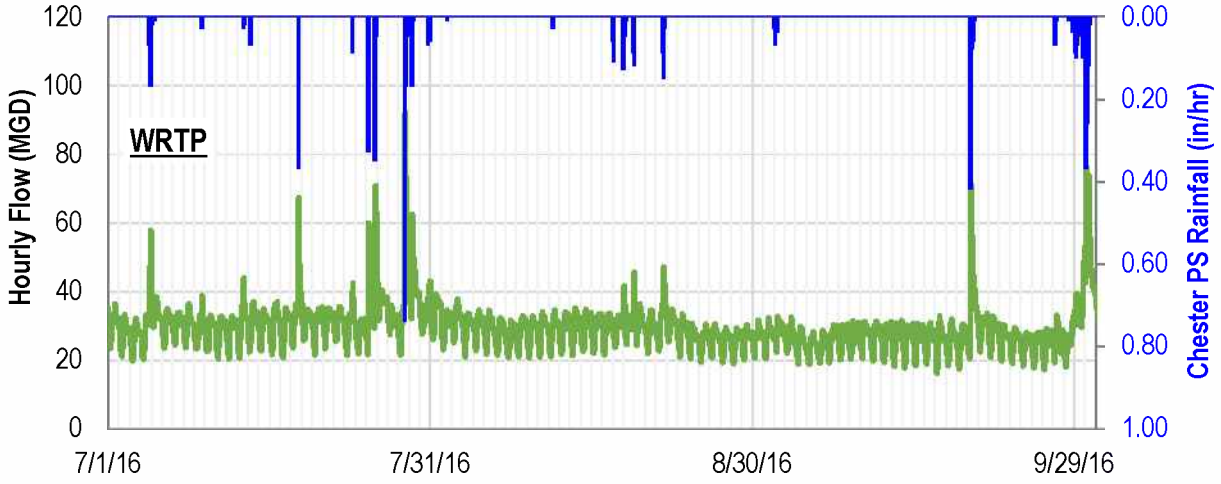

Figure 6-4: DELCORA WRTP Influent Flow (10/16 – 12/16)

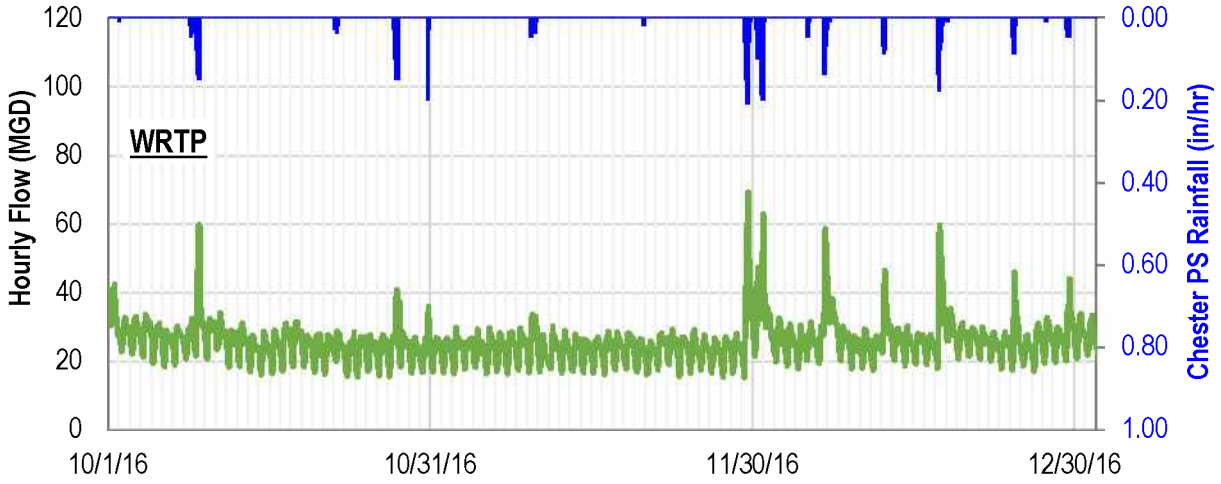

Figure 6-5: DELCORA WRTP Influent Flow (1/17 – 4/17)

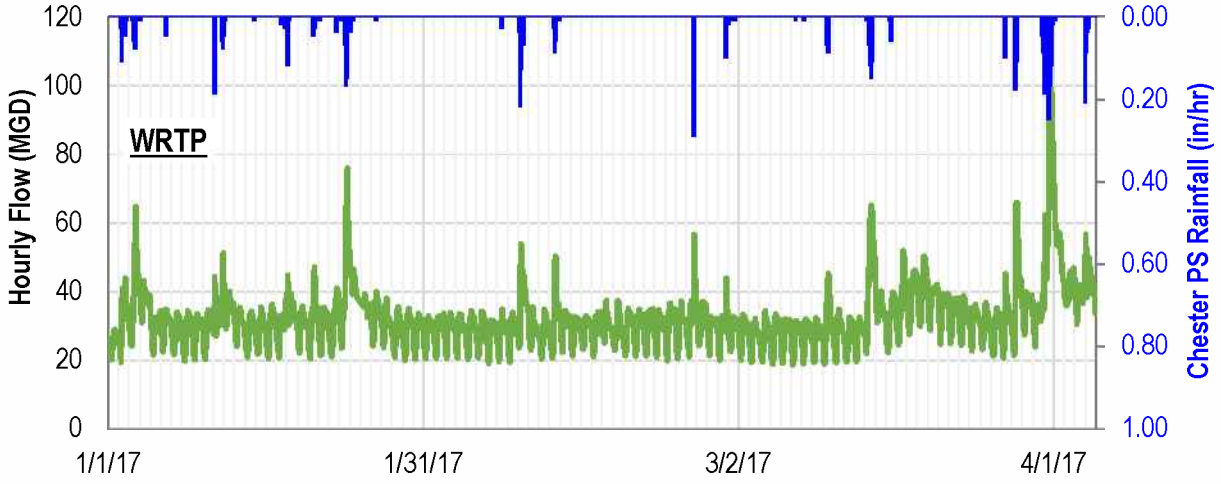

Figure 6-6: Zones of the Delaware River and Bay

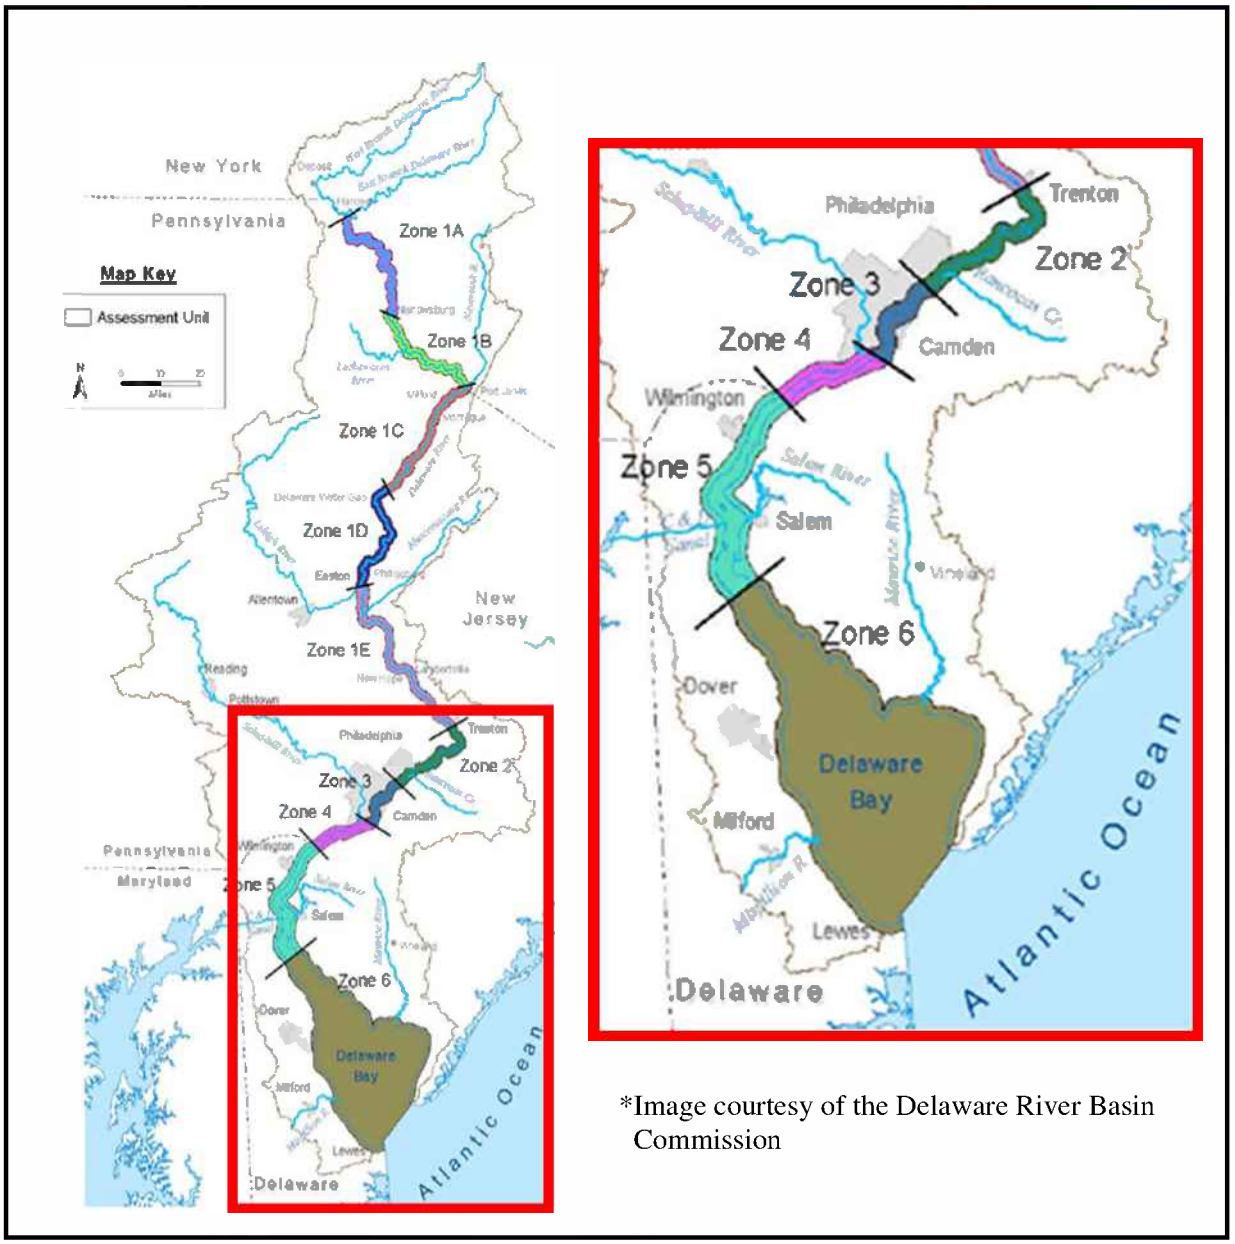

*Image courtesy of the Delaware River Basin Commission

In March 2017, an elevation (bathymetric) survey was conducted by LimnoTech for the lower portions of the Chester and Ridley Creeks. **Figure 6-7** shows the transect locations where elevation measurements were collected. Reaches surveyed included the lower 2.75 miles of Chester Creek and 3.25 miles of Ridley Creek to their discharge into the Delaware River. Transects were collected on ¼-mile interval spacing. Access to the creeks on the upper portions, generally greater than 1 mile upstream, was by wading where the bottom was shallow and firm. The portions below 1 mile were too deep and soft to be accessed on foot and a john boat with tagline was utilized.

Each creek cross section was surveyed at approximately five locations across the bed, water surface, bank toe, and bank top. Access to the entire upland bank at transect locations was not always possible; so the closest points safely accessed to the bank toe were surveyed. Elevation measurements from this survey were compared with similar elevation data from a 1977 Federal Emergency Management Agency Flood Insurance Study of the creeks (FEMA, 2015). To serve as a useful check on the accuracy and sufficiency of the bathymetric survey data.

6.9.2 Watershed Drainage Basins

The Chester Creek and Ridley Creek watersheds extend from the mouth of the tributaries upstream through Delaware County and into Chester County, well beyond the boundaries of DELCORA's Model Area. The extent of the watersheds within Delaware County is illustrated in **Figure 1-1**, along with the boundaries of DELCORA's Model Area.

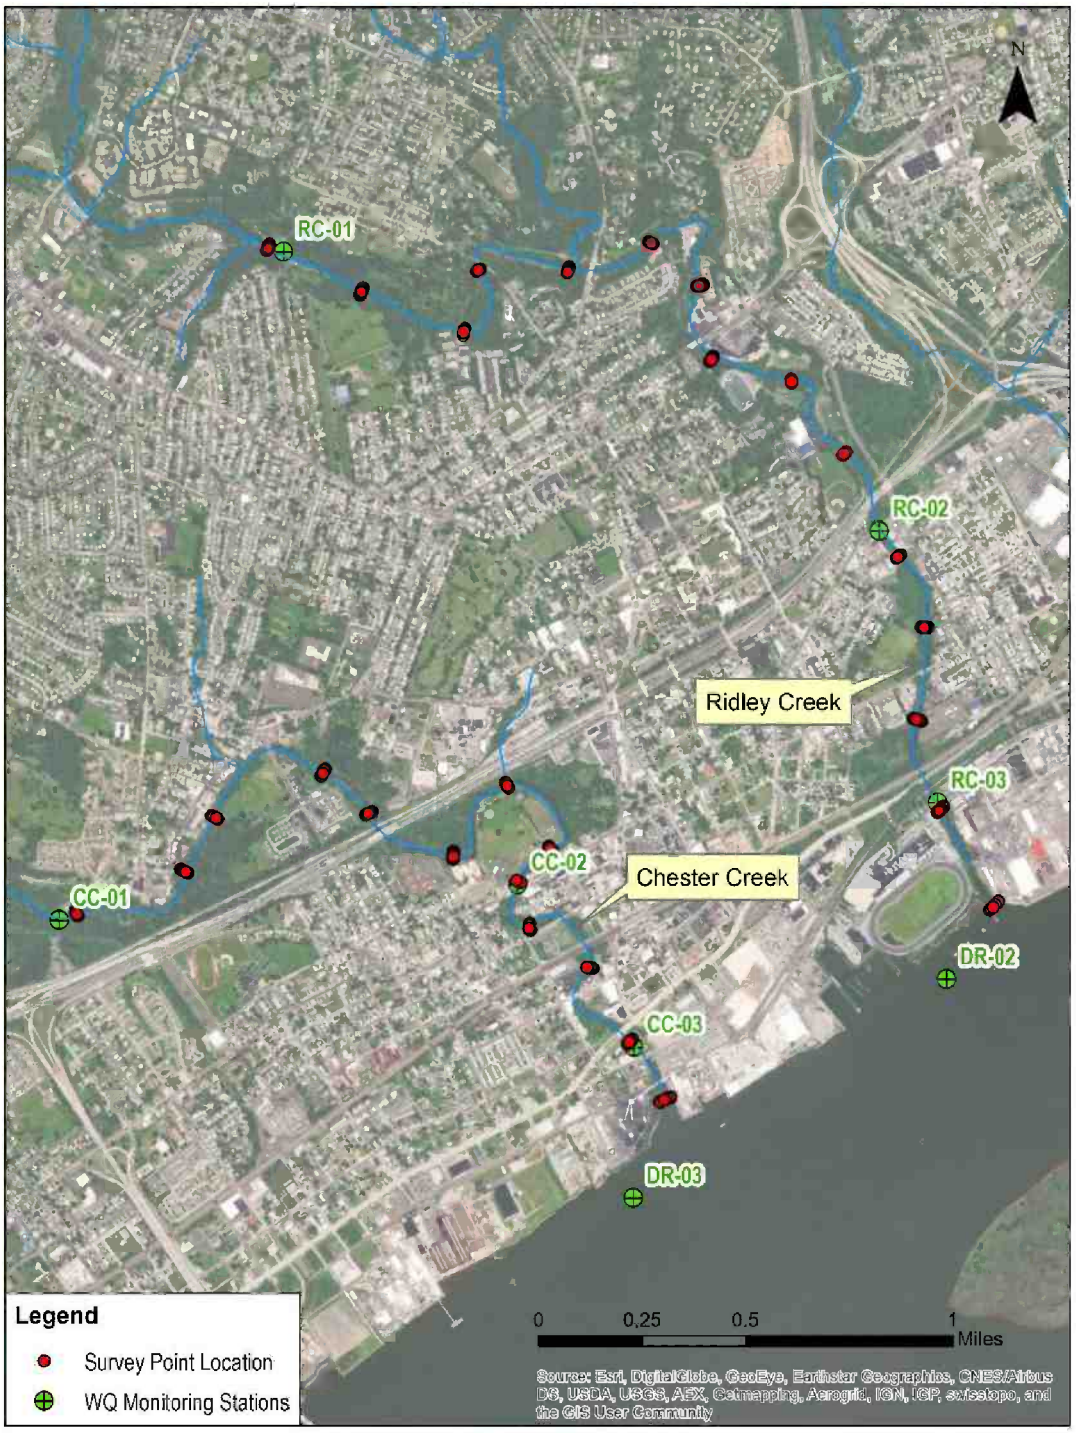
6.9.3 Receiving Water Use Designations and Applicable Water Quality Standards

Information about the water quality standards, the designated uses and the impairment status for the three receiving water bodies impacted by DELCORA's CSOs was obtained from the PADEP's 2014 Integrated Water Quality Monitoring and Assessment Report (or "303(d) list"), the Pennsylvania Code, the Delaware River Basin Commission's (DRBC's) Water Quality Regulations (WQRs) and from the DRBC's 2014 Delaware River and Bay Water Quality Assessment (DRBC, 2014). This information is presented in **Section 2** of this LTCPU.

6.10 Summary of the Identified POCs for each Receiving Water

The determination of the Pollutants of Concern for each of DELCORA's three receiving water bodies occurred as part of the development of the *Identification of Sensitive Areas and Pollutants of Concern Report* and this information was also summarized as part of the *Existing Service Area Characterization Report*. The methodology used for determining the POCs and the POCs that were identified are detailed in **Subsection 2.5** of this LTCPU.

Figure 6-7: Locations of Elevation Measurements in Chester and Ridley Creeks



6.11 Summary of Sensitive and Priority Areas

The determination of the Sensitive Areas for DELCORA's receiving water bodies occurred in the development of the *Identification of Sensitive Areas and Pollutants of Concern Report,* and this information was also summarized as part of the *Existing Service Area Characterization Report*. The methodology used and the identified Sensitive Areas are detailed in **Subsection 2.3** of this LTCPU report.

6.12 Collection of Water Quality Data

The *Existing Service Area Characterization Report* included information about DELCORA's Water Quality Monitoring Program and included water quality data collected from DELCORA's CSO discharges, storm water discharges, and from the three receiving waters. This information is presented within this LTCPU report within **Section 5 - Water Quality Monitoring and Modeling**.

6.13 Typical Hydrologic Period

The *Existing Service Area Characterization Report* included information describing DELCORA's statistical evaluation of long-term local rainfall patterns and the identification of an appropriate Typical Hydrologic Period for LTCPU development purposes. This information had been summarized from the previously submitted *Typical Hydrologic Period Report* (Greeley and Hansen, 2016a), which was approved by PADEP and USEPA on May 23, 2016. The details of the determination of the Typical Hydrologic Period (1994 through 1996) are presented within this report in **Section 3 - Typical Hydrologic Period**.

6.14 Hydrologic and Hydraulic Modeling

The *Existing Service Area Characterization Report* also included information describing the development and application of the Hydrologic and Hydraulic Model for DELCORA's combined sewer system, which was used to help identify and evaluate the range of potential water pollution/control alternatives. Information regarding the development and application of the H&H Model is presented within this report in **Section 4 - Sewer System Hydrologic and Hydraulic Model Update and Calibration**.

The Sewer System Hydrologic and Hydraulic (H&H) Model Report was submitted to USEPA and PADEP on June 30, 2017, as was approved on April 17, 2018 after DELCORA responded to comments received on January 2, 2018. The approved report is included in **Appendix F**. It is to be noted that the H&H model was updated and recalibrated after the June 2017 submission as a result of receiving additional monitoring data, pump station operation data, and sewer system characteristics data. The H&H Model Calibration and Validation Results (updated July 2018) are provided in **Appendix T**. The baseline number of overflows by regulator and regulator overflow volumes predicted by the final version of the H&H model used for this LTCPU are summarized in **Table 9-3** and **Table 9-4**, respectively.

THIS PAGE INTENTIONALLY LEFT BLANK

Section 7 Public Participation

DELCORA's Public Participation Plan (PPP) was developed to employ an on-going public participation process that actively involves the public by informing and soliciting input from stakeholders, including the public, customer communities and regulatory agencies as the LTCPU is developed and implemented and to meet the requirements of the USEPA's CSO Policy and DELCORA's Consent Decree.

7.1 Expectations of the CSO Policy

The goals of the PPP during the development of the CSO LTCPU included addressing the specific requirements of the United States Environmental Protection Agency Combined Sewer Overflow Control Policy (dated April 19, 1994) by:

> *"employing a process that actively involves the affected public in the decision-making to select the long-term CSO controls. The affected public includes rate payers, industrial users of the sewer system, persons who reside downstream from the CSOs, persons who use and enjoy these downstream waters, and any other interested persons."*

Additionally, in accordance with Section V.A.17 of the Consent Decree between the United States of America, the Commonwealth of Pennsylvania, Department of Environmental Protection, and DELCORA, (lodged on August 17, 2015) the PPP "*shall describe in detail how DELCORA will inform and solicit input to its updated LTCP from stakeholders, including the public, customer communities and the regulatory agencies. The plan shall specifically describe how the LTCP update process will:*

> *(i) address the impact of DELCORA's CSOs and LTCP on environmental justice populations,*
> *(ii) seek input from communities that may have historically borne a disproportionate share of the negative environmental consequences resulting from DELCORA's CSOs, and*
> *(iii) ensure that the LTCP and selected CSO Control Measures will not impose a disproportionate share of negative environmental consequences on such communities in the future.*
>
> *The plan shall also include a schedule for DELCORA's implementation of the plan."*

The USEPA's *Combined Sewer Overflows Guidance for Long-Term Control Plan* indicates that public participation and Agency interactions should occur at the following steps of the LTCP development process:

1. System Characterization
2. Development and Evaluation of Alternatives for CSO Controls
3. Selection and Implementation of the Long-Term Plan

The PPP has been developed to actively involve the affected public in each of the above steps via Public Participation Meetings and other methods as further described in the herein and in the PPP. In addition to these minimum requirements, one additional Public Participation Meeting will be considered prior to the required meetings (listed above) to inform the public early in the planning process about the scope and goals of the program.

The PPP was implemented to address the above requirements of the CSO Control Policy, Section V.A.17 of the Consent Decree, and the USEPA's CSO Guidance for LTCP Document. DELCORA submitted the PPP to the USEPA and PADEP on October 21, 2015, within three months of the lodging of the Consent Decree meeting the first step of the Consent Decree Public Participation requirements. The final PPP was approved by the USEPA and PADEP on April 28, 2016 and is included in **Appendix L** of this report.

7.2 Public Meetings and Engagement Tools

The main objective of the public meetings and the engagement tools that were implemented under the PPP was to foster public awareness and actively facilitate public involvement by taking into consideration public input during the decision making process and selection of the final long term CSO controls. Public engagement was encouraged and accomplished during each public meeting by incorporating a Questions and Answer session at the end of every meeting.

7.3 Meeting Schedule

Public meetings were held over the course of the LTCPU development effort to inform and actively solicit input to its LTCPU from stakeholders, including the public, customer communities, and the regulatory agencies. The LTCPU meeting subject and actual meeting dates are noted in **Table 7-1**.

7.3.1 Inputs During the Public Participation Process

Four public meetings were planned and implemented at different steps in the development of the DELCORA CSO LTCPU as recommended by the CSO Guidance Document. In summary, the Public Participation Meetings that were held are as noted in **Table 7-1** below including the meeting dates, topic and location:

Table 7-1: Public Meetings, Locations and Meeting Dates

Meeting No	Meeting Topic	Location	Meeting Dates
Meeting No. 1	Scope and Purpose of the Study	Chester City Hall	March 15, 2016
Meeting No. 2	System Characterization	Ridley Township Municipal Building	June 27, 2017
Meeting No. 3	Development and Evaluation of Alternatives for CSO Controls	Chester City Hall	December 5, 2017
Meeting No. 4	Selection and Implementation of the Long-Term Plan	Aston Township Administration Building	September 26, 2018

The location of the each meeting was different to provide opportunities throughout the DELCORA Service area for residents to attend.

7.3.2 Facilities Description and Location

The public meetings were held at different locations in order to maximize the likelihood of attendance and participation from the residents and stakeholders with in the service area. The facilities were checked ahead of time and had ample meeting space. These locations serve a vital role in Delaware County as

central meeting places and serve as gathering places for the local community as well as for the hosting of numerous public events, including public information meetings.

7.3.3 Responsiveness Summary

Each public meeting provided an opportunity for the public to be activity involved in the decision – making process to select the LTCPU CSO controls. By informing the public early in the planning process about the scope and goals of the program and continuing public involvement conflicts could be identified and address more expeditiously. Each Public Meeting included a presentation of status of the LTCPU and an update from the previous meeting. Questions from the public were taken during the presentation and at the end of the presentation for each meeting. Responses to each comment or question was provided during the meetings. A 30-day period after each meeting was allowed for questions and comments to be mailed to DELCORA.

At the beginning of each meeting a Public Comment Form was handed out to attendees allowing them to submit questions or comments in writing. Comment Forms could be handed in at the end of the meeting or mailed to DELCORA. After each Public Meeting a Responsiveness Summary was prepared to memorialize all comments; statements and questions raised by the public during the meeting.

A final copy of the Meeting presentation and responsiveness summary was placed on DELCORA's CSO LTCPU website. In addition, the responsiveness summary was also made available at each offline repository location.

7.3.4 Public Engagement Tools

The public engagement program was developed in collaboration with DELCORA and the Engineering and Program Management Consultant. This program included multiple tools nested in primarily the two following strategies:

1. Direct Engagement Strategy: This strategy was implemented at the Public Meetings, as well as the Stakeholder Meetings, and addressed the complex issues of the LTCPU program by providing an opportunity for public participation that is active, interactive, and encourages people to provide ideas and comments and continue to learn about DELCORA's CSO LTCPU program and its objectives. Poster boards were displayed at each meeting to encourage discussion during the presentation for a better understanding of the DELCORA system.

2. Digital Engagement Strategy: This strategy actively engaged the public in providing feedback and comments through the use of digital technology on the DELCORA CSO Website.

The two strategies listed above are detailed further in the approved PPP.

7.3.5 Public Meeting Descriptions

Four public engagement meetings were held over the duration of 42 months of the development of the updated Long-Term Control Plan Update. Meetings were developed to sync with the needs on the development of the LTCPU and informing those that are affected by the strategies implemented for the selection of CSO control alternatives. Each public meeting consisted of a presentation to the public that

included elements of the following topics suggested by the USEPA's *Combined Sewer Overflows Guidance for Long-Term Control Plan*:

1. System Characterization
2. Development and Evaluation of Alternatives for CSO Controls
3. Selection and Implementation of the Long-Term Control Plan

At each public meeting copies of the meeting presentation were made available as a handout to the public in attendance. The public meeting presentations were provided as requested to other listed stakeholders (as discussed in Section 3) and posted on the website. Meeting notes were drafted after each public meeting memorializing the proceedings and public questions. See **Appendix M** for Public Meeting Nos. 1, 2, 3 and 4 meeting notes, sign-in sheet, presentation and list of public comments with responses.

The first public meeting was used to brief the public on the history, scope and purpose of the study and to obtain their general views on the study. At this meeting a general presentation with information on DELCORA and its CSO LTCPU program was given to the public.

The second public meeting focused on updating the public on the scope of activities that make up the system characterization, the analysis of existing data and development of the monitoring and modeling programs, the identification and status of implementation of the Nine Minimum Controls, and the process for evaluating alternative CSO controls. **Figure 7-1** provides a photograph of the 2nd Public Meeting. DELCORA and the Engineering and Program Management Consultant provided a Powerpoint presentation with hand-outs to the public for the following information:

- Scope of monitoring and assessment programs for system characterization
- The watershed approach to CSO control planning
- Identification of watersheds in the CSO area
- Identification and quantification of non-CSO sources
- Existing sewer system conditions and problems (e.g., flooding, basement backups)
- Quantification of CSO flows and loads and impacts of CSOs on receiving waters
- Results of CSS and receiving water monitoring programs
- Development and calibration of the CSS and receiving water models
- Identification and implementation status of the NMC
- Process for evaluating CSO control alternatives

There were approximately 7 individuals from the public in attendance for the 2nd Public Meeting. During the second public meeting a question was asked relating to CSOs near the Flower Street Boat Ramp located in Chester near the new Soccer Stadium. DELCORA considered and has addressed this concern through a selection of alternatives that will provide significate CSOs reduction at each regulator upstream and downstream of the boat ramp area.

Figure 7-1: Photographs of Public Meeting Nos. 2 and 3

The goals of the third public meeting was to actively involve the public in the development of the alternative solutions to protect the receiving streams, as well as to consider the financial impacts to the community as a whole. Any suggestions, comments and financial impacts to the community were considered. **Figure 7-1** provides a photograph of the 3rd Public Meeting. The following key information was presented to the public during this meeting:

- Water quality goals for each receiving water segment
- CSO control goals for each receiving water segment as developed under the Presumption and/or Demonstration approach options
- Types of control alternatives available to meet CSO control goals
- CSO control alternatives identified to meet the control goals
- Process of evaluating and comparing various alternatives for CSO control

During the CSO control measures evaluation stage, alternative measures to reduce the impact of CSO discharges typically fall into one of the following four categories:

1. Source Control Technologies/Alternatives - eliminating or preventing pollution before it is created.
2. Collection System Control Reducing Technologies/Alternatives – reducing the discharge volume, concentration, or frequency.
3. Storage Technologies/Alternatives - capturing all or some of the discharge and then releasing it for treatment.
4. Treatment Technologies/Alternatives - treating as much as possible.

As part of the 3rd public meeting participation process, various CSO control measures investigated through engineering analysis were presented by the LTCPU Engineering Consultant and DELCORA. Some of the major CSO mitigation measures that were considered are listed below:

- Capacity Recovery in the existing CSS
- CSO Regulator Improvement Program
- Sewer System Cleaning/Flushing to avoid backups

- Sewer/ CSO Regulator replacement
- Tide Gate Maintenance or replacement
- Reduction of fats, oil and grease (FOG) in the sewers
- Outfall Maintenance Program;
- Private Property Inflow and Infiltration Elimination
- Outfall Combined Wastewater Diversion and Separation
- Outfall Consolidation, Relocation, or Elimination
- Additional Conveyance Systems
- Inlet Replacement Program
- Downspout Disconnect Program

There were approximately 35 individuals from the public in attendance for the 3rd Public Meeting. A major focus of the public concern, questions and discussion for the third public meeting revolved around the Chester Stormwater Authority. Many individuals at the meeting were concerned that a new Chester Stormwater Authority was formed imposing a separate stormwater fee on the resident of Chester. However they saw this authority as a duplication of effort of DELCORA responsibility. The City of Chester was present and the city engineer clarified the responsibility of the City of Chester relating to the Municipality MS4 area of Chester.

The fourth public meeting was held to discuss and present progress on the development and selection of the alternatives for implementation of the Long-Term Plan Update. The alternatives were evaluated in detail and prior to selection of specific CSO controls. The fourth meeting was held to inform the public of each CSO control alternative and ranking based on Knee-of-the-Curve (KOC) analysis. **Figure 7-2** provides photographs of the 4th Public Meeting. The fourth Public was originally advertised as starting at 6:00 however the start time had to be adjusted to 5:00 PM. The following key informational items were presented to the public during the 4th Public Meeting:

- LTCPU Completed Early Action Items and System Improvements to Date
- Review of National CSO Policy Requirements for the Alternative Analysis
- LTCPU Alternative Analysis
- "Knee-of-the-Curve" Analysis and the Recommended Plan for the Selected Alternative
- LTCPU Implementation Schedule and Milestones

There were no individuals from the public in attendance for the 4th Public Meeting. However there were two consultants that arrived after meeting adjournment. They indicated that the LTCPU website showed that the meeting started at 6:00 PM. DELCORA met separately with the two consultants on November 1, 2018 and provided a hardcopy of the Public Meeting No. 4 presentation and handout materials and reviewed the materials with them. They had no questions or feedback that would influence the LTCPU. They signed the meeting sign-in sheet, see Appendix M.

A Public Briefing Document was posted on the website and delivered to the repositories 2 weeks before the 4th Public Meeting. The Public Briefing Document summarized the DELCORA Recommended Long-Term Control Plan to address Combined Sewer Overflows in Chester, Pennsylvania where necessary. Also covered in the summary were the following key issues: (1) an overview of the DELCORA System and Wet Weather Issues, (2) a summary of progress to date, (3) response to public comments to date, (4)

review of sensitive areas, (5) the range of alternatives considered, (6) DELCORA's recommended overflow control plan, (7) the implementation schedule and, (8) post construction monitoring of the overflow control program.

Figure 7-2: Photographs of Public Meeting No. 4

7.3.6 Meeting Advertisements

To meet the requirements of Pennsylvania's Sunshine Act (see the PPP in **Appendix L**), DELCORA provided public notice of its meetings not less than three days in advance of the meeting and gave the schedule for each of the remaining meetings during the first meeting presentation.

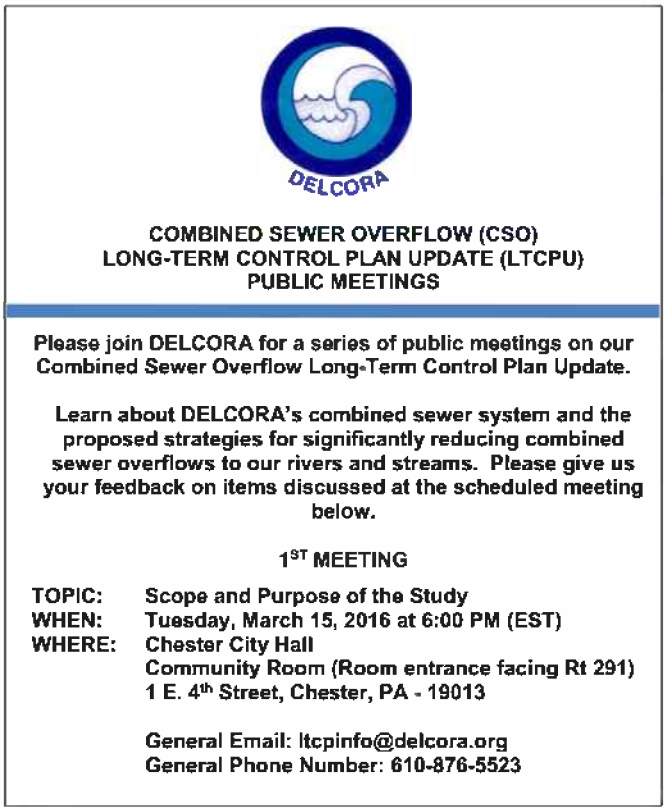
In accordance with the Sunshine Act, DELCORA invited the public to participate in the LTCPU meetings by placing an advertisement indicating place, date and time in the following four local newspapers or circulations and by also posting the notice on DELCORA's CSO LTCPU website in advance.

1. Chester Spirit
2. Delaware County Daily Times
3. Philadelphia Inquirer
4. Press Newspaper

Figure 7-3 presents an example of the LTCPU public meeting advertisement. This notice was for the first LTCPU Public Meeting. The other public meeting advertisements were similar.

DELCORA also provided public notice of any special meeting or rescheduled meeting at least 24 hours in advance of the time of the convening of the meeting specified in the notice.

Figure 7-3: Advertisement for the First Public Meeting



7.4 Stakeholder Members and Meetings

In addition to the Public Meetings and Engagement Tools described in **Subsection 7.2**, a group comprising of stakeholder members were formed for this PPP.

7.4.1 Selection of Members

To reflect a balance of perspectives, stakeholder members consisted of representatives from the public, customer communities, regulatory agencies, and special interest groups. The list of stakeholders considered by DELCORA is provided below.

1. Darby Creek Joint Authority
2. Central Delaware County Authority
3. Muckinipates Authority
4. Delaware River Basin Commission
5. Radnor, Haverford, Marple Authority
6. Southern Delaware County Authority
7. Southwest Delaware County Municipal Authority
8. Middletown Township Sewer Authority
9. Chester Environmental Partnership

10. Department of Environmental Protection - Southeast Regional Office
11. Delaware County Planning Department
12. State Elected Officials
13. Local Municipal Officials
14. National Association for the Advancement of Colored People (NAACP)
15. Chester City Council
16. Pennsylvania Resource Council
17. Chester, Ridley & Crum Creek Watershed Association
18. Chester Water Authority (CWA)
19. Delaware County Public Relations Department
20. Delaware Riverkeeper
21. PA Sea Grant
22. Delaware County Council
23. Delaware County Chamber of Commerce
24. Industrial Contributors
25. Chester Business Association
26. Chester Economic Development Authority
27. Stormwater Authority of Chester
28. Chester Stormwater Authority

7.4.2 Meeting Site Format and Time

Stakeholder Meetings convened in a meeting room at a predetermined and mutually agreed upon location. The location of the meetings were coordinated with the Stakeholder members. Some of these meetings were held at DELCORA's Western Regional Treatment Plant and at the DELCORA Municipal Building. DELCORA chaired each meeting and provided an update on the progress and status of current issues regarding the development of the LTCPU. Regular stakeholder meetings were held on an as-needed basis throughout the course of the LTCPU program. Some of the Stakeholders meetings that were held during 2015 and 2016 are listed in **Table 7-2** below:

Table 7-2: Stakeholders Meetings and Meeting Dates

Meeting Dates	Meeting Topic	Goal
September 24, 2015	Combined Sewer Overflow – Long Term Control Plan Update	Review requirements of new Consent Decree
March 8, 2016	Combined Sewer Overflow – Long Term Control Plan Update	Review of progress of the LTCPU

DELCORA has provided the stakeholders an active role and opportunity to provide comments at each meeting by encouraging questions and comments during each meeting and a questions and answer session at the end of each meeting. The stakeholders were able to receive updates of the LTCPU project by reviewing the DELCORA Website which posted project updates, USEPA / PADEP approved project reports and information. The CSO Website was noted at the end of each presentation. Educational material was also provided at meetings and reviewed during the meetings.

7.5 Public Information Plan

7.5.1 Notices and Advertisements

To encourage public awareness of, and involvement in the public meetings, notifications and background information was be made available to the public at least three days prior to each meeting as required by Pennsylvania's Sunshine Act. Access to public information will be provided as required by the Pennsylvania Right-to-Know Law Act 3 of 2008 (provided in the PPP).

Announcements were communicated to the public through the following media devices:

- Local Newspapers
- Internet Websites
- Notice by Mail

7.5.2 Public Education and Involvement

A concerted effort was made to make the public aware of the CSO LTCPU development process and to actively involve and educate them about CSO issues through the following media:

1. DELCORA Provided Updates and Educational Material in Sewer Bills

2. CSO Website: DELCORA created a special section of its Internet website devoted exclusively to CSO issues. This section of the website is called "Combined Sewer System". The website includes information on the nature of CSOs, maps showing the location of outfalls, descriptions of the LTCPU development process, CSO monitoring results, information on pollution prevention, ways in which the public can get involved, previous meeting responsiveness summaries, and an option to post comments or questions on the program. Notices for public meetings were also posted on the website. The website provided a means to sign up to receive any newsletters. A downloadable copy of the newsletter was uploaded to the CSO website as well.

3. CSO Newsletters Project updates have been sent out to the mailing list created through the first public meeting, as well as subsequent requests from the public and interested stakeholders.

4. Handouts

5. Literature and Documentation: Literature and documentation were also made available by DELCORA at the repository locations listed below. Documents on display for the public and included in the repositories included presentations, public meeting notes, billing insert newsletters, DELCORA's educational materials and documents that were distributed at the public meeting and reports that had received final approval from the USEPA and the PADEP. These can be found in **Appendix M.** Each repository included a Chain of Custody Form with a description of articles which were delivered to each repository.

Figure 7-4 shows an example of a chain of custody sheet for the J. Lewis Crozer Library. This custody sheet indicates the name, title and address of the authorized person from whom the documents could be received and the authorized person to receive. Each binder delivered had a unique binder number to be able to track and account for all documents delivered. Each binder also included a sign-in sheet which allows all those reviewing the DELCORA LTCPU documents to sign up for additional information. All of the documents which were posted in the repository binders were also made available on the DELCORA Web site.

6. Presentations to Stakeholder Members

7.6 Public Participation Program Other Meetings

In addition to the above stated Public Participation Meetings, DELCORA has maintained a working relationship with the municipalities and authorities in its service area, and has made efforts to coordinate any improvements to the LTCPU with them. Most notably is the City of Chester, where the Combined Sewer System CSO outfalls are located. Chester City wanted to do more regarding stormwater runoff, and developed the Stormwater Authority of Chester (also known as SAC) to coordinate these efforts with DELCORA, especially in the combined sewer areas. Chester City also hired a sub consultant, Corvias, to develop green infrastructure in the areas of the city where DELCORA could use the technology most. These entities have also held public meetings to gather public feedback and are able to communicate effectively with DELCORA in any areas of mutual concern. The support of these entities is instrumental to incorporating the LTCPU effectively.

Section 8 Preliminary Screening of CSO Control Technologies

8.1 Introduction

This section describes how DELCORA assessed the technical feasibility of the use of a wide range of demonstrated CSO Control Technologies to address the requirements of the Consent Decree, which states the following according to Paragraph V.A.19.a (Screening of Available CSO Control Technologies):

> *"DELCORA shall assess the technical feasibility of the use of a wide range of demonstrated CSO control technologies. DELCORA shall provide descriptions of the following types of CSO control technology – Source Controls, Collection System Controls, Storage Technologies and Treatment Technologies – and an assessment of the feasibility of applying each technology type for long-term CSO control in the Model Area, based on existing and anticipated future conditions affecting the Model Area. This evaluation is not intended to consider cost or cost effectiveness, but rather to exclude control technologies that are not technically or physically applicable to the Model Area. Partial and complete separation of sewers in each CSO Outfall tributary area, and deep tunnel storage, shall be considered feasible technologies for this purpose and be carried forward for further evaluation. Expansion of the primary and secondary capacity of the WRTP shall also be considered feasible technologies for this purpose and be forward for further evaluation, as required by Section II.C.4 of the CSO Control Policy".*

A range of CSO Control Technologies has been identified and categorized into four categories: Source Controls, Collection System Controls, Storage Technologies, and Treatment Technologies. The Technologies were then assessed for their impact on reducing bacterial and volume loading from CSO outfalls. Any technology thought to be a significant contributor to either of these requirements was recommended for further evaluation. The Consent Decree lists required Technologies for evaluation, and includes sewer separation, tunnels, plant expansion, and green infrastructure. Appropriate combinations of these technologies have been determined in the Alternatives Evaluation to meet the requirements of the Consent Decree, which states the following (Paragraph V.A.19):

> *"DELCORA shall carry out and include in the LTCP an Alternatives Evaluation that complies with the requirements of the CSO Control Policy Section II.C.4, and that is consistent with EPA's "Guidance for Long-Term Control Plan," EPA 832-B-95-002,September 1995. The Alternatives Evaluation shall consist of: (1) a technology screening process, (2) a detailed evaluation of specific CSO control alternatives, and (3) selection of an appropriate range of proposed CSO controls to achieve compliance with the Clean Water Act. DELCORA shall specifically evaluate the feasibility of eliminating or relocating all CSO Outfalls that discharge to Sensitive Areas. DELCORA shall give a high priority to the control of those CSO Outfalls that discharge to Priority Areas, and those that have the highest frequency or greatest volume of discharge of wastewater."*

8.2 Long Term Control Plan Approach

USEPA CSO control guidance calls for the identification of alternatives through brainstorming, preliminary screening of alternatives, and the selection of alternatives for further evaluation. As discussed above, the Consent Decree also requires the evaluation of specific technologies. In addition to the specific technologies called for in the Consent Decree, alternative technologies are developed and screened and brainstormed alternatives are developed and evaluated as called for in Subsection 3.3.1.3 of the CSO Guidance Document (Creative Thinking):

> *"The initial identification of alternatives should involve some degree of brainstorming and free thinking. CSO control can be a challenging problem, where lack of available sites, potential impacts on sensitive receptors, and stringent water quality goals are common issues. The CSO Control Policy encourages 'Permittees and permitting authorities...to consider innovative and alternative approaches and technologies that achieve the objectives of this policy and the CWA.'"*

Subsection 1.1.3 (Regulatory Requirements) of this report describes that the Presumption approach will be used for the development of the LTCPU. The criteria being used in this analysis is achieving the 85% capture by volume. This will be met by looking at two different approaches: the Consent Decree requirements and a more targeted CSO specific approach.

With regard to the Consent Decree requirements, as previously stated, Paragraph V.A.19.a (Screening of Available CSO Control Technologies) describes the overall Control Technologies to be analyzed, which consist of partial and complete separation of sewers in each CSO Outfall tributary area, deep tunnel storage, green infrastructure, and expansion of the primary and secondary capacity of the WRTP. This essentially is a more global approach to analyzing Alternatives as opposed to a more targeted approach, which looks at specific CSOs based on number of overflows and pollutant loading. The targeted CSO specific approach is designed to get to 85% overall capture by volume, whereas the global approach may obtain a higher percent volume capture and overshoot the targeted 85%, thereby making it less cost effective. These two approaches will be looked at further in **Subsection 9.3.1** and **9.3.2**. For the purposes of the preliminary siting of Control Alternatives being discussed in this Section, the specific approach being utilized going forward in the Analysis does not impact this exercise.

8.3 Water Quality and CSO Control Goals

With respect to water quality, control technologies are screened for their effectiveness on addressing the pollutants of concern and CSO control goals to achieve compliance with the CWA, including:

- Reducing the count of fecal coliform colonies
- Reducing the count of Enterococcus colonies
- Reducing the count of Escherichia coli colonies
- CSO discharge volume reduction.

The bacteria above have been identified as POCS and .exceeding the maximum water quality standards and **Table** 8-1 contains the concentrations approved by the USEPA in the *Identification of Sensitive Areas and Pollutants of Concern Report* (Greeley and Hansen, 2016).

Table 8-1: Water Quality Standards in the Receiving Streams

Pollutant of Concern	Protected Water Use	Primary Contact	Secondary Contact
Fecal Coliform	200/400/200 #/100 mL[1]	200 #/100 mL	770 #/100 mL
Enterococcus	---	33 #/100 mL	88 #/100 mL
E. Coli	126/410 #/100 mL[2]	126/410 #/100 mL[2]	---

[1] First value is a geometric mean standard, second is a statistical threshold value standard (no more than 10% of concentrations can be above this value), third value is a non-recreational season standard (Oct 1- Apr 31).
[2] E. coli standards likely to be codified by PADEP 12-24 months from July 2017. These criteria would apply to the non-tidal tributaries and Delaware River below R.H. 81.8., during recreational months only (May 1 - Sep 30). First value is a geometric mean standard, second is a statistical threshold value standard (no more than 10% of concentrations can be above this value).

For addressing the CSO discharge volume reduction, **Table 8-2** presents the baseline existing percent system wide capture during wet weather events by the receiving waterbody, based on EPA-SWMM modeling of regulator overflows.

Table 8-2: Existing Conditions Percent Capture

Percent Capture by Segment			Total Percent Capture
Delaware River	Ridley Creek	Chester Creek	
81.7%	74.5%	89.5%	82.3%

An arbitrary example of the discharge volumes necessary to achieve 85% overall capture was generated from the EPA-SWMM baseline model. These values are presented in **Table 8-3** below. These volume capture amounts can be adjusted by segment to get an end calculation of 85% overall volume capture. The sum if these values is the average amount of overflow that must be captured during wet weather events per year to meet 85% system wide capture. A more in-depth analysis with regard to these capture goals is presented in Section 9 of this LTCPU.

Table 8-3: Capture Goals for LTCPU Compliance – Percent Capture

Target Capture Volume by Segment (MG)			Total Percent Capture
Delaware River	Ridley Creek	Chester Creek	
21.23	7.79	6.51	85.0%

The goals above serve as an initial roadmap to look at how to narrow down to the best Control Technologies for utilization during the Alternatives Analysis. The following subsection describes the process by which the preliminary screening of CSO Control Technologies was completed.

8.4 Development of CSO Control Technologies

To determine the appropriate CSO Control Technologies, a preliminary comprehensive review of combined sewer overflow technologies was completed in order to determine those that have the greatest potential to help DELCORA meet the requirements of the USEPA Consent Decree. Per the DELCORA Consent Decree, DELCORA shall carry out and include in the LTCPU an Alternative Evaluation that complies with the requirements of the CSO Control Policy Section II.C.4 and that is consistent with the USEPA's "Guidance for Long-Term Control Plan." The Alternatives Evaluation will consist of:

- Technology screening process
- Evaluation of specific CSO Control Alternatives
- Selection of a range of CSO controls to achieve CWA compliance

The evaluation does not consider cost or cost effectiveness and is only meant to exclude CSO Control Technologies that are not technically or physically applicable to the Model Area. The results of this screening have brought several CSO Control Technologies forward for more detailed consideration in the final Evaluation and Selection of CSO Control Alternatives.

8.4.1 Evaluation Methodology Used for This Study

The CSO Control Technologies evaluated have been assigned a value based on their effectiveness at reaching primary and secondary CSO control goals. Descriptions of the goal effectiveness categories are detailed below:

- High: The CSO Control Technology will have a significant impact on this CSO control goal and is among the best technologies available to achieve that goal. These technologies may be considered for further evaluation for this reason.
- Medium: This technology is effective at achieving the CSO control goal but is not considered among the most effective technologies to achieve that goal.
- Low: This technology will have a minor impact on this CSO control goal. These technologies will need other positive attributes to be considered for further evaluation.
- None: The CSO Control Technology will have zero or negative effect on the CSO control goals.

CSO Control Technologies are recommended for further evaluation based on multiple factors. The first factor is the goal-effectiveness value that generally quantifies the impact a technology will have towards achieving a water quality goal. The second factor is whether or not the DELCORA Consent Decree requires further investigation of a Technology. The third and final factor in determining whether a technology was evaluated further are current or future implementation and operation. If the technology is already currently in place, will be in place, or is mandated to be in place by the Nine Minimum Controls, then an evaluation was unnecessary. The tables at the end of the section contain a brief description of the implementation and operation factors for each technology, and those highlighted in green are recommended for further evaluation. A CSO technology that is considered to have a "high" effectiveness in one or all evaluation factors will likely be recommended for further evaluation. A CSO technology that does not reach at least a "medium" effectiveness rating for bacteria or volume reduction will not be recommended.

8.4.2 Identification of Potential Control Technologies

In order to develop the most effective solution to help DELCORA meet EPA requirements, a wide variety of CSO control technologies were identified from past projects and research into emerging technologies. Potential CSO control technologies generally fall into the following broad categories:

- Source Controls (Green Infrastructure): Public and private Infiltration and Inflow (I/I) reduction and removal; sewer separation; best management practices (BMPs)/Nine Minimum Controls including floatables control.
- Collection System Controls: Gravity sewers; pump stations; hydraulic relief structures; in-line storage; outfall relocation/consolidation; and regulator/diversion structure modification
- Storage Technologies: Above and below ground tanks; and tunnels
- Treatment Technologies: Screening and disinfection; vortex separation; retention/treatment basins; high rate clarification; and satellite sewage treatment

In order to develop the most effective solution to help DELCORA meet EPA requirements, a wide variety of CSO Control Technologies were identified from past projects and research into emerging technologies. The following subsections give a more detailed breakdown of each of these technologies that were chosen out of the preliminary screening that was completed. Summary tables containing the control technologies discussed are located near the end of each subsection, with the recommended technologies highlighted in green in the tables. All recommended CSO Control Technologies are listed in **Table 8-7** at the end of this section.

8.5 Source Controls

EPA defines source controls as those that impact the quality or quantity of runoff entering the combined sewer system. Source control measures can reduce volumes, peak flows, or pollutant discharges that may decrease the need for more capital-intensive technologies downstream in the CSS. However, source controls typically require a high level of effort to implement on a scale that can achieve a measureable impact. A summary of select Source Control Technologies can be found described in the following subsections along with a full list presented in **Table 8-4**.

8.5.1 Green Infrastructure

Green infrastructure (GI) is a source control that reduces runoff volumes, peak flows, and/or pollutant loads. According to the Greening CSO Plans: Planning and Modeling Green Infrastructure for Combined Sewer Overflow Control, GI utilizes the processes of infiltration, evapotranspiration, and capture for re-use to reduce the amount of runoff volume (USEPA, 2014). It is effective at increasing the time of concentration of remaining runoff and reducing pollutant loads through sedimentation and filtration. This technology can be used alone in a scalable manner, or it can be used in conjunction with gray infrastructure using traditional materials like concrete and steel, to reduce its size and cost.

GI's benefits extend beyond reducing the flow of water into CSSs during wet weather events. Through mimicking a more naturalized system, GI can deliver a broad range of ecosystem services or benefits to people, some of which include: improved community livability (aesthetics and property values), human health, air quality, water quality, groundwater recharge, wildlife habitats and connectivity, reduced heat island effects, reduced energy use, green jobs, and recreational opportunities (USEPA, 2014). It can also help reduce flooding and is flexible for addressing Climate Change (droughts or increased precipitation).

As described in *Greening CSO Plans: Planning and Modeling Green Infrastructure for Combined Sewer Overflow (CSO) Control* (USEPA, 2014), the USEPA requires that any incorporation of GI into a LTCP include analysis in two areas:

1. Community and political support for GI
2. Realistic potential for GI implementation

DELCORA assessed the public support from stakeholders in the community and government for the GI alternatives through the implementation of the LTCPU Public Participation Plan. The practical potential implementation for these technologies was evaluated by in Green Storm Water Infrastructure Evaluation in **Appendix N**.

There are a wide range of potential GI technologies currently in use throughout the country, and many of these include numerous design variations incorporated into a variety of documents and design manuals. Corvias Group, LLC has joined DELCORA to help assess GI and feasible locations for their implementation. The intent of this section is to summarize important aspects of the relevant practices, rather than to provide a comprehensive catalog or detailed design documents.

In addition, there are watershed-scale GI options that are not appropriate for DELCORA due to the relatively small size and highly urbanized nature of the CSS area. These include land conservation efforts and creation, preservation, or restoration of riparian buffers, floodplains, wetlands, open space, and forests. These GI options should be encouraged when land use can easily be converted for this intention, but this report will not consider these technologies to reduce runoff volume and bacterial loading.
With the above considerations in mind, feasible and appropriate GI technologies were evaluated for implementation in the following areas for publicly owned property:

- Buildings
- Impervious Areas
- Pervious Areas

8.5.2 Green Roofs

Green roofs have bioretention media that collect runoff to promote evapotranspiration and achieve water quality standards through soil media filtration. They are typically shallow in depth (4-8") based on the ability of the building to support the weight of the media, plantings, and captured rainfall. Green roofs may be built in layers on a roof or installed as cells in crates. An example green roof section can be found in **Figure 8-1**.

Figure 8-1: Example Green Roof Section

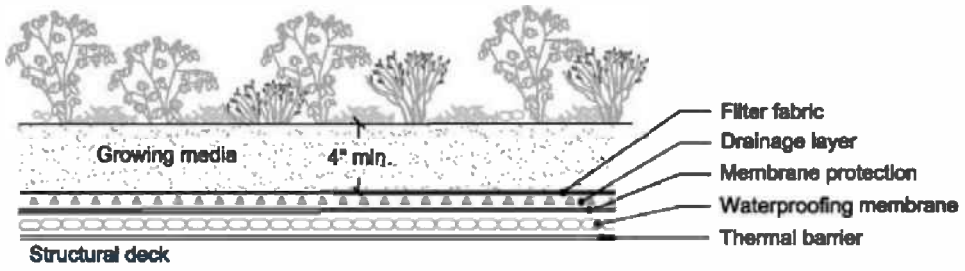

Table 8-4: Source Control Alternatives

Technology Group	Practice	Primary Goals		Implementation & Operation Factors	Being Implemented	Consider Combining w/ Other Technologies	Recommendation for Alternatives Evaluation
		Bacteria Reduction	Volume Reduction				
Stormwater Management	Street/Parking Lot Storage (Catch Basin Control)	Low	Low	Flow restrictions to the CSS can cause flooding in lots, yards and buildings; potential for freezing in lots; low operational cost. Effective at reducing peak flows during wet weather events but can cause dangerous conditions for the public if pedestrian areas freeze during flooding.	No	No	No
	Catch Basin Modification (for Floatables Control)	Low	None	Requires periodic catch basin cleaning; requires suitable catch basin configuration; potential for street flooding and increased maintenance efforts. Reduces debris and floatables that can cause operational problems with the mechanical regulators.	No	No	No
	Catch Basin Modification (Leaching)	Low	Low	Can be installed in new developments or used as replacements for existing catch basins. Require similar maintenance as traditional catch basins. Leaching catch basins have minor effects on the primary CSO control goals.	No	No	No
Public Education and Outreach	Water Conservation	None	Low	Chester Water Authority is responsible for the water system and all related programs in the City of Chester. However, water conservation is a common topic for public education programs. Water conservation can reduce CSO discharge volume but would have little impact on peak flows.	No	Yes	No
	Catch Basin Stenciling	None	None	Inexpensive; easy to implement; public education. Is only as effective as the public's acceptance and understanding of the message. Public outreach programs would have a more effective result.	No	Yes	No
	Community Cleanup Programs	None	None	Inexpensive; sense of community ownership; educational BMP; aesthetic enhancement. Community cleanups are inexpensive and build ownership in the city.	No	Yes	No
	Public Outreach Programs	Low	None	DELCORA has an ongoing public education program. DELCORA should continue its public education program as control measures demonstrate implementation of the NMC.	Yes	Yes	No
	FOG Program	Low	None	Requires communication with business owners; City of Chester has no enforcement authority. Reduces buildup and maintains flow capacity. Only as effective as business owner cooperation	No	Yes	No
	Garbage Disposal Restriction	Low	None	The City of Chester is responsible for Garbage Disposal. This requires an increased allocation of resources for enforcement while providing very little reduction to wet weather CSO events.	No	Yes	No
	Pet Waste Management	Medium	None	Low cost of implementation and little to no maintenance. This is a low cost technology that can significantly reduce bacteria loading in wet weather CSO's.	No	Yes	No

Technology Group	Practice	Primary Goals		Implementation & Operation Factors	Being Implemented	Consider Combining w/ Other Technologies	Recommendation for Alternatives Evaluation
		Bacteria Reduction	Volume Reduction				
	Lawn and Garden Maintenance	Low	Low	Requires communication with business and homeowners. Guidelines are already established per USEPA. Educating the public on proper lawn and garden treatment protocols developed by USEPA will reduce waterway contamination. Since this information is already available to the public it is unlikely to have a significant effect on improving water quality.	No	Yes	No
	Hazardous Waste Collection	Low	None	Ongoing Industrial Users (IUs) program prohibits the discharge of hazardous waste to the collection system; Delaware County sponsors four household hazardous waste events annually.	Yes	Yes	No
	Construction Site Erosion & Sediment Control	None	None	In building code; Reduces silt loads to waterways; DELCORA has no enforcement authority. Contractor or owner pays for erosion control; reduces clogging of catch basins; reduces sediment and silt loads to stream; little O&M for City of Chester; DELCORA has no enforcement authority.	Yes	Yes	No
	Illegal Dumping Control	Low	None	Enforcement of current law requires large number of code enforcement personnel; recycling sites maintained. Local ordinances already in place can be used as needed to address illegal dumping complaints.	Yes	Yes	No
Ordinance Enforcement	Pet Waste Control	Medium	None	Requires resources to enforce pet waste ordinances. Public education and outreach is a more efficient use of resources, but this may also provide an alternative to reducing bacterial loads.	No	Yes	No
	Litter Control	None	None	Aesthetic enhancement; labor intensive; City function. Litter control provides an aesthetic and water quality enhancement. It will require city resources to enforce. Public education and outreach is a more efficient use of resources.	No	Yes	No
	Illicit Connection Control	Low	Low	Site specific; more applicable to separate sanitary system; new storm sewers may be required; interaction with homeowners required. The primary goal of the LTCPU is to meet the USEPA CD requirements limiting CSO's, Total Suspended Solids (TSS) and Biochemical Oxygen Demand (BOD). Illicit connection control is not particularly effective at any of these goals and is not recommended for further evaluation unless separate sewers are in place.	No	Yes	No
Good Housekeeping	Street Sweeping/Flushing	Low	None	Labor intensive; specialized equipment; doesn't address flow or bacteria; City function. Street sweeping and flushing primarily addresses floatables entering the CSS while offering an aesthetic improvement.	No	Yes	No
	Leaf Collection	Low	None	Requires additional seasonal labor. Leaf collection maximizes flow capacity and removes nutrients from the collection system.	No	Yes	No
	Recycling Programs	None	None	The City of Chester has an ongoing recycling program.	Yes	Yes	No

Technology Group	Practice	Primary Goals		Implementation & Operation Factors	Being Implemented	Consider Combining w/ Other Technologies	Recommendation for Alternatives Evaluation
		Bacteria Reduction	Volume Reduction				
	Storage/Loading/Unloading Areas	None	None	Requires Industrial & commercial facilities designate and use specific areas for loading/unloading operations. There are few major commercial or industrial users upstream of CSO regulators.	No	Yes	No
	Industrial Spill Control	Low	None	Pretreatment program regulated by PADEP. There are two commercial or industrial users upstream of CSO regulators.	No	Yes	No
Green Infrastructure – Buildings	Green Roofs	None	Medium	Adds modest cost to new construction; not applicable to all retrofits; low operational resource demand; will require the City of Chester or private owners to implement; requires regular cleaning of gutters & pipes; upkeep of roof vegetation. Portions of the City of Chester have densely populated areas, but this technology is limited to rooftops. Can be difficult to require on private properties.	No	Yes	Yes
	Blue Roofs	None	Medium	Adds modest cost to new construction; not applicable to all retrofits; low operational resource demand; will require the City of Chester or private owners to implement; requires regular cleaning of gutters & pipes; upkeep of roof debris. Portions of the City of Chester have densely populated areas, but this technology is limited to rooftops. Can be difficult to require on private properties.	No	Yes	Yes
	Rainwater Harvesting	None	Medium	Simple to install and operate; low operational resource demand; will require the City of Chester or private owners to implement; requires regular cleaning of gutters & pipes. Portions of the City of Chester have densely populated areas, but this technology is limited to capturing rooftop drainage. Capture is limited to available storage, which can vary on rainwater use. Can be difficult to require on private properties.	No	Yes	Yes
Green Infrastructure – Impervious Areas	Permeable Pavements	Low	Medium	Not durable and clogs in winter; oil and grease will clog; significant O&M requirements with vacuuming and replacing deteriorated surfaces; can be very effective in parking lots, lanes and sidewalks. Maintenance requirements could be reduced if located in low-traffic areas, and can utilize underground infiltration beds or detention tanks to increase storage.	No	Yes	Yes
	Planter Boxes	Low	Medium	Site specific; good BMP; minimal vegetation & mulch O&M requirements with regular overflow and underdrain cleaning; effective at containing, infiltrating and evapotranspirating runoff in developed areas. Flexible and can be implemented even on a small-scale to any high-priority drainage areas. Underground infiltration beds or detention tanks can be utilized to increase storage.	No	Yes	Yes
Green Infrastructure – Pervious Areas	Bioswales	Low	Low	Site specific; good BMP; minimal vegetation & mulch O&M requirements; not as flexible or infiltrate as much stormwater as planter boxes. Technology requires open space and is primarily a surface conveyance technology with additional storage & infiltration benefits. Can be modified with check dams to slow water flow. Limited open space in the City of Chester means land can be utilized in more effective ways with the existing infrastructure.	No	Yes	Yes
	Free-Form Rain Gardens	Low	Medium	Site specific; good BMP; minimal vegetation & mulch O&M requirements with regular overflow and underdrain cleaning; effective at containing, infiltrating and evapotranspirating diverted runoff. Rain Gardens are flexible and can be modified to fit into the previous areas. Underground infiltration beds or detention tanks can be utilized to increase storage.	No	Yes	Yes

Green roofs are recommended for use on buildings with flat roofs (recommended 1-2% slope) that have the structural capacity to support the weight of the media, plantings, and water. Structural improvements to an existing building to support the additional weight associated with a green roof are not typically recommended; therefore this technology is more feasible on new construction. Green roofs can be installed in a section or across an entire roof. An overflow system is typically installed. The vegetation may require irrigation during the first 1-2 years to establish growth. Recommended maintenance for green roofs includes semi-annual maintenance of vegetation.

Many rooftop retrofits are required for this GI technology to have measureable impact. Most of the buildings in the CSS are privately owned. Implementing this technology on a scale that would have a measureable impact would require retrofits on private property, which would be very difficult for DELCORA to require.

8.5.3 Blue Roofs

Blue roofs collect runoff to promote evaporation (they do not have plantings) through detention. They are typically shallow in depth (4-8") based on the ability of the building to support the weight of the media and captured rainfall. Blue roofs may be built in layers on a roof or installed as cells in crates. Unlike green roofs, a blue roof may not provide any water quality benefits, unless filters or storage media are used specifically for this purpose. The water detained from blue roofs may be used on-site instead of being released with the appropriate modifications.

As with green roofs, blue roofs are recommended for use on buildings with flat roofs (recommended 1-2% slope) that have the structural capacity to support the weight of the media and water. Structural improvements to an existing building to support the additional weight associated with a blue roof are not typically recommended; therefore, this option is more feasible on new construction. Blue roofs can be installed in a section or across an entire roof. An overflow system is typically installed to direct the detained water off of the roof. Recommended maintenance for blue roofs includes semi-annual maintenance for clearing of debris.

Similar to green roofs, blue roofs would require implementation on private property to have a measureable impact. It is unlikely that DELCORA would be able to require roof retrofits on private property.

8.5.4 Rainwater Harvesting

Rainwater harvesting is the collection and storage of rainfall from buildings to delay or eliminate runoff. The reduction in runoff volume varies based on the size of the rain barrel or cistern storage unit, and the reuse of the stored rainfall. Typical reuse options are irrigation and vehicle washing. Indoor reuse options, such as toilet flushing and heating and cooling, may be possible if coordinated with building policies.

Rainwater harvesting is applicable to all types of buildings with gutters and downspouts but may be reserved for buildings where green or blue roofs are not appropriate (roof slopes greater than 2%). Storage units may be sized and installed for each downspout or for the building as a whole. Rain barrels, such as those in **Figure 8-2**, are typically used for residential installations and larger cisterns are typically used for non-residential applications. They are typically placed at grade but can be buried below grade if a pumping system for water reuse is provided. An overflow system is typically installed. Recommended

maintenance for rainwater harvesting includes semi-annual maintenance for clearing of debris in the piping or storage unit.

Figure 8-2: Rain Barrels

Similar to green and blue roofs, this technology is limited by the number of available roofs, most of which are private. Private residential uses of cisterns are much less common than on private commercial properties, but are encouraged to help reduce combined sewer overflows. Previous "*Free Rain Barrel Workshops*" held within the City of Chester by the Pennsylvania Resources Council offered attendees the basics of how to construct, install, and maintain a rain barrel, as well as a recycled barrel and fittings for installation.

8.5.5 Permeable Pavements

Permeable pavements promote runoff infiltration and rely on a permeable substrate (engineered soils) to store runoff and remove pollutants. There are different types of permeable pavements, most commonly constructed with asphalt, concrete, or prefabricated pavers. Permeable asphalt and concrete are similar to traditional mixes except that the amount of fine aggregates is reduced or eliminated. Permeable pavers are individual paver units laid together to create a paved surface. The depth of the permeable substrate, anywhere from 3-10 feet, will have the largest impact on runoff volume reduction. Substrate design may incorporate stormwater retention chambers to increase storage volume. Underdrains may be necessary depending on the local soil types, depth of substrate, and groundwater elevation.

Permeable pavements are recommended for low traffic and low speed traffic areas such as sidewalks, parking lanes, parking lots, driveways, and alleys. **Figure 8-3**, **Figure 8-4** and **Figure 8-5** show slightly different permeable pavement details for each of these surfaces. Recommended maintenance for permeable pavement includes semi-annual inspection and vacuuming. Preventative maintenance is also necessary to minimize the introduction of soil and other fine particles that could clog the pavement pores.

Figure 8-3: Example Permeable Sidewalk Section

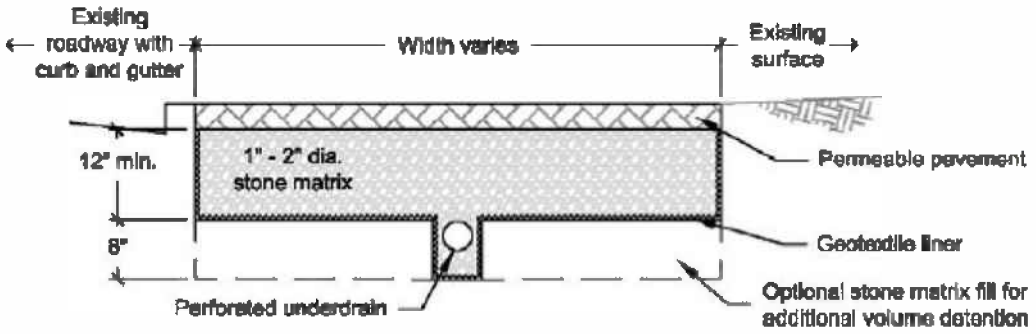

Figure 8-4: Example Permeable Alley Section

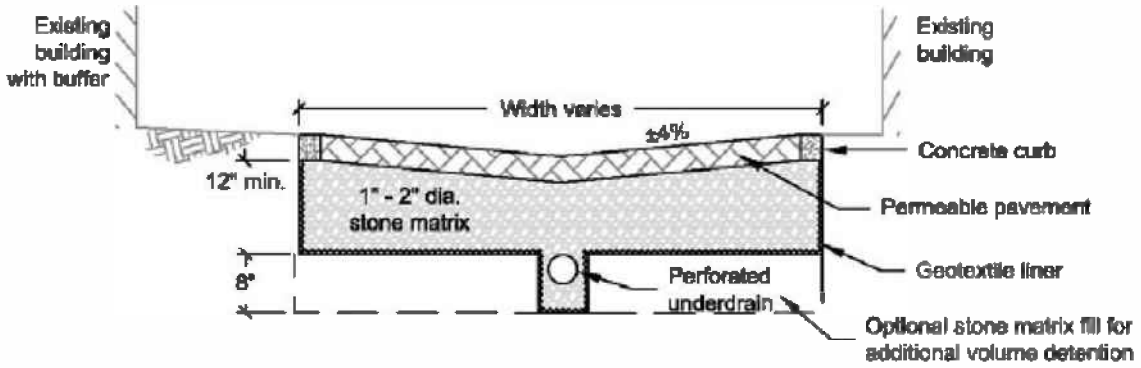

Figure 8-5: Example Permeable Parking Lane Section

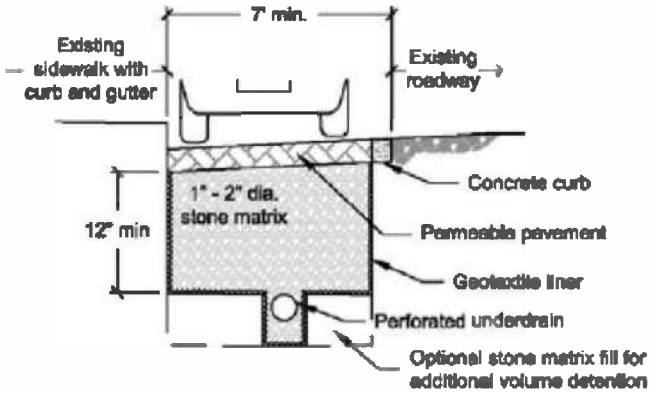


Notes:
1. Depth of stone matrix will be determined by structural requirements, storage desired, and permeable pavement type.
2. Top of existing sewer and other utilities shall be a minimum of 1' below the invert of the stone matrix.
3. All underdrains will connect to the existing storm sewer system via solid pipe.

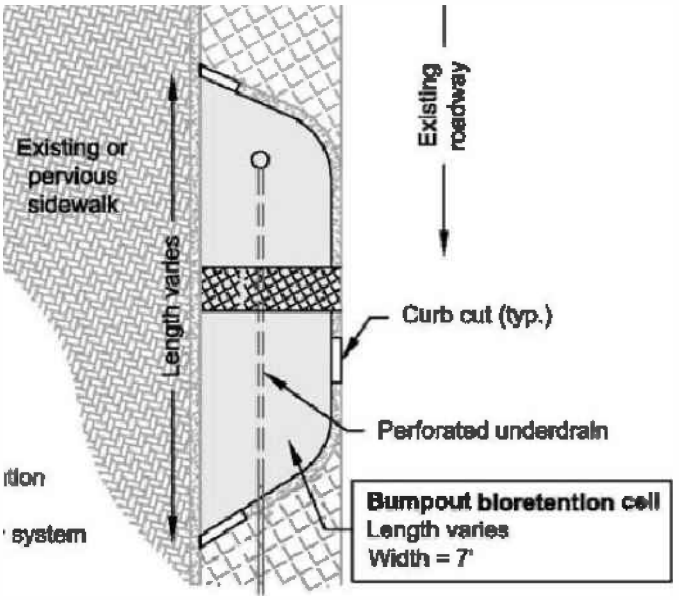
This GI technology can be very effective when implemented in parking lots, parking lanes, and narrow sidewalks where planter boxes cannot be implemented.

8.5.6 Planter Boxes

Planter boxes are bioretention cells that collect runoff and promote runoff infiltration. These walled units are similar to free-form rain gardens as vegetated depressions (12-24 in) that rely on ponding and a permeable substrate (engineered soils) to store runoff and remove pollutants. The depth of the permeable substrate, anywhere from 3-10 feet, will have the largest impact on runoff volume reduction. Substrate design may incorporate stormwater retention chambers to increase storage volume. Properly designed planter boxes limit ponding to 3-6 hours after a storm. Ponding overflow pipes and/or underdrains may be necessary depending on the local soil types, depth of substrate, and groundwater elevation. The vegetation promotes evapotranspiration to reduce the volume of the stored runoff.

There are two primary sizes of planter boxes used based on the drainage pattern in developed areas: sidewalk planter boxes and bumpout planter boxes. Sidewalk planter boxes may also be more specifically referred to as a Tree Well Best Management Practice (BMP), a Tree Well with Soil Panels, a Continuous Planting Strip, Mid-Sidewalk BMP, or a Back of Sidewalk BMP. Sidewalk planter boxes are depressed below the elevation of the existing sidewalk. Bumpout planter boxes are larger units that extend from the sidewalk curb into an area of a parking lane. An example of this design can be found in **Figure 8-6**. Curb cuts into planter boxes allow roadway runoff to enter the cells and overflow to street inlets once the maximum ponding depth has been reached. Planter boxes are recommended for use in regularly spaced intervals in the downstream drainage path in areas of impervious cover.

Figure 8-6: Example Planter Bumpout Section



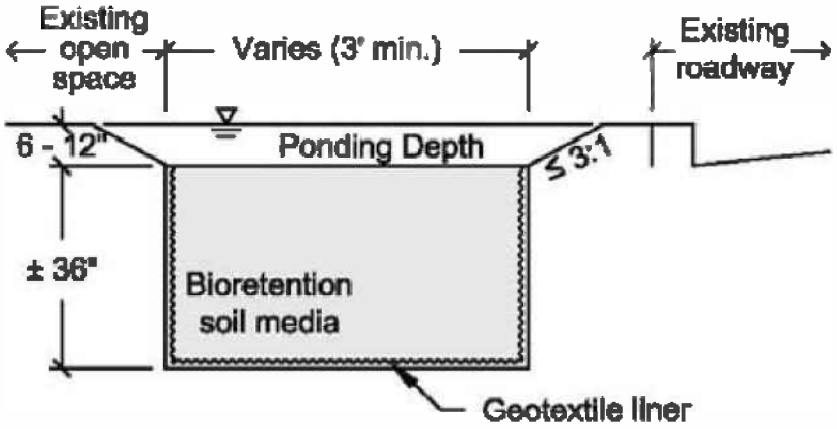
Recommended maintenance for planter boxes includes semi-annual inspections and improvements to vegetation and mulch and annual inspection of overflow pipes and underdrains, if applicable. Inspection after a large storm is also recommended. If there is evidence of ponding after 48 hours, mulch replacement or overflow pipe cleaning may be necessary.

Planter boxes are well suited for highly developed areas where space allows. They can be installed block by-block to contain, infiltrate, and evapotranspirate stormwater runoff.

8.5.7 Bioswales

Bioswales are vegetated channels that reduce runoff velocity and promote runoff infiltration. These are linear channels with shallow depressions (6-12") that incorporate vegetation and a permeable substrate (engineered soils). As a channel, runoff not infiltrated does not pond, but flows through the swale and is conveyed elsewhere. The channels, especially those with slopes greater than 6%, may incorporate check dams to assist in reducing runoff velocity and promote infiltration and pollutant removal. A design example for a bioswale is found in **Figure 8-7**.

Figure 8-7: Example Bioswale Detail



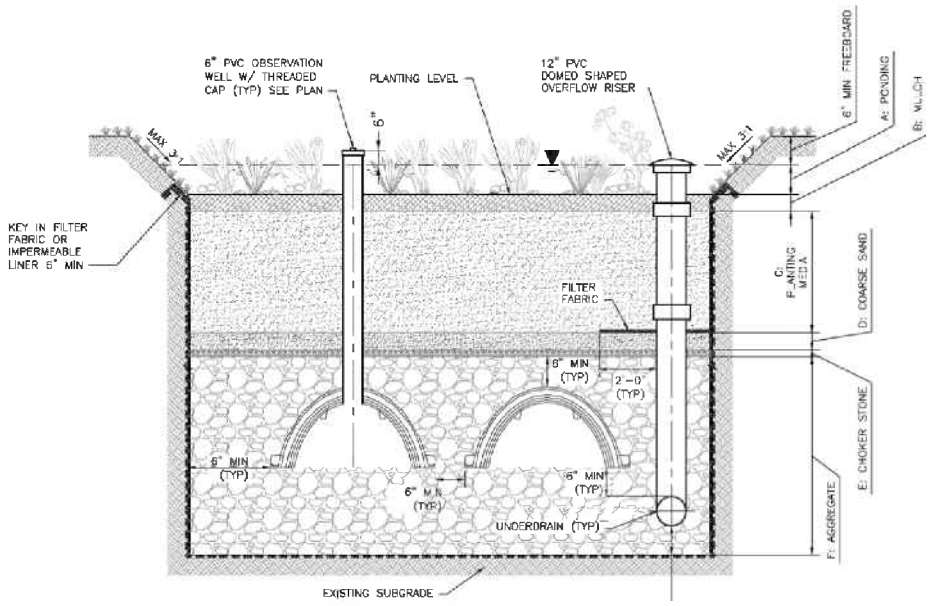
Bioswales are recommended for use in parks and areas of natural cover since they primarily reduce runoff velocity and have a low volume reduction per square foot. Due to their linear nature, bioswales may also be effective in the buffer between open space areas and impervious areas with high volumes of runoff such as roads and parking lots. Recommended maintenance for bioswales includes semi-annual inspections and improvements to vegetation and mulch.

This technology incorporates both stormwater treatment and stormwater conveyance. While not as flexible as planter boxes, there may be locations in the DELCORA CSS where a bioswale could be effective.

8.5.8 Free-Form Rain Gardens

Rain gardens are bioretention basins that collect runoff and promote runoff infiltration. These are vegetated depressions (12-24") that rely on ponding and a permeable substrate (engineered soils) to store runoff and remove pollutants. The size and shape of rain gardens can be tailored to site-specific needs, but the depth of the permeable substrate (anywhere from 3-10 feet) will have the largest impact on runoff volume reduction. Substrate design may incorporate stormwater retention chambers to increase storage volume. Properly designed rain gardens limit ponding to 3-6 hours after a storm. Ponding overflow pipes and/or underdrains may be necessary depending on the local soil types, depth of substrate, and groundwater elevation. The vegetation promotes evapotranspiration to reduce the volume of the stored runoff, and infiltration helps improve water quality. An example of a rain garden design is found in **Figure 8-8**

Figure 8-8: Example Rain Garden Section



Rain gardens are recommended for use in low points in parks and areas of natural cover so they can blend in seamlessly with a grassed buffer and enhance the vegetation without appearing to be a stormwater control mechanism. Locations near the transition from pervious to impervious cover can provide runoff reduction for nearby impervious areas.

Recommended maintenance for rain gardens includes semi-annual inspections and improvements to vegetation and mulch and annual inspection of overflow pipes and underdrains, if applicable. Annual inspection after a large storm is also recommended; if there is evidence of ponding after 48 hours, mulch and/or soil replacement or overflow pipe cleaning may be necessary.

Rain gardens are very effective at capturing and treating stormwater and have versatile footprints that make them advantageous for use in highly developed urban environments, such as the City's CSS area.

8.6 Collection System Control

The USEPA defines collection system controls as measures that can reduce CSO volume and frequency by removing or diverting stormwater runoff to maximize the capacity of the collection system. Collection system controls have no impact on water quality, but do have the potential to reduce the volume of CSO events. A summary of select collection system control technologies can be found below along with a full list in **Table 8-5**.

8.6.1 Infiltration/Inflow Reduction

I/I can significantly limit the hydraulic capacity of a collection system, if not held in check. Inflow comes from sources such as roof drains, manhole covers, cross connections from storm sewers, catch basins, and surface runoff. Infiltration comes from groundwater that seeps in through leaking pipe joints, cracked pipes, manholes, and other similar sources. Identifying I/I sources is labor intensive and requires specialized equipment. Additionally, significant I/I reductions can be difficult and expensive to achieve. However the benefit of a good I/I control program is that it can save money by extending the life of the system, reducing the need for expansion, and lowering treatment costs. I/I reduction for combined sewers provides limited gains, since water tends to find another way into the system. However, I/I reductions in sanitary sewers can have significant impacts on increasing the available capacity in the downstream CSS.

8.6.2 Combined Sewer Separation

Sewer separation is the conversion of a CSS into a system of separate storm sewers and sanitary sewers. This can be accomplished by installing a new sanitary sewer and using the existing combined sewer as a storm sewer or vice versa. This practice can be very expensive, disruptive to the public, and difficult to implement, especially in downtown areas or other densely developed urban environments. It typically requires closure of public streets for construction while the new pipes are installed and the sewer is separated. Combined sewer separation shall be considered a feasible technology and be carried forward for further evaluation as required by Section 5.A.19.a of the DELCORA Consent Decree.

8.6.3 Additional Conveyance

Conveyance is a technology that transports the combined sewage out of a particular area to a location where the flow can be stored, treated, or discharged where direct public contact with the water is less likely. Conveyance is accomplished by providing additional conveyance pipes or upsizing the existing conveyance pipe to a greater capacity. This practice can effectively reduce overflow volume and frequency in the affected areas. Large conveyance projects can be expensive and may require a lengthy permitting process.

Table 8-5: Collection System Alternatives

Technology Group	Practice	Primary Goals		Implementation & Operation Factors	Being Implemented	Consider Combining w/ Other Technologies	Recommendation for Alternatives Evaluation
		Bacteria Reduction	Volume Reduction				
Operation and Maintenance	I/I Reduction	Low	Medium	Requires labor intensive work; changes to the conveyance system require temporary pumping measures; repairs on private property required by homeowners. Reduces the volume of flow and frequency; Provides additional capacity for future growth; House laterals account for 1/2 the sewer system length and significant sources of I/I in the sanitary sewer.	No	Yes	Yes
	Advanced System Inspection & Maintenance	Low	Low	Requires additional resources towards regular inspection and maintenance work. Inspection and maintenance programs can provide detailed information about the condition and future performance of infrastructure. Offers relatively small advances towards goals of the LTCPU.	Yes	Yes	No
	Combined Sewer Flushing	Low	Low	Requires inspection after every flush; no changes to the existing conveyance system needed; requires flushing water source. Ongoing: CSO Operational Plan; maximizes existing collection system; reduces first flush effect.	Yes	Yes	No
	Catch Basin Cleaning	Low	None	Labor intensive; requires specialized equipment. Catch Basin Cleaning reduces litter and floatables but will have no effect on flow and little effect on bacteria and BOD levels.	Yes	Yes	No
Combined Sewer Separation	Roof Leader Disconnection	Low	Low	Site specific; Includes area drains and roof leaders; new storm sewers may be required; requires home and business owner participation. The City of Chester is densely populated and disconnected roof leaders have limited options for discharge to pervious space. Disconnection may be coupled with other GI technologies but is not considered an effective standalone option.	No	Yes	No
	Sump Pump Disconnection	Low	Low	Site specific; more applicable to separate sanitary system; new storm sewers may be required; interaction with homeowners required. The City of Chester is densely populated and disconnected sump pumps have limited options for discharge to pervious space. Disconnection may be coupled with other GI technologies but is not considered an effective standalone option.	No	Yes	No
	Combined Sewer Separation	High	High	Very disruptive to affected areas; requires homeowner participation; sewer asset renewal achieved at the same time; labor intensive.	No	No	Yes
Combined Sewer Optimization	Additional Conveyance	High	High	Additional conveyance can be costly and would require additional maintenance to keep new structures and pipelines operating. Reduces a bottleneck in the interceptor system to reduce backup in the Delaware River Interceptor.	No	No	Yes

Technology Group	Practice	Primary Goals		Implementation & Operation Factors	Being Implemented	Consider Combining w/ Other Technologies	Recommendation for Alternatives Evaluation
		Bacteria Reduction	Volume Reduction				
	Regulator Modifications	Medium	Medium	Relatively easy to implement with existing regulators; mechanical controls requires O&M. May increase risk of upstream flooding. DELCORA has an ongoing O&M program and system wide replacement program for CSO regulators and tide gates completed by 2022.	Yes	Yes	Yes
	Outfall Consolidation/Relocation	High	High	Lower operational requirements; may reduce permitting/monitoring; can be used in conjunction with storage & treatment technologies. Combining and relocating outfalls may lower operating costs and CSO flows. It can also direct flow away from specific sensitive areas.	No	Yes	Yes
	Real Time Control	High	High	Requires periodic inspection of flow elements; highly automated system; increased potential for sewer backups. RTC is only effective if additional storage capacity is present in the system.	No	Yes	Yes

8.6.4 Outfall Consolidation/Relocation

Consolidation of one or multiple outfalls can help eliminate CSO discharges in sensitive areas. Outfall consolidation may require modification or relocation of an outfall, the installation of additional conveyance to accommodate new flow configurations, and may also require additional permitting with government agencies. This practice typically lowers O&M requirements for the CSS by limiting the number of outfall structures that need to be monitored. Outfall consolidation works best in areas where outfalls are located in close proximity to each other and require limited additional conveyance. Similar to regulator modifications, outfall consolidation is especially effective at reducing high frequency, low volume CSOs. This practice typically doesn't add a significant amount of extra capacity to the CSS (depending on the amount of conveyance pipe associated with the consolidation project), so its impact on infrequent, large volume CSO events can be limited. The H&H Model can determine the level of impact that outfall consolidation will have in terms of reducing the number of CSO events.

8.6.5 Regulator Modifications

A CSO regulator can be uniquely configured to control combined sewer overflow frequency and volume. The existing overflow control structures may be modified based on site-specific conditions - for example, by increasing the overflow weir height and length or raising the overflow pipe elevation. This technology is especially effective for CSO outfalls with high overflow frequency and low overflow volume, because the additional volume held back in the system is small and less likely to have negative impacts on upstream conditions.

8.6.6 Real Time Control

Real Time Control (RTC) is a highly automated system in which sewer level and flow data are measured at key points in the sewer system and used to operate system controls to maximize the storage capacity of the CSS and limit overflows. The collected data is typically transferred to a control device where program logic is used to operate gates, pump stations, inflatable dams and other control components. Local dynamic controls are used to control regulators to prevent flooding and system-wide dynamic controls are used to implement control objectives such as maximizing flow to the treatment plant or transferring flows from one portion of the CSS to another to fully utilize the system. Predicative control, which incorporates use of weather forecast data is an optional feature, but is complex and requires sophisticated operational capabilities. It should be noted that RTC can only reduce CSO volumes where in-system storage capacity is available. Additionally this measure involves the installation of numerous mechanical controls which require upkeep and maintenance. Due to these limitations and complexities, this measure has been identified as a complementary technology.

8.7 Storage

The objective of storage is to reduce overflows by capturing and storing wet weather flows in excess of the CSS conveyance/treatment plant capacity for controlled release back into the system once the treatment and conveyance capacity have been restored. A storage facility can attenuate peak flows in the CSS and provide a relatively constant flow into the treatment plant after peak events. Storage technologies do not prevent water from entering the CSS or treat bacterial loads in CSO discharge, but are very effective at reducing or eliminating CSO events. Storage technologies typically have fairly high construction and O&M costs compared to other CSO control technologies, but are a very reliable means

of achieving CSO control goals. A summary of the various storage technologies is listed below and in **Table 8-6**.

8.7.1 Pipeline Storage

Large diameter parallel pipelines or conduits can provide significant storage in addition to the ability to convey flow. Pipelines are typically constructed between an overflow point and a pump station or treatment facility. The pipelines include discharge controls to allow flow to be stored within the pipeline during wet weather events, and slowly released by gravity following the event. Pipelines have the advantage of requiring less area for construction compared to point storage technologies. If trenchless technologies can be utilized, such as horizontal directional drilling (HDD), land requirements can be reduced even further.

One disadvantage of pipelines is that a larger volume is typically required to accommodate combined sewer storage needs. The installation of large diameter pipelines is typically less cost-effective than tunneling, and the installation of smaller diameter pipes typically requires a significant length in order to provide adequate storage. Additionally, the installation of pipelines is very disruptive, typically requiring open trenches and the temporary closure of public streets.

8.7.2 Tunnel Storage

Tunnels provide more storage volume than pipelines, while maintaining the ability to convey flow. Tunnel excavation is accomplished completely underground, and therefore results in minimal surface disruption and requires little right-of-way. Costs for tunnel storage is fairly reasonable compared to other storage technologies, depending on local geology. Tunnels are typically used in congested urban areas where available land is scarce. Tunnels shall be considered a feasible technology and be carried forward for further evaluation as required by section 5.A.19.a of the DELCORA Consent Decree.

8.7.3 Tank Storage

This technology reduces overflow quantity and frequency by storing all or a portion of diverted wet weather combined flows in off-line storage tanks. Stored flows are returned to the interceptor for conveyance to the treatment plant once system capacity becomes available. Storage tanks are generally fed by gravity and the stored flow is typically pumped back to the interceptor after the storm. The benefit of off-line storage tanks is that they are well suited for early action projects at critical CSO outfalls. Storage tanks capture the most concentrated first flush portion wet weather peak flow and help to reduce the downstream capacity needs for conveyance and treatment.

A disadvantage of off-line storage tanks is that they typically require large land area for installation, which may not be available in congested urban areas. Off-line storage tanks typically have higher costs per volume captured compared to other technologies. Additionally, if the existing sewers are deep, then the storage tank must also be deep, which results in additional construction costs. Operation and maintenance costs can also be high, especially if the application includes provisions for partial treatment and discharge, rather than simple storage and bleed-back to the sewer. Depending on the application, odor problems may also be an issue. However, storage tanks can be a very effective means of CSO control.

Table 8-6: Storage and Treatment Alternatives

Technology Group	Practice	Primary Goals		Implementation & Operation Factors	Being Implemented	Consider Combining w/ Other Technologies	Recommendation for Alternatives Evaluation
		Bacteria Reduction	Volume Reduction				
Linear Storage	Pipeline	High	High	Can only be implemented if in-line storage potential exists in the system; increased potential for basement flooding if not properly designed; maximizes use of existing facilities. Pipe storage for a CSS typically requires large diameter pipes to have a significant effect on reducing CSOs. This typically requires large open trenches and temporary closure of streets to install.	No	No	Yes
	Tunnel	High	High	Requires small area at ground level relative to storage basins; disruptive at shaft locations; increased O&M burden.	No	No	Yes
Point Storage	Tank	High	High	Storage tanks typically require pumps to return wet weather flow to the system which will require additional O&M; disruptive to affected areas during construction. Several CSO outfalls have space available for tank storage. There may be existing tanks in abandoned commercial and industrial areas to be converted to hold stormwater. Tanks are an effective technology to reduce wet weather CSO's.	No	No	Yes
	Industrial Discharge Detention	Low	Low	Requires cooperation with industrial users; more resources devoted to enforcement; depends on IUs to maintain storage basins. IUs hold stormwater or combined sewage until wet weather flows subside; few commercial or industrial users upstream of CSO regulators.	No	Yes	No
Treatment-CSO Facility	Vortex Separators	None	None	Space required; challenging controls for intermittent and highly variable wet weather flows. Vortex separators would remove floatables and suspended solids when installed. It does not address volume, bacteria or BOD.	No	Yes	No
	Screens and Trash Racks	None	None	Prone to clogging; requires manual maintenance; requires suitable physical configuration; increased O&M burden. Screens and trash racks will only address floatables.	No	Yes	No
	Netting	None	None	Easy to implement; labor intensive; potential negative aesthetic impact; requires additional resources for inspection and maintenance. Netting will only address floatables.	No	Yes	No
	Contaminant Booms	None	None	Difficult to maintain requiring additional resources. Contaminant booms will only address floatables.	No	Yes	No
	Baffles	None	None	Very low maintenance; easy to install; requires proper hydraulic configuration; long lifespan. Baffles will only address floatables.	No	Yes	No
	Disinfection & Satellite Treatment	High	None	Requires additional flow stabilizing measures; requires additional resources for maintenance; requires additional system analysis. Disinfection is an effective control to reduce bacteria and BOD in CSO's.	No	Yes	Yes
	High Rate Physical/Chemical Treatment (ActiFlo)	None	None	Challenging controls for intermittent and highly variable wet weather flows; smaller footprint than conventional methods. This technology primarily focuses on TSS & BOD removal, but does not help reduce the bacteria or CSO discharge volume.	No	Yes	No

Technology Group	Practice	Primary Goals		Implementation & Operation Factors	Being Implemented	Consider Combining w/ Other Technologies	Recommendation for Alternatives Evaluation
		Bacteria Reduction	Volume Reduction				
	High Rate Physical (Fuzzy Filters)	None	None	Relatively low O&M requirements; smaller footprint than traditional filtration methods. This technology primarily focuses on TSS removal, but does not help reduce the bacteria or CSO discharge volume.	No	Yes	No
Treatment-WRTP	Additional Treatment Capacity	High	High	May require additional space; increased O&M burden.	No	No	Yes
	Wet Weather Blending	Low	Low	Requires upgrading the capacity of influent pumping, primary treatment and disinfection processes; increased O&M burden. Wet weather blending does not address bacteria and overflow volume reduction, as it is a secondary treatment bypass for the POTW. Permittee must demonstrate there are no feasible alternatives to the diversion for this to be implemented.	No	Yes	No
Treatment-Industrial	Industrial Pretreatment Program	Low	Low	Requires cooperation with Industrial User's; more resources devoted to enforcement; depends on IU's to maintain treatment standards. DELCORA has an ongoing Industrial Pretreatment program that includes 3 IU's and requires a permit be renewed every 4 years.	Yes	Yes	No

8.8 Treatment Technologies

Treatment technologies are intended to reduce the pollutant loads to receiving waters by treating wet weather flows prior to discharging to the environment. Specific technologies can address different pollutant constituents, such as settleable solids, floatables, or bacteria. Where treatment facilities are to be considered, the LTCPU should contain provisions for the handling, treatment, and ultimate disposal of sludge and other treatment residuals. A summary of various treatment technologies are listed in **Table 8-6**.

8.8.1 Disinfection & Satellite Treatment

This technology consists of disinfecting & treating sewer overflows at a local facility near the CSO outfall. Disinfection is very effective at reducing bacteria through inactivation, but provides only limited opportunities for volume reduction. Disinfection alone cannot provide reductions in TSS, floatables, and nutrient loads unless other processes (e.g. screening, high-rate clarification, etc.) are provided upstream of the disinfection facility. The combination of these other processes with disinfection can provide a satellite treatment facility that helps reduce Pollutants of Concern.

Disinfection of wet weather flow is more challenging to design and control than traditional disinfection at a treatment plant, because of the complex characteristics of the flow. Intermittent occurrence and highly variable flowrate make it more challenging to regulate the addition of disinfectant. One way to address the variable flow issue is to provide flow retention facilities that provide for disinfectant contact time and capture through storage of the first flush of TSS, floatables and nutrients.

Wet weather flows can vary widely in temperature, suspended solids concentrations, and bacterial composition. Therefore, pilot studies are usually needed to characterize the range of conditions that exist for a particular area and the design criteria that need to be considered. Experience has shown that the long contact time required for conventional wastewater treatment is not appropriate for the treatment of wet weather flows. Disinfection can be achieved by providing an increased disinfection dosage and intense mixing to ensure disinfectant contact with the maximum number of microorganisms.

Various disinfection technologies are available, both with and without chlorine compounds. In addition to disinfection effectiveness, many factors should be considered when selecting a disinfectant, including potential toxic effects to the environment, regulations for residuals, safety precautions, and ease of operation and maintenance. Ultraviolet (UV) light and peracetic acid (PAA) are two alternatives to chlorine compounds for wet weather disinfection.

- The main advantages of UV light include its ability to quickly respond to flow variation and the absence of a disinfectant residual, among others. The size of the UV system mainly depends on the UV transmittance (i.e. the ability of wastewater to transmit UV light) and the TSS concentrations in the wastewater. One of the challenges for UV disinfection is determining how to manage the disinfection of effluent during a power outage. In addition, UV typically has higher capital cost compared to chlorine disinfection systems.

The main advantage of peracetic acid over sodium hypochlorite is its long "shelf life" without product deterioration. Due to the intermittent nature of CSO flows, stored sodium hypochlorite may degrade over time if not used; however, PAA systems generally have higher operating costs than chlorine systems.

8.8.2 Additional Treatment Capacity - WRTP

CSOs can potentially be reduced by increasing the treatment capacity of the WRTP. Plans are currently being evaluated to increase the capacity of the WRTP from the currently permitted effluent limits of 44 MGD to 50 MGD. The plant is also being evaluated for necessary improvements to handle up to 60 MGD average flow capacity loading. In combination with increased plant capacity, additional conveyance would be needed to accommodate flow to the WRTP for treatment. Additional treatment plant capacity shall be considered a feasible technology and be carried forward for further evaluation as required by section 5.A.19.a of the DELCORA Consent Decree

8.8.3 Recommended Control Technologies for Evaluation

Based on the evaluation criteria, the following CSO Control Technologies are recommended for further evaluation. They have been selected based on their rating of bacteria and volume reduction. Should any CSO control technology rank as "medium" or "high" in either category, it will be retained for further evaluation. Technologies will also be further evaluated if they have been identified as a feasible technology by the Consent Decree. See **Table 8-7** for the Selected Alternative Technologies Summary.

Table 8-7: Selected Alternative Technologies Summary

Technology Group	Practice	Primary Goals		Consider Combining w/ Other Technologies
		Bacteria Reduction	Volume Reduction	
Source Controls (Green Infrastructure)	Green Roofs	None	Medium	Yes
	Blue Roofs	None	Medium	Yes
	Rainwater Harvesting	None	Medium	Yes
	Permeable Pavements	Low	Medium	Yes
	Planter Boxes	Low	Medium	Yes
	Bioswales	Low	Low	Yes
	Free-Form Rain Gardens	Low	Medium	Yes
Collection System Controls	I/I Reduction	Low	Medium	Yes

Technology Group	Practice	Primary Goals		Consider Combining w/ Other Technologies
		Bacteria Reduction	Volume Reduction	
	Combined Sewer Separation	High	High	Yes
	Additional Conveyance	High	High	Yes
	Regulator Modifications	Medium	Medium	Yes
	Outfall Consolidation/Relocation	High	High	Yes
	Real Time Control	High	High	Yes
Storage Technologies	Pipeline	High	High	No
	Tunnel	High	High	No
	Tank	High	High	No
Treatment Technologies	Disinfection & Satellite Treatment	High	None	Yes
	Additional Treatment Capacity	High	High	No

8.9 Preliminary Siting of CSO Control Technologies

Following the determination of appropriate Alternative Technologies to utilize in the final analysis, Control Alternatives were sited for the various CSO areas based on a variety of factors such as suitability for placement at a particular CSO, the type of land use, the CSO's location in relation to the WRTP, available land for Control Technology placement, and the ultimate feasibility of the Control Technology installation. For the preliminary siting of green infrastructure, an evaluation was completed in November 2017 by Corvias. The entire DELCORA CSO area was analyzed for green infrastructure Control Technology placement with specific siting recommended based on several factors such as the "life-cycle costs, the ability to develop effective green infrastructure, availability of land, and combined sewer overflow control levels achieved". This analysis was incorporated into the preliminary siting. The completed preliminary siting matrix can be viewed in **Table 8-8**.

Table 8-8: Preliminary Siting of CSO Alternative Control Technologies

Practice		Bacteria Reduction	Volume Reduction	DELAWARE RIVER												CHESTER CREEK									RIDLEY CREEK

Notes:
= Corvias's Recommendation
-Source controls are incorporated from Corvias along with GH separate analysis.
-Table is specific to siting at each specific outfall/CSO.
-This table does not qualify whether these locations impact other CSOs downstream.

Section 9 Evaluation and Selection of CSO Control Alternatives

9.1 Introduction

This Section is intended to evaluate the CSO Control Technologies presented in Section 8. As described previously in Section 8, preliminary Control Technologies that have a rating of "medium" or "high" with regard to bacteria and volume reduction were retained for consideration for inclusion in the Evaluation and Selection of CSO Control Alternatives. The remaining Technologies were then utilized throughout the process of developing the Alternative Analysis methodology. The chosen Alternatives, whether it is the Consent Decree requirement approach or the Targeted approach, both to be discussed in subsequent subsections, rely mainly on the following: tunnel storage, green infrastructure, storage tanks, WRTP expansion, sewer separation, regulator modifications, parallel interceptors, and most importantly, the utilization of existing infrastructure. The storage volume and location of these Technologies were completed after an exhaustive analysis process to look at volume capture and the unique characteristics of each CSO area for ultimate placement of the Technologies. Following this investigation of appropriate technologies within each sewer shed, further modeling was completed along with developing opinions of probable construction cost. Knee-of-the-Curve graphs to compare each alternative developed from a suite of viable technologies in each sewer shed were developed to graphically see where the cost benefit per million gallon of CSO captured is maximized. Subsequent subsections provide additional details into the overall processes to develop cost effective alternatives to achieve various levels of CSO control in the DELCORA combined sewer area.

9.2 CSO Control Policy Alternatives Analysis Requirements

As previously stated, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania on August 17, 2015 that requires DELCORA to complete and submit a revised and updated LTCP to the USEPA and/or PADEP for review and approval. With regard to the Alternatives Analysis, Consent Decree Paragraph V.A.19 (Alternatives Evaluation) states:

> *"DELCORA shall carry out and include in the LTCP an Alternatives Evaluation that complies with the requirements of the CSO Control Policy Section II.C.4, and that is consistent with EPA's "Guidance for Long-Term Control Plan," EPA 832-B-95-002,September 1995. The Alternatives Evaluation shall consist of: (1) a technology screening process, (2) a detailed evaluation of specific CSO control alternatives, and (3) selection of an appropriate range of proposed CSO controls to achieve compliance with the Clean Water Act. DELCORA shall specifically evaluate the feasibility of eliminating or relocating all CSO Outfalls that discharge to Sensitive Areas. DELCORA shall give a high priority to the control of those CSO Outfalls that discharge to Priority Areas, and those that have the highest frequency or greatest volume of discharge of wastewater."*

Described in Section 8, the first step in the Alternatives Evaluation is the screening of available CSO Control Technologies as outlined in Consent Decree Paragraph V.A.19.a (Screening of Available CSO Control Technologies):

> *"DELCORA shall assess the technical feasibility of the use of a wide range of demonstrated CSO control technologies. DELCORA shall provide descriptions of the following types of CSO control technology – Source Controls, Collection System Controls, Storage Technologies and Treatment*

Technologies – and an assessment of the feasibility of applying each technology type for long-term CSO control in the Model Area, based on existing and anticipated future conditions affecting the Model Area. This evaluation is not intended to consider cost or cost effectiveness, but rather to exclude control technologies that are not technically or physically applicable to the Model Area."

The Consent Decree specifically states as part of the Alternative Evaluation preliminary screening process certain alternatives shall be carried forward for final consideration:

*"**Partial and complete separation of sewers** in each CSO Outfall tributary area, and **deep tunnel storage**, shall be considered feasible technologies for this purpose and be carried forward for further evaluation. **Expansion of the primary and secondary capacity of the WRTP** shall also be considered feasible technologies for this purpose and be forward for further evaluation, as required by Section II.C.4 of the CSO Control Policy."*

Additional Control Technologies to be considered include green infrastructure as well, as stated in Consent Decree Paragraph V.A.19.c (Green Infrastructure):

"DELCORA shall consider Green Infrastructure ("GI") alternatives as part of the combined sewer system control alternatives under the LTCP. The LTCP shall contain the following minimum considerations for proposing a GI alternative to traditional controls:

(i) Identification of potential locations for GI. DELCORA shall specifically identify potential areas within the service area that would be suitable for development of a GI control measure. Each potential area shall be prioritized using considerations such as lifecycle cost (including cost of long-term operation and maintenance),the ability to develop effective GI control measures, availability of land, CSO control levels achieved, environmental and socioeconomic benefits and impacts, and benefits and impacts to minority and low income neighborhoods.

(ii) Applicability and Performance Assessment. Any GI control measure proposed shall include an applicability and performance assessment that includes consideration of unique sewer shed-specific features such as diversion structures/outfalls, Receiving Waters, and land uses. Information and data gathered from other existing GI control measure studies and/or projects can inform, to the extent appropriate, applicability and performance assessments required under this Paragraph.

(iii) For any GI controls to be sited on private property, or operated by an entity other than DELCORA, DELCORA shall describe how DELCORA will ensure the continual operation and maintenance of such controls."

In terms of early action CSO Control Technologies, Consent Decree V.B.26 (Early Action CSO Control Measure) states:

"DELCORA shall Place in Operation a new EPS-1 Pump Station to reduce discharges from CSO Outfalls #2, #3, #4, #5 and #7, by December 31, 2018. DELCORA shall update its NMC Plan to reflect this Early Action CSO Control Measure within 60 days of its Placement in Operation, as required by Section V.B.26 of the Consent Decree."

This Early Action Item, construction of new Pump Station PS-6 (reconstructed EPS-1) will be included as part of the baseline for each CSO Control Alternative. Further description of requirements of the Alternatives Analysis in the Consent Decree it the following with regard to evaluating controls to achieve a certain number of overflows events per year (CSO Control Policy Section II.C.4 (Evaluation of Alternatives):

> *"EPA expects the long-term CSO control plan to consider a reasonable Range of alternatives. The plan should, for example, evaluate controls that would be necessary to achieve zero overflow events per year, an average of one to three, four to seven, and eight to twelve overflow events per year. Alternatively, the long-term plan could evaluate controls that achieve 100% capture, 90% capture, 85% capture, 80% capture, and 75% capture for treatment. The long-term control plan should also consider expansion of POTW secondary and primary capacity in the CSO abatement alternative analysis. The analysis of alternatives should be sufficient to make a reasonable assessment of cost and performance as described in Section Q.C.5. Because the final long-term CSO control plan will become the basis for NPDES permit limits and requirements the selected controls should be sufficient to meet CWA requirements."*

These relevant regulatory requirements have been extracted from the Consent Decree and the USEPA's CSO Guidance for LTCP. The Consent Decree contains the regulatory requirements related to Alternatives Evaluation, Screening of Available CSO Control Technologies and Green Infrastructure. The USEPA's CSO Guidance for LTCP contains the regulatory requirements related to Creative Thinking, Definition of Water Quality and CSO Control Goals and the Identification of Control Alternatives. The following subsections address the overall process used to develop the Alternatives to be utilized.

9.3 Alternatives Analysis Approach

9.3.1 Consent Decree Requirement Approach

The Consent Decree requirement approach consists of a system wide method to addressing water quality and overflows. As stated earlier, the Consent Decree specifically states as part of the Alternative Evaluation preliminary screening process certain alternatives shall be carried forward for final consideration:

> *"**Partial and complete separation of sewers** in each CSO Outfall tributary area, and **deep tunnel storage**, shall be considered feasible technologies for this purpose and be carried forward for further evaluation. **Expansion of the primary and secondary capacity of the WRTP** shall also be considered feasible technologies for this purpose and be forward for further evaluation, as required by Section II.C.4 of the CSO Control Policy."*

Green infrastructure must also be considered as well as part of the Consent Decree and is included as part of the analysis.

For items that are considered "early action", DELCORA was required to construct a new pump station to replace existing pump station EPS-1. This new pump station, designated as PS-6 and placed in operation on September 5, 2018, is included as part of the modeling scenarios for each CSO Control Alternative and

will help in reducing discharges from Outfalls #2-5 and #7 along the Delaware River Interceptor and the West End Interceptor.

The Consent Decree approach consists of analyzing tunnel storage, sewer separation, WRTP expansion, and storage tanks separately coupled with adding in recommended green infrastructure practices from Corvias. For example, Alternative 1 consists of storage tanks throughout the CSS area as the LTCPU solution, Alternative 2 provides tunnel storage as the principal technology. These single technology practices are sized along with costs being developed to reduce the number of untreated CSOs in a Typical Year to frequencies of 0, 2, 4, 6, 8, and 12. Capital costs along with operation and maintenance costs are developed, in present value, utilizing cost curves to develop Knee-of-the-Curve cost performance. The impact of the size of practices are analyzed in the following subsection. In the event two Control Technologies give identical benefits, the lower cost option is evaluated. The goal of this analysis is to develop implementable and cost effective Control Technologies.

To give an idea of current conditions, specifically with regard to percent capture, **Table 9-1** gives current percent capture by segment during wet weather flow. Wet weather is categorized as the time during precipitation and the 6 hours following the end of precipitation.

Table 9-1: Current Conditions Percent Volume Capture by Segment

Percent Capture by Segment			Total Percent Capture
Delaware River	Ridley Creek	Chester Creek	
81.7%	74.5%	89.5%	82.3%

Table 9-2 gives a detailed breakdown of the resulting wet weather percent capture for each of these overflow scenarios (0, 2, 4, 6, 8, and 12 overflow events required by the consent decree, as well as 20 overflow events, and the approximate overflows given by reaching 85% volume capture). These scenarios all assume that no outfall discharges more than a given number per year and no one outfall can exceed that number of discharges at any point during the typical year that is modeled for estimating wet weather flow for estimation of CSO volumes.

Table 9-2: Current Conditions Percent Volume Capture

Overflows	% Captured	Vol Captured (MG)
0	100.0%	272.22
2	98.4%	246.18
4	97.7%	235.79
6	96.5%	217.15
8	95.5%	199.94
12	94.1%	178.98
20	91.7%	140.48
43	85.0%	35.61

Current number of overflows at each regulator based on baseline conditions for the typical year as modeled by the H&H model are listed in **Table 9-3**. The number of overflows is shown at each regulator, with the Typical Year average given as well. **Table 9-4** lists the current or baseline overflow volumes for each regulator per year with the Typical Year average.

Table 9-3: Current Conditions Number of Overflows by Regulator

	Rainfall	NREG02	NREG03	NREG04	NREG05	NREG07	NREG08	NREG09	NREG11	NREG12	NREG13	NREG14	NREG15	NREG16	NREG17	NREG18	NREG19	NREG20	NREG21	NREG22	NREG23	NREG24	NREG25	NREG26	NREG32	NREG33

9.3.2 Targeted Approach

Compared to the Consent Decree approach, the Targeted approach utilizes information obtained from analysis of hydrologic/hydraulic and water quality modeling. By narrowing down areas to site Control Technologies, this allows for a more strategic focus to add more value to the Technologies being used as opposed to blanketing the combined sewer area with Alternatives to meet certain overflow scenarios.

The first step in determining which CSO areas to focus in was to look at the preliminary water quality modeling analysis. Results looked at each CSO outfall to the next downstream CSO. When examining the impact of CSOs on WQSs with background source exceedances left out of the analysis, there are no enterococcus, fecal coliform, or E. coli monthly geomean levels above the limits set by WQSs. The number of months when water quality standards were exceeded for the three receiving water segments for background and CSO sources and CSOs only are presented in **Table 5-3**

CSO volume capture still provides a pollution control benefit, and Control Technologies should be focused on the largest CSO overflow discharge volumes to maximize these benefits. The total percent capture needed is 85%, and the Control Technologies utilized should focus on the volume capture needed on each segment or regulator to attain the desired volume capture. This is the first step in the Targeted approach: identify a starting point to focus efforts to site Control Technologies.

9.4 Cost/Performance Evaluation of CSO Control Alternatives

An overview of the cost methodology utilized for looking at different Control Technologies is given in **Appendix O**. This overview looks at the development of cost curves for both capital and life cycle costs, along with the methodology to come up with Operation and Maintenance costs, contingencies, and escalation factors. The finalized costs for the Control Alternatives is given in the Implementation Plan presented in Section 10. The cost factors that have been considered for the ultimate ranking and selection of Control Technologies:

- Aligns with typical engineering practice
  - Normal design guidelines are followed with proven technology being able to serve as an example or precedent
  - The local construction market able to handle the installation
- Site constraints
  - Added variables making the construction more difficult to design, such as existing utilities or infrastructure, adjacent structures to the building site, or narrow streets
- Land availability
  - Public or private
  - Land can be utilized for its intended purpose
  - Is the site expandable for variations for the alternative in the future
- "Expandable" Alternatives
  - Fluctuations in population and the CSS sewershed will result in variations of flow in the future
  - Can the Alternative expand or be modified in its services and capacity with the changing needs of the city
- Ease of permitting/potential permitting issues
  - How easily can permits be obtained for local, state, or federal agencies regarding areas such as wetlands, roads/streets, open space, etc.
  - How does the Alternative couple with the effluent permit?

9.5 Non-Monetary Factors for CSO Control Alternatives

Non-Monetary factors consist of multiple items that go into the ultimate ranking and selection of Control Technologies. Some of these factors involve certain aspects of cost, but aren't related to the direct capital cost as dictated in the cost curve information. The following is a breakdown of the non-cost factors that have been considered for ultimate ranking and selection of Control Technologies:

- Short term public impact during construction
  - Minimizing negative impacts like traffic and water shut-off
- Long-term public impact post-construction
  - Maximizing direct benefits like new park installation or improvement
- Incorporating multiple ancillary community benefits
  - Consideration of community benefits such as aesthetics, green stormwater infrastructure utilization, energy efficiency, and resource recovery.
- Effective at reducing CSO-related items
  - Flooding reduction
  - Effective at reducing the number and volume of CSOs beyond the Consent Decree requirements
- Consideration of sensitive/priority areas

9.6 Development of CSO Control Technology Alternatives

9.6.1 Consent Decree Approach Control Alternatives

The Consent Decree approach is used in this LTCPU to size alternatives for each of the overflow event scenarios. In the model itself, the Technologies located are theoretical locations where they would more than likely be sited if taken further in design. For example, a large tunnel for storage would most likely be placed along the Delaware River Interceptor on Route 291. Storage tanks would be placed next to the regulator as opposed to higher up in the sewershed. Green infrastructure will be included from recommendations from Corvias in specific CSO locations, which consist of green streets, permeable pavement, and underground storage.

The sizing of the Control Technologies is completed by a combination of spreadsheet calculation and formal modeling using EPA-SWMM. In situations where the control technology will have an impact on the hydrology of the downstream areas, such as sewer separation or green infrastructure, modeling is necessary. For technologies that will only detain overflow for release back into the conveyance system to the WRTP, spreadsheet calculations can be utilized to store the appropriate storm event. For instance, if the goal is to find the size of a storage tank for 4 overflow events a year, the storm event causing the fifth-largest CSO overflow volume that year is identified. The storage tank will then be sized to accommodate the entire overflow volume equivalent for this storm for the corresponding regulators. All storm events with less CSO overflow volumes will be fully captured, and any overflows occurring from volumes greater than this storage tank will still be significantly reduced.

Some Control Technologies have been identified by the Consent Decree to help meet the maximum number of yearly overflow events (0, 2, 4, 6, 8, and 12). Some of these Control Technologies can be used globally to help reduce the volume and number of overflows, but make it difficult to meet the desired overflow conditions. Sewer separation, for example, completely disconnects an area, to allow no

overflows in a year, but can be difficult to predict which areas would be ideal for any other overflow amount. Storage Technologies (tanks, tunnels) are the most reliable Control Technologies to guarantee these overflow conditions are met.

In addition, the overflow volumes for each regulator was calculated from current, or baseline, conditions to determine what the system wide sanitary sewer capture percentage would be to meet Consent Decree compliance. These can be found in **Table 9-2**, along with 20 overflows a year, and the compliance minimum of 85% system wide capture. By calculating these capture percentages for the yearly overflows, it provides a good comparison between the alternatives developed from the Consent Decree approach and the Targeted approach by providing equivalent capture.

9.6.2 Targeted Control Alternatives

The Targeted approach is used in this LTCPU to determine groupings of control technologies to help achieve the water quality requirements of the Consent Decree while still following the cost and non-cost factors listed in **Subsections 9.4 and 9.5**, respectively. The relative importance of these factors' weights on the control technologies used was determined in an internal DELCORA workshop in Spring 2018. After the workshop, the cost factors were determined to be significantly more important to the final control technologies than the non-cost factors, and are the primary influence on the alternatives' development. The non-cost factors are still considered in the grouping of control technologies as a secondary influence, when possible. For example, tanks can be used for stormwater capture along the well-trafficked areas along Edgmont Avenue, but green infrastructure provides an additional aesthetic the public can enjoy, while also capturing stormwater flows that would otherwise drain toward CSOs in Ridley Creek.

The primarily targeted overflows are from CSO regulators 2, 5, 7, 17, 18, and 19. These areas generally correspond to the highest CSO volume discharges (found in **Table 9-2)** in the Delaware River, Ridley Creek, and Chester Creek with the exception of CSO regulator 7, which is located near the Flower Street Chester City Boat Ramp on the Chester Riverfront, an area identified by the public as an area of interest. Other CSO regulators in nearby areas are included as secondary targets if any control technologies can also provide capture in addition to the primarily targeted overflows. Corvias recommended a number of locations for green infrastructure, and DELCORA requested a focus on maximizing the use of locations near CSO regulators 18 and 19. Regulator modifications are a low-cost option DELCORA can implement in all regulators, and are included in every one of the Targeted control alternatives. This creates a distinction between "global" alternatives created by the control technologies listed in the Consent Decree to control for various overflow levels, and "regulator modification" alternatives created through this targeted control of overflow.

Once the technologies were identified, they were combined into alternatives and modeled in EPA-SWMM. Storage tanks were sized and added to some of the alternatives to provide additional options for the Consent Decree approach. This continued until a total of 15 alternatives were finalized for final discharge and cost analysis.

9.7 Alternatives for Final Analysis

To assemble alternatives for a final selection, the technologies required by the Consent Decree were first considered. These include the following:

- Tunnel Storage
- Tank Storage
- Green Stormwater Infrastructure
- Plant Expansion
- Sewer Separation

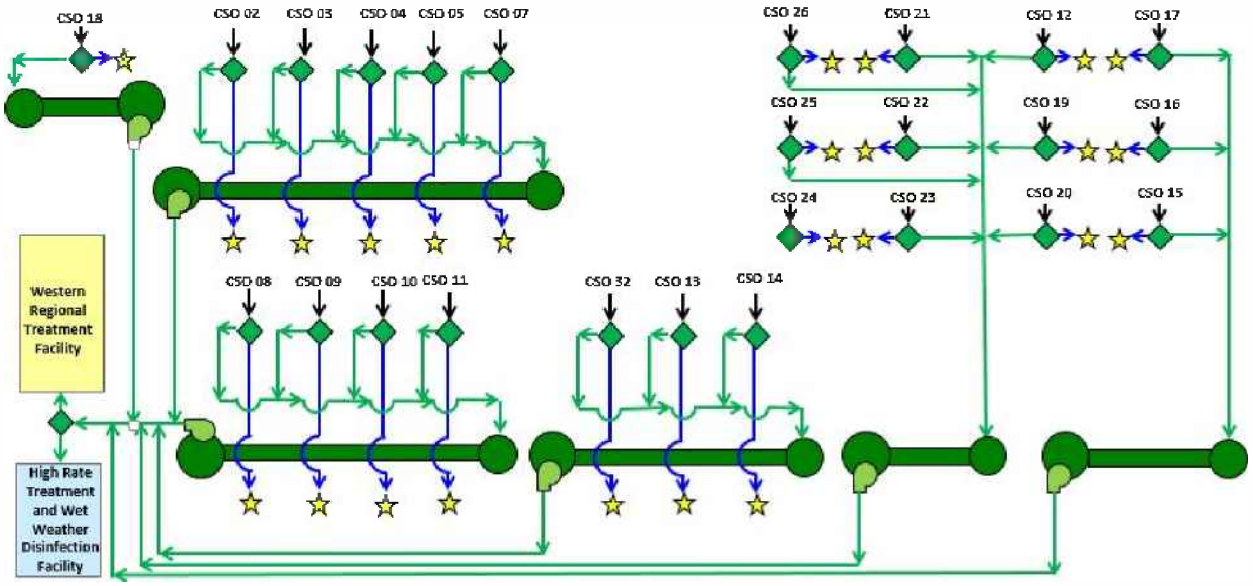
Other feasible CSO control technologies identified through the alternative screening and targeted approach include the following:

- Regulator Modification
- CSO 5 Partial Separation
- West End Interceptor Expansion to PS-6
- Delaware River Parallel Interceptor

Tunnel Storage

This CSO control technology consists of 6 storage tunnels of various diameters at the most downstream point of grouped CSO areas through various transmission mains that lead from the CSO regulators to the downstream storage tunnels. The diameters of the tunnels are sized for the level of overflow control desired, and can be used to supplement other control technologies. It is assumed that these tunnels will be gravity fed (no pumping required). **Figure 9-1** shows a schematic of the grouped CSO areas that feed the various tunnels serving as temporary storage devices.

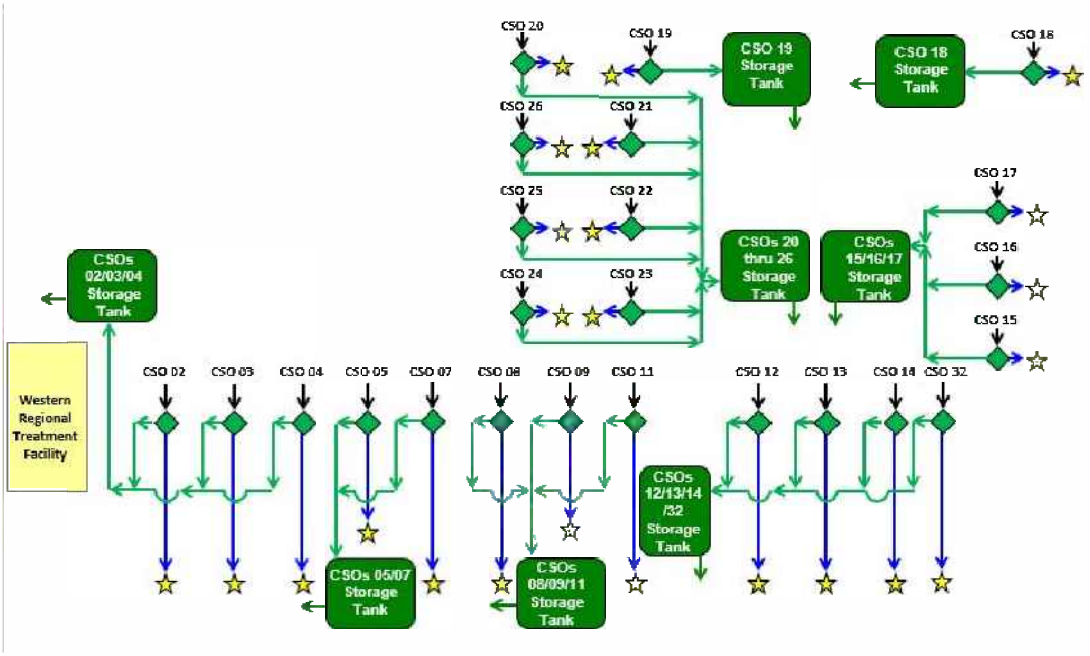
Figure 9-1: Schematic of Tunnel Storage Grouping



Tank Storage

This CSO control technology consists of 8 storage tanks throughout the study area at a depth of 15-feet at the most downstream point of grouped CSO areas through various transmission mains that lead from the CSO regulators to the downstream storage tanks. The tanks are sized for the level of overflow control desired, and can be used to supplement other control technologies. It is assumed that these tanks will be gravity fed (no pumping required). **Figure 9-2** shows a schematic of the grouped CSO areas that feed the various tanks serving as temporary storage devices.

Figure 9-2: Schematic of Tank Storage Grouping



Green Stormwater Infrastructure

This CSO control technology consists of 4 green infrastructure Control Technologies identified by Corvias in CSO areas 18 and 19. **Appendix N** in this document describes the overall process to determine the type and placement of the green infrastructure Control Technologies, also known as Green Stormwater Infrastructure (GSI). Strategically placed to ensure value in its installation, the GSIs include underground storage, permeable pavement, and green streets. Refer to **Subsection 8.5** for more details regarding Green Infrastructure Technologies applicable in these areas. One major constraint of this technology is its inability to achieve the levels of overflow control desired alone. However, GSI is a gravity fed source control and removes some levels of CSO-contributing stormwater through infiltration, making it an effective supplemental technology.

Plant Expansion

This CSO control technology consists of an expansion of the primary and secondary capacity of the WRTP by modeling ideal pumps, increased interceptor capacity, and regulator modifications to get this additional flow to the expanded WRTP. Pump station upgrades will be needed for an ideal pumping rate that allows all water at a pump station to reach the WRTP and not the CSO outfall. The additional

conveyance does not consider the piping outside of interceptor improvements to get flow from the inlets to the pump stations, so there may still be overflows that occur before reaching the interceptors. Plant expansion examined the following three options: equalization/storage tank at the WRTP, chemically enhanced primary treatment with discharge to CSO 002, and side stream secondary treatment/secondary treatment equivalent. These three options were estimated for cost, and the lowest-price option for each overflow requirement was selected for the most cost-effective treatment. The wet weather blending and side stream treatment sizing and costs were developed into a cost curve based on WRTP Process and Hydraulic Evaluation report in **Appendix P** for system modifications to receive increased flows at the wastewater treatment plant.

Sewer Separation

Sewer separation is a technology used to approach zero overflow events in a Typical Year. To comply with the Consent Order evaluation of alternatives, sewer separation has been applied as a system wide approach to reducing CSOs, implemented within the whole CSO area. By converting the combined sewer system into separate stormwater and sanitary sewage collection systems, this prevents any sanitary wastewater from being discharged to receiving water.

Regulator Modifications

Regulator modification is a Control Technology that allows the current regulator structures to be altered to maximize existing inline storage and flow, and minimize CSOs. Building diversion weirs up inside of the regulator prevents CSOs during smaller storm events, pushes more water into the interceptors, and utilizes upstream pipes as temporary storage. The regulator gates, orifice plates, and outflow pipes to the interceptors must also be altered to accommodate the increased flow. Should the increased flow be significant enough, plant expansion will also need to be incorporated utilizing one of the options presented in Alternative 5. **Table 9-5** gives more detail for the proposed regulator modifications that should be undertaken to obtain the desired conditions within the sewer network.

Each of the regulator modifications were made with a specific purpose. In general, the modifications can be classified in five categories: increasing the regulator gate opening, increasing the orifice plate opening, increasing the weir length, increasing the weir height, and increasing the effluent pipe diameter. The regulator gate and orifice plate sizes generally change together, as they both regulate flow. Increasing one may provide some increase of flow to the interceptor, but increasing both will decrease the hydraulic limitation. Increasing the length and height of the weir generally occurs together, but it depends on the existing weir height. Since the pipes are circular, if the existing weir is not covering at least half of the overflow pipe, then the weir length will increase with the weir height as the pipe gets wider at its center point. If the weir is already at covering at least half of the pipe, the length will actually decrease with the increasing height. This weir length adjustment is only done for modeling purposes, as the height is the important concept to understand when constructing the modifications. Increasing the weir's height holds back combined flow from the overflow pipe, and provides a very small form of inline storage utilizing the existing upstream piping. The water surface level of the inline storage is at its peak at the weir's new height, and provides some additional pressure for the stored water toward the interceptor. The last category, the increased effluent pipe diameter, is used when the additional water being pushed to the interceptor is limited by the existing pipe size. As this modification requires construction outside of the regulator to make a new connection to the interceptor, it is the most expensive, and used sparingly. Each of these modifications are made with the intent to make sure the downstream interceptor capacity is fully utilized before overflow occurs, to maintain a similar hydraulic grade line during peak flow, and to not cause significant surcharging from existing manholes.

Table 9-5: Overall List of Proposed Regulator Modifications

		Regulator Modifications				Increase Effluent Pipe Size
		Increase Gate Opening	Increase Orifice Plate Opening	Increase Weir Length	Increase Weir Height	
RCI	#013	x	x	x	x	x
	#014	x	x	x	x	
	#015	x		x	x	x
	#016	x	x	x	x	
	#017	x		x	x	x
	#018	x		x	x	x
CCEI	#019	x			x	
CCWI	#020	x	x		x	
PSI	#024					
	#025	x	x			
	#026	x	x			
EAI	#012					
	#021	x	x			
	#022	x	x			
	#023	x	x			
SSI	#08	x	x		x	
	#09	x	x		x	
	#11	x	x			
DRI	#05		x		x	
	#02					
	#03					
	#04					
	#07					

WEI Add a 36" connection at MH-1765 for #10 overflow

Note:

RCI: Ridley Creek Interceptor (CSO 33, 18, 17, 16, 15, 14, 13, 32)
CCEI: Chester Creek East Interceptor (CSO 19)
CCWI: Chester Creek West Interceptor (CSO 20)
PSI: Penn Street Interceptor (CSO 26, 25, 24)
EAI: Edgmont Ave Interceptor (CSO 21, 22, 23, 12)
SSI: Second Street Interceptor (CSO 11, 10, 9, 8)
DRI: Delaware River Interceptor (CSO 7, 5, 4, 3, 2)
WEI: West End Interceptor (CSO 10)

In addition to these changes, a specific modification will be made to CSO Regulator #10, where the orifice plate will be completely removed, the weir opening for overflow covered more, and the 15" effluent pipe fully replaced with a 36" pipe connected to the West End Interceptor. Before these changes, all overflow went to Regulator #9, where it would either flow into the 2nd Street Interceptor or overflow into the Delaware River. After these changes, the underutilized West End Interceptor will receiving significantly more flow from Regulator #10, providing in-line storage should the WRTP need to detain flow during larger storms. Detail of this connection can be found in **Figure 9-3**.

Figure 9-3: CSO Regulator #10 Modifications

All regulator modification costs assume a fixed cost based on an approximate regulator gate replacement size, which was obtained from discussions with the current contractor replacing upgrading the existing regulators for DELCORA. The three fixed costs are:

- 12" x 12" = $175,000
- 15" x 15" = $180,000
- 18" x 18" = $215,000

$12,000 is added for each regulator to account for access covers, 1 week of labor, traffic control, asphalt replacement, and scaffolding.

CSO 5 Partial Combined Sewer Separation

This CSO control technology differs from the complete separation option in scale. A partial sewer separation was identified specifically for the combined sewer area north of Veterans Memorial Park. By separating combined flow at Townsend St, stormwater flow will be reduced to the overloaded Delaware River Interceptor. The separated sanitary line will continue to CSO 5 with the remaining combined flow. Only a fraction of the stormwater is from the City of Chester; the remainder comes from the separated Chester Township lines that discharge over the surface at Veterans Memorial Park and into the existing CSS system. With this disconnection, the overland flow from Chester Township and the City of Chester will be diverted away from the CSS system and back into an existing storm sewer line. The estimate for this Alternative was provided by Remington & Vernick Engineers.

West End Interceptor Expansion to PS-6

The Delaware River Interceptor (DRI) has a bottleneck before it reaches the WRTP, not providing the correct amount of pipe conveyance capacity for the combined sewer area flow during storm events. A segment of the West End Interceptor (WEI) was discontinued, and flow was joined to the Delaware River Interceptor, placing the active 54" line into an already full 24" going to EPS-1. With the construction of PS-6, more flow can be pumped to the WRTP. Rehabilitating the discontinued segment of the West End Interceptor and building a connecting line to PS-6 would help relieve overflows along the Delaware River Interceptor regulators caused by this bottleneck.

Parallel Delaware River Interceptor

The DRI has a bottleneck before it reaches the WRTP, which limits the pipe conveyance capacity for the combined sewer area flow during storm events. The interceptor increases to a maximum of 24", but experiences frequent CSO overflows, especially near CSO regulator #5. This CSO control technology adds a 30" parallel interceptor to the DRI flow. The parallel interceptor connects CSO regulators 2, 3, and 4 to PS-6, following the same path as the existing DRI as a complimentary flow path when the 24" DRI line needs the additional conveyance capacity, as well as the additional pumping capacity necessary at PS-6 to handle the desired level of control.

The evaluation of some technologies for grouping led to some being utilized more than others. Green stormwater infrastructure cannot meet the water quality standards of the Presumption Approach in isolation, so this technology was combined to provide a system wide alternatives with other of those required by the Consent Decree. However, due to its ease of use and effectiveness, regulator modifications were used as a base modification for the targeted alternatives. The details the various alternatives that will be looked into further for final selection are presented in **Table 9-6.**

Table 9-6: Alternatives for Final Analysis

Alternative Number	Alternative Description
1	Tunnel Storage
2	Tank Storage
3	GSI + Tunnel Storage
4	GSI + Tank Storage
5	Plant Expansion
6	Sewer separation
7	Regulator Modifications
8	Regulator Modifications + Tank Storage
9	Regulator Modifications + GSI
10	Regulator Modifications + CSO 5 Partial Separation
11	Regulator Modifications + WEI Expansion to PS-6
12	Regulator Modifications + WEI Expansion to PS-6 + Parallel Interceptor
13	Regulator Modifications + WEI Expansion to PS-6 + Parallel Interceptor + Storage
14	Regulator Modifications + WEI Expansion to PS-6 + Parallel Interceptor + Storage + GSI + CSO 5 Partial Separation
15	Regulator Modifications + WEI Expansion to PS-6 + Parallel Interceptor + GSI + CSO 5 Partial Separation

Of note is the breakdown of alternatives between those system wide alternatives required by the Consent Decree (Alternatives 1-6), and the targeted alternatives built on regulator modifications (Alternatives 7-15). Based on the results of the model analysis and spreadsheet calculations, the volume capture percentages for each alternative will be understood, and costs assigned. The final alternative selection for each equivalent capture percentage will essentially be chosen based on the cheapest life-cycle cost option.

The following subsections are descriptions of each of the Alternatives listed in **Table 9-6**. Costs have been escalated to Philadelphia July 2018 using the Engineering News Record Construction Cost Index.

9.7.1 Alternative 1

- Tunnel Storage

Figure 9-4 depicts the locations of the various transmission mains that lead from the CSO regulators to the downstream storage tunnel. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-7**. These costs assume 45% Heavy Utilities Pipe Contingency, 50% Heavy Utilities Storage Contingency, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; and 1 COP @ $470,000/COP/yr, 1% Tunnel Maintenance/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

Figure 9-4: Tunnel Storage and Transmission Locations (Alt 1)

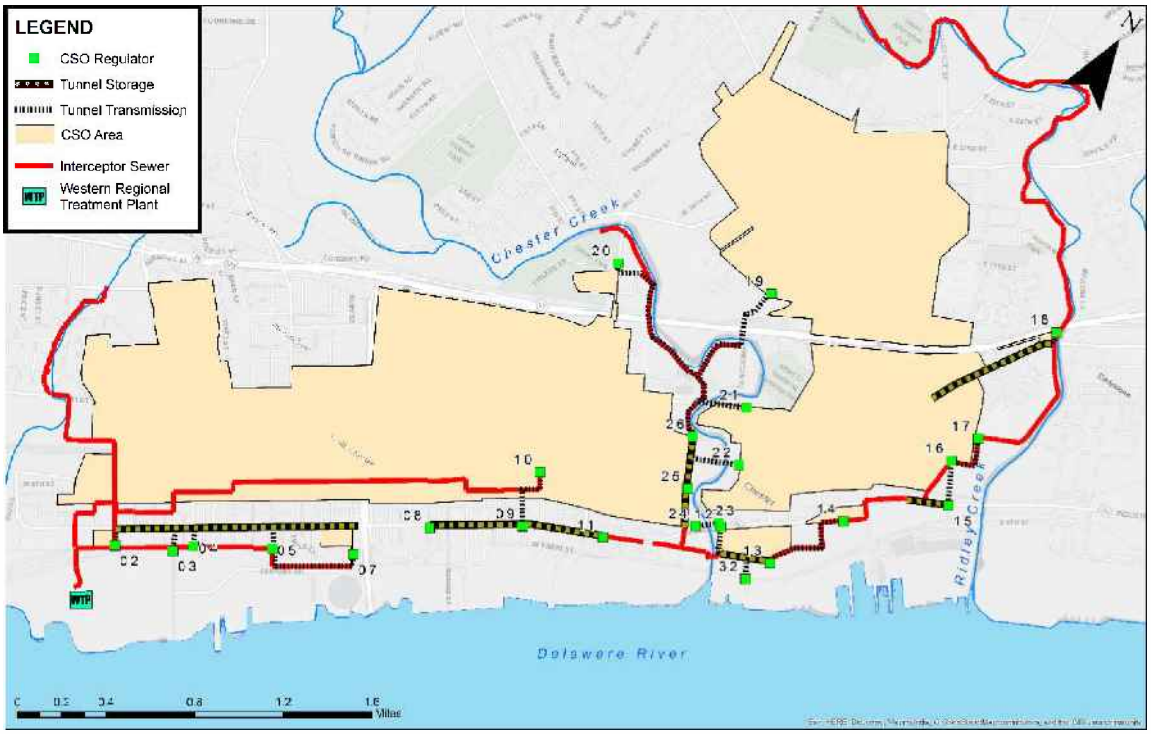


Table 9-7: Capital and Life Cycle Costs by Overflow for Alternative 1

OF/yr	Capital Cost ($)	Life Cycle Cost ($)
0	$ 198,300,000	$ 232,200,000
2	$ 165,900,000	$ 195,300,000
4	$ 153,900,000	$ 181,800,000
6	$ 133,300,000	$ 158,400,000
8	$ 126,100,000	$ 150,300,000
12	$ 111,700,000	$ 133,900,000
20	$ 76,500,000	$ 94,000,000
43	$ 27,600,000	$ 38,500,000

9.7.2 Alternative 2

- Tank Storage

Figure 9-5 depicts the various transmission mains that lead from the CSO regulators to the downstream storage tank The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-8**. These costs assume 45% Heavy Utilities Pipe Contingency, 50% Heavy Utilities Storage Contingency, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; and 0.5 COP @ $470,000/COP/yr, 3% Tanks and Structure

Maintenance Cost/yr, 0.25% Transmission Pipe Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

Figure 9-5: Tank Storage and Transmission Locations (Alt 2)

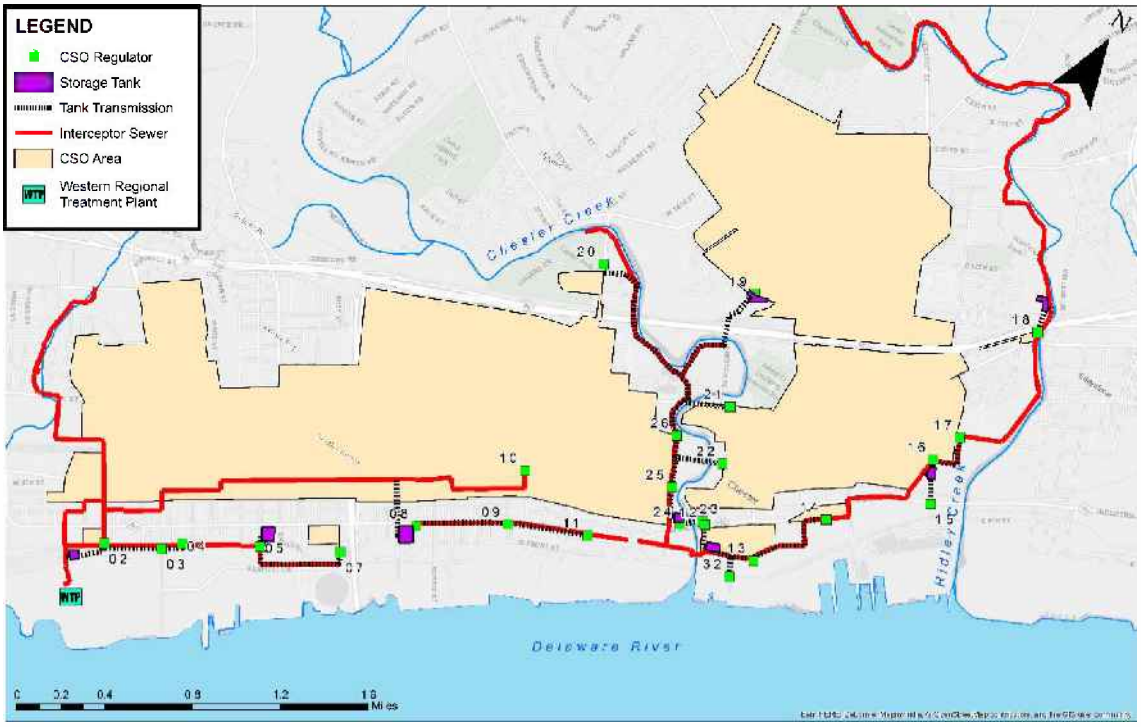

Table 9-8: Capital and Life Cycle Costs by Overflow for Alternative 2

OF/yr	Capital Cost ($)	Life Cycle Cost ($)
0	$ 246,000,000	$ 338,500,000
2	$ 159,700,000	$ 217,500,000
4	$ 142,800,000	$ 193,900,000
6	$ 123,300,000	$ 166,500,000
8	$ 108,900,000	$ 147,100,000
12	$ 95,100,000	$ 128,600,000
20	$ 73,000,000	$ 99,800,000
43	$ 52,900,000	$ 71,600,000

9.7.3 Alternative 3

- Tunnel Storage
- Green Stormwater Infrastructure

Figure 9-6 has the layout for Control Technologies comprising Alternative 3. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-9**. These costs assume 45% Heavy Utilities Pipe Contingency, 50% Heavy Utilities Storage Contingency, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; GSI costs are estimated in the Green Stormwater Infrastructure report in **Appendix N**; and 1 COP @ $470,000/COP/yr, 1% Tunnel Maintenance/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

Figure 9-6: GI, Tunnel Storage and Transmission Locations (Alt 3)

Table 9-9: Capital and Life Cycle Costs by Overflow for Alternative 3

OF/yr	Capital Cost ($)	Life Cycle Cost ($)
0	$ 199,500,000	$ 233,800,000
2	$ 164,100,000	$ 193,700,000
4	$ 146,200,000	$ 173,300,000
6	$ 130,100,000	$ 155,100,000
8	$ 124,500,000	$ 148,700,000
12	$ 110,800,000	$ 133,200,000
20	$ 78,500,000	$ 96,500,000
43	$ 37,700,000	$ 50,200,000

9.7.4 Alternative 4

- Tank Storage
- Green Stormwater Infrastructure

Figure 9-7 presents the layout for the Control Technologies included in Alternative 4. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-10**. These costs assume 45% Heavy Utilities Pipe Contingency, 50% Heavy Utilities Storage Contingency, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; GSI costs are estimated in the Green Stormwater Infrastructure report in **Appendix N**; and 0.5 COP @ $470,000/COP/yr, 3% Tanks and Structure Maintenance Cost/yr, 0.25% Transmission Pipe Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

Figure 9-7: GI, Tank Storage, and Transmission Locations (Alt 4)

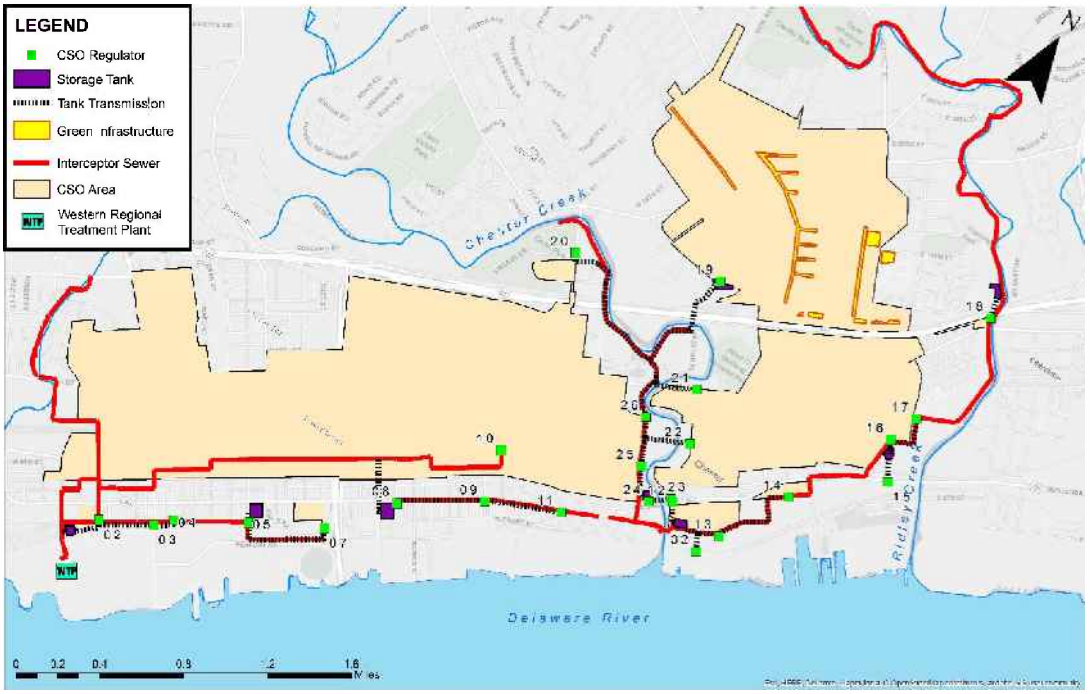

Table 9-10: Capital and Life Cycle Costs by Overflow for Alternative 4

OF/yr	Capital Cost ($)	Life Cycle Cost ($)
0	$ 247,900,000	$ 338,800,000
2	$ 163,500,000	$ 220,400,000
4	$ 145,500,000	$ 195,200,000
6	$ 128,100,000	$ 170,800,000
8	$ 114,200,000	$ 152,100,000
12	$ 101,700,000	$ 135,300,000
20	$ 79,700,000	$ 106,800,000
43	$ 63,000,000	$ 83,300,000

9.7.5 Alternative 5

- Plant Expansion

Figure 9-8 demonstrates which interceptor pipes would be upgraded for Alternative 5. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-11, Table 9-12** and **Table 9-13**. These costs assume 45% Heavy Utilities Pipe Contingency, 50% Heavy Utilities Storage Contingency, 45% Pump Station - Difficult Installation, 50% WWTP Upgrade – Difficult Modification, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; and 1 COP @ $470,000/COP/yr, 3% Tanks and Structure Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

9.7.6 Alternative 6

- Sewer Separation

Figure 9-9 depicts the combined sewer area to be separated – the entirety of the Combined Sewer Area in the City of Chester. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-14**. All separated sewer costs assume a per acre cost calculation except the regulator 18 drainage area, which uses the recommended approach cost in the Draft Feasibility Study for Pipe Repairs From M.H. 329 to M.H. 3070 and Combination Flow Mitigation for C.S.O. No. 18 in **Appendix Q**. These costs assume 45% Heavy Utilities Pipe Contingency, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from pipe installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; and 1 COP @ $470,000/COP/yr, 3% Tanks and Structure Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

Figure 9-9: Total Sewer Separation (Alt 6)

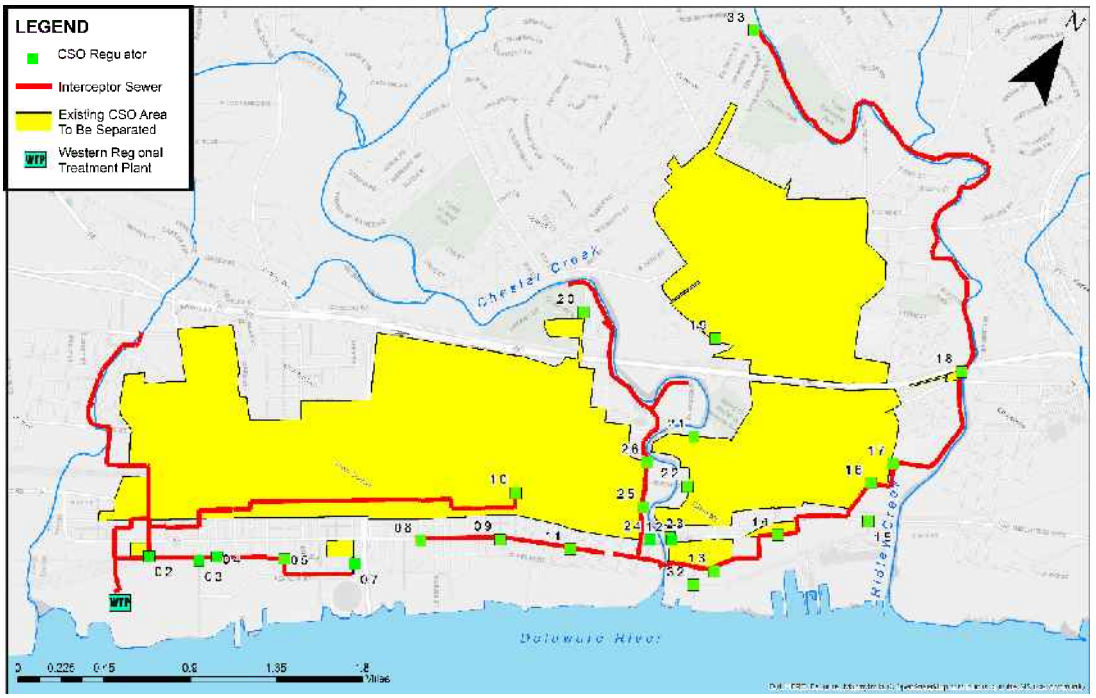

Table 9-14: Capital and Life Cycle Costs by Overflow for Alternative 6

OF/yr	Capital Cost ($)	Life Cycle Cost ($)
0	$ 186,000,000	$ 193,100,000

9.7.7 Alternative 7

- Regulator Modifications

The locations for any regulators identified for modification are listed on **Figure 9-10**. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-15.** These costs assume 45% Heavy Utilities Pipe Contingency, 25% Regulator/Real Time Control Contingency - Difficult Modification, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from pipe installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; and 18 Operational Labor Costs @ $2,500/regulator/yr, 3% Tanks and Structure Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

% Capture	Capital Cost ($)	Life Cycle Cost ($)
88.8%	$ 5,100,000	$ 14,200,000

9.7.8 Alternative 8

- Tank Storage
- Regulator Modifications

Figure 9-11 shows specific locations of storage tanks needed in addition to the implementation of regulator modifications. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-16**. These costs assume 45% Heavy Utilities Pipe Contingency, 50% Heavy Utilities Storage Contingency, 25% Regulator/Real Time Control Contingency - Difficult Modification, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; and 0.5 COP @ $470,000/COP/yr, 18 Operational Labor Costs @ $2,500/regulator/yr, 3% Tanks and Structure Maintenance Cost/yr, 0.25% Transmission Pipe Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

20	$ 54,800,000	$ 74,300,000

9.7.9 Alternative 9

- Tank Storage
- Regulator Modifications

See **Figure 9-12** for the layout of the GSI and the locations for any regulators identified for modification in this Alternative. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-17**. These costs assume 45% Heavy Utilities Pipe Contingency, 25% Regulator/Real Time Control Contingency - Difficult Modification, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; GSI costs are estimated in the Green Stormwater Infrastructure report in **Appendix N**; and 18 Operational Labor Costs @ $2,500/regulator/yr, 3% Tanks and Structure Maintenance Cost/yr, 0.25% Transmission Pipe Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital cost for life cycle costs.

% Capture	Capital Cost ($)	Life Cycle Cost ($)
89.0%	$ 9,400,000	$ 26,000,000

9.7.10 Alternative 10

- Regulator Modifications
- CSO 5 Partial Combined Sewer Separation

Figure 9-13 displays this Alternative's implementation of the partial sewer separation with the locations of regulators identified for modification. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-18**. These costs assume 45% Heavy Utilities Pipe Contingency, 25% Regulator/Real Time Control Contingency - Difficult Modification, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; the estimate for the partial separation of the regulator 5 drainage area was gathered from Remington & Vernick Engineers, which included 20% Sewer Separation – Heavy Utilities, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from transmission installation costs and 15% Engineering and Inspection, and 3% Permitting markups from construction costs for capital costs; and 18 Operational Labor Costs @ $2,500/regulator/yr, 3% Tanks and Structure Maintenance Cost/yr, 0.25% Transmission Pipe Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the total of both capital costs for life cycle costs.

9.7.11 Alternative 11

- Regulator Modifications
- West End Interceptor Expansion to PS-6

Figure 9-14 is an overall plan view of the layout of the WEI pipe expansion with the regulators identified for modification. The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-19**. These costs assume 45% Heavy Utilities Pipe Contingency, 25% Regulator/Real Time Control Contingency - Difficult Modification, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/ Demobilization markups from transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; the pipe rehabilitation and installation capital cost estimate for the WEI portion of this alternative taken from the Weston Solutions, Inc. LTCPU (April, 2012); and 18 Operational Labor Costs @ $2,500/regulator/yr, 3% Tanks and Structure Maintenance Cost/yr, 0.25% Transmission Pipe Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the total of both capital costs for life cycle costs.

9.7.15 Alternative 15

- Green Stormwater Infrastructure
- Regulator Modifications
- CSO 5 Partial Combined Sewer Separation
- West End Interceptor Expansion to PS-6
- Parallel Delaware River Interceptor

Figure 9-18 is an overall plan view of the layout of the WEI pipe expansion, DRI parallel interceptor, GSI additions, and partial sewer separation in the CSO regulator #5 drainage area, with the regulators identified for modification.

The Capital and Life Cycle Costs for this alternative are estimated in **Table 9-23**. Jack and bore costs for the parallel DRI pipe were estimated at 500 LF @ $1,500/LF based on the same work for the regulator 5 partial sewer separation. These costs assume 45% Heavy Utilities Pipe Contingency, 25% Regulator/Real Time Control Contingency - Difficult Modification, 15% Overhead & Profit, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from storage and transmission installation costs for construction costs; 10% Engineering, and 3% Permitting markups from construction costs for capital costs; the pipe rehabilitation and installation capital cost estimate for the WEI portion of this alternative taken from the Weston Solutions, Inc. LTCPU (April, 2012); the estimate for the partial separation of the regulator 5 drainage area was gathered from Remington & Vernick Engineers, which included 20% Sewer Separation – Heavy Utilities, 3% Bonds and Insurance, and 5% Mobilization/Demobilization markups from transmission installation costs and 15% Engineering and Inspection, and 3% Permitting markups from construction costs for capital costs; GSI costs are estimated in the Green Stormwater Infrastructure report in **Appendix N**; and 0.5 COP @ $470,000/COP/yr, 18 Operational Labor Costs @ $2,500/regulator/yr, 3% Tanks and Structure Maintenance Cost/yr, 0.25% Transmission Pipe Maintenance Cost/yr, O&M Present Value @ 20 yrs, 2.75% interest from the capital costs for life cycle costs.

Figure 9-18: Regulator Modifications w/DRI BN, DRI PI, CSO 18 GI, and CSO 5 PSS (Alt 15)

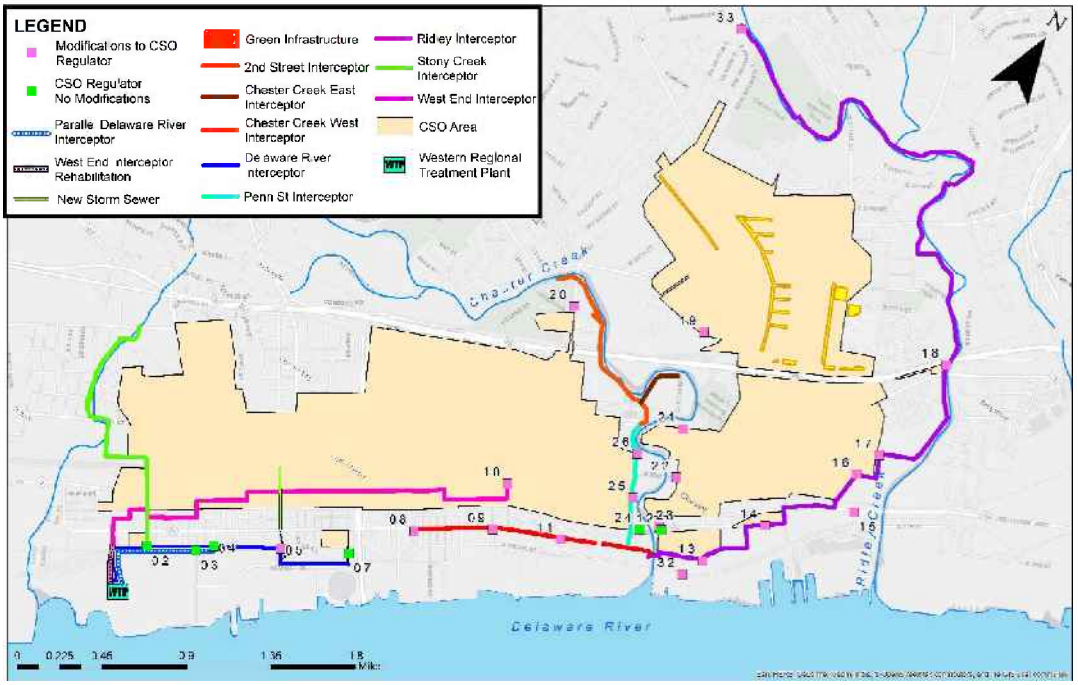

Table 9-23: Capital and Life Cycle Costs by Overflow for Alternative 15

% Capture	Capital Cost ($)	Life Cycle Cost ($)
94.0%	$ 43,000,000	$ 59,300,000

9.8 CSO Control Technology Knee of the Curve (KOTC) Analysis

The alternative plans above were modeled in EPA-SWMM before having the typical year run to find each plan's impact on CSOs and system wide percent capture. Alternative plans that allowed for CSOs to be limited to a specific number of discharges for a given year used spreadsheet analysis to determine the necessary storage sizes for each regulator grouping. The equivalent capture percent by overflows per year is presented in **Table 9-2**, and allows for a comparison between the alternatives that are tied to a maximum number of overflows per year, and the targeted approach alternatives based on system wide wet weather capture. The estimated capital cost for each project is presented in **Table 9-24**.

Table 9-24: Capital Costs by Control Technology Project

Project	Capital Costs (July 2018)
Regulator Modifications	$ 5,100,000.00
Parallel DRI	$ 3,500,000.00
WEI Interceptor Rehab & Extension	$ 2,400,000.00
CSO 18 & 19 GSI	$ 10,100,000.00
Plant Expansion/Upgrade	$ 15,500,000.00
CSO-5 Partial Separation	$ 4,400,000.00

The Unless a specific control technology cost was gathered from another estimate or quote, typical markups from the initial capital costs include the following list, where applicable, due to the heavily urbanized area of Chester City:

- Pipe Installation – Heavy Utilities Contingency (45%)
- Tank/Storage Conduit – Heavy Utilities Contingency (50%)
- Pump Station – Difficult Installation Contingency (45%)
- WWTP Upgrade – Difficult Modification Contingency (50%)
- Sewer Separation – Heavy Utilities Contingency (45%)
- Overhead and Profit (15%)
- Bonds and Insurance (3%)
- Mobilization/Demobilization (5%)

These costs are combined for a construction cost subtotal. This subtotal then has the following additional markups applied to get a Total Cost:

- Engineering (10%)
- Permitting (3%)

The total cost then has the following O&M costs applied, where applicable:

- Continuous Operating Post (1 COP = $470,000/yr)
- Tank/Structure Maintenance (3% of Construction Cost)
- Tunnel Maintenance (1% of Construction Cost)
- Pipe Transmission Maintenance (0.25% of Pipe Construction Costs)
- Regulator Cleaning Maintenance ($2,150/month)

The Present Values for these combined costs are then found for the next 20 years at $i = 2.75\%$. The sum of the Total Cost and the Present Value yields the Total Life Cycle Cost for each alternative plan. These costs can then be categorized by system wide capture percentage and compared. The Life Cycle costs for each alternative can be found on **Table 9-25.** This allows the lowest-cost Alternative to be identified by capture percentage. The lowest-cost Alternatives are selected and plotted by cost and capture percentage. This comparison is used to find which Alternative will yield the greatest results before significant increases in cost are needed. The point where this is to occur is the Knee of the Curve, and can be found on **Figure 9-19**. Alternative 15 was found to be this point on the KOTC curve, capturing 94.0% of the wet weather flow during wet weather conditions for $59.3M in Life-Cycle costs. Per the consent decree, the 0, 2, 4, 6, 8, and 12 overflow conditions for every CSO regulator were also specifically examined using the same procedure above. This KOTC by overflow can also be found in **Table 9-25.**

9.9 Current LTCPU Progress

DELCORA is currently making progress to improve WQ in the Delaware River, Ridley Creek, and Chester Creeks. The design and construction of the Regulator Monitoring System and replacement of Regulators 2, 3, 4, 5, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 21, 23, 24, 25 and 26 has been completed. Pipe grouting and other miscellaneous repairs have been made to the Ridley Creek Interceptor. In collaboration with Brookhaven Borough, DELCORA has performed partial sewer separation for the combined sewer area flowing into CSO regulator 33, reducing its overflow volume and frequency, and therefore the POC introduced into Ridley Creek. This action corresponds to reducing flows into an area of the Ridley Creek upstream of an area designated as Approved Trout Waters and Trout Stocked Streams, which were identified as a priority area because of this special environmental use. Chester East and Chester West Interceptors have also had grouting work performed on their pipe joints. Property has been purchased to expand the available area for future projects relating to the LTCPU. Construction of pump Station 6 is complete, and now conveys more flow to the WRTP. A table of all of the improvements made since the original LTCP in 1999 through 2018, including those implemented for the Nine Minimum Controls, can be found in **Table 9-26.** These costs have amounted to roughly $150M in work performed.

9.10 Selection of Alternative Plans

Of all the alternatives, Alternative Plans 7 and 15 efficiently utilize the pollution control benefits of the existing CSO system through reduction of wet weather overflows into the receiving waters. Alternative 15 has a higher cost and public disturbance, balanced by increased overall community benefit.

Alternative 7 was modeled to achieve almost 89% capture through regulator modifications alone. This technology alone best utilizes the existing infrastructure, and therefore provides the best cost savings of any of the proposed alternatives. Alternative 7 requires minimal investment into the infrastructure, but does not provide any further advantages outside of cost and minimizing short-term land disturbance. Wet weather flows to the WRTP will increase, and an additional study of the impact of these modifications on the WRTP may need to be performed after the alternative's operation.

Alternative 15 achieves a 94% system wide capture of wet weather flows before costs significantly increase for the higher capture rates. There are more CSO control technologies proposed in this alternative than in Alternative 7, but if further investment is possible, there is an argument that this is the best alternative based on the KOTC. All of the proposed targeted control technologies are utilized in this alternative. This means that all of the higher volume CSOs will be reduced in some form from this

alternative, something Alternative 7 does not guarantee. It also means that the non-cost factors considered in the development of the Targeted control technologies will be employed.

Utilizing green infrastructure for the regulator 18 and 19 drainage areas provides additional benefits for the surrounding community. The residential neighborhood, Widener University, and Edgmont Ave areas with the green street additions provide an aesthetic dimension to the road that was not there before. The Edgmont Ave corridor benefits even more from this green infrastructure beautification as a main thoroughfare into the city. The Stormwater Authority of Chester will ensure the continual operation and maintenance of the GSI.

The other additional control technologies implemented in Alternative 15 support DELCORA in the long-term to handle future increases in wet weather flow. The partial separation of the CSO regulator 5 drainage area is the most efficient control technology by cost per MG of overflow, and provides more capacity in the DRI during wet weather. Removing the DRI bottleneck and adding a parallel DRI interceptor line significantly increases flow to the WRTP instead of out of the CSO outfalls along the Delaware River. The newly completed PS-6 allows for these greater flows to be conveyed to the WRTP. Further studies on the impact of these flows to the WRTP need to be conducted after the completion of each control technology, but the CSO impact on receiving streams will be greatly lessened.

After evaluating the cost factors from the KOTC analysis, the non-cost factors and the existing infrastructure improvements made through LTCP early action items, an adaptive management plan that incorporates both Alternatives Plans 7 and 15 is the plan selected by DELCORA. Through adaptive management, improvements from Alternative 7 will be evaluated after their implementation, and further control technologies added from Alternative 15 pending the results of post-construction monitoring. A summary of the current baseline, Alternative 7, and Alternative 15 conditions are in **Table 9-27**, **Table 9-28** and **Table 9-29**. The control technologies can be modified based on flow data received from post-construction monitoring.

9.11 Unauthorized Releases

The selected CSO alternative plans will address most of the unauthorized releases within the DELCORA CSS. Based on the current modeling and monitoring, the LTCPU has identified four areas where the conveyance capacity level of service is known to be inadequate, leading to unauthorized releases. Four areas will require control technologies for the remaining unauthorized releases. These include the following:

- Central Delaware Pump Station
- Manhole 2897 in Nether Providence Township
- Manhole 591 in Upland Borough
- Old Mill Pump Station (OMPS)

Projects and Schedules to address these areas are described as follows:

The June 2018 Central Delaware Pump Station Act 537 plan addresses overflows above the DELCORA Central Delaware Pump Station (CDPS) through the construction of the Crum Creek Diversion Pipeline. This will reduce flows to the CDPS at an estimated cost of $8.6 Million and reduce the incidence of SSOs above the CDPS. This project is moving forward. DELCORA's evaluation of metered flows above the

CDPS indicates that there is likely excessive infiltration inflow that can be removed from the drainage area thereby further reducing the risk of SSOs.

Manhole 2897, located in Taylor Arboretum along the RCI, has a history of unpermitted CSOs. The following adaptive plan is incorporated into the LTCPU addressing Manhole 2897:

- Regulator and overflow modifications at CSO regulators 18 and 33 to reduce surcharge conditions in the Ridley Creek Interceptor
- Evaluation/implementation of manhole modifications to address additional surcharging without damaging existing infrastructure or causing sewer backups
- Evaluation/implementation of controls to address excessive I/I
- Adaptive management review after implementation of the above steps to determine if storage or pumping upgrades are needed to meet the design level of service and/or if continued cost effective I/I control should continue

Regulator, manhole, and I/I actions needed to address Manhole 2897 will occur in the DELCORA-owned and operated service in Nether Providence. If adaptive management indicates a need for storage, DELCORA believes at least one appropriate location is available in Nether Providence.

Manhole 591 is located in the Upland are of the DELCORA Owned and Operated service area, near the intersection of 10th and Church Streets. It has a history of capacity-related SSOs. Current modeling of the collect system indicates that installation of a relief sewer line will mitigate unauthorized releases and provide the design level of service. This parallel sewer is to be installed from Manhole 591 to Manhole 641. In addition, cost effective I/I control will be evaluated and implemented if needed to meet the design level of service.

The Rose Valley service area includes the OMPS which conveys flow to the Rose Valley Pump Station (RVPS), which pumps flow out of the Middletown Township collection system and ultimately to the Chester Ridley Creek Pump Station and Force Main to the WRTP. In 2018 it was discovered that the OMPS includes a wet well overflow to a submerged outfall in Ridley Creek. The following actions have been taken and are planned as a part of the LTCPU:

- The OMPS overflow has been sealed
- A supplemental pump has been installed at the OMPS
- I/I studies have begun
- I/I controls including manhole rehabilitation, public sewer lining, and pump station capacity increases will be implemented based on the results of the I/I studies
- Adaptive management review after completion of the above steps to determine if private I/I sources need to be addressed or increases in wet well storage capacity are needed.

Most of the sewer infrastructure in the Rose Valley service area is owned and operated by DELCORA with the exception of sewers in Nether Providence. These sewers contribute significant peak wet weather flows to the OMPS. Controls in Nether Providence will need to be implemented to control peak flows.

The above actions will be evaluated for adequate levels of service based on the two-year storm recurrence design. These projects will be implemented regardless of the selected alternative, and the implementation schedule for these projects in addition to the CSO control alternatives is in **Subsection 10.3.6**.

9.12 Satellite System Infiltration and Inflow Control Program

Monitoring and modeling conducted by DELCORA indicates that there is I/I in the satellite systems. Satellite systems are areas served by but not owned by DELCORA. Such excessive peak flows must be addressed for the following reasons:

- The Consent Decree requires that SSOs be addressed. Excessive infiltration and Inflow is the cause of capacity-related SSOs;
- The success of the CSO control program laid out in the LTCPU is contingent on controlling existing and future excessive I/I in the satellite systems;
- System deterioration over the long-term must be addressed in order to minimize future capacity-related SSOs and CSOs;
- Addressing excessive I/I should reduce the long term cost to all DELCORA users

Based on the LTCPU studies there are opportunities to cost-effectively address peak wet weather flows to provide higher levels of system service. Examples include the overflow at the Taylor Arboretum and at the Central Delaware Pump Station discussed above in **Subsection 9.11**.

DELCORA has begun a program of I/I evaluation and remediation in areas where DELCORA owns the sewer infrastructure. In areas where DELCORA does not own the sewer system, the responsible jurisdiction will be asked to conduct an I/I evaluation with DELCORA's assistance to meet the four objectives listed above. DELCORA may also offer its services to conduct I/I evaluations for any jurisdiction which requests it.

The determination of cost effective I/I control requires balancing the cost of reducing I/I against the costs to convey and treat such flows. Because cost effective evaluation is based in part on the cost of treatment, cost effectiveness will be evaluated based on the receiving treatment facilities. A cost effectiveness evaluation will be performed for the Western Service Area served by the DELCORA WRTP and another cost evaluation will be performed for the Eastern Service Area served by the Philadelphia Water Department's Southwestern treatment facility.

THIS PAGE INTENTIONALLY LEFT BLANK

Section 10 Implementation of the CSO LTCP Update

10.1 Introduction

The conclusion reached from the Alternatives Analysis (**Section 9**) was a selected plan for the completion of implementing the CSO control technologies as capital projects in an affordable manner. The purpose of this section is to discuss the overall execution of the LTCPU, including the financial capabilities of DELCORA and the impact of the selected plan to determine how and when DELCORA will be able to implement the chosen control technologies. This implementation will provide a path for the completion of these capital projects within 10 years.

10.2 Financial Environment

At the request of USEPA and PADEP, a draft Financial Capability Assessment (FCA, **Appendix R**) and Supplement (**Appendix S**) was submitted prior to the completion of an H&H model for the DELCORA system. As a result, a number of assumptions regarding contributions of the separate and combined systems to wet weather flow and CSO discharges were made. As LTCPU development continued, the H&H model was updated, calibrated, and validated. As a result of this modeling effort, the assumptions utilized for the preparation of the Draft FCA have been superseded by the information obtained through the H&H model. Modeling results of the DELCORA system suggest that reducing excessive I/I in the separate areas will be necessary in order to achieve the required reduction of CSOs in the combined system. Therefore, this LTCPU has been developed with the understanding that both separate and combined systems will fund the LTCPU as appropriate. The current recommended plan is affordable without exceeding acceptable levels of cost on an MHI basis, as long as:

- Upstream communities' excessive I/I into downstream sewer infrastructure is affordably addressed;
- DELCORA's Eastern Service Area costs do not upset the City of Chester's financial capability to implement its share of these wet weather controls;
- Excess flow wet weather treatment as recommended at DELCORA's WRTP to obtain over 90%, is approved by PADEP and/or USEPA.

Out of the 44 municipalities DELCORA serves, the City of Chester is the poorest municipality in the DELCORA service area, and also the only municipality with a combined sewer system. The City of Chester is a financially distressed municipality as defined by the 1987 Financially Distressed Municipalities Act 47, and will remain in the Act 47 program until financial health improves. When 37% of Chester's citizens are living under the poverty line but the population is increasing, and median household income is flat, it can be difficult to fund the projects required for the selected plan. DELCORA also does not own or operate all of the wastewater collection systems in their service area, making the exact costs to residential customers unknown and difficult to assess all costs across their service area.

The following values provide a good assessment of financial capability of the City of Chester, and if values are weak or strong financial indicators according to the FCA:

- Median household income: $28,350 (weak)
- Total annual wastewater and CSO control costs per household as a percent of median household income: 1.6% (mid-range)

- Overall net debt as a percent of full maker property value: 13.4% (weak)
- Property tax revenues as a percent of full market property value: 1.2% (strong)
- Property tax collection rate: 81.7% (weak)
- Unemployment: 8.6% (weak)
- Bond rating: A (mid-range, suspended 1/6/2014)

Whatever approach is taken to increase rates, the City of Chester must avoid a "high burden" by refining a proportional cost methodology to attribute CSO events to each municipalities. Current rate of increase averages out to approximately 4% rate increase in DELCORA's fees per year.

The current Chester base rate is $5.32 per 1,000 gallons in 2019, or $372.40/EDU/yr (assuming 70,000 gallons/EDU/yr). Under the Long Term Control Plan, the City of Chester is responsible for completely financing the regulator modifications to reach 85% capture in the CSO area for the typical year. The allocation of the remainder of the LTCP costs will be determined in the future by the DELCORA Board. Additional needs beyond the LTCP may result in greater increases to customer rates.

10.3 Long-Term Control Plan Implementation

10.3.1 Combined Sewer Overflow & Unauthorized Release Projects

The following is a list of LTCPU CSO & SSO capital projects to be completed based on the selection of the chosen plan, listed by the receiving water body:

Delaware River

- Modifications in regulators 5, 8, 9, 11, 13, and 14 to push more flow into the interceptors and build higher diversion weirs to hold flow back from outfalls to the Delaware River.
- Regulator 10 outfall connection modification to the WEI using a 36" pipe, redirecting additional flow from the Second Street Interceptor from this regulator.
- A sewer separation of the combined sewer area upstream of Veterans Memorial Park in the Regulator 5 drainage area will be separated at Townsend Street, and reduce stormwater flow to the overloaded DRI. The separated sanitary line will still flow to Regulator 5, along with the remaining combined sewer piping in the drainage area.
- Construction of a parallel 30" interceptor next to the DRI. This will be connected to regulators 2, 3, and 4 and allow more flow to reach the new Pump Station 6 (PS-6).
- Rehabilitating an existing portion of the 54" WEI, then extending it for a direct connection to PS-6 to relieve a bottleneck of flow where the WEI and DRI join at a single 24" line.

Ridley Creek

- Modifications in regulators 15, 16, 17, and 18 to push more flow into the Ridley Creek Interceptor and construction of higher diversion weirs to hold flow back from outfalls to the Ridley Creek.
- Subsurface infiltrating Green Stormwater Infrastructure (GSI), or equal, between Providence Ave, Upland St. and 13th St.

- Permeable pavement and possible bioretention GSI (or equal) along Walnut St. from 13th to 18th Streets.
- Evaluation and implementation of modifications and I/I control along the RCI to determine if storage or pumps are needed near Taylor Memorial Arboretum.

Chester Creek

- Modifications in regulators 19, 20, 21, 22, 23, 25, and 26 to push more flow into the interceptors and construction of higher diversion weirs to hold flow back from outfalls to the Chester Creek.
- Permeable pavement and bioretention GSI (or equal) along Crozer St. from Gray to 21st Streets.
- Permeable pavement and bioretention GSI (or equal) along Edgmont Ave. from 14th to 22nd Streets.
- Installation of relief sewer line to mitigate unpermitted manhole discharge in Upland Borough.

Other

- I/I controls in the Rose Valley area pending the results of the ongoing I/I studies.
- WRTP construction to meet criteria for 50 MGD daily rerate and new wet weather flow capacity beyond 88 MGD.
- Installation of a visual public notification system for CSOs at regulators 2, 7, 11, 16, 18, 19, 22, 24, and 33.

Additionally, DELCORA will evaluate whether it would be more cost-effective to transfer ESA flows to a new/expanded DELCORA facility. Such evaluation will factor into the financial analysis reimbursement from PWD of the value of DELCORA's right to use 50 MGD (long-term average) and 100 MGD (peak) at the PWD's Southwest Water Pollution Control Plant. Based upon the outcome of that evaluation, DELCORA may propose an amendment to this overflow control plan and/or implementation schedule for the regulatory agency's review and approval.

10.3.2 Performance Criteria

Upon completion of the CSO and SSO projects described in **Subsection 10.3.1**, post-construction monitoring should be in place to study the changes in overflow rates and volumes. The selected plan was modeled to achieve 94.0% capture, which equates to an average of 78.5 MG of CSO overflows per year occur, with zero SSO events. The consent decree requires an 85% wet weather capture on an annual system wide basis for the typical year, however, and is the performance criteria that will be used for the LTCPU capital projects, with the potential for additional capture. The additional LTCPU capital projects will be monitored internally by DELCORA to achieve a minimum wet weather capture percentage of 90%, with the intention of capturing as close to the modeled capture percentage as possible, if not more with the selected plan.

10.3.3 Anticipated Water Quality Improvements

The Water Quality Model confirmed that the contributions of the selected plans do not cause CSOs to preclude WQS in their respective discharge waters. **Table 10-1** contains the number of baseline exceedances for the POCs. The WQSs for these POCs can be found in **Table 2-3**. The Applicable Water Quality Standards Master Table that was developed to identify the specific WQS for each of the three receiving water bodies is presented in **Appendix B**.

The results are the same as the baseline except that for Alternative 15, the fecal coliform excursions in Ridley Creek are reduced from 24/36 to 23/26 (1 month). Both selected plans help decrease the relative contribution from CSOs to water quality impairments, however, and the impact on receiving water quality is relatively greater for Alternative 15 than Alternative 7, as evident by the one-month decrease in fecal coliform excursions. **Figure 10-1** is a bar graph comparing each of the CSO regulator's discharge volumes between the three scenarios. The results of this bar graph presents a reduction in CSO volume from the Baseline condition to Alternative 7 and Alternative 15, respectively.

Table 10-1: Baseline Water Quality Standard Excursions for Pollutants of Concern

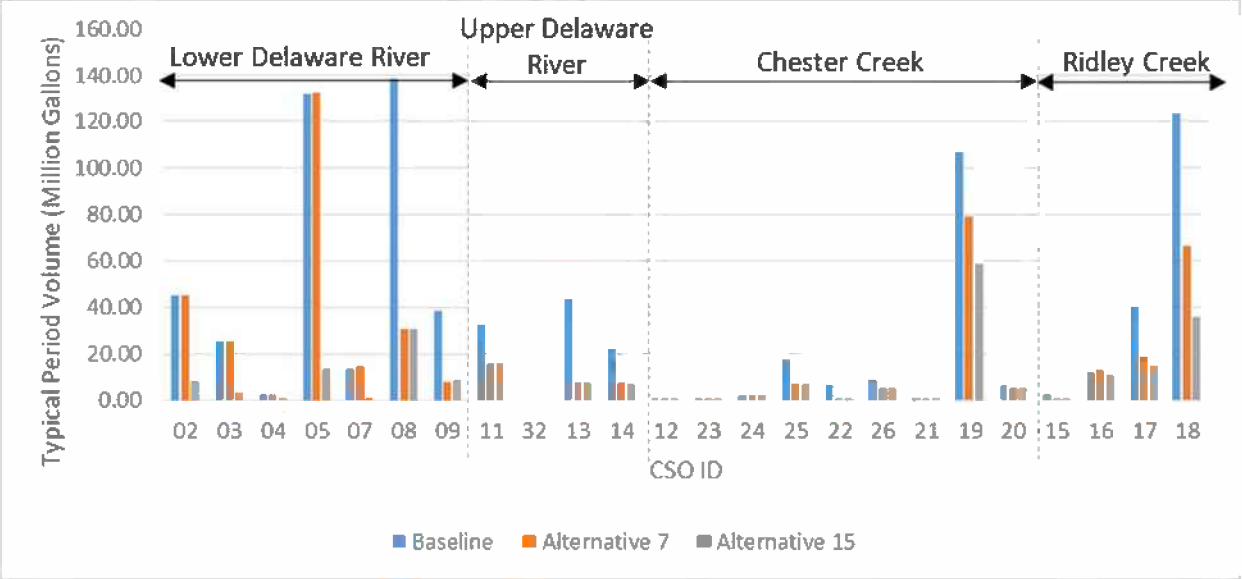
Figure 10-1 CSO Volumes Discharged (3-yr typical year period)



This reduction in volume decreases the CSO contributions of the POCs into the receiving streams. For fecal coliforms, Alternative 15 had enough impact to reduce the POCs to a level that met WQSs by one month. This POC reduction can be observed in **Figures 10-2**, **10-3**, and **10-4** through the decreasing size of the black portion of the bar graphs. The increased efforts to reduce bacteria loading in the Delaware River from CSO outfalls demonstrates DELCORA's readiness to improve the water quality upstream for year-of-young Atlantic Sturgeon. This habitat is approximately one-half mile downstream of DELCORA's southernmost outfall, CSO regulator #2, but the proposed improvements along the Delaware River Interceptor will also improve water quality by decreasing CSOs from upstream regulators #3, #4, #5, and #7.

10.3.4 WRTP Peak Flow Treatment

Implementing the parallel DRI will result in significantly increased flow delivered to the WRTP. Based on estimates developed early in the LTCPU process, PS-6 was added to the WRTP as an early action item. PS-6 was planned to increase the available peak pumping capacity to the WRTP to about 128 MGD, providing the potential for additional flow in excess of the peak hourly treatment capacity to come to the plant. It has been determined that 128 MGD is the required peak flow rate into the WRTP with the LTCPU capital projects. Based on the current peak flow analysis of all LTCPU capital projects, the Existing Service Area Characterization in **Section 6 – Existing Service Area Characterization** and the H&H model in **Section 4 – Sewer System Hydrologic and Hydraulic Model Update and Calibration**, and the WRTP Process and Hydraulic Evaluation from Weston Solutions, Inc. in **Appendix P**, complete secondary treatment is not possible with the current infrastructure at the plant.

The WRTP is currently rated for dry-weather treatment of 44 MGD, with a peak maximum of 88 MGD, twice the plant's rated flow. While flows in excess of 88 MGD do come through the plant, there is a decrease in efficiency from full secondary treatment at levels exceeding this flow rate. Attempting to provide a sufficient secondary treatment equivalent while providing at least primary clarification and solids and floatables removal and disposal could result in severe property damage as higher flows wash out the WRTP's secondary treatment system. DELCORA has a wet weather operations plan they follow during precipitation to handle wet-weather flows, which follow graduated steps dependent on the inflow volume. WRTP improvement projects were evaluated to provide the additional 40 MGD of secondary treatment up to the new estimated 128 MGD peak flow, but they were determined to be either technically or financially unattainable or practical based on the Weston report found in **Appendix P**, respectively. The list of projects at the WRTP that can address the LTCPU peak flow treatments needs include, but is not limited to, wet weather blending, chemically enhanced primary treatment, redirecting excess flow out of the CSO regulator #2 outfall, and additional storage detention at PS-6. Satellite treatment is also an option to address the peak flows offsite. An adaptive management assessment of these available projects

will be performed after the initial implementation of LTCPU capital projects in the selected plan to determine what modifications are necessary.

The WRTP has already been approved for 50 MGD rerating upgrade if an outfall extension in installed. The outfall extension projects in included in an Act 537 plan approved by a PADEP NPDES permit in February 2009, and Delaware River Basic Commission docket approval given in September 2011. This upgrade is possible due to DELCORA properly operating and maintaining their current secondary treatment system in order to meet secondary limits for flows greater than the peak dry weather flow, plus an appropriate quantity of wet weather flow.

10.3.5 Final Program Costs

The Life Cycle Costs to meet 85% wet weather capture for the typical year in Chester through regulator modifications alone is estimated at $14.2M. This cost will be recovered from the City of Chester. The funding for the remaining projects will be obtained from all contributing parties. This is expected to result in the City of Chester contributing $18.2M toward CSO control capital projects. **Table 10-2** contains the all estimated costs for the proposed projects. I/I flows from surrounding municipalities contribute significantly to the Chester CSS, and remaining capture costs for the CSOs and unauthorized releases is expected to be $103.7M.

Table 10-2: Estimated Capital & Life Cycle Costs of the Proposed Improvement Projects

Regulator Control Improvements	Capital Cost ($M)	Life Cycle Cost ($M)
Regulator Modifications	$ 5.1	$ 14.2
Targeted Overflow Reduction		
Parallel Delaware River Interceptor	$ 3.5	$ 3.6
WE Interceptor Rehab & Extension	$ 2.4	$ 2.5
CSO-5 Partial Sewer Separation	$ 4.4	$ 4.5
CSO 18 & 19 Green Infrastructure	$ 10.1	$ 11.7
RCI Arboretum Modifications	$ 7.2	$ 17.0
Upland Relief Sewer Line	$ 0.8	$ 1.0
Rose Valley I/I Controls	$ 3.0	$ 3.0
Monitoring and Modeling	$ 5.0	$ 5.0
Public Outreach	$ 3.0	$ 3.0
WRTP Plant Expansion/Upgrade	$ 15.2	$ 27.4
Visual CSO Public Notification System	$ 0.3	$ 1.4
Real Time Control	$ 0.4	$ 1.0
Crum Creek Diversion Pipeline	$ 8.6	$ 8.6
Adaptive Management		
Adaptive Management	$ 13.0	$ 13.0
Project Management	$ 5.0	$ 5.0
Total	$ 86.9	$ 121.9

10.3.6 Implementation Schedule

Based on the final program costs, an implementation schedule for the selected plan has been developed based on three elements, each containing different projects based on the element's purpose.

The first element consists of only regulator control improvements. These improvements increase the level of system wide annual average wet weather flow capture to 88.8%. This level of capture exceeds Federal Clean Water Act requirements under USEPA's Presumption approach. These modifications can also be paid for by the City of Chester in their entirety. For that reason, implementation of this project can begin immediately, but divided into three groups due to the number of modifications to be completed.

The second element encompasses the remaining projects that target overflow reduction to specific CSO regulator areas, but is dependent on other factors. While the regulator control improvements meet the Presumption approach requirements, monitoring and modeling indicate that the frequency and volume of CSOs are exacerbated by excessive peak flows from the separate sewer areas. The I/I from the separate areas upstream are filling the interceptors during wet weather, preventing the CSS in Chester from utilizing more of the interceptor conveyance capacity to prevent CSOs. These separate area flows can be addressed cost-effectively by adding to the regulator modifications with the following additional controls to alleviate the wet weather flow loading to the interceptor:

- Multiple locations for green infrastructure, including currently identified areas in Widener University's campus, between Providence Ave and Upland Street, on Edgmont Avenue north of I-95, Crozer Street, and other viable areas[10].
- Partial sewer separation of the neighborhood upstream of Veterans Memorial Park.
- Improving flow in conveyance piping along the Delaware River by adding to, extending, and rehabilitating the existing piping to alleviate bottlenecks.
- Overflow modifications at CSO Regulators 18 and 33 to reduce surcharge conditions in the RCI[11].
- Installation of a relief sewer line in Upland to mitigate unauthorized releases[11].
- I/I controls implemented to prevent wet weather flow from Rose Valley Pump Station[11].
- Public outreach to inform the general public about the status of the DELCORA system.

Each of these LTCPU capital projects have specifically targeted effects to reduce overflow in the DELCORA service area. For example, the removal of the noted sewer bottlenecks significantly increases the peak wet weather flows that can be delivered to the wastewater plant instead of overflowing. These controls will also significantly reduce the impact on the Flower Street Chester City Boat Ramp on the Delaware River as requested at public meetings.

As a result of delivering greater peak wet weather flows to the treatment plant through the regulator control improvements and these targeted overflow reduction projects, the current capacity of the treatment plant (88 MGD) would be exceeded about 3 times in the design year. While these flows could be

---

[10] In addition to the specific Green Infrastructure Project in the (CSO 18 & CSO 19) Neighborhoods, DELCORA anticipates funding additional Green Projects where such projects contribute to the cost-effective reduction of overflows.

[11] The location and scope of this technology has not been determined and will be open to public comment after more study is completed and before implementation

discharged out the combined system, real-time controls will be evaluated during a post-construction monitoring period. It will be necessary to study the peak wet weather flows and determine if real-time motor operated valves and controls in the regulators and conveyance system are necessary. The evaluation will provide confidence that any increased flows do not back up into homes or deliver excessive flow to the treatment plant without losing hydraulic and process control. After the flows are evaluated, additional improvements to the WRTP will be addressed. Excess flow wet weather treatment will include screening to remove trash and grit settling, (settling of solids and removal of floatables). This treated excess wet weather flow will be discharged out the existing CSO located adjacent to the plant. This partially treated flow will not increase the frequency of overflows at this CSO. This approach will simply capture more flow for partial treatment a few times in a typical year, whereas the flow would otherwise be discharged out of a CSO outfall without any treatment. Details of this wet weather treatment will be evaluated further, at a future date once the first group of LTCPU capital projects are implemented.

With regulatory approval, the Regulator Control Improvements can proceed with the current and anticipated finances available to DELCORA. Targeted Overflow Reduction implementation is dependent on a number of factors including the three stated in **Subsection 10.2.** If these factors can be addressed, it is anticipated that the Regulator Control Improvements and the Targeted Overflow Reduction projects can be fully implemented within the next 10 years.

The third element is adaptive management of the post-construction monitoring plan, which is further detailed in Section 11. The expected results of the previous two elements will meet the necessary requirements of the Presumption approach, but additional monitoring is still planned by DELCORA, especially in locations with CSOs that may continue at a higher frequency. The completed projects will be monitored to determine if they are operating as intended, and the Clean Water Act and community goals are met. This monitoring period is an appropriate time to compare observed flow growth to population growth projections, and revise projects based on the results. If this post construction monitoring indicates more investment or actions are needed, those investments and actions will be evaluated and a supplemental control plan will be developed for review and approval by the PADEP. This would allow for DELCORA to assess if the flow growth aligns with the Delaware Valley Regional Planning Commission's projected population increases, and revise projects based on the flow data from the post-construction monitoring and studies. However, should the LTCPU capital projects perform as modeled or better, future projects of significant cost can be scaled back or eliminated from the proposed schedule. In order to account for the schedule to be flexible enough for adaptive management, the CSO control projects are split up into one of two categories: 1) High-Efficiency and Unauthorized Release Projects, and 2) WRTP Inflow Projects.

The projects in the first category can be completed relatively inexpensively and quickly to meet the requirements of the Consent Decree or resolve issues identified in public meetings. After the completion and operation of the first category of projects in December 2023, a post-construction monitoring period of one year will be conducted in 2024 to investigate if the projects are all performing as modeled and to find the new CSS wet weather baseline. The completed report from this investigation will be delivered in June 2025. Special attention to locations with higher overflow & flooding frequencies will be evaluated during this post construction monitoring period. Based on the results, DELCORA will continue to examine sewer system optimization through additional monitoring and potentially using real time control and other I/I measures to further reduce the surcharge frequency at these overflow & discharge points. Further measures will be implemented to the modeled area as necessary, depending on the projects' performance,

and a schedule will be developed that takes into the account the modeled area's financial capability at that time.

The projects in the second category are higher-cost and create more of a public disturbance than the first category, but are also focused around the WEI and DRI. This should allow projects to be concentrated in specific sections of the City before completion, preventing city-wide construction and the increased traffic that may result. Pending the results of the one-year post-construction monitoring, the second category of projects can be adapted to meet the 90% wet weather capture percentage goal and begin in 2025. An updated WRTP plant flow evaluation for proposed upgrades will also be conducted, and is expected to be completed in 2025. By providing additional time for these larger projects, DELCORA can find ways to further increase efficiencies based on financial capability, whether it is combining other planned projects with this work or making use of improved technologies developed since LTCPU approval. After the second category of projects are completed, a second year-long post-construction monitoring will take place to again confirm the modeled results meet the DELCORA's goals.

DELCORA's goals involve actions within two areas:

- Addressing CSO controls in its owned and contracted service areas
- Addressing the cost of the Eastern Service Area treatment provided by the Philadelphia Water Department

Given the localized nature of the peak wet weather flow issues and control measures proposed along with State delegation and oversight of program implementation, State oversight of our program implementation makes the most sense. DELCORA plans to propose a State implementation mechanism to PADEP and/or USEPA in the near future for their consideration. Streamlined State implementation oversight is particularly warranted because EPA/DEP program approval will substantively control other State planning mechanisms, such as Act 537 plan updates. It will be important for PADEP to assist DELCORA to timely secure any actions required by DELCORA's satellite customers, such as the requirement that they update their Act 537 plans to reflect the EPA/PADEP-approved program, in order to maintain the approved implementation schedule.

The implementation plan schedule includes assumes time for facility planning, design, permitting, approvals, land acquisitions, notice to proceed, construction, and place in operation. The initial schedule can be found in **Table 10-3**, incorporating the regulator modifications immediately and the other projects within 10 years of LTCPU approval. All projects will be evaluated using an adaptive management approach, where the selected plan may be adjusted when monitoring and modeling show cost-effectiveness. The implementation schedule itself is also separated into two 5-year periods (2020-2024 & 2025-2029) not only for the purpose of adaptive management, but more importantly, to align with DELCORA's current NPDES permit schedule. Once the post-construction monitoring is completed, the results can be submitted with the next permit application. The timeline for all reports proposed by this plan can be found in **Table 10-4**. The O&M Plans will be updated 60 days after the full implementation of the Taylor Arboretum storage tank and again after the WRTP modifications are first placed in operation.

Section 11 Post-Construction Monitoring Plan

11.1 Introduction

Paragraph V.A.21 of the Consent Decree requires that a post-construction compliance monitoring program be developed to ascertain the effectiveness of CSO controls and to verify compliance with water quality standards and protection of designated uses. This section describes the Post-Construction Monitoring Program (PCMP) that will be used to monitor the effectiveness of the long-term CSO controls and complies with NPDES permit conditions for measuring compliance. This monitoring program is consistent with and informed by National CSO Control Policy and USPEA's *CSO Post Construction Compliance Monitoring Guidance*, May 2012. The main elements of the PCMP include the following:

- A process to determine whether the CSO control measures are meeting the Performance Criteria established in Section 10.
- A monitoring schedule, initial CSO outfall monitoring locations, receiving water sampling locations, and rain gauge locations.
- The approach for analysis of the PCMP data for CSO control measure performance assessment and for reporting progress to regulatory agencies and the general public.
- A Public Notification System to visually notify the public of the occurrence of Combined Sewer Overflows at each receiving water body.

11.2 Purpose and Scope

Post-construction monitoring is anticipated to provide enough data to evaluate the effectiveness of the CSO control measures constructed during the implementation of DELCORA's CSO Long-Term Control Plan Update. The evaluation of the control measures will be based on the Performance Criteria described in this section, and whether DELCORA's CSO discharges comply with its NPDES permit limits. The general scope of the PCMP will include the implementation of a monitoring program as well as a detailed analysis and evaluation of the CSO control measures' efficacy. The PCMP has been developed for the DELCORA service area and its discharges into the receiving waters, including the Delaware River, Chester Creek and Ridley Creek. The program will be conducted during the LTCPU implementation to corroborate that the CSO control measures that are constructed perform adequately, while providing sufficient data to identify and remedy underperforming control measures.

As mentioned in Section 5 of this report, since there are various sources contributing to bacteria water quality impairments including CSOs, urban stormwater, and wild life, WQS will not be achieved in the receiving waters if CSOs are the only source controlled. Post construction monitoring will serve its role in demonstrating that CSOs will be reduced to the levels predicted in the recommended LTCPU based on Typical Hydrologic Period (1994-1996) conditions and therefore are not causing or contributing to the exceedance of the current WQS. When the control measures for pollutant sources other than DELCORA's CSOs are completed, it is expected that the WQSs will be attained.

In accordance with the CSO Policy, the LTCPU is based on "typical year" conditions. Rainfall varies substantially from year to year and from storm to storm. It will require normalizing a given year's rainfall to the Typical Hydrologic Period to assess performance. The same is true for receiving water monitoring where the variables include other pollutant sources that are also driven by wet weather conditions. For these reasons, considerable judgment must be employed when assessing results. The post-construction

monitoring will focus on verifying that the CSO control facilities are being operated as described in the LTCPU.

DELCORA will evaluate the performance of the control measures through use of the H & H model. The model output will be compared with actual CSO flow data for the post-construction monitoring period to determine whether recalibration of the H&H model is needed. Once the H&H model has been determined to be adequately calibrated, a continuous simulation of the Typical Hydrologic Period (1994-1996) will be run to determine whether the CSO control measures have achieved the Performance Criteria.

11.3 Performance Criteria and Compliance Assessment

The Performance Criteria developed in **Subsection 10.3.2** were based on a percentage of total volume entering the CSS that is "captured" for treatment at the WRTP, as part of the Presumption approach. Upon full implementation of the CSO control measures of the LTCPU, the Performance Criteria will be a minimum of 85% capture by volume of the system-wide wet weather volume for treatment at the WRTP based on the Typical Hydrologic Period (1994-1996), also referred to as the "typical year". The minimum 85% capture by volume meets the requirements of the Presumption approach, and this minimum capture amount may increase based on the selected CSO control measures detailed in Section 9. Actual overflow volume will vary from one year to another after full implementation of the CSO control measures, based on real-life precipitation conditions. Recognizing the hydraulics of the combined sewer system and the interconnection between CSO regulators, CSO control measures that do not achieve the performance criteria as a result of other controls that have yet to be completed will not be fully evaluated until all CSO control measures are constructed.

11.4 Post-Construction Compliance Monitoring Data Collection

Data collection is a central element of the PCMP. The type, location and frequency of monitoring to be performed for the LTCPU capital projects will be determined after their scheduled implementation in 2024 and 2029. Currently, the monitoring that was used during the development of the LTCPU is planned on being used as a basis for the PCMP, albeit on a reduced scale. The types of planned monitoring will include:

- Rainfall Monitoring
- CSO Outfall Monitoring
- Sewer System Flow Monitoring

A PCMP schedule with monitoring locations is proposed in **Table 11-1**.

11.5 Data Management and QA/QC

DELCORA has been collecting flow metering data, system-wide CSO outfall data, and rainfall data for several years. The continued collection of this data as part of the PCMP will be integrated into DELCORA's existing data retrieval, management, and quality assurance and control protocols, including their extensive SCADA system. As data management and analysis techniques continue to develop over the implementation period, DELCORA will consider new and improved approaches for managing this data. Monitoring and modeling will be taken to provide proper data validation and QA/QC.

Table 11-1: Proposed Post-Construction Monitoring Plan

Monitoring Type	Delaware River	Chester Creek	Ridley Creek	Frequency
Rainfall Monitoring (9 Locations)	Rose Valley, Chester PS, Central Delaware PS, Muckinipates PS, Darcy Creek PS, Naamans Creek PS, Springfield, Upper Providence, WRTP			Monitor for 1-year period every 5 years*
CSO Overflow Monitoring (6 Locations)	02, 03, 05, 08	19	18	Monitor for 1-year period every 5 years*
CSO Visual Notification System Locations (9 Locations)	02, 07, 11	19, 22, 24	16, 18, 33	Post-Construction Continuous

11.6 Performance Assessment

Under the Presumption approach to demonstrate compliance, DELCORA will continue to update and calibrate the H&H model after the implementation of CSO control measures and after the post-construction monitoring phase data has been collected. The models will be used to simulate CSS performance in the DELCORA collection system and to demonstrate compliance with the performance criteria identified in **Subsection 11.3**, a minimum of 85% capture by volume of the system-wide wet weather volume during the typical year. The models will also be used to assess the performance of green infrastructure control measures. DELCORA will submit a series of milestone reports to the USEPA and/or PADEP detailing the implementation and performance of CSO control measures. A corrective action plan shall be developed in the event that CSO control measures do not meet the Performance Criteria. The Performance Assessment approach, reporting, and corrective action plan are outlined in the following subsections.

11.6.1 Approach

DELCORA will evaluate the performance of the CSO control measures through the use of its H&H model. The following steps will be used to determine compliance with the Performance Criteria:

1. Collect flow monitoring data, CSO outfall data, and rainfall data for the continuous 12-month post-construction monitoring period of each phase of CSO control measures. Perform QA/QC on the data.

2. Once every five years, update the H&H model to include all completed CSO control measures and any other modifications to the CSS since the H&H model was calibrated for the 2018 LTCPU.

3. Run a continuous simulation for the 12-month post-construction monitoring period for the updated model, for the typical year.

11.6.2 Corrective Action Plan

DELCORA is confident that the CSO control measures implemented prior to the 2024 post construction monitoring period will meet the 85% wet weather capture percentage Performance Criteria based on the simulation of the Typical Hydrologic Period (1994-1996). However, should the post construction monitoring suggest the CSO control measures do not perform anticipated, performance factors and deficiencies responsible for this shortfall will be identified. Additional control measures will then be implemented to allow DELCORA to meet the 85% Performance Criteria. A Corrective Action Plan shall be developed that details this analysis, including the implementation plan and schedule of the additional controls. This Corrective Action Plan will include any adaptive management modification based on Post-Construction Monitoring and evaluation. The Corrective Action Plan shall be submitted to USEPA and/or PADEP as part of each Five-Year Milestone Report and include the Post Construction Compliance Monitoring Plan (PCCMP) Reports for the 2024 and 2029 monitoring periods.

DELCORA will consider multiple corrective actions for underperforming CSO control measures, including constructing additional grey infrastructure (i.e. storage tanks) or green infrastructure (i.e. bioretention). Upon review and approval of the Corrective Action Plan by the USEPA and/or PADEP, DELCORA shall implement those measures in accordance with the schedule set forth in the Corrective Action Plan.

11.6.3 Reporting

The PCCMP will evaluate whether the CSO control measures are achieving the Performance Criteria and assess water quality conditions in DELCORA's receiving waters. The progress and evaluation of the CSO control measure implementation and water quality assessment will be reported to the USEPA and/or PADEP, and to the public through a series of milestone reports, including Annual Progress Reports, Five-Year Milestone Reports, and a Final PCCMP Report. DELCORA will also continue to submit annual CSO status reports in the form of the Municipal Wasteload Management Report, in accordance with its NPDES permit requirements.

The Five-Year Milestone Reports shall follow the same timeline as DELCORA's NPDES permits, and shall be submitted alongside their permit application, providing the following information:

- A statement setting forth the deadlines and other terms that DELCORA was required to meet since the last Reporting Period;
- A general description of work completed within the prior period, and a projection of work to be completed within the succeeding period;
- A summary principal contacts with USEPA and/or PADEP during the reporting period relating to CSOs, SSOs, or implementation of the Consent Decree;
- NDPES permit violations;
- A summary of all known SSOs, Unauthorized Releases, and Unpermitted Discharges occurring within the previous reporting Period, including estimated frequency duration, and volume, of each discharge.
- The results of water quality sampling conducted during the five-year reporting period;
- An analysis of the impact in water quality observed within the DELCORA receiving waters related to the implementation of the CSO control measures;
- A summary of all monitoring data collected by DELCORA during the five-year reporting period;

- A description of the CSO control measures completed within the five-year reporting period and a projection of CSO control measure work to be performed during the next five-year period; and,
- An evaluation of the effectiveness of the CSO control measures constructed to date, including Corrective Actions, if needed and as outlined in **Subsection 11.6.2**.

Within one NPDES permit cycle following achievement of full operation for all of the LTCPU projects, DELCORA shall submit a Final PCCMP Report to the USEPA and/or PADEP for their review and approval. This is currently scheduled for 2030 alongside the second and final Five-Year Milestone Report. The purpose of the Final PCCMP Report shall be to evaluate and document the system-wide performance of DELCORA's fully implemented LTCPU CSO control measures. The report shall include an assessment of whether the control measures are meeting the Performance Criteria and complying with water-quality based CWA requirements and DELCORA's NPDES permit, including the following information:

- A complete Post-Construction Monitoring Period data summary and analysis;
- A reporting of all of the CSO control measures that have been constructed, implemented, and that are in operation;
- An evaluation of the system-wide CSO control measure performance, and whether the controls meet the Performance Criteria
- An analysis and discussion of the long-term trend in water quality within DELCORA service area receiving waters; and,
- A description of any Corrective Actions that need to be implemented to meet the Performance Criteria, if the Performance Criteria are not achieved.

11.7 Future Regulatory Requirements

Chester CSO loadings are a very small/insignificant part of the overall bacteria loadings to both the Delaware River and Ridley Creek.

The Delaware River appears to generally meet the bacteria water quality standard. Thus, existing programs addressing NPDES dischargers and upstream loadings may well achieve compliance. Accordingly, any future regulatory requirements, including TMDLs, should be given a low priority due to the low level of non-attainment. Because CSO loadings will be a truly insignificant source, the level of control to be achieved by the implementation of this LTCP should be established as the wasteload allocation for the CSO system.

Ridley Creek experiences significant upstream bacteria loadings along with relatively small/insignificant Chester CSO loadings. To the extent Ridley Creek is the subject of a future effort to reduce bacteria loadings, a use attainability analysis will be warranted given the substantial upstream loadings which appear to preclude consistent water quality standards attainment. As with the Delaware River, any future regulatory effort to further reduce bacteria loadings to the Creek should assign a wasteload allocation to the CSOs which is consistent with the reduced loadings that will be achieved by this LTCP for Chester's CSOs.

11.8 Public Notification

In order to advise the public of overflows, a visual notification system will be installed at three locations on each receiving body of water (9 total) at public access locations. This system will serve to notify the public of the occurrence of CSOs based on the outfall monitoring at the representative CSO outfalls. The system will be comprised of two colored lights that will operate as follows:

- Color A (red) will be displayed as long as flow is detected from the representative outfall;
- Color B (yellow) will be displayed for 24 hours after flow is no longer detected from the representative outfall;
- The visual notification system will be described and explained on DELCORA's website.

The CSO locations where the visual notification lights will be installed are illustrated in **Figure 11-1**.

Figure 11-1 CSO Visual Public Notification Light Locations

Section 12 Revision of Operation and Maintenance Plans

DELCORA has a comprehensive Operation and Maintenance (O & M) Program to ensure the appropriate and consistent operation its collection system facilities. DELCORA has developed this plan in accordance with CSO Policy requirements for Nine Minimum Controls and its NPDES permit. However under Consent Decree Paragraph V.A.22 (Revision of Operation and Maintenance Plan), the LTCPU is required to identify CSO control measures that require a revised O&M plan and include a procedure for the revision and dissemination of such plans within sixty days of the Placement in Operation of each such control. As defined under the Consent Decree, the Placement in Operation shall mean a CSO control measure is operational with the level of control designed, even if construction close-out activities may not yet be complete. This section summarizes the current DELCORA Operation and Maintenance Program and how that program will be updated as the CSO control measures are implemented.

12.1 Current Operation and Maintenance Plan

DELCORA's current O & M Program consists of the following elements:

- Operation and Maintenance Manuals: DELCORA maintains a library at its Western Regional Treatment Plant as a central location for current O&M manuals for critical operations equipment. Procedures for routine maintenance, including maintenance and inspection of CSO regulators and tide gates are also kept at the library. Manuals detailing specific pump operations are available at DELCORA's remote pumping stations. When new equipment is installed operating instructions, a maintenance summary, description and frequency of maintenance activity, and recommended spare parts are obtained from the vendor. DELCORA has a procedure for cataloging and disseminating these manuals to the on-site library and other appropriate locations. In addition, as new equipment is acquired, procedures are in place to add data to DELCORA's computerized maintenance management database and to place recommended spare parts into inventory.
- Routine Inspections Schedule: Critical elements of the CSS are inspected routinely according to a schedule that is maintained electronically. Video inspections, maintenance records, and work orders are likewise, all maintained electronically for future reference.
- Organizational Structure: The organization, authority, and responsibility of operations and maintenance are clearly communicated through chain of command, which comes from the Director of Operations and Maintenance and follows to the Sewer Maintenance Supervisor, Foremen, Crew Chiefs, and sewer maintenance personnel, including key on-call personnel.
- Critical Facilities List: DECLORA has an established inventory list of critical facilities, including CSO regulators and tide gates. Information about these critical facilities is electronically maintained and updated in DELCORA's internal system for accuracy and reliability.
- Emergency Response Plans: DELCORA maintains on-call staff that are available 24 hours a day every day throughout the year to respond to sewer related problems. Specific Emergency Response Plans and protocol have been developed to allow a swift response from DELCORA's staff to resolve the issue.
- Training and Safety Programs: Upon hiring, all new employees experience a period of probation where they receive on the job training by supervisors and experienced personnel. It is the policy of DELCORA to provide an active workplace Safety & Health Program. The objective of the program is to ensure a safe environment for all employees and visitors as well as to protect Authority buildings, equipment, and other property. As part of the Safety & Health Program, employees are issued a Health and Safety Manual, which is reviewed yearly with the employees.

- Periodic Review of O&M Program: Each year, the Director of Operation and Maintenance and the Sewer Maintenance Supervisor review O&M practices on the sewer system as part of the Chapter 94 Municipal Wasteload Management Annual Report. All revisions are incorporated swiftly into the existing program.

12.2 Operation and Maintenance Program Updates for CSO Control Measures

As required by the Consent Decree, DELCORA will prepare updates to the current O&M manuals to include any new facilities which are a part of this LTCPU and disseminate those plans within sixty days of the Placement in Operation of each CSO control measure. O & M manuals are stored in the central database with the physical copies handed to the relevant staff when necessary. Typically, an O&M Manual will be developed for each facility constructed as part of this LTCPU. These manuals will include a description of the equipment and features of the facility, operating instructions, maintenance guides, and safety considerations. Manuals should be reviewed for the optimization of LTCPU capital projects after new projects are brought online.
Year

The updates to the O & M Program will begin within sixty days of placing the following CSO Control Measures into operation, and will follow a two-step process:

1. Proposed Operation and Maintenance Manual Updates – DELCORA will submit to USEPA and/or PADEP for review and commit the proposed O&M Manual updates for
    a. a Ridley Creek Interceptor SSO tank improvement at Taylor Memorial Arboretum and
    b. WRTP modifications

    that are placed into operation for the first time, if and when construction is completed, within ninety days of the full operation of the CSO Control Measure in accordance with the implementation schedule presented in Section 10.

2. Integrated Operation and Maintenance Manual – Once approved by USEPA and/or PADEP, DELCORA will incorporate the proposed updates into the current O&M Manuals, described in the preceding section.

12.3 Staffing Needs

In developing the LTCPU, DELCORA has made preliminary estimates of O&M costs, which include labor. The exact number of staff, and the specific staff responsibilities and qualifications will be determined during the implementation of the LTCPU and reviewed annually as part of the annual budget process. It is expected that operator experience will increase as similar facilities come online, potentially reducing end-of-program staffing requirements.

Section 1 Introduction

1.1 Background

The Delaware County Regional Water Quality Control Authority (DELCORA) is a municipal wastewater authority that owns, operates and maintains collection systems that serve approximately a half-million people in southeastern Pennsylvania, including 42 municipalities in Delaware and Chester Counties. DELCORA operates a Combined Sewer System (CSS) that is comprised of sewer sections that accept both stormwater and sanitary wastewater, which is treated at DELCORA's Western Regional Treatment Plant (WRTP).

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP).

1.2 Purpose

As part of the Long Term Control Plan Update (or "LTCPU"), the Consent Decree requires DELCORA (in coordination with the USEPA and PADEP) to propose what approach to the Long Term Control Plan Alternative Evaluation (i.e., the "Presumption Approach" or the "Demonstration Approach") is appropriate for the each of DELCORA's receiving waters, and to submit a written explanation to the USEPA and PADEP for review and approval. The three water bodies that receive overflows from DELCORA's CSS include the Delaware River, Chester Creek and Ridley Creek.

DELCORA is in the process of developing the LTCPU for its Combined Sewer System, and the purpose of this report is to meet the requirement in the Consent Decree for the submission of a written explanation of DELCORA's Alternatives Evaluation Approach to the USEPA and PADEP, while also addressing those requirements from USEPA's "Combined Sewer Overflow Control Policy," April 1994 and also considering the "Combined Sewer Overflows Guidance for Long-Term Control Plan," September 1995 (CSO Guidance Document). Determination of the use of the Presumption or Demonstration Approach is important because it can potentially affect the development of the CSO control alternatives.

Section 2 Regulatory Framework

There are various documents that discuss the Alternatives Evaluation Approach that may be taken for the development of a long term control plan. These documents are discussed in further detail in this Section.

2.1 Consent Decree Requirements

The Consent Decree requires DELCORA to complete and submit a LTCPU to the USEPA and PADEP for review and approval. Section V.A.13 of the Consent Decree ("Alternatives Evaluation Approach") specifically requires that:

> *"Within nine (9) months after the Date of Lodging, DELCORA shall propose, in coordination with the EPA and PADEP and in accordance with Section II.C.4 of the CSO Control Policy, what approach to LTCP Alternative Evaluation (i.e., Presumption or Demonstration) is appropriate for each of DELCORA's Receiving Waters, and to submit a written explanation of such determination to Plaintiffs for review and approval pursuant to Section VI (Review and Approval of Submittals)."*

The Consent Decree further states that:

> *"Use of the Presumption Approach will be allowed only where EPA and PADEP each agree that the specific presumption(s) to be used in a particular water body are reasonable pursuant to Section II.C.4.a of the CSO Control Policy".*

2.2 USEPA's CSO Control Policy Requirements

Section II.C.4 of the USEPA's CSO Control Policy states that the long term CSO control plan should adopt one of the following two approaches for CSO controls sufficient to meet CWA requirements: 1) the Presumption Approach, and 2) the Demonstration Approach.

2.2.1 Presumption Approach from USEPA's CSO Control Policy

Sub-section II.C.4.a of the USEPA's CSO Control Policy (Presumption Approach) states that:

> *"A program that meets any of the criteria listed below would be presumed to provide an adequate level of control to meet the water quality-based requirements of the CWA, provided the permitting authority determines that such presumption is reasonable in light of the data and analysis conducted in the characterization, monitoring, and modeling of the system and the consideration of sensitive areas... These criteria are provided because data and modeling of wet weather events*

often do not give a clear picture of the level of CSO controls necessary to protect WQS."

Under the Presumption Approach, CSO controls proposed in the LTCPU are presumed to protect water quality in the receiving water bodies if the Combined Sewer System achieves any of the following three criteria:

i. *"No more than an average of four overflow events per year, provided that the permitting authority may allow up to two additional overflow events per year. For the purpose of this criterion, an overflow event is one or more overflows from a CSS as the result of a precipitation event that does not receive the minimum treatment specified below; or*

ii. *The elimination or the capture for treatment of no less than 85% by volume of the combined sewage collected in the CSS during precipitation events on a system-wide annual average basis; or*

iii. *The elimination or removal of no less than the mass of the pollutants identified as causing water quality impairment through the sewer system characterization, monitoring, and modeling effort, for the volumes that would be eliminated or captured for treatment under the paragraph ii above."*

"Minimum treatment," as noted in Item "*i*" above, is defined in Sub-section II.C.4.a of the CSO Control Policy as:

- *"Primary Clarification (Removal of floatables and settleable solids may be achieved by any combination of treatment technologies or methods that are shown to be equivalent to primary clarification.);*
- *Solids and floatables disposal; and*
- *Disinfection of effluent, if necessary, to meet WQS, protect designated uses and protect human health, including removal of harmful disinfection chemical residuals, where necessary."*

2.2.2 Demonstration Approach from USEPA's CSO Control Policy

Sub-section II.C.4.b of the USEPA's CSO Control Policy (Demonstration Approach) states that:

"A permittee may demonstrate that a selected control program, though not meeting the criteria specified in II.C.4.a. above is adequate to meet the water quality-based requirements of the CWA."

Under the Demonstration Approach, the municipality would be required to successfully demonstrate compliance with each of the following criteria from the CSO Control Policy:

i. *"The planned control program is adequate to meet WQS and protect designated uses, unless WQS or uses cannot be met as a result of natural background conditions or pollution sources other than CSOs;*

ii. *The CSO discharges remaining after implementation of the proposed control program will not preclude the attainment of WQS or the receiving waters' designated uses or contribution to their impairment. Where WQS are not met in part because of natural background conditions or pollution sources other than CSO discharges, a total maximum daily load, including a waste load allocation and a load allocation or other means should be used to apportion pollutant loads;*

iii. *The planned control program will provide the maximum pollution reduction benefits reasonably attainable; and*

iv. *The planned control program is designed to allow cost effective expansion or cost effective retrofitting if additional controls are determined to be necessary to meet WQS or designated uses."*

2.3 USEPA's CSO Guidance for Long-Term Control Plan Requirements

The USEPA's CSO Guidance for Long-Term Control Plan (or "CSO Guidance Document") states that the Demonstration Approach and the Presumption Approach are the two general approaches to attainment of WQS, and that these two approaches provide municipalities with targets for CSO controls that achieve compliance with the Clean Water Act, particularly the protection of designated uses.

Section 1.3 of the CSO Guidance Document states:

> *"Permittees should develop long-term control plans (LTCPs) for controlling CSOs. A permittee may use one of two approaches: 1) demonstrate that its plan is adequate to meet the water quality-based requirements of the CWA ("demonstration approach"), or 2) implement a minimum level of treatment (e.g., primary clarification of at least 85 percent of the collected combined sewage flows) that is presumed to meet the water quality-based requirements of the CWA, unless data indicate otherwise ("presumption approach")."*

Section 2.6.2.1 states that:

> *"Under the CSO Control Policy, a municipality should develop an LTCP that adopts either the demonstration or the presumption approach to attainment of*

WQS. The demonstration approach is based on adequately demonstrating that the selected CSOs will provide for the attainment of WQS, including designated uses in the receiving water. The presumption approach does not explicitly call for analysis of receiving water impacts. The presumption approach usually involves at least screening-level models of receiving water impacts, however, because the approach will not apply if the NPDES permitting authority determines that the LTCP will not result in attainment of CWA requirements."

2.3.1 Presumption Approach from USEPA's CSO Guidance for LTCP

For the Presumption Approach, Section 3.2.1 of the USEPA's CSO Guidance Document states that:

"If the data collected by a community do not provide "...a clear picture of the level of CSO controls necessary to protect WQS", the presumption approach may be considered. Use of the presumption approach is contingent, however, on the municipality presenting sufficient data to the NPDES permitting authority to allow the agency to make a reasonable judgment that WQS will probably be met with a control plan that meets one of the three presumption criteria."

Furthermore, the CSO Guidance Document states:

"Use of the presumption approach does not release municipalities from the overall requirement that WQS be attained. If data collected during system characterization suggest that use of the presumption approach cannot be reasonably expected to result in attainment of WQS, the municipality should be required to use the demonstration approach instead. Furthermore, if implementation of the presumption approach does not result in attainment of WQS, additional controls beyond those already implemented might be required."

2.3.2 Demonstration Approach from USEPA's CSO Guidance for LTCP

For the Demonstration Approach, Section 3.2.1 of the USEPA's CSO Guidance Document states that:

"Generally, if sufficient data are available to demonstrate that the proposed plan would result in an appropriate level of CSO control, then the demonstration approach will be selected. The demonstration approach is particularly appropriate where attainment of WQS cannot be achieved through CSO control alone, due to the impacts of non-CSO sources of pollution. In such cases, an appropriate level of CSO control cannot be dictated directly by existing WQS but must be defined based on water quality data, system performance modeling, and economic factors."

The Demonstration Approach is consistent with the total maximum daily load (TMDL) development approach and may be used in the TMDL process where the WQS and designated uses are not met in part because of natural background conditions or pollution sources other than CSOs. Section 3.2.1.1 of the CSO Guidance Document states:

> *"the demonstration approach encourages the development of total maximum daily loads and/or the use of a watershed approach throughout the LTCP process. In conducting the existing baseline water quality assessments as part of the system characterization, for example, the specific pollutants causing nonattainment of WQS, including existing or designated uses, would be identified, and then the sources of these pollutants could be identified and loads apportioned and quantified."*

2.4 Comparison of the Two Approaches

The following table summarizes the major differences between the Presumption Approach and the Demonstration Approach.

Table 2-1: Comparison of the Two Approaches

Item	Presumption Approach	Demonstration Approach
Criteria	• Meet one of three criteria and compliance is **presumed**: 1) No more than an average of 4-6 overflow events per year; 2) 85% capture (by volume) 3) Elimination or removal of the mass of pollutants, identified as causing water quality impairment.	• Number of CSO events, flow or pollutant loading limited by a proposed CSO system Waste Load Allocation which will comply with Water Quality Standards (WQS). • Relies on data collection and model simulation to **demonstrate** that the proposed LTCP results in meeting the current WQS and designated uses.
Monitoring Data Collection	• Flow metering of the collection system and/or water quality sampling of CSOs.	• Flow metering of the collection system and water quality sampling of CSOs **and** receiving water bodies.
Modeling	• Combined sewer system (CSS) hydrologic and hydraulic (H&H) model.	• CSS H&H Model **and** Receiving Water Quality Model(s).
Pollutant Sources Evaluated	• Only CSOs.	• The contributing pollutant sources in the watershed including urban stormwater, agricultural (if any), wildlife, etc.

The Demonstration Approach takes a holistic watershed based approach to understand the pollutant sources and their relative contributions, so that appropriate level of controls can be cost-effectively applied to each pollutant source instead of focusing on just the CSOs. The

Demonstration Approach can help to understand where the current CSO program is in terms of meeting the WQS and demonstrate the impact of future WQS changes on the CSO controls. Under the Demonstration Approach, the permittee must document that their CSO control program is adequate to meet the water quality-based requirements of the CWA.

Use of the Presumption Approach for a particular water body is only allowed when approved by the USEPA and PADEP and each agree that the specific presumption(s) to be used in a particular water body are reasonable pursuant to Section II.C.4.a of the CSO Control Policy.

Certain tasks must be completed regardless if the Presumption or Demonstration Approach is used, such as system characterization, sewer and GIS mapping, and the evaluation of alternatives. However, it is to be noted that the study phase for the Demonstration Approach also requires water quality sampling and water quality modeling of the receiving waters.

Section 3 CSO System Description

3.1 Background of DELCORA's Facilities

The Delaware County Regional Water Quality Control Authority is responsible for the safe collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 3-1. The total service area served by DELCORA, as shown on Figure 3-2, is approximately 82,977 acres which illustrates that DELCORA serves a significant and widespread portion of Delaware County.

The combined sewer area simulated in DELCORA's existing Hydrologic and Hydraulic (H&H) model is located within the City of Chester and consists of a drainage area of approximately 1,510 acres. It comprises approximately half of Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows.

Historically, DELCORA has characterized its service areas as the "Eastern" and "Western." The Western Service Area wastewater is treated at DELCORA's Western Regional Treatment Plant, located at 3201 W. Front Street in Chester, Pennsylvania. The WRTP treats all wastewater from Southern Delaware County Authority, Marcus Hook Borough, Trainer Borough, Upland Borough, Parkside Borough, Eddystone Borough, Chester Township and the City of Chester as well as a portion of the wastewater from Brookhaven Borough and Nether Providence Township.

The Eastern Service Area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWDSWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are directed to the PWDSWPCP. As such, dry weather flows and a portion of the wet weather flows (total flow less than 20 MGD) from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

There are a total of 26 combined sewer overflows with 25 discharge points listed in DELCORA's existing National Pollutant Discharge Elimination System (NPDES) Permit. Under its NPDES Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection, DELCORA is authorized to discharge from the Western Regional Treatment Plant (#001), four storm water outfalls at the WRTP (#028-031),

and from 26 combined sewer overflow outfalls (#002-#026, #032, #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek. CSOs #009 and #010 both discharge at CSO #009.

3.2 City of Chester CSO System

As noted in Section 3.1, the combined portion of DELCORA's sewer system is located within the City of Chester (City) and it comprises approximately half of the City's serviced area. The combined wastewater/stormwater system in the City of Chester is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, CSO regulators and CSO outfalls. The City owns, operates and maintains the inlets, stormwater-only sewers that connect to the combined sewer system and any stormwater-only outfalls. The City is also responsible for the maintenance and cleaning of the streets, planning, zoning, and development controls.

The Chester CSO system contains 26 permitted outfalls as listed in Table 3-1 that discharge to three receiving water bodies; the Delaware River, Chester Creek and Ridley Creek. Figure 3-3 depicts the locations of CSO regulators and outfalls that are DELCORA's responsibility.

Notes:
(1) CSO Outfall 010 discharges to the Delaware River through CSO Outfall 009.

Figure 3-3 and Table 3-2 also provide a sewer system characterization and illustrate the breakdown of each outfall and how each drainage area has combined sewers and separate sewers. Figure 3-4 is a schematic of the Chester CSO system and shows the outfalls and the interceptors that are connected to each CSO.

3.3 CSO System Modeling

Since 1997, DELCORA has conducted annual modeling of the CSO system using the USEPA's Storm Water Management Model (SWMM) to estimate overflows to its receiving waters. SWMM is a dynamic rainfall-runoff model for "single-event" or "continuous" simulations of runoff quantity and quality from primarily urban areas. The model simulates the time-varying process of rainfall onto land surfaces, the conversion of rainfall to infiltration, evaporation, or surface runoff, and the routing of mixed stormwater runoff and sanitary sewage through the collection system. DELCORA's SWMM is also referred to in this report as the Hydrologic and Hydraulic (H&H) model.

Section 2.6.1 (Combined Sewer System Modeling) of the USEPA's CSO Guidance for Long-Term Control Plan states that:

> *"The primary objective of CSS modeling is to understand the hydraulic response of the CSS to a variety of precipitation and drainage area inputs. CSS modeling can also be used to predict pollutant loadings to receiving waters. Once the model is calibrated and verified, it can be used for numerous applications that support CSO planning efforts, including (EPA, 1995d):*

CSO Long-Term Control Plan
Delaware County Regional Water Quality Control Authority

GREELEY AND HANSEN

Figure 3-4
SCHEMATIC OF CHESTER CSO SYSTEM

- *To predict overflow occurrence, volume, and, in some cases, quality for rain events other than those which occurred during the monitoring phase. These can include a storm event of large magnitude (long recurrence period) or numerous storm events over an extended period of time.*

- *To predict the performance of portions of the CSS that have not been extensively monitored.*

- *To develop CSO statistics, such as annual number of overflows and percent of combined sewage captured in response to the presumption approach of the CSO Control Policy.*

- *To optimize CSS performance as part of NMC implementation. In particular, modeling can assist in locating storage opportunities and hydraulic bottlenecks and demonstrate that system storage and flow to the POTW are maximized.*

- *To evaluate and optimize control alternatives, from simple controls described under the NMC to more complex controls proposed in a municipality's LTCP. An example of a simple control would be to raise weir heights to increase in-line storage. The model can be used to evaluate the resulting reductions in CSO volume and frequency."*

The original DELCORA H&H model was developed and calibrated for the 1999 LTCP. The model was set up to simulate monthly CSO discharges in EPA SWMM 5.0, and it is used to estimate the frequency and volume of CSO overflows in the City of Chester and to evaluate long-term strategies for minimizing CSO overflows. The model uses data from the rain gauge located at the WRTP and is supplemented with data from a gauge at the Central Delaware Pump Station. The current model has been updated and expanded over the years to account for changes in the CSO system, but it has not been re-calibrated. Updating and additional calibration and validation of the SWMM model will occur in a subsequent task as part of the requirements of DELCORA's Consent Decree.

Monthly Reports of CSO Modeling using the SWMM are provided to the PADEP as part of DELCORA's Annual Municipal Wasteload Management Report (Chapter 94 Report), and are also provided monthly with the PADEP electronic Discharge Monitoring Report (e-DMR). For the purposes of this report, a run of the existing H&H model was performed using the typical hydrologic period established for DELCORA's CSO LTCPU. The typical hydrologic period was previously determined to be the 3-year period from 1994 – 1996, as detailed in the "Typical Hydrologic Period Report" submitted to the USEPA in November 2015. The hydrologic period from 1994 – 1996 contains a wet year (1996 with 52.1 inches), a dry year (1995 with 31.6 inches) and a year close to average conditions (1994 with 44.9 inches).

A series of monthly simulations of the existing H&H model was executed to estimate the overflow frequency, duration and volume to each of the three receiving water bodies (the Delaware River, Chester Creek and Ridley Creek) as well as the percent volume captured for treatment. The model was run in continuous mode for each month for the 1994 – 1996 period. Evaporation was not included in the simulation since it does not affect the model in a meaningful way, and may cause underreporting of CSO discharges in some cases. It is also to be noted that the snowfall recorded at the rain gauges was simulated in SWMM as rainfall and since peak runoff from snowmelt is typically lower than from rainfall, the SWMM model simulates a conservative estimate of CSO overflows.

The outputs from the H&H model run for the typical hydrologic period are summarized in Table 3-3. Based on the model results for the 1994 – 1996 typical hydrologic period, Table 3-3 indicates that:

- Only four (4) of the 25 outfalls (i.e., #012, 024, 032 and 033) are currently estimated by the model to have had less than 4-6 annual overflow events, which is a prime requirement for use of the Presumption Approach. The next lowest number of overflow events is shown to occur at CSO #020, for which the model indicates an annual average of 21 overflow events. All of the remaining outfalls are shown to have to an annual average of 25 or more overflow events.

- The response of certain regulators (i.e., #002, 003, 004, 005, 007, 008, 009, 011, 013, 015, 017, 018, 019, 022 and 025) is sensitive to even the smallest amounts of precipitation. The model indicates that these outfalls had the highest frequency of discharges.

- The Delaware River received overflows from 11 of the 25 discharge points in the CSS, which was approximately 50% of the total annual average overflow volume and accounted for approximately 49% of the overall number of discharge events.

- The Ridley Creek received overflows from 5 of the 25 discharge points in the CSS, which was approximately 12% of the total annual average overflow volume and accounted for approximately 23% of the overall number of discharge events.

- The Chester Creek received overflows from 9 of the 25 discharge points in the CSS, which was approximately 38% of the total annual average overflow volume and accounted for approximately 28% of the overall number of discharge events.

- The existing H&H model estimates that the percentage of the combined flow treated at the wastewater treatment plant was approximately 61% for the 1994 - 1996 period, which is significantly less than the 85% capture rate for treatment required for use of the Presumption Approach.

A bar chart is also included below Table 3-3 that graphically illustrates the information in the table. The chart shows the large gap that exists between the modeled number of overflow events for the typical hydrologic period, and the limit prescribed for use of the Presumption Approach of only 4-6 overflow events per year.

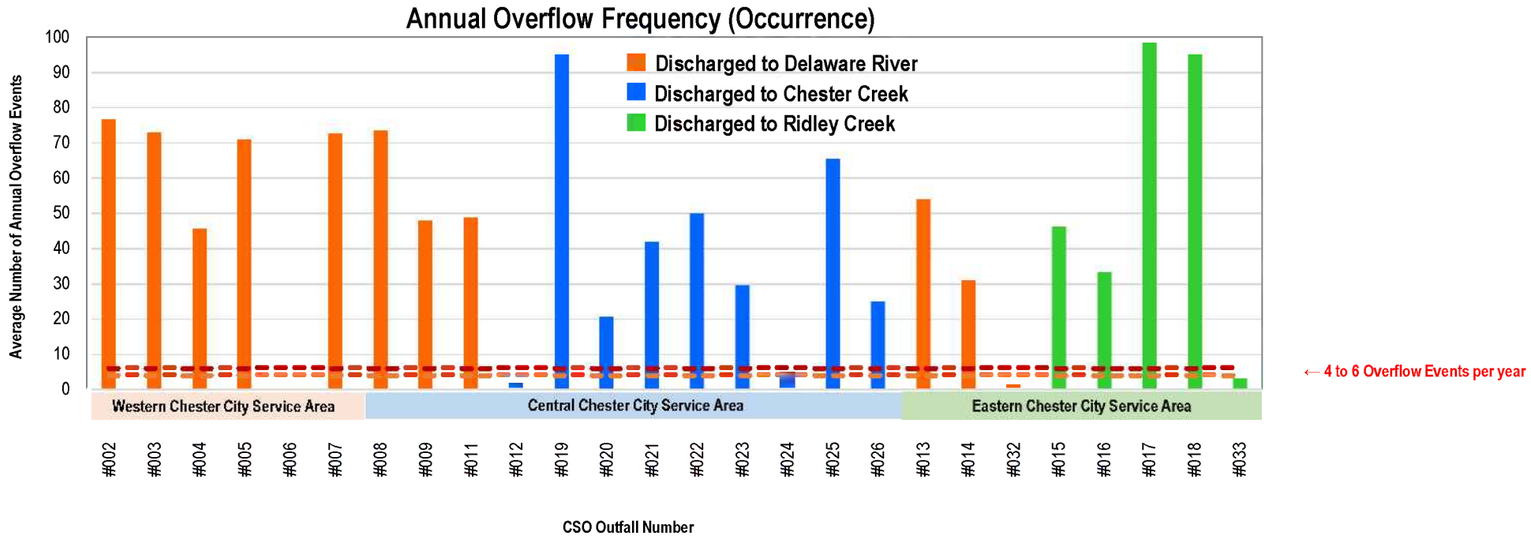
1995	47%
1996	43%
Average	44%

Percent of Combined Flow Treated by WWTP

1994	59%
1995	64%
1996	59%
Average	61%

Notes:

1. Modeled was test run for June, July and August, 2014, the results are in line with Weston's 2014 report.
2. The model only include the Chester City Service Area, it does not include flows from the other service areas and the Central Delaware PS.
3. Modeled max flow to the WWTP is only 86.64 MGD, less than the plant record of 105.54 MGD
4. We checked Regulator #08 set up in the model and the drawing, they are different.
5. The "Percent of Combined Flow Treated by WWTP" is estimated based on precipitation inter-event time (IET) of 12 hr.
6. CSO #006 has been separated and no longer discharges combined storm/wastewater flow.
7. CSO #010 discharges to the Delaware River through CSO #009.



Section 4 Characterization of Receiving Water Bodies

In order to select the Presumption Approach or the Demonstration Approach, it is necessary to understand the existing condition of the receiving water bodies. Use of the Presumption Approach is contingent on the municipality presenting sufficient data to make a reasonable judgment that the water quality standards in the receiving water body will presumably be met with a control plan that meets one of the three presumption criteria (see Section 2.2.1). The Demonstration Approach is appropriate where attainment of water quality standards cannot be achieved through CSO controls alone, due to the impacts of background conditions or pollution sources other than CSOs.

For the characterization of receiving water bodies, Section 2.6.2 (Receiving Water Modeling) of the USEPA's CSO Guidance Document states that:

> *"Under the CSO Control Policy, a municipality should develop an LTCP that adopts either the demonstration or the presumption approach to attainment of WQS. The demonstration approach is based on adequately demonstrating that the selected CSOs will provide for the attainment of WQS, including designated uses in the receiving water. The presumption approach does not explicitly call for analysis of receiving water impacts. The presumption approach usually involves at least screening-level models of receiving water impacts, however, because the approach will not apply if the NPDES permitting authority determines that the LTCP will not result in attainment of CWA requirements."*

In February 2016, DELCORA submitted to the USEPA its "Identification of Sensitive Areas and Pollutants of Concern Report" as a requirement of the Consent Decree. The report reviewed the impairment status of each of the three receiving water bodies and identified parameters associated with CSOs that are exceeding the water quality standards as "Pollutants of Concern".

Figure 4-1 (from the Identification of Sensitive Areas and Pollutants of Concern Report) shows the Non-Attaining and TMDL streams and river within the area impacted by DELCORA's CSO discharges, as determined from the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report. The location of each of DELCORA's CSOs for each of the water bodies is shown in the figure.

Section 5 Selection of the Presumption or Demonstration Approach for Each of DELCORA's Receiving Waters

The development of an LTCPU allows for either the Presumption Approach or the Demonstration Approach to be utilized. DELCORA's approach is to establish the most reliable CSO Program that meets the Consent Decree requirements, the USEPA's CSO Policy and Guidance Document, and the applicable water quality standards.

5.1 Methodology Used in this Study

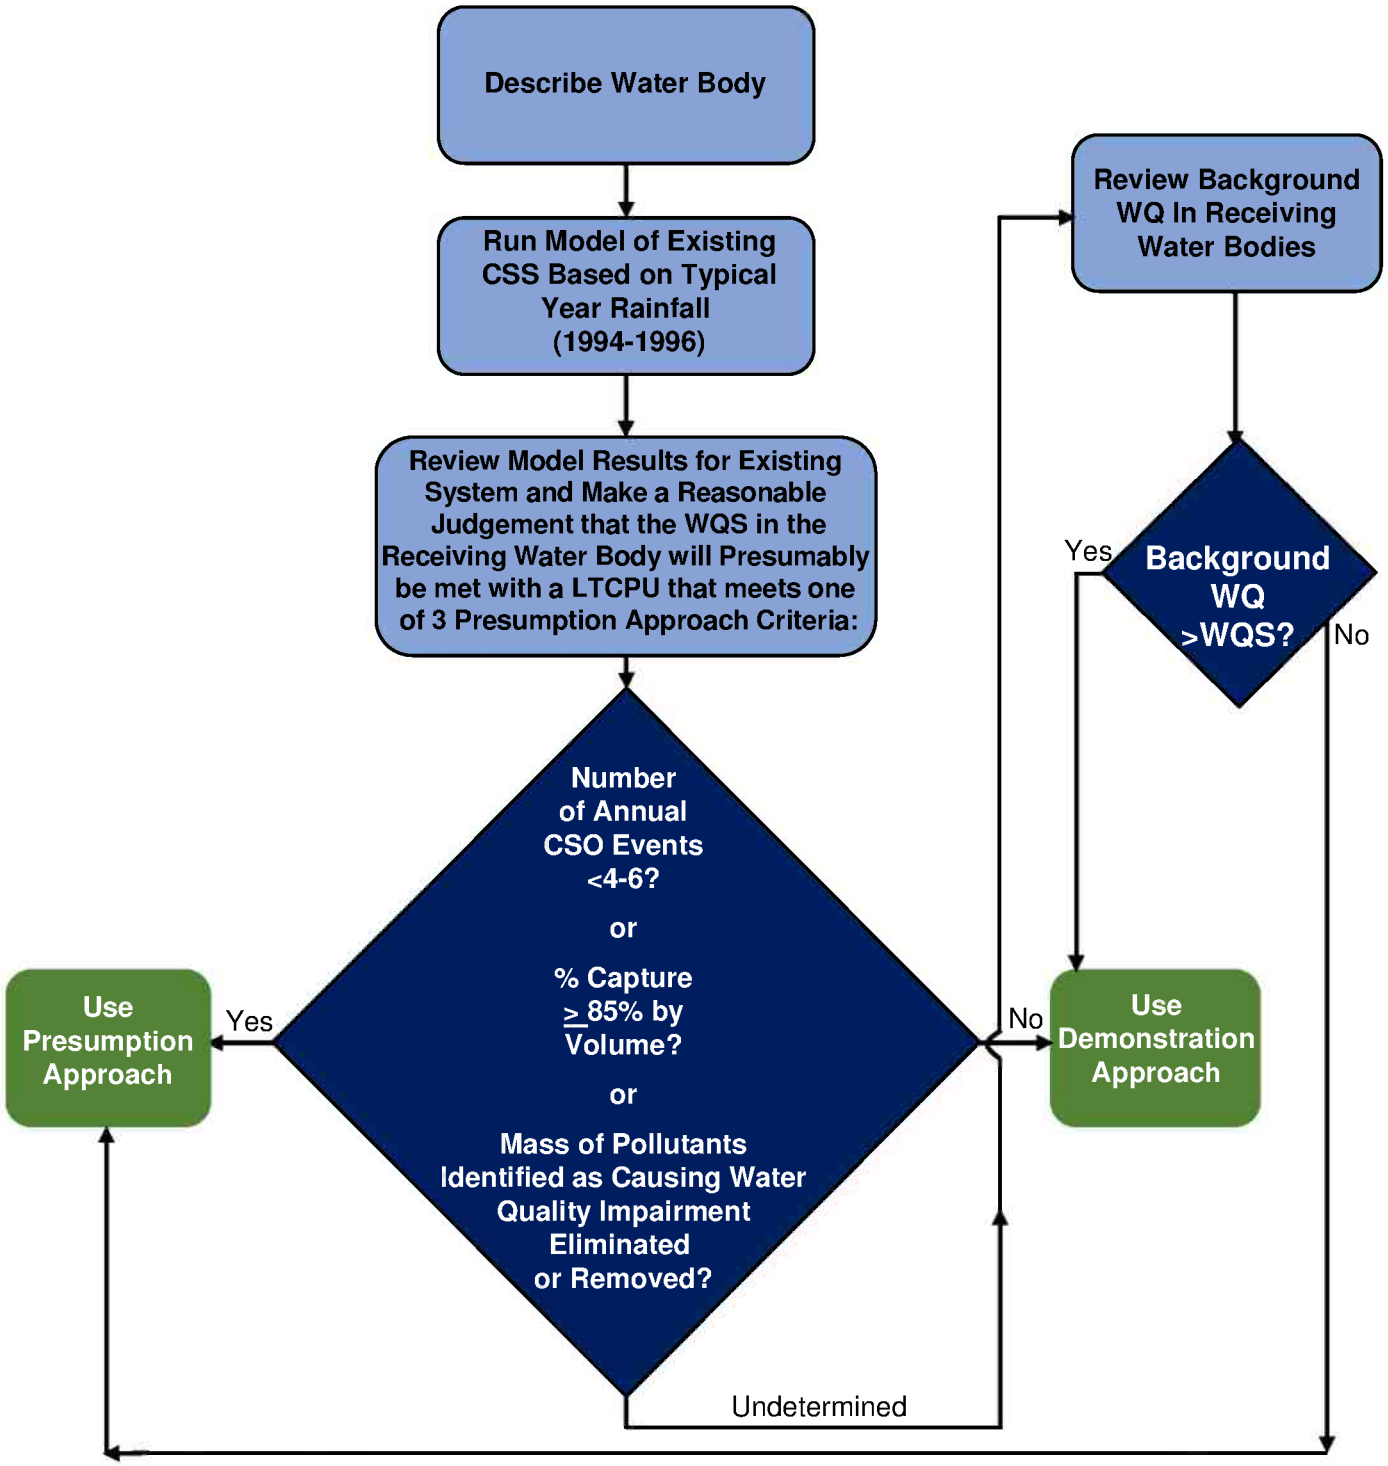
A flowchart was created to help illustrate the decision-making methodology used to assist in determining the recommended Alternatives Evaluation Approach for each of DELCORA's three receiving water bodies. This flowchart is presented in Figure 5-1.

The flowchart emphasizes two main decision making steps that lead to the recommendation of either the Demonstration or Presumption Approach, and these decision making steps are shown as dark blue diamonds. The primary decision step is to make a reasonable judgement that after all of the future CSO controls have been installed (1) will the annual average number of overflow events be less than 4 - 6 events, or (2) will the annual average percent capture for treatment of the combined wastewater be greater than or equal to 85%, or (3) for the volumes that would be eliminated or captured for treatment under item "(2)" will the mass of pollutants identified as causing water quality impairment be eliminated or removed? An answer of "Yes" to any one of these three questions is required for use of the Presumption Approach.

The results from the H&H model run for the typical hydrologic period of 1994 – 1996 were used to estimate the annual average number of overflow events per outfall, and the average percentage of the combined flow treated at the WWTP. The existing H&H model is not able to estimate if the mass of pollutants identified as causing water quality impairment will be eliminated or removed for the volumes that would be eliminated or captured for treatment, and therefore no determination can be made on that specific question at this time.

It was concluded that if the H&H model (Section 3.3) shows substantially more than 4 - 6 annual overflow events per outfall for the CSOs or if significantly less than 85% of the combined flow is shown to be captured for treatment, it will likely not be economically justifiable to install the full range of CSO control measures needed to meet the overflow frequency requirements of the Presumption Approach, and the Demonstration Approach will be favored. This determination is based on the use of Best Professional Judgement.

If it cannot be determined from the H&H model results as to whether the future CSO controls will likely be able to meet the annual number of overflow events or the percent capture rate for the Presumption Approach, then the flowchart indicates a secondary decision making step in



LEGEND

CSS = Combined Sewer System
CSO = Combined Sewer Overflow

CSO Long Term Control Plan Delaware County Regional Water Quality Control Authority	GREELEY AND HANSEN	Figure 5-1 METHODOLOGY FLOWCHART FOR THE ALTERNATIVES EVALUATION APPROACH

which the existing water quality of the receiving water bodies is reviewed and compared to the applicable water quality standards. This determination is required since use of the Presumption Approach is contingent on the municipality presenting sufficient data to make a reasonable judgment that water quality standards will probably be met with a control plan that meets one of the three presumption criteria.

If the review of the background concentrations of those parameters typically associated with CSOs in the receiving water bodies are less than the applicable water quality standards, then the flow chart indicates that the Presumption Approach can be considered. However, if the background concentrations for those parameters are above the applicable water quality standards, then the Demonstration Approach should be used.

A review of the methodology flowchart was performed for each of the three receiving water bodies and is described in the following sub-sections.

5.1.1 Delaware River

Eleven (11) of DELCORA's 25 CSO outfalls discharge to the Delaware River. The H&H model run for the typical hydrologic period shown in Table 3-3 estimates that the Delaware River received discharges from these 11 outfalls accounting for approximately 50% of the total annual average overflow volume from the CSS, and approximately 49% of the overall number of discharge events.

Table 3-3 indicates that 10 of the 11 outfalls to the Delaware River had substantially more than the 4 – 6 annual overflow events that are the target for using the Presumption Approach. Only CSO #032 is shown to have had less than 4 – 6 annual overflows. Of the 10 CSOs that were modeled to overflow more than 4 - 6 times a year, the model estimates that all 10 of them had at least 31 annual overflow events and five of the outfalls are modeled as having had more than 71 overflow events.

Following the methodology described in the flowchart, the answers to the questions in the first decision making step indicate that the **Demonstration Approach** is the most appropriate to be used for the CSO discharges to the Delaware River.

5.1.2 Chester Creek

Nine (9) of DELCORA's 25 CSO outfalls discharge to the Chester Creek. The H&H model run for the typical hydrologic period of 1994 – 1996 shown in Table 3-3 estimates that the Chester Creek received discharges from these 9 outfalls accounting for approximately 38% of the total annual average overflow volume from the CSS, and approximately 28% of the overall number of discharge events.

Table 3-3 indicates that 7 of the 9 outfalls to the Chester Creek had substantially more than the 4 – 6 annual overflow events that are the target for using the Presumption Approach. Only CSOs #012 and #024 are shown to have had less than 4 – 6 overflows. Of the 7 CSOs that were modeled to overflow more than 4-6 times a year, the model estimates that all 7 of them had at least 21 or more annual overflow events and four of the outfalls are modeled as having had more than 42 overflow events.

Following the methodology described in the flowchart, the answers to the questions in the first decision making step indicate that the **Demonstration Approach** is the most appropriate to be used for the CSO discharges to the Chester Creek.

5.1.3 Ridley Creek

Five (5) of DELCORA's 25 CSO outfalls discharge to the Ridley Creek. The H&H model run for the typical hydrologic period of 1994 – 1996 shown in Table 3-3 estimates that the Chester Creek received discharges from these 5 outfalls accounting for approximately 12% of the total annual average overflow volume from the CSS, and approximately 23% of the overall number of discharge events.

Table 3-3 indicates that 4 of the 5 outfalls to the Ridley Creek had substantially more than the 4 – 6 annual overflow events that are the target for using the Presumption Approach. Only CSOs #033 is shown to have had less than 4 – 6 overflows. Of the four CSOs that were modeled to overflow more than 4- 6 times a year, the model estimates that all four of them had at least 33 or more annual overflow events and two of the outfalls are modeled as having had more than 95 overflow events.

Following the methodology described in the flowchart, the answers to the questions in the first decision making step indicate that the **Demonstration Approach** is the most appropriate for the CSO discharges to the Ridley Creek.

Section 6 Recommendations

It is recommended that the Demonstration Approach be utilized for the Delaware River, Chester Creek and Ridley Creek.

The Demonstration Approach relies on data collection and model simulation to demonstrate that the proposed LTCPU will meet applicable water quality standards and designated uses, and it provides a reliable tool to identify, evaluate and compare the selection and recommendation of the CSO control measures to be installed.

In addition to flow metering of the combined sewer system and water quality sampling of the CSOs to help refine and calibrate the H&H Model for the collection system, the Demonstration Approach requires a water quality model be developed for the Delaware River, Chester Creek and Ridley Creek. Water quality sampling of the receiving water bodies will be required to calibrate the water quality model and to identify and quantify the contributing pollutant sources in the watersheds other than CSOs.

The Demonstration Approach will be a better predictor than the Presumption Approach of actual resulting water quality at the end of the LTCPU program, and use of the Demonstration Approach will allow DELCORA to make more informed decisions regarding the long term control plan update investments that will result in compliance with the applicable water quality-based requirements.

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Alternatives Evaluation Approach Report (AEAR) dated April 27, 2016. EPA understands DELCORA has chosen the "Demonstration Approach" and hereby approves the AEAR.

Sincerely,

Andrew F. Seligman, Environmental Scientist

(A) Temperature shall not exceed 5 °F (2.8 °C) above the average 24-hour temperature gradient displayed during the 1961-66 period, or a maximum of 86 °F (30.0 °C) - whichever is less.

(B) Using M.B.A.S assay, with a maximum 30-day average of 1.0 mg/L.

(C) Unless exceeded due to natural conditions.

NOTES:

DRBC standards in their WQRs are referred to as "Stream Quality Objectives". DRBC's Stream Quality Objectives have primacy over the PA Code standards for the Delaware River.

PA CODE refers to the standards as "Water Quality Standards".

Ridley Creek is "TSF & MF" Critical Use from Rt. 320 Bridge upstream to the Media Water Intake. Ridley Creek is "WWF & MF" downstream from the Rt. 320 Bridge to mouth.

Chester Creek has a "TSF" Critical Use designation as well, but this is well upstream of the CSO discharge furthest upstream on Chester Creek and does not apply for this analysis.

Executive Summary

ES-1 Background

The Delaware County Regional Water Quality Control Authority (DELCORA) is a municipal authority originally organized under the Pennsylvania Municipal Authorities Act of 1945 (P.L. 382), as amended and supplemented, pursuant to action taken by the Delaware County Council on October 20, 1971. Under County of Delaware Ordinance 2002-1, the term of existence of DELCORA was extended to January 15, 2052.

DELCORA is in the process of developing a Long Term Control Plan (LTCP) Update for the Combined Sewer System (CSS) as part of a Consent Decree entered with the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP). DELCORA's Combined Sewer System is comprised of a sewer that accepts stormwater and sanitary wastewater which is treated at DELCORA's Western Regional Treatment Plant WRTP. As part of this comprehensive effort, DELCORA is to submit a report to the USEPA and PADEP that identifies all Sensitive Areas and Pollutants of Concern (POCs) that are impacted by Combined Sewer Overflows (CSOs) and are within the Model Area for each of its receiving waters. DELCORA is also to identify any additional areas that have been determined by DELCORA as being appropriate for prioritization.

The purpose of this report is to meet the requirement in the Consent Decree for the submission of a report that identifies the Sensitive Areas and Pollutants of Concern that are impacted by DELCORA's CSOs.

ES-2 Consent Decree Requirements

The Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania on August 17, 2015, and was approved by the Federal District Court on November 10, 2015. The Consent Decree requires DELCORA to complete and submit a revised and updated LTCP to the USEPA and the PADEP for review and approval. Consent Decree Paragraph V.A.11 (Identification of Sensitive Areas and Pollutants of Concern) requires that within six (6) months after the Date of Lodging, DELCORA shall submit a report that identifies all Sensitive Areas and Pollutants of Concern that are impacted by CSOs and are within the Model Area for each of its receiving waters. The receiving water bodies impacted by DELCORA's CSOs include the Delaware River, Chester Creek and Ridley Creek.

For the Identification of Sensitive Areas, Section V.A.11 of the Consent Decree specifically states:

> *"For each of its Receiving Waters, DELCORA shall contact appropriate agencies, access available data sources, and collect additional data as necessary to identify Sensitive*

Areas. DELCORA shall fully document all such contacts and the associated responses, and all additional investigations carried out to identify Sensitive Areas. DELCORA shall also identify any additional areas that, while not Sensitive Areas, have been identified by DELCORA as being appropriate for prioritization ("Priority Areas")." Additionally, *"For each of its Receiving Waters, DELCORA shall conduct community outreach and appropriate studies to determine whether and to what extent primary contact recreation is occurring in each Receiving Water, and shall fully document its outreach and study methods, and its findings."*

For the Identification of Pollutants of Concern, Section V.A.11 of the Consent Decree specifically states:

"For each of its Receiving Waters, DELCORA shall review existing water quality data and recent PADEP CWA § 303(d) listings to identify POCs. Even if a water body has not been formally listed as out of compliance with its water quality standards and designated uses, if available data indicate such impairment exists and such impairment involves pollutants associated with CSOs, DELCORA shall consider the related pollutants to be POCs."

ES-3 Sensitive Areas Summary

A comprehensive review of online databases, correspondence with regulatory agencies and local environmental organizations and review of responses to the public survey was conducted to identify potential Sensitive Areas within the combined sewer system portion of the collection system.

Outstanding National Resource Waters (ONRW) are maintained and protected by Tier 3 of the USEPA's Antidegradation Policy which can be accessed through the Agency's web portal. Only waters of "exceptional ecological significance" qualify as ONRWs, and States and Tribes determine whether or not a water body will be classified as such. In Chapter 93 of the Pennsylvania Code, it is stated that a water body will be classified as having Exceptional Value (EV) if it is considered by the Commonwealth of Pennsylvania to be an ONRW. No Outstanding National Resource Waters were located within the project boundaries.

The goal of the National Marine Sanctuaries Act (Title 16, Chapter 32, Section 1431 last amended in November 2000) is to identify and designate as National Marine Sanctuaries (NMS) areas of the marine environment which are of special national significance and to manage these areas as the National Marine Sanctuary System. The Office of National Marine Sanctuaries (ONMS) is the trustee of all national marine sanctuaries and as such, it currently recognizes fourteen (14) national marine sanctuaries, none of which are located within DELCORA's service area. Therefore, none of DELCORA's receiving waters, the Delaware River, Chester Creek or Ridley Creek, are considered to be a National Marine Sanctuary.

There are no commercial shellfish harvesters that operate within the study area. The Partnership for the Delaware Estuary reported shellfish areas well downstream of the most southern outfall in DELCORA's system. The uppermost shellfish harvesting area is approximately 32 miles outside the project boundaries. No shellfish beds are located within the project boundaries.

There are numerous drinking water intakes in this geographical area but none are located on the Delaware River downstream in close proximity to DELCORA's CSOs. There are no drinking water intakes located along Chester Creek or Ridley Creek in proximity to DELCORA's service area. Therefore, the Sensitive Area criteria for Drinking Water Intakes does not apply to the Chester or Ridley Creeks.

While the US Fish and Wildlife Service identified several Endangered or Threatened species which potentially could live in the project area, critical habitat was found for Atlantic Sturgeon only. The habitat for year-of-young Atlantic Sturgeon downstream of CSO #002 in the Delaware River meets the Sensitive Area criteria for Endangered or Threatened species. The Atlantic Sturgeon is listed as a threatened species by the US Fish and Wildlife Service with documented habitat in the Delaware River downstream approximately one-half mile downstream of DELCORA's most southern outfall. Therefore, the habitat for year-of-young Atlantic Sturgeon is considered a sensitive area.

The northern reaches of Ridley Creek within DELCORA's service area are designated as Approved Trout Waters and Trout Stocked Streams. The portion of the approved trout waters from CSO #033 downstream to Chestnut Street is considered a Priority Area because of this special environmental use.

The boat launch located between CSO #007 and #008 along the Delaware River is located within the portion of the waterbody rated for primary contact and may be impacted by CSO discharge. The boat launch is considered a Priority Area.

ES-4 Pollutants of Concern Summary

A comprehensive review of existing receiving water quality data was conducted to identify the Pollutants of Concern and this review was performed in accordance with the requirements of the Consent Decree and the CSO Guidance Manual. This review included on-line USEPA STORET data from the Years 2010-2015, results of sampling performed during the preparation of DELCORA's 1999 LTCP and additional CSO sampling. A parameter associated with CSO discharges was considered to be a POC when more than 10% of the total samples reviewed indicated an exceedance of the applicable water quality standard. A secondary category called Parameters of Potential Concern (POPC) was established for those parameters associated with CSO discharges where 2 to 10% of the total samples reviewed indicated an exceedance of the applicable water quality standard.

The specific parameters identified by DELCORA as POCs in each of the receiving water bodies are listed below.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria

- For the upper Delaware River (Upstream of R.M. 81.8)
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria

- For the Chester Creek
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria

- For the Ridley Creek
  - Fecal Coliform Bacteria
  - Enterococcus Bacteria
  - E. coli Bacteria

The identified POCs for DELCORA's receiving water bodies have been listed and discussed in detail in Section 3.7. No POCP (Parameters of Potential Concern) were identified.

Section 1 Introduction

1.1 Background of DELCORA's Facilities

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1. The total service area served by DELCORA, as shown on Figure 1-2, is approximately 82,977 acres which illustrates that DELCORA serves a significant and widespread portion of Delaware County.

The combined sewer area simulated in DELCORA's existing Hydrologic and Hydraulic model is located within the City of Chester and consists of a drainage area of approximately 1,510 acres. It comprises approximately half of Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows. The location of Chester City's service area is illustrated on Figure 1-2.

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western service area discharges to DELCORA's Western Regional Treatment Plant (WRTP). The Eastern service area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWDSWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are directed to the PWDSWPCP. As such, dry weather flows and a portion of the wet weather flows (total flow less than 20 MGD) from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

There are a total of 26 combined sewer overflow outfalls listed with 25 discharge points (Outfall #009 and #010 both discharge at Outfall #009) in DELCORA's existing National Pollutant Discharge Elimination System (NPDES) Permit. Under its NPDES Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow outfalls (#002-#026, #032, #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

Part C – Other Requirements, Section V – Combined Sewer Overflows of the NPDES Permit details DELCORA's responsibilities with respect to the CSO system including reporting, continued implementation of and continued compliance with the Nine Minimum Controls (NMC), and implementation of the existing Long-Term Control Plan (LTCP) dated April 1999 and the July 2008 addendum to the LTCP until the updated LTCP is approved.

1.2 Consent Decree

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated LTCP to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. Consent Decree Paragraph V.A.11 (Identification of Sensitive Areas and Pollutants of Concern) requires that within six (6) months after the Date of Lodging, DELCORA shall submit a report to the USEPA and PADEP that identifies all Sensitive Areas and Pollutants of Concern that are impacted by CSOs and are within the Model Area for each of its receiving waters. Details of the Consent Decree requirements for Sensitive Areas and POCs are respectively found in Sections 1.2 and 3.1.

1.3 CSO System Description

1.3.1 DELCORA Facilities

DELCORA's Western service area wastewater is treated at the WRTP located at 3201 W. Front Street in Chester, Pennsylvania. The WRTP treats all wastewater from Southern Delaware County Authority, Marcus Hook Borough, Trainer Borough, Upland Borough, Parkside Borough, Eddystone Borough, Chester Township and the City of Chester as well as a portion of the wastewater from Brookhaven Borough and Nether Providence Township. The City of Chester CSO system is described in detail in Section 1.3.2.

One of the facilities in the City of Chester is the 40-MGD Chester Pump Station and the 48-inch-diameter, PCCP force main that runs to the WRTP. DELCORA has completed construction of a 54-inch-diameter ductile iron force main to replace the existing force main. In 2002, DELCORA completed a force main that connects the Central Delaware Pump Station via a 3.4-mile, 24-inch ductile iron force main to the Chester Force Main. This connection allows DELCORA to send up to 27 MGD of flow from the CDPS to the WRTP, however, DELCORA's operating policy limits this flow to 20 MGD, with flows above this point to be directed to PWD SWPCP. Figure 1-1 shows the interconnections in DELCORA's system. The left side of the figure indicates the Western service area and the right side indicates the Eastern service area. This interconnectivity coupled with the legal agreements DELCORA maintains with the municipalities and conveyance authorities in Delaware County creates the complicated legal/financial framework under which DELCORA operates.

1.3.2 City of Chester CSO System

As noted in Section 1.1, the combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's serviced area. The combined wastewater/stormwater system in the City of Chester is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, and CSO regulators and CSO outfalls. The City owns, operates and maintains the inlets, stormwater-only sewers that connect to the combined sewer system and any stormwater-only outfalls. The City is also responsible for the maintenance and cleaning of the streets, planning, zoning, and development controls.

The Chester CSO system contains 26 permitted outfalls as listed in Table 1-1, and they discharge to three receiving water bodies: the Delaware River, Chester Creek, and Ridley Creek. However, there are only 25 CSO discharge locations, as CSO #010 discharges to the Delaware River through CSO #009. Figure 1-3 depicts the locations of CSO regulators and outfalls that are DELCORA's responsibility.

Table 1-1: Permitted CSOs in the City of Chester

Name of Receiving Stream	CSO Outfall	Interceptor/CSO Regulator Location	Latitude	Longitude

Section 2 Identification of Sensitive Areas

2.1 Regulatory Requirements

2.1.1 Consent Decree Requirements

For the Identification of Sensitive Areas, Section V.A.11 of the Consent Decree states:

> *"For each of its Receiving Waters, DELCORA shall contact appropriate agencies, access available data sources, and collect additional data as necessary to identify Sensitive Areas. DELCORA shall fully document all such contacts and the associated responses, and all additional investigations carried out to identify Sensitive Areas. DELCORA shall also identify any additional areas that, while not Sensitive Areas, have been identified by DELCORA as being appropriate for prioritization ("Priority Areas")."*
>
> Additionally, *"For each of its Receiving Waters, DELCORA shall conduct community outreach and appropriate studies to determine whether and to what extent primary contact recreation is occurring in each Receiving Water, and shall fully document its outreach and study methods, and its findings."*

2.1.2 Requirements of the USEPA's CSO Control Policy and Sensitive Areas Definition

The USEPA's CSO Control Policy (Federal Register 59 [April 19, 1994]: 18688-18698) "expects a permittee's long-term CSO control plan to give the highest priority to controlling overflows to sensitive areas" (Section II.C.3). The CSO Control Policy states the six (6) criteria for defining an area as a "Sensitive Area" include:

1. Designated Outstanding National Resource Waters
2. National Marine Sanctuaries
3. Waters with threatened or endangered species and their habitat
4. Waters with primary contact recreation
5. Public drinking water intakes or their designated protected areas
6. Shellfish beds

The CSO Control Policy states that if Sensitive Areas are present and impacted, the LTCP should include provisions to:

- Prohibit new or significantly increased overflows
- Eliminate or relocate overflows wherever physically possible and economically achievable

- Treat overflows where necessary
- Where elimination or treatment is not achievable, reassess impacts each permit cycle

Sensitive Areas should be considered prior to the evaluation of CSO control alternatives. This allows a CSO community to identify and estimate costs for controls that could eliminate or relocate CSOs from Sensitive Areas where pollutant loadings pose a high environmental or public health risk and where control efforts should be focused. The cost of these controls can then be considered, along with the community's financial capability, to evaluate cost-effective controls for all of the receiving waters.

2.2 Priority Areas Definition

The term "Priority Areas" is not specifically defined by the USEPA in the Consent Decree nor in the CSO Control Policy or Guidance Document. For the purposes of this report, the term "Priority Areas" is defined as follows:

> *"Areas having some environmental significance but not to the level of "sensitive areas" as defined in the federal CSO Control Policy. These priority areas may include: public access areas (i.e., near marinas, schools, playgrounds, parks, or athletic fields); or use of shallow streams for recreational activity, with something less than full contact (i.e., wading)".*

In compliance with the Consent Decree, DELCORA conducted community outreach in order to determine whether and to what extent primary contact recreation is occurring in each Receiving Water. In order to cover DELCORA's large service area, a public survey was deemed to be the most comprehensive method to actively solicit community outreach. Multiple regulatory agencies and environmental organizations were also contacted.

2.3 Assessment of Sensitive and Priority Areas

The six criteria for Sensitive Areas identified in the CSO policy were evaluated for the Delaware River, Chester Creek and Ridley Creek within DELCORA's service area including reaches upstream of the CSOs. Special consideration was given to areas downstream and within the tidal influence of DELCORA's CSOs as any potential Sensitive Areas within hydraulic proximity to outfalls that may be impacted by their discharge.

2.3.1 Methodology

In order to develop a comprehensive understanding of the presence of designated Sensitive Areas within the study area, multiple strategies were used to complete these investigations including searching online data resources, sending letters to regulatory agencies and environmental organizations, and conducting a public survey. The goal of this multi-faceted approach was to

gain a thorough understanding of the presence of sensitive and priority areas to support the development of future CSO control alternatives.

2.3.1.1 Letters with Regulatory Agencies

Letters were drafted and issued to key regulatory agencies at the federal and state levels, and environmental organizations at the state and local levels. Contacts were identified based on their governance over the three waterbodies of concern including the Delaware River, Chester Creek and Ridley Creek, or their local involvement with those associated watersheds. Agencies in New Jersey and Delaware were also contacted to further understand the surrounding environment even though the study area is limited to the boundaries of the Commonwealth of Pennsylvania. Table 2-1 lists the agencies which received requests for information. Follow-up telephone calls were made to all agencies that had not responded by November 30, 2015.

Table 2-1: Letters Issued to Agencies and Organizations

Agency	Contact	Title	Date Sent	Response Date
U.S. Fish and Wildlife Agency	Robert Anderson	Fish & Wildlife Biologist	10/29/2015	11/2/2015
U.S. Fish and Wildlife - John Heinz NWR Birds	Brendalee Phillips	Wildlife Biologist	10/29/2015	No Comments
PA DEP	Jennifer Fields	Clean Water Section Program Manager	10/29/2015	11/17/15 - phone call
Delaware River Basin Commission (DRBC)	Steve Tambini	Executive Director	10/29/2015	No Comments
PA Game Commission	Patti Barber	Endangered Bird Biologist	10/29/2015	12/29/2015 – phone call
PA Game Commission	Ian Gregg	Wildlife Biologist	10/29/2015	No Response
PA Environmental Council	Carol F. McCabe, Esq.	Chair	10/29/2015	No Response
Chester Ridley Crum Watersheds Association	Brian Byrnes	Executive Director	10/29/2015	11/23/15 – phone call

Agency	Contact	Title	Date Sent	Response Date
New Jersey Department of Environmental Protection (NJDEP)	David Chanda	Director Fish and Wildlife	10/29/2015	No Response
Delaware Department of Natural Resources and Environmental Control (DNREC)	Matt Fisher	Director Fish and Wildlife	10/29/2015	11/30/2015
PA Fish and Boat Commission (PFBC)	John Buzzar, Kathy Gipe and Greg Murphy	Fisheries Biologists	10/29/2015	12/22/15; follow-up 3/11/16 and 5/2/16
Partnership for the Delaware Estuary (PDE)	Dr. Danielle Kreeger	Science Director	10/29/2015	11/25/2015

Each letter requested information related to all six Sensitive Area criteria with the exception of the letter to the U.S. Fish and Wildlife Service, which was tailored based on telephone conversations held prior to issuance of the letter. Copies of the letters issued requesting information and responses are included in Attachment A.

2.3.1.2 Online Database Searches

An abundance of information is available online regarding the Delaware River, Chester Creek, and Ridley Creek waterbodies. The following entities and on-line databases were searched for information related to Sensitive Areas and Priority Areas within the study area boundary:

- National Oceanic and Atmospheric Administration (NOAA)
  - NOAA 2014 Environmental Sensitivity Index Maps
- United States Environmental Protection Agency
- Pennsylvania Department of Environmental Protection
- Office of National Marine Sanctuaries
- John Heinz National Wildlife Refuge
- Chester Creek Rails-to-Trails Project
- Ridley Creek State Park
- Pennsylvania Department of Conservation and Natural Resources (PA DCNR)

The results of these searches were used to determine the presence of Sensitive Areas and/or Priority Areas located within the study area boundaries.

2.3.1.3 Public Survey

DELCORA prepared a public survey requesting information from local residents specifically about how the public is using the waterbodies within the CSS. Furthermore, the public survey also asked for the frequency that the residents are using the waterbody and within what time of the year they use the waterbody. Respondents were also provided an opportunity to leave comments in an open-ended format. The survey was mailed to approximately 14,000 customers within DELCORA's service area. The individuals contacted had the option to complete a hard copy of the survey or to complete the survey online. In addition to the 14,000 customers that received a hard copy of the survey, all members of the public (not just the individuals that received a copy of the survey) had the ability to complete the survey online at DELCORA's website. A copy of the survey, survey map, and the Public Survey Tally Sheet is included as Attachment B. A summary of the responses received by the residents in the Public Survey is included in Table 2-2.

Table 2-2: River and Creeks Use Survey Summary

Rivers and Creek Use Survey Summary						
	Delaware River		Chester River		Ridley Creek	
Activities	Percent Use per Year	Percent Never Used	Percent Use per Year	Percent Never Used	Percent Use per Year	Percent Never Used
Fishing Bank/Boat	1.28%	98.72%	1.53%	98.47%	0.55%	99.45%
Fishing from Wading	0.25%	99.75%	0.84%	99.16%	0.51%	99.49%
Rowing/Canoeing	0.05%	99.95%	0.02%	99.98%	0.02%	99.98%
Motor Boating	0.55%	99.45%	0.02%	99.98%	0.02%	99.98%
Kayaking	0.05%	99.95%	0.03%	99.97%	0.02%	99.98%
Jet Skiing	0.25%	99.75%	0.01%	99.99%	0.01%	99.99%
Water Skiing	0.01%	99.99%	0.00%	100.00%	0.00%	100.00%
Swimming	0.01%	99.99%	0.03%	99.97%	0.04%	99.96%
Wading	0.24%	99.76%	0.09%	99.91%	0.26%	99.74%
Other	0.01%	99.99%	0.01%	99.99%	0.01%	99.99%

2.3.2 Outstanding National Resource Waters

Outstanding National Resource Waters (ONRW) are maintained and protected by Tier 3 of the USEPA's Antidegradation Policy which can be accessed through the Agency's web portal at http://www.epa.gov/sites/production/files/2014-10/documents/diamond-outstanding-memo.pdf. Only waters of "exceptional ecological significance" qualify as ONRWs, and States and Tribes determine whether or not a water body will be classified as such.

In Chapter 93 of the Pennsylvania Code, it is stated that a water body will be classified as having Exceptional Value (EV) if it is considered by the Commonwealth of Pennsylvania to be an

ONRW. Chapter 93 of the PA Code lists water bodies alongside their protected water uses. Neither the Delaware River, Chester Creek nor Ridley Creek are listed as being of Exceptional Value. Therefore, none of DELCORA's receiving waters, the Delaware River, Chester Creek or Ridley Creek, are considered to be an ONRW.

2.3.3 National Marine Sanctuaries

The goal of the National Marine Sanctuaries Act (Title 16, Chapter 32, Section 1431 last amended in November 2000) is to identify and designate as National Marine Sanctuaries (NMS) areas of the marine environment which are of special national significance and to manage these areas as the National Marine Sanctuary System. Receiving this designation results in the conservation and management of these special habitats, support of the natural biological communities through protection and restoration, enhances the public's awareness, understanding and appreciation for the marine sanctuary, and supports the vitality of these communities through research and Federal, State and Local government collaboration.

In order for a marine environment to be designated a National Marine Sanctuary, the United States Secretary of Commerce will determine if any of the following criteria apply:

"Criteria 1
The area's natural resources and ecological qualities are of special significance and contribute to: biological productivity or diversity; maintenance or enhancement of ecosystem structure and function; maintenance of ecologically or commercially important species or species assemblages, or both; or maintenance or enhancement of connectivity to other ecologically significant resources.

Criteria 2
The area contains submerged maritime heritage resources of special historical, cultural, or archaeological significance, that: individually or collectively are consistent with the criteria of eligibility for listing on the National Register of Historic Places; have met or which would meet the criteria for designation as a National Historic Landmark; or have special or sacred meaning to the indigenous people of the region or nation.

Criteria 3
The area supports present and potential economic uses, such as: tourism; commercial and recreational fishing; subsistence and traditional uses; diving; and other recreational uses that depend on conservation and management of the area's resources.

Criteria 4
The publically-derived benefits of the area, such as aesthetic value, public recreation, and access to places depend on conservation and management of the area's resources."

The above criteria for National Marine Sanctuaries was taken directly from the Sanctuary Nomination Process Guide which can be found at http://www.nominate.noaa.gov/guide.html#document.

The Office of National Marine Sanctuaries (ONMS) is the trustee of all national marine sanctuaries and as such, it currently recognizes fourteen (14) national marine sanctuaries, none of which are located within DELCORA's service area. Therefore, none of DELCORA's receiving waters, the Delaware River, Chester Creek or Ridley Creek, are considered to be a National Marine Sanctuary.

2.3.4 Threatened or Endangered Species Criterion

The Federal CSO Policy states "waters with threatened or endangered species and their habitat" are considered a Sensitive Area. The U.S. Fish and Wildlife Service and PA Fish and Boat Commission were contacted and the NOAA Environmental Sensitivity Index maps reviewed to identify any threatened or endangered species with habitat within the project boundaries. Threatened and endangered species that could potentially occur within the project study area are listed in Table 2-3 below. A copy of the letters received from the U.S. Fish and Wildlife Service and PA Fish and Boat Commission can be found in Attachment A to this report.

Table 2-3: Federally-Listed Threatened and Endangered Species

Species	Status
Bog Turtle	Threatened
Eastern Redbelly Turtle	Threatened
Indiana Bat	Endangered
Northern Long-Eared Bat	Endangered
Atlantic Sturgeon	Threatened
Shortnose Sturgeon	Endangered

These species could potentially use the Delaware River, Chester Creek or Ridley Creek as habitat. However, the U.S. Fish and Wildlife Service stated that no critical habitat has been designated for any of the threated and endangered listed species in the Delaware River, Chester and Ridley Creeks as of November 2015.

The NOAA Environmental Sensitivity Index Maps for the project area, ESI-18 and ESI-19, were then reviewed to locate specific habitat for the above listed species. These NOAA maps are included as Attachment K. No habitat was found for the Bog Turtle, Indiana Bat, or Northern Long-Eared Bat within the project boundaries. The NOAA ESI maps do indicate the Shortnose Sturgeon concentrations are "medium" from April through October, and "high" November through March in the Delaware River. However, the NOAA ESI maps generically state this migratory species is present in the Delaware River and does not include any specific portion of the project area as being a nursery, spawning or year-of-young habitat for the species.

The Eastern Redbelly Turtle habitat is located within the Heinz National Wildlife Refuge which enters the Delaware River approximately 2 miles upstream of the northern most CSO outfall. The Refuge is not directly on the Delaware River and outside the project boundaries.

Atlantic Sturgeon habitat is shown on NOAA map ESI-18 spanning the Pennsylvania/Delaware border. High concentrations of year-of-young Atlantic Sturgeon has been documented in this area. The most northern portion of the Atlantic Sturgeon habitat, as shown on Figure 2-1, is one-half mile from DELCORA's most down steam CSO #002. The criteria for a Sensitive Area is met because both a threatened species and its habitat are identified.

In the previously submitted 2012 DELCORA LTCP report, tidal flats were identified as a Sensitive Area meeting the criteria of critical habitat for threatened or endangered species. However, the current request for information from the U.S. Fish and Wildlife Service on threatened or endangered species and their habitat present within the project boundaries found that no critical habitat has been identified. The response from the U.S. Fish and Wildlife Service stating the same can be found in Attachment A. Therefore, the most current information is used in this report and the tidal flats are no longer considered a Sensitive Area.

2.3.4.1 Bald and Golden Eagle

Bald eagles are known to nest in the vicinity of the project area. While the bald eagle has been removed from the Federal list of threatened and endangered species, the bald eagle along with the golden eagle continues to be protected under the Bald and Golden Eagle Protection Act (BGEPA) and the Migratory Bird Treaty Act (MBTA). These Acts prohibit anyone to "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, destroy, molest, disturb, or otherwise harm eagles, their nests, or their eggs". Under the BGEPA, "disturb" means to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, based on the best scientific information available: (1) injury to an eagle; (2) decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior; or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior. Since the Bald Eagle has been removed from the Federal list of threatened and endangered species, the Sensitive Area criteria for Threatened or Endangered Species does not apply to the project study area. However, it is acknowledged that these species require special consideration. During the development of CSO abatement alternatives, the project will be evaluated for project size, location and layout in order to comply with the BGEPA and MBTA.

2.3.4.2 Special Considerations

The northern reaches of Ridley Creek within DELCORA's service area are designated as Approved Trout Waters and Trout Stocked Streams. The portion approved for stocking trout begins at Brookhaven Road upstream of CSO #033 and ends downstream of CSO #033 at Chestnut Street in Chester City as shown on Figure 2-1. The portion of the approved trout waters from CSO #033 downstream to Chestnut Street is considered a Priority Area because of

this special environmental use and the need to meet water quality standards to continue to support trout stocking. Additionally, the public is provided an opportunity to use Ridley Creek for recreational purposes and that may include wading which further meets the criteria of a Priority Area.

2.3.5 Primary Contact Recreation Criterion

Primary contact is defined as an activity where people come directly in contact with the waterbody, such as at bathing beaches. The Upper Delaware River (defined as the portion of the river upstream of River Mile 81.8), Chester Creek and Ridley Creek are all designated for secondary contact and are not suitable for direct contact with the waterbody. The Lower Delaware River (downstream of River Mile 81.8), is rated for primary contact. Special water quality standards are used for water contact areas in order to protect the public from being exposed to waterborne diseases. The study area is located in a densely populated urban area with a mix of recreational uses including boating, fishing, hiking, and other uses by the public.

2.3.5.1 Delaware River

The Delaware River is designated as suitable for Water Contact (WC) Recreation below River Mile (R.M.) 81.8 (between CSO #009 and #011). It is to be noted that this stretch (Zone 4) of the Delaware River is not listed in the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report (PADEP, 2014) (a.k.a. the "303(d) list") as impaired for its WC use, and it has not been reported as impaired or not meeting designated uses from coliform bacteria or any other parameter commonly associated with CSOs or municipal wastewater treatment plant discharges. There are no designated bathing beaches or approved swimming facilities along the Delaware River within the project area boundaries.

There is one boat launch owned by the Chester Economic Development Authority located along the Delaware River within the project study area boundaries as shown on Figure 2-1. This boat launch is located between CSO #007 and #008 and may be impacted by CSO discharges. Additionally, this boat ramp is located within the portion of the waterbody rated for primary contact. Therefore, it was determined that this location does not qualify as a Sensitive Area because it is neither impaired, failing to meet the associated water quality standards, the public is not provided with access to the waterbody and is not using it for primary contact recreation activities according to the public survey. It is however considered a Priority Area because it provides the public with direct access to the Delaware River in a portion rated for primary contact. The Priority Area at the boat launch is shown in Figure 2-1 to extend for a total length of 500 feet along the shoreline; or 250 feet upstream and 250 feet downstream from the location of the boat launch. The Priority Area around the boat launch is also shown to extend into the river 250 feet from the shoreline. There are no defining boundaries for priority areas, however, a buffer zone of 250 feet around the boat launch includes the area one block upstream and one block downstream of the boat launch.

2.3.5.2 Chester Creek and Ridley Creek

There are no identified boat launch ramps, boat docks, or designated bathing beaches within Chester or Ridley Creek within the project area boundaries. Results of the public survey indicate the public is not using Chester Creek or Ridley Creek for primary contact activities. Of all the activities listed, fishing was the most frequently identified use of the waterbodies which does not qualify as primary contact. Of the over 460 respondents only a few reported using the waterbodies for boating, wading or swimming. It was therefore concluded these waterbodies are not considered a Sensitive Area for primary contact.

As mentioned above, the approved trout waters of Ridley Creek are being considered a Priority Area. In addition to its environmental significance as approved trout waters, they provide the public with wading access to the water for recreational fishing activities. This further supports this section of Ridley Creek being considered a Priority Area worthy of special consideration.

2.3.6 Drinking Water Intakes

Several drinking water providers are located within the study area. The majority of Delaware County is served by Aqua Pennsylvania. Chester Water Authority serves portions of western Delaware County in Thornbury Township, Chester Heights Borough, Chadds Ford Township, Concord Township, Bethel Township, Aston Township, Upper Chichester, Lower Chichester, Trainer, Brookhaven, Parkside, Upland, Chester Township, and Chester City. All drinking water intakes for both Aqua Pennsylvania and the Chester Water Authority are upstream of the CSOs and are not affected by their discharges as they are located on tributaries of the Delaware River.

Upstream of DELCORA's service area (and upstream of Center City Philadelphia), the Delaware River is still tidal and the Philadelphia's Water Department's Baxter Water Treatment Plant is located alongside the tidal portion of the river. DELCORA's most upstream CSO on the Delaware, CSO #014, is over 26 miles downstream of this drinking water intake.

Downstream of DELCORA's service area and located in the State of Delaware, United Water customers receive most of their water from the Stanton Water Treatment Plant, which is capable of treating 30 million gallons of water per day. The Stanton Plant draws water from the White Clay and Red Clay Creeks which are tributary to the Christiana River, itself a tributary to the Delaware River. DELCORA's most downstream CSO, CSO #002, is over 10 miles upstream of the confluence of the Delaware and Christiana Rivers. The Stanton's plant drinking water intake is several miles upstream of this location.

Due to the large distances of the drinking water intakes noted above to DELCORA's CSOs, the Sensitive Area criteria for Drinking Water Intakes on the Delaware River does not apply to the areas associated with DELCORA's CSO discharges.

There are no drinking water intakes located along Chester Creek or Ridley Creek in proximity to DELCORA's service area. Therefore, the Sensitive Area criteria for Drinking Water Intakes does not apply to the Chester or Ridley Creeks.

2.3.7 Shellfish Beds

There are no commercial shellfish harvesters that operate within the study area. The Partnership for the Delaware Estuary reported shellfish areas well downstream of the most southern outfall in DELCORA's system. Shellfish consumption as a DRBC designated use, only applies to DRBC WQM Zone 6. The DRBC's 2014 Delaware River and Bay Water Quality Assessment presents a map that shows the approved shellfish harvesting areas in the Delaware Bay, and this map is re-presented in this report as Figure 2-2. The uppermost shellfish harvesting area is approximately 32 miles downstream from DELCORA's closest CSO discharge (CSO #002). The influence of tidal mixing and dilution coupled with the 32 mile separation between the most downstream discharge point and beginning of the shellfish harvest zone result in the CSO discharge having a negligible impact on the shellfish beds. Therefore, the Sensitive Area criteria for Shellfish Beds does not apply to the areas associated with DELCORA's CSO discharges.

2.4 Summary of Sensitive and Priority Areas

A comprehensive review of online databases, correspondence with regulatory agencies and local environmental organizations, and responses to the public survey was conducted to identify potential Sensitive Areas and Priority Areas within the CSS portion of the collection system.

2.4.1 Summary of Sensitive Areas

The habitat for year-of-young Atlantic Sturgeon downstream of CSO #002 in the Delaware River meets the Sensitive Area criteria for Endangered or Threatened species. The Atlantic Sturgeon is listed as a threatened species by the US Fish and Wildlife Service with documented habitat in the Delaware River downstream approximately one-half mile downstream of DELCORA's most southern outfall.

There are no Outstanding National Resource Waters nor National Marine Sanctuaries within the project area. Shellfish beds are located well downstream of the CSO locations and are outside the project boundaries. There are numerous drinking water intakes in the geographical area but none are located in close proximity downstream of DELCORA's CSOs on the Delaware River. No drinking water intake locations were found that meet the criteria of a Sensitive Area.

Figure 2-2: Shellfish Harvesting Areas in Zone 6 of the Delaware River

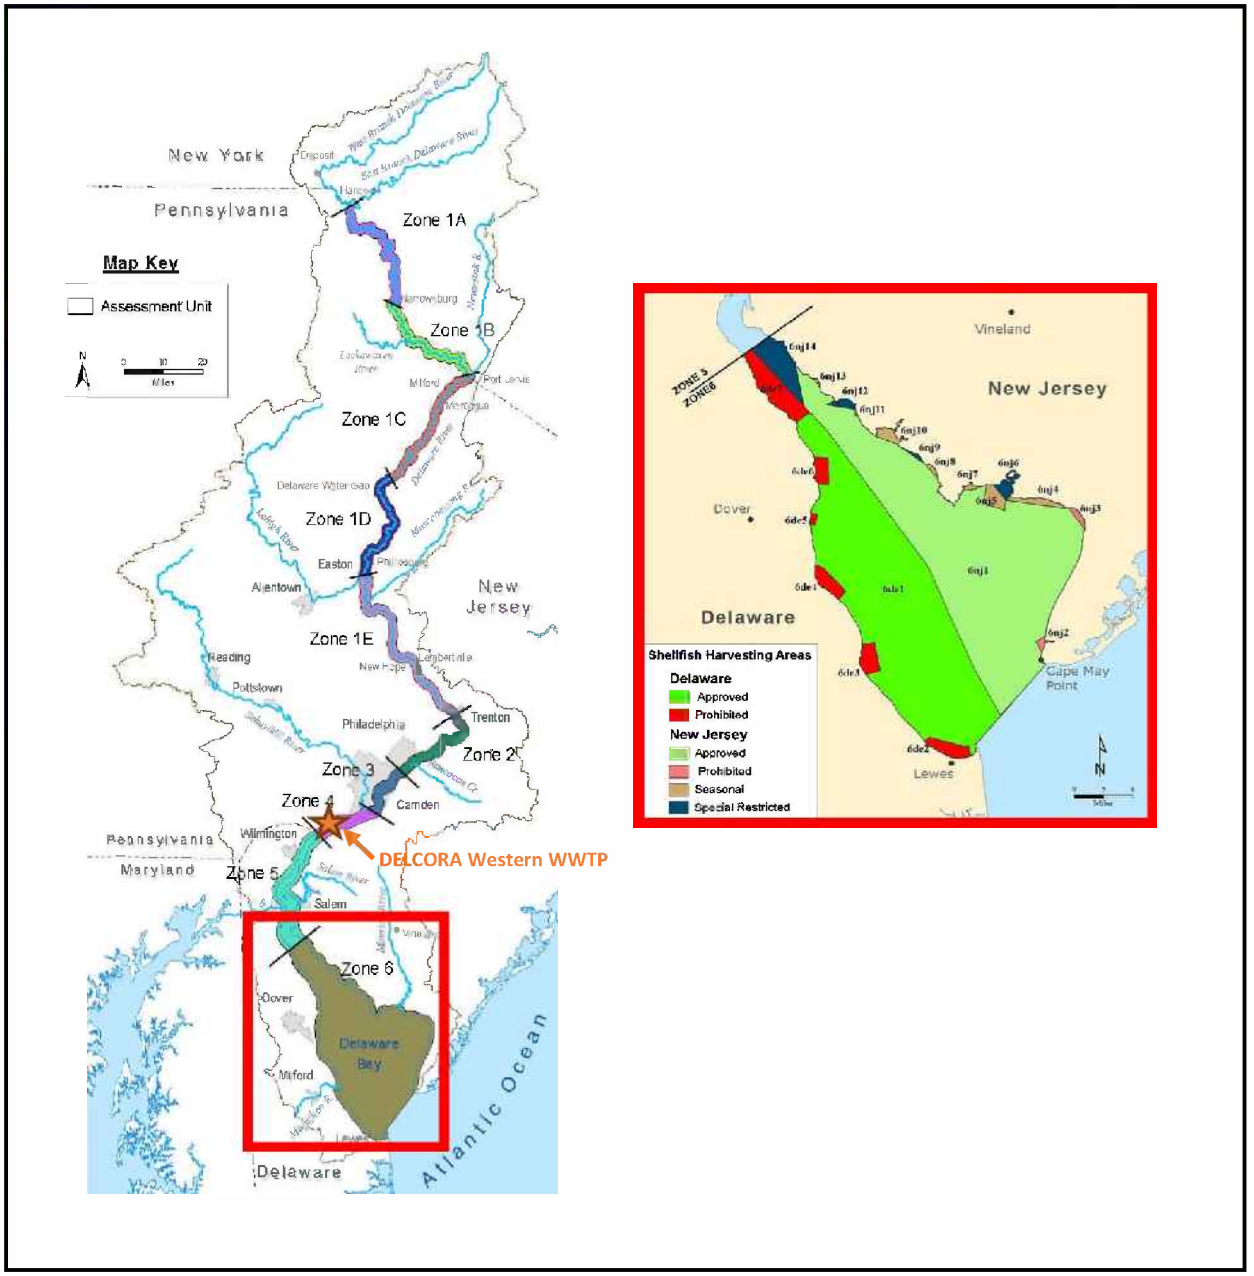

*Image courtesy of the Delaware River Basin Commission

2.4.2 Summary of Priority Areas

Priority Areas include areas having some environmental significance but not to the level of "Sensitive Areas" as defined in the federal CSO Control Policy. Two Priority Areas were identified:

- Approved trout waters in Ridley Creek,
- Chester Economic Development Authority's boat launch in Chester City.

The northern reaches of Ridley Creek within DELCORA's service area are designated as Approved Trout Waters and Trout Stocked Streams. The portion of the approved trout waters from CSO #033 downstream to Chestnut Street is considered a Priority Area because of this special environmental use.

The boat launch located between CSO #007 and #008 along the Delaware River is located within the portion of the waterbody rated for primary contact. The boat launch is considered a Priority Area due to its location to CSO #007 and #008.

Section 3 Pollutants of Concern

3.1 Regulatory Requirements

3.1.1 Consent Decree Requirements

For the Identification of Pollutants of Concern, Section V.A.11 of the Consent Decree specifically states:

> *"For each of its Receiving Waters, DELCORA shall review existing water quality data and recent PADEP CWA § 303(d) listings to identify POCs. Even if a water body has not been formally listed as out of compliance with its water quality standards and designated uses, if available data indicate such impairment exists and such impairment involves pollutants associated with CSOs, DELCORA shall consider the related pollutants to be POCs."*

3.1.2 Requirements of the USEPA's CSO Guidance Document

Section 2.5.3.3 of the USEPA's CSO Guidance document states that to assess the impacts of wet weather runoff, the water quality of the receiving waters should be understood for normal dry weather periods. The water quality data that is collected during dry weather conditions provides a basis for comparing the data collected during wet weather conditions. The CSO Guidance Document says:

> *"Receiving water monitoring should include identified parameters of concern. These parameters typically include those previously identified for combined sewage and CSO monitoring.*
>
> - *pH*
> - *BOD*
> - *TDS*
> - *TSS*
> - *Nutrients*
> - *Metals*
> - *Indicator bacteria*
>
> *Knowledge of the site-specific water quality concerns could expand the list to include dissolved oxygen, toxics, biological assessment, and sediment."*

3.2 Receiving Water Use Designations and General Water Quality Standards

Information about the applicable water quality standards (WQS) and designated uses for the three receiving water bodies impacted by DELCORA's CSOs were obtained from the PADEP's 2014 Integrated Water Quality Monitoring and Assessment Report (or "303(d) list"), the Pennsylvania Code, the Delaware River Basin Commission's (DRBC's) Water Quality Regulations (WQRs) and from the DRBC's 2014 Delaware River and Bay Water Quality Assessment.

3.2.1 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report (303(d) list)

The primary source of information about the causes of impairment, and the Total Maximum Daily Load (TMDL) status of the water bodies (if any) is the 2014 PA Integrated Water Quality Monitoring and Assessment Report (PA Integrated Report), which satisfies Pennsylvania's requirement of both Section 303(d) and 305(b) of the Clean Water Act (CWA). The PA Integrated Report lists all impaired surface waters within Pennsylvania that are not attaining designated and existing uses, even after appropriate and required pollution control technologies have been applied. A TMDL is designed to reduce pollutant loads to impaired waters and enable these waters to meet water quality standards.

The Integrated Report uses a five-part categorization (lists) of water according to their use attainment status. The categories represent varying levels of use attainment, ranging from Category 1, where all designated water uses are met to Category 5, where impairment by pollutants required the development of a TMDL to correct. Each segment of the waterbody is placed into one of these five categories.

The PADEP's website explains the categories as follows:

- *"Category 1: Waters attaining all designated uses.*
- *Category 2: Waters where some, but not all, designated uses are met. Attainment status of the remaining designated uses maybe unknown because data are insufficient to categorize a water body consistent with the states' listing methodology or may be impaired.*
- *Category 3: Waters for which there are insufficient or no data and information to determine, consistent with the state's listing methodology, if designated uses are met.*
- *Category 4: Waters impaired for one or more designated use but not needing a TMDL. States may place these waters in one of the following three subcategories:*
    - *Category 4A: TMDL is approved.*
    - *Category 4B: Expected to meet all designated uses within a reasonable timeframe (three years).*
    - *Category 4C: Not impaired by a pollutant.*

- *Category 5: Waters impaired for one or more designated uses by any pollutant and requiring the development of a TMDL. Category five includes waters shown to be impaired as the result of biological assessment used to evaluate aquatic life even if the specific pollutant is not known unless the state can demonstrate that non-pollutant stressors cause impairment or that no pollutant(s) causes or contribute to the impairment.*"

The Category 5 list constitutes the Section 303(d) list that the USEPA will approve or disapprove under the CWA. For the purposes of the determination of Pollutants of Concern, Categories 4A and 5 are the relevant categories as they indicate the need for a TMDL in the receiving water body and the limiting of additional loadings for those parameters. All of the lists are sorted by an 8-digit Hydrologic Unit Code (HUC) that is particular for the water body of interest. For DELCORA's drainage area, the HUC for the Lower Delaware River (02040202) was used for searching the data in the PA Integrated Report for all three of DELCORA's receiving water bodies.

3.2.2 PA Code Chapter 25 §93.9g

The primary source of information for the Critical Use Designation for each section of the three receiving water bodies is Chapter 25 §93.9g – Drainage List from the Pennsylvania Code. The relevant Critical Use Designations for DELCORA's receiving water bodies include Warm Water Fishes (WWF), Migratory Fishes (MF), Trout Stocking (TSF), and Water Contact Sports/Recreation (WC).

- The "WWF" designation indicates the maintenance and propagation of fish species and additional flora and fauna which are indigenous to a warm water habitat.
- The "MF" designation indicates the passage, maintenance and propagation of anadromous and catadromous fishes and other fishes which move to or from flowing waters to complete their life cycle in other waters.
- The "TSF" designation indicates maintenance of stocked trout from February 15 to July 31 and maintenance and propagation of fish species and additional flora and fauna which are indigenous to a warm water habitat.
- The "WC" designation indicates the use of the water for swimming and related activities.

3.2.3 DRBC's Water Quality Regulations and PA Code Chapter 25 §93.7

The applicable water quality standards for the three receiving water bodies were found in the Delaware River Basin Commission's Water Quality Regulations, and in Water Quality Criteria lists found in Chapter 25 §93.7 and §93.8c of the Pennsylvania Code. For the Delaware River, the water quality standards are dictated by the DRBC's WQRs that have primacy over the standards in the PA Code. The water quality standards in the PA Code apply to the non-tidal

portions of the Chester Creek and Ridley Creek, and to the Delaware River if there is no standard listed for a particular parameter in the DRBC's WQRs.

3.2.4 DRBC's 2014 Delaware River and Bay Water Quality Assessment

The DRBC's 2014 Delaware River and Bay Water Quality Assessment (2014 Assessment) reports the extent to which waters of the Delaware River and Bay are attaining designated uses in accordance with Delaware River Basin Commissions' Water Quality Regulations for the period October 1, 2008 through September 30, 2013. The 2014 Assessment involves the comparison of key water quality parameters with the applicable DRBC water quality regulations. The states of Pennsylvania, New Jersey, Delaware and New York consider the DRBC's Assessment report as part of their determinations as to whether sections of the Delaware River should be listed on the state 303(d) list for a certain pollutant.

3.2.5 Delaware River

3.2.5.1 303(d) List Designation

The 2014 PA Integrated Water Quality and Assessment Report ("the 303(d) List") lists a 61.02 mile segment of the Lower Delaware River in Category 4A as having an approved TMDL for polychlorinated biphenyls (PCBs) from an unknown source related to its fish consumption use. The USEPA approved a TMDL for PCBs for Zone 2 through Zones 5 in 2003, and a second PCB TMDL was approved for Zone 6 in 2006. The TMDLs for PCBs encompass the Delaware River Estuary and stretch from the mouth of the Delaware River upstream to the Trenton, NJ /Morrisville, PA Bridge. The segment of the Delaware River having an approved TMDL for PCBs is shown in yellow in the map in Figure 3-1, which was derived from the PADEP's eMapPA website. Attachment C presents an excerpt from the 2014 PA Integrated Water Quality Monitoring and Assessment Report, and includes the applicable pages for the Delaware River.

Consequently, the impacts of DELCORA's CSO discharges on the level of PCBs within the Delaware River was evaluated further and is discussed herein.

3.2.5.2 Designated Critical Uses and Specific Water Quality Criteria from PA Code

The Critical Uses for the Delaware River in the area of DELCORA's CSO discharges are designated in Chapter 25 §93.9 of the PA Code. All stretches of the Delaware River in this area are designated as Warm Water Fishes (WWF) (maintenance only) and Migratory Fishes (MF) (passage only). Additionally the Delaware River has a Water Contact (WC) designation downstream of River Mile 81.8, which is located directly adjacent to the City of Chester between CSO #009 and #011.

Delaware County Regional Water
Quality Control Authority

GREELEY AND HANSEN

Identification of Sensitive Areas and Pollutants of Concern Report

Figure 3-1
Non-Attaining and TMDL Streams/River
Within DELCORA's Service Area

For WC-designated waters, Chapter 25 §93.7 of the PA Code establishes the following as the water quality criterion for fecal coliform bacteria:

- **Fecal Coliform** – A geometric mean of 200 colonies per 100 mL during the swimming season (May 1 through September 30) based on a minimum of five samples collected during a 30-day period. For the remainder of the year, the maximum fecal coliform level shall be a geometric mean of 2,000 colonies/100 mL based on a minimum of five samples collected during a 30-day period. There are no fecal coliform bacteria criteria for the Delaware River or tributaries that are not designated as WC waters or for Potable Water Supply (PWS).

For WWF and MF waters the WWF designation is the more restrictive of the two, and Chapter 25 §93.7 of the PA Code establishes the following additional standards for WWF waters:

- **Dissolved Oxygen** – The minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 5.5 mg/L
- **Alkalinity** – A minimum of 20 mg/L as $CaCO_3$, except where naturally occurring conditions are less
- **Ammonia Nitrogen** – the maximum total ammonia nitrogen concentration (in mg/L) at all times shall be the numerical value given by un-ionized ammonia nitrogen (NH_3-N) x ($\log^{-1}[pK_T\text{-}pH] + 1$)
- **Iron** – 30-day average 1.5 mg/L as total recoverable
- **pH** – From 6.0 to 9.0 inclusive
- **Temperature** – A table is included within Chapter 25 §93.7 for maximum water temperatures in the receiving water body at various times of the year
- **Total Residual Chlorine** – Four-day average 0.011 mg/L; 1-hour average 0.019 mg/L

3.2.5.3 Designated Zone and Water Quality Regulations from the DRBC

Chapter 25 §93.9 of the PA Code lists the DRBC regulations for Water Quality Zone 4 as exceptions to PA Code's specific water quality criteria. The DRBC's water quality regulations have primacy over the standards in the PA Code for the Delaware River.

The DRBC defines Zone 4 as that part of the Delaware River extending from R.M. 78.8 to R.M. 95.0, the Pennsylvania-Delaware state boundary line to the upstream side of the Philadelphia Navy Yard, including the tidal portions of the tributaries thereof. The DRBC states that the quality of Zone 4 waters shall be maintained in a safe and satisfactory condition for the following uses:

- Industrial water supplies after reasonable treatment
- Maintenance of resident fish and other aquatic life

- Passage of anadromous fish
- Wildlife
- Recreation - secondary contact above R.M. 81.8
- Recreation (all water-contact sports) below R.M. 81.8
- Navigation

The DRBC's Stream Quality Objectives for Zone 4 are as follows:

1. **Dissolved Oxygen**
   - 24-hour average concentration shall not be less than 3.5 mg/L.
   - During the periods from April 1 to June 15, and September 16 to December 31, the DO shall not have a seasonal average less than 6.5 mg/L.

2. **Temperature** shall not exceed:
   - 5°F (2.8°C) above the average 24-hour temperature gradient displayed during the 1961-66 period, or
   - A maximum of 86°F (30.0°C), whichever is less.

   (NOTE: The DRBC's 2014 Delaware River and Bay Water Quality Assessment states that *"atmospheric temperatures and meteorological conditions are strong drivers of water temperature. DRBC previously demonstrated that water temperatures are strongly liked to air temperatures, and that a notable increase in air temperatures is observable between the temperature gradient period (1961-1966) and the current period. At present, we* [i.e., DRBC] *lack the tools to determine which portion of the exceedance is attributable to potentially controllable anthropogenic thermal inputs, and which portion is due to metrological drivers beyond our control".*

3. **pH** between 6.5 and 8.5 inclusive, unless outside this range due to natural conditions.

4. **Phenols** maximum 0.02 mg/l, unless exceeded due to natural conditions.

5. **Threshold Odor Number** not to exceed 24 at 60°C.

6. **Synthetic Detergents.** (M.B.A.S.). Maximum 30- day average 1.0 mg/L.

7. **Radioactivity**
   - Alpha emitters - maximum 3 pc/L (picocuries per liter);
   - Beta emitters - maximum 1,000 pc/L.

8. **Bacteria**
   - **Fecal Coliform**
     - Above R.M. 81.8: maximum geometric average 770 per 100 milliliters
     - Below R.M. 81.8: maximum geometric average 200 per 100 milliliters
   - **Enterococcus**
     - Above R.M. 81.8: maximum geometric average 88 per 100 milliliters
     - Below R.M. 81.8: maximum geometric average 33 per 100 milliliters

9. **Total Dissolved Solids** not to exceed 133% of background.
(NOTE: The background TDS concentration is at present undefined, according to the DRBC's 2014 Delaware River and Bay Water Quality Assessment.)

10. **Turbidity** unless exceeded due to natural conditions.
    - Maximum 30-day average 40 units (NTU)
    - Maximum 150 NTU

11. **Alkalinity** between 20 and 120 mg/L.

12. **Toxic Pollutants**
    - Applicable criteria to protect the taste and odor of ingested water and fish are presented in the DRBC's WQRs Table 4.
    - Applicable freshwater stream quality objectives for the protection of aquatic life are presented in the DRBC's WQRs Table 5.
    - Applicable freshwater stream quality objectives for the protection of human health are presented in the DRBC's WQRs Tables 6 and 7.

3.2.5.4 DRBC Evaluation of Use Attainment Status

Table 3-1 presents a summary of Table 23 from the DRBC's 2014 Delaware River and Bay Water Quality Assessment for Zone 4 of the Delaware River. Zone 4 is the portion of the Delaware River directly impacted by DELCORA's CSO discharges and it extends from R.M. 95.0 to R.M. 78.8, the Pennsylvania-Delaware state line including the tidal portions of the tributaries thereof. The extent of Zone 4 can be seen in Figure 2-2.

Table 3-1: Summary of the 2014 DRBC Integrated Assessment for Zone 4 of the Delaware River

Zone	Designated Use			
	Aquatic Life	Drinking Water	Recreation	Fish Consumption
4	NS	N/A	S	NS

Notes:
N/A - Not applicable
NS - The Designated Use is not supported
S - The Designated Use is supported

3.2.5.4.1 Water Contact Recreation

Table 3-1 shows that the designated use for Water Contact Recreation is being attained for the Delaware River below R.M. 81.8.

3.2.5.4.2 Aquatic Life

Table 3-1 shows that the designated use for Aquatic Life is not being attained. According to the DRBC's Assessment report, "*the composite aquatic life assessment for 2014 yields a result of "Not Supporting" for all assessment units* (or zones). *It is important to note, however, that this result is largely driven by the requirement to categorize as not meeting criteria any assessment unit* (or zone) *with 1 exceedance plus 1 confirmatory exceedance.*"

The DRBC's Assessment Report also states: "*Data showed multiple exceedances of aluminum acute and chronic freshwater objectives for the support of aquatic life in Zone 4. Of 35 surface water samples tested for aluminum in Zone 4 during the assessment period, 34 exceeded the chronic criterion and 8 exceeded the acute criterion at 21PA_WQX-WQN0182 near Marcus Hook, PA. No exceedances of aluminum were reported in Zones 2, 3, 5 and 6.*" As part of the Recommendations for Future Action at the end of the report, the DRBC states that the "*exceedances of aluminum criteria in Zone 4 warrant further attention*".

3.2.5.4.3 Fish Consumption

Table 3-1 shows that the designated use for Fish Consumption is not being attained. The DRBC's 2014 Delaware River and Bay Water Quality Assessment report states that their assessment criterion for fish consumption is based on the presence of fish consumption advisories from the four Basin states for the mainstem of the Delaware River. If a fish consumption advisory is present, this resulted in the DRBC making an assessment of "not supporting the designated use".

The Assessment report states that the violation criteria for PCBs is also supported by the presence of measureable concentrations of PCBs in the river that exceeded the surface water quality standard. Twenty-two mainstem channel sites were sampled for PCBs in 2012, from

Biles Channel near Trenton, NJ to the ocean boundary between Cape May and Lewis. It was found that all of the samples exceeded the current PCB water quality criteria of 16 µg/L for the protection of human health from carcinogenic effects.

The 2016 Commonwealth of Pennsylvania Fish Consumption Advisories for Zones 2, 3, and 4 of the Delaware River (Trenton, NJ/Morrisville, PA Bridge to PA/DE border) are as shown below in Table 3-2. These advisories identify PCBs as a pollutant of concern in fish tissue.

Table 3-2: PA Fish Consumption Advisory Summary for PCBs in the Delaware River

Fish Species	Meal Frequency	Contaminant
White Perch	1 meal/month	PCB
Flathead Catfish	1 meal/month	PCB
Channel Catfish	1 meal/month	PCB
Striped Bass: over 28 inches in length	1 meal/month	PCB
Carp	6 meals/year	PCB
American Eel	Do Not Eat	PCB

3.2.6 Chester Creek

3.2.6.1 303(d) List Designation

Chester Creek is listed in Category 5 of the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report as not meeting its recreational use due to pathogens, and for not meeting its aquatic life use due to siltation. "Pathogens" were listed in 2006 for three segments totaling 0.94 miles, and a TMDL is anticipated in 2019. The source for the pathogens is listed as "unknown", and these three stream segments are all well upstream of DELCORA's service area. Therefore it appears that the noted impairment of the Chester Creek due to pathogens is not related to DELCORA' CSO discharges.

"Siltation" was listed in 2014 for four segments of the creek totaling 18.41 miles, and a TMDL is anticipated in 2027. The source for the siltation was identified as "urban runoff/storm sewers". The majority of Chester Creek is not attaining its designated use for aquatic life due to siltation, and the vast majority of these impaired segments are located upstream of DELCORA's service area and are shown in red in the map in Figure 3-1. However, one of DELCORA's CSO outfalls does discharge to the furthest downstream segment of the Chester Creek that is impaired by siltation, which is Outfall #020 near Kerlin Street and Finland Drive. Siltation is measured by the water quality parameter Turbidity with units of Nephelometric Turbidity Units (NTU). The impacts of DELCORA's CSO discharges on the levels of Turbidity within the impaired sections of the Chester Creek have been evaluated further and are discussed herein.

Category 4A lists a 0.81-mile segment of Chester Creek at its mouth that does not meet its designated use for fish consumption due to PCBs from an unknown source, and for which a TMDL for PCBs was issued in 2006. This is shown in yellow in the map in Figure 3-1, and is related to the TMDL for PCBs in the Delaware River Estuary. As a consequence, the impacts of DELCORA's CSO discharges on the level of PCBs within the section of the Chester Creek for which there is an approved TMDL for PCBs has been evaluated further and is discussed herein.

Attachment C presents an excerpt from the 2014 PA Integrated Water Quality Monitoring and Assessment Report, and includes the applicable pages for the Chester Creek. It is to be noted that the Integrated Report also identifies an approved TMDL for the protection of two segments of the creek for aquatic life, but after consultation with staff in the Clean Water Section of the PADEP's Southeast Regional Office it was determined that those two stream segments were listed in the Integrated Monitoring Report in error.

3.2.6.2 Designated Critical Uses and Specific Water Quality Criteria from PA Code

The Critical Uses for the Chester Creek in the area of DELCORA's CSO discharges are designated in Chapter 25 §93.9 of the PA Code. All stretches of the Chester Creek in this area are designated as Warm Water Fishes (WWF) (maintenance only) and Migratory Fishes (MF) (passage only). The same specific water quality criteria apply to the WWF and MF Critical Use designations for Chester Creek as was listed previously for the Delaware River in Section 3.2.5.2.

3.2.7 Ridley Creek

3.2.7.1 303(d) List Designation:

Ridley Creek is listed in Category 5 of the 2014 Pennsylvania Integrated Water Quality Monitoring and Assessment Report as not meeting its aquatic life use due to siltation. The "Siltation" was listed in 2012 for five segments totaling 26.76 miles, and a TMDL is anticipated in 2025. The source for the siltation was identified as "unknown" or from "urban runoff/storm sewers".

In actuality, it appears that the majority of Ridley Creek is not attaining its designated use for aquatic life due to siltation, and the vast majority of these impaired segments are located well upstream of DELCORA's service area and are shown in red in the map in Figure 3-1. However, all of Ridley Creek within DELCORA's service area is shown as impaired for aquatic life due to siltation. Attachment C presents an excerpt from the 2014 PA Integrated Water Quality Monitoring and Assessment Report, and includes the applicable pages for the Ridley Creek.

Siltation is measured by the water quality parameter Turbidity, and consequently the impacts of DELCORA's CSO discharges on the levels of Turbidity within the impaired sections of the Ridley Creek have been evaluated further and are discussed herein.

3.2.7.2 Designated Critical Uses and Specific Water Quality Criteria from PA Code:

The Critical Uses for the Ridley Creek in the area of DELCORA's CSO discharges are designated in Chapter 25 §93.9 of the PA Code. All stretches of the Ridley Creek in this area are designated as Warm Water Fishes (WWF) (maintenance only), Migratory Fishes (MF) (passage only), or Trout Stocking (TSF). The TSF stretch only applies in the sections of the Ridley Creek upstream of the Chestnut Street bridge crossing.

The same specific water quality criteria apply to the WWF and MF Critical Use designations for Ridley Creek as was listed previously for the Delaware River in Section 3.2.5.2, except for the parameters of Dissolved Oxygen and Temperature – which are more stringent because of the high oxygen needs of trout.

Specifically, for TSF waters Chapter 25 §93.7 of the PA Code establishes the following additional standards:

- **Dissolved Oxygen** – For the period February 15 to July 31 of any year, the minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 6.0 mg/L. For the remainder of the year, the minimum value for dissolved oxygen must be above 5.0 mg/L, with the 7-day average value above 5.5 mg/L.
- **Temperature** – A separate table is included within Chapter 25 §93.7 for maximum water temperatures in the receiving water body at various times of the year for TSF waters.

3.3 Approach for the Identification of the Applicable Water Quality Standards

For the Delaware River and the tidal portions of its tributaries, the DRBC's Water Quality Regulations are the prime source for the water quality standards, and the PA Code Chapter 93 WQS for the designated use serves as a secondary source. The DRBC's regulations have primacy over the PA Code for the Delaware River and the tidal portions of its tributaries. For the non-tidal portions of the Chester Creek and Ridley Creek, the specific designated use for the water body in the PA Code serves as the prime source of the WQS. If a parameter is not listed in the DRBC's Water Quality Regulations or in the PA Code, then there is not a WQS for that parameter that applies to the Delaware River, Chester Creek or Ridley Creeks.

A conservative approach was taken in the identification of the applicable WQS, such that the more stringent standard was used where the standards from the DRBC's Water Quality Regulations and the PA Code overlapped. The methodology for identifying the applicable WQS was complicated by the fact that the WQS vary for the three receiving water bodies and can also vary within the same water body depending on where the sample was taken.

Attachment D in the List of Attachments contains the master table that was developed to determine the applicable water quality standards for the expanded list of Parameters Considered for the Delaware River downstream of R.M. 81.8, the Delaware River upstream of R.M. 81.8,

the Chester Creek and Ridley Creek within the area impacted by DELCORA's CSO discharges. The specific methodology for identification of the applicable water quality standards is described in greater detail below.

In order to determine WQS for metals, an average hardness value of 84 mg/l (as $CaCO_3$) was used for the Delaware River based on an average of the hardness values obtained from the USEPA's Storage and Retrieval Data Repository (STORET) study data from the Years 2010-2015 for this portion of the Delaware River. Due to unavailable hardness data on STORET for the Chester and Ridley Creeks, an average hardness value of 74 mg/l (as $CaCO_3$) was used for the Chester and Ridley Creeks based on guidance in the DRBC Water Quality Regulations, Section 4.20.05, Paragraph A.2.

3.3.1 Delaware River Downstream of R.M. 81.8 (Water Contact Use Designation)

The "lower" Delaware River downstream of R.M. 81.8 has a Water Contact designated use. Therefore, there is stricter criteria for the lower Delaware River below R.M. 81.8 than there is for the "upper" Delaware River upstream of R.M. 81.8 that does not have the Water Contact use designation.

The following bullets describe the approach that was used for the identification of the applicable water quality standards on the Delaware River downstream of R.M. 81.8:

- The basis for determining the WQRs was to first look to the DRBC's WQRs in Section 3.30.4 for Zone 4.
- If there were no listings for a parameter in Section 3.30.4, we next referred to the "Human Health Criteria" in 25 PA Code Ch. 93 WQS, 93.8c, Table 5 as the primary water quality standard, unless a more restrictive standard was listed in the PA Code that applies to the Delaware River. The Human Health Criteria includes probable modes of exposure such as, but not limited to ingestion from drinking water and fish consumption, inhalation and dermal absorption and is the most appropriate for protecting human health from water contact or immersion.
- If there were no Human Health Criteria listed in Table 5 of the PA Code, we referred to the standards in the DRBC WQRs Tables 6 and 7 and used the more restrictive standard for Fish and Water Ingestion. These tables are respectfully titled "Stream Quality Objectives for Carcinogens" and "Stream Quality Objectives for Systemic Toxicants".

3.3.2 Delaware River Upstream of R.M. 81.8 (WWF and MF Use Designation)

The following bullets describe the approach that was used for the identification of the applicable water quality standards on the Delaware River upstream of R.M. 81.8:

- The basis for determining the WQRs was to first look to the DRBC's WQRs in Section 3.30.4 for Zone 4.
- If there was no listing for a parameter in Section 3.30.4, we next referred to the DRBC's WQRs Table 5 "Stream Quality Objectives for Toxic Pollutants for the Protection of Aquatic Life" and used both the Acute and Chronic standards. If none was listed, we referred to DRBC Tables 6 and 7, and used the listed standard that is the next less restrictive than the Primary Contact standard that was used above for the Water Contact portion of the Delaware River. We used the Fish Ingestion Only criteria, not the Fish and Water Ingestion criteria for the Upper Delaware.
- If there is no DRBC standard listed for the parameter, we used the 25 PA Code Ch. 93 WQS Table 3 – "Specific Water Quality Criteria" for the particular Critical Use Designation of the water body and also the 25 PA Code Ch. 93 WQS Table 5 "Fish and Aquatic Life Criteria" (for both Acute and Chronic) as the source of the water quality standard – these tables are complimentary and do not overlap.

3.3.3 Chester Creek and Ridley Creek (TSF, WWF and MF Use Designations)

The following bullets describe the approach that was used for the identification of the applicable water quality standards on the Chester and Ridley Creeks:

- For the tidal portions of the creeks, we used as the basis the DRBC's WQRs in Section 3.30.4 for Zone 4. The DRBC regulations that were applied were for the Delaware River upstream of R.M. 81.8, since both creeks discharge to the Delaware River upstream of R.M. 81.8.
- For the non-tidal portions of the creeks, we used the 25 PA Code Ch. 93 WQS Table 3 – "Specific Water Quality Criteria" for the particular Critical Use Designation of the water body and also the 25 PA Code Ch. 93 WQS Table 5 "Fish and Aquatic Life Criteria" (for both Acute and Chronic) as the source of the water quality standard – these tables are complimentary and do not overlap.

3.4 Sampling of Select CSO Outfalls

3.4.1 Historical Sampling of Select CSO Outfalls

Under the current permit (NPDES Permit No. PA 0027103, Amendment 1, dated December 17, 2013), DELCORA is required to conduct on-going monitoring of its CSO outfalls at the following three locations within thirty (30) minutes of a rainfall:

- 2nd and Dock Streets Pump Station (wet well) (Chester Pump Station-CPS)
- CSO Outfall #018 – Sun Drive and Hancock Street
- CSO Outfall #019 – 14th Street and Crozer Hospital

The NPDES permit requires that the three (3) above locations be monitored for the five (5) parameters, sample type and at the frequency specified in Table 3-3 below. The grab samples are to be collected within the first 30 minutes of the discharge.

Table 3-3: Permit-Specified CSO Monitoring Program Parameters, Sample Type and Frequency

Parameter	Sample Type	Measurement Frequency
Biological Oxygen Demand (BOD_5)	Grab (mg/l)	Annual
Ammonia	Grab (mg/l)	Annual
Total Suspended Solids (TSS)	Grab (mg/l)	Annual
Phosphorus	Grab (mg/l)	Annual
Fecal Coliform	Grab (#/ 100 ml)	Annual

DELCORA annually obtains CSO water quality samples in conformance with the NPDES permit requirements. The permit required CSO sampling results for the most recent three years (2012, 2013 and 2014) are contained in Attachment E and summarized in Table 3-4. Analyses for the consideration of these 5 parameters as a Pollutant of Concern are included within Sections 3.7 and 3.8.

Table 3-4: Summary of NPDES Permit-Required CSO Samples (2012-2014)

Sample Location	Parameters				
	BOD5 (mg/L)	Ammonia (mg/L)	TSS (mg/L)	Phosphorus (mg/L)	Fecal Coliform (#/100 mL)
2012 Samples					
2nd & Dock Streets (Chester Pump Station) (wet well) 10/29/2012	35	2.18	106	0.823	>600,000
Sun Drive & Hancock Street (CSO #018) 10/29/2012	28	1.79	47	0.813	>600,000
14th Street & Crozer Hospital (CSO #019) 10/29/2012	21	0.81	48	0.499	>600,000
2013 Samples					
2nd & Dock Streets (Chester Pump Station) (wet well) 11/27/2013	65	2.1	204	1.32	>200,000
Sun Drive & Hancock Street (CSO #018) 11/27/2013	13	0.2	40	0.35	150,000

Sample Location	Parameters				
	BOD5 (mg/L)	Ammonia (mg/L)	TSS (mg/L)	Phosphorus (mg/L)	Fecal Coliform (#/100 mL)
14th Street & Crozer Hospital (CSO #019) 11/27/2013	40	0.9	163	1.21	190,000
2014 Samples					
2nd & Dock Streets (Chester Pump Station) (wet well) 09/25/2014	100	6.72	134	1.6	811,000
Sun Drive & Hancock Street (CSO #018) 09/25/2014	42.5	1.88	56	0.55	169,000
14th Street & Crozer Hospital (CSO #019) 09/25/2014	39.5	3.26	45	0.78	430,000

3.4.2 Additional Sampling of CSO Outfalls

Additional sampling was undertaken at the three monitored CSOs by DELCORA on November 19th and December 1st, 2015 for a much longer list of parameters than is required by the NPDES permit. The sampling results were used to confirm the actual parameters prevalent in DELCORA's CSO discharges.

Attachment F in the List of Attachments includes the laboratory data for the additional sampling of the CSOs. Wet weather samples were collected primarily to analyze for the parameters thought to have been present at the plant influent due to the industrial wastewater discharged at that location (see Section 3.6.1). These wet weather samples were also intended to capture those parameters due to the first flush during a wet weather overflow event. The wet weather samples were collected when the minimum rainfall was 0.5" with a high intensity, and the samples were collected within 30 minutes from the beginning of a wet weather overflow event as required by the NPDES permit.

Figure 3-2 presents a map that shows the locations that were used for DELCORA's sampling of the combined sewer system, select CSOs, for the historical sampling of the Chester and Ridley Creeks, and for the USEPA's STORET Database monitoring stations on the receiving water bodies.

3.5 Sampling of Receiving Waters

3.5.1 USEPA'S STORET Database

The USEPA's STORET database was used as the primary source for existing water quality data for all three receiving water bodies. Data was extracted using the appropriate hydrologic unit code for the Lower Delaware River, and all monitoring stations associated with the three receiving bodies within the area of DELCORA's CSO discharges were selected for gathering of water quality data. The water quality data was first extracted from STORET for the period of September 1, 2014 through September 1, 2015. The water quality data for this period was evaluated against the applicable water quality standards. The parameters (during this period) that were found to be exceeding the water quality standards and/or were found to be associated with CSO discharges (as "detects" through the additional CSO sampling) were considered for further evaluation. The water quality data of these particular parameters was then extracted from STORET for a five year period ranging from September 1, 2010 through September 1, 2015 and evaluated against the applicable water quality standards. This five-year STORET data was used to confirm the presence of these parameters and to calculate the total number of observations as well as exceedance percentages in the receiving bodies. The evaluation of the STORET data is discussed in detail under Section 3.7 and 3.8.

Table 3-5 shows a list of the STORET monitoring stations that were used, along with their station identification numbers. There were a total of two stations that belong to Delaware River Basin Commission on the Delaware River and three station that belong to Pennsylvania Department of Environmental Protection on the Delaware River, Chester Creek and Ridley Creek. Figure 3-2 shows the locations of the STORET database monitoring stations with their respective identification numbers.

The parameters that were searched within the STORET database from the monitoring stations in Table 3-5 were based on the expanded list of the Parameters Considered discussed in Section 3.6 of this report. Once the data from the USEPA STORET database was extracted, each parameter was sorted based on its characteristic name and station identification number.

Station Name	Station Identification Number	Agency	Period of Record	Latitude	Longitude
Marcus Hook (R.M. 78.1)	332049	DRBC	9/1/2014 – 9/1/2015	39.798611	-75.430111
Eddystone (R.M. 84.0)	892062	DRBC	9/1/2014 – 9/1/2015	39.849139	-75.329628
Chester Creek	DRBC422094	PADEP	9/1/2014 – 9/1/2015	39.8447	-75.36
Ridley Creek	DRBC422120	PADEP	9/1/2014 – 9/1/2015	39.8533	-75.3461
Delaware River	WQN0182	PADEP	9/1/2014 – 9/1/2015	39,8069	-75.4064

3.5.2 Historical Sampling of Chester and Ridley Creeks

The USEPA's STORET Database only has data for one monitoring station each for both the Chester and Ridley Creeks, and those stations are each located near the mouths of the creeks. In order to supplement the receiving water data for the Chester and Ridley Creeks and to obtain representative samples of the water quality in the creeks upstream of DELCORA's CSO discharge locations, DELCORA took its own water quality samples for the Chester and Ridley Creeks on five dates in 2010. Two samples were obtained during a storm event on October 14, 2010, including a sample taken at the beginning of the storm and a second sample taken after a minimum of 0.45 inch of rain had fallen.

In addition to the parameters listed in Table 3-3 for DELCORA's NPDES permit-specified CSO monitoring program, the following in-situ field measurements were also collected during the 2010 sampling:

- Temperature
- pH
- Conductivity
- Dissolved Oxygen (DO)

Besides being specified in DELCORA's NPDES permit, the parameters in Table 3-5 are indicative of the presence of wastewater. Dissolved Oxygen can also be used to indicate a water body that is being stressed and may inhibit natural biological activity.

The sampling plan for the collection of the 2010 water quality samples from the Chester and Ridley Creeks specified collection during dry weather and during storm events in order to examine the impacts of CSO discharges on the water bodies. Discrete samples of receiving water collected for laboratory analyses were specified at four locations along the Chester and Ridley Creeks. The dry- and wet-weather water quality sampling locations that were used are listed below in Table 3-6, and are shown on the map in Figure 3-2. The data from the 2010 historical receiving water quality sampling is presented in Attachment G.

Table 3-6: Receiving Water Body Sample Locations for Chester and Ridley Creeks

Sample Location Name as Shown in Figure 3-2	Sample Collection Location	Latitude	Longitude	Closest Upstream CSO	Closest Downstream CSO	Nearest Access Road or Address
Ridley Creek 1 (RC1)	Upstream Chester Park Drive crossing of Ridley Creek	39°52'23.83"N	75°22'30.82"W	None	33	Chester Park Drive
Ridley Creek 3 (RC3)	Downstream East 2nd Street Bridge crossing of Ridley Creek	39°51'12.58"N	75°20'47.13"W	15	None	Old East 2nd Street
Chester Creek 1 (CC1)	Upstream Kerlin Street crossing of Chester Creek	39°51'20.76"N	75°22'36.02"W	None	20	1556 Kerlin Street
Chester Creek 3 (CC3)	Downstream 2nd Street Bridge crossing of Chester Creek	39°50'41.08"N	75°21'36.15"W	023, 024	12	Adjacent to Chester Pump Station

The sampling locations were carefully selected to provide an upstream (or background) sample above the furthest upstream CSO discharges on each creek to compare against a sample from a downstream location that is impacted by the CSO discharges.

3.6 Methodology for Identification of the Parameters Considered

For the identification of the POCs, DELCORA took an inclusive approach to determine that all relevant water quality parameters were appropriately considered and evaluated. The first step was to develop a comprehensive list of the overall "Parameters Considered", which was then further evaluated and refined to determine the list of the applicable POCs. Development of the list of Parameters Considered was meant to cast a wide net as the first step towards identifying any parameters that might possibly be of concern.

3.6.1 Development of the Parameters Considered List

The initial list of the Parameters Considered was compiled from six (6) primary reference sources from the USEPA, PADEP and the DRBC. The Parameters Considered list initially consisted of those specific parameters listed in the USEPA's CSO Guidance Document (as noted in Section 3.1.2). Additional parameters were added from the parameters requiring sampling per DELCORA's NPDES permit, from the PA Code's specific water quality criteria for DELCORA's three receiving water bodies, from the DRBC's Water Quality Regulations for Zone 4 of the Delaware River, from the 2014 PA Integrated Water Quality Monitoring and Assessment Report (a.k.a. "303(d) List"), and from the DRBC's 2014 Delaware River and Bay Water Quality Assessment report. Attachment H provides the full version of the table used to develop the initial Parameters Considered list and includes the reference source for each of the parameters noted.

Table 3-7 provides a summary of the initial Parameters Considered list that was developed by compiling the parameters listed in each of the six primary reference sources noted above.

Table 3-7: Initial List of Parameters Considered

Bacteria - Enterococcus	Nutrients
Bacteria - Fecal Coliform	Oil and Grease
Alkalinity	PCBs (Fish Consumption)
Aluminum (Aquatic Life)	pH
Ammonia	Phenols
Biological Oxygen Demand (BOD)	Phosphorus
Cadmium	Radioactivity - alpha emitters
CBOD20	Radioactivity - beta emitters
CBOD5	Synthetic Detergents
Chlorine	Temperature
Chlorodibromomethane	Threshold Odor Number (TON)

Copper	Total Kjeldahl Nitrogen (TKN)
Cyanide	Total Dissolved Solids (TDS)
Dichlorobromomethane	Total Phosphorus
Dissolved Oxygen	Total Residual Chlorine (TRC)
Iron	Total Suspended Solids (TSS)
Lead	Toxics
Metals	Turbidity
Nitrate	Zinc
Nitrite	

As shown in the table in Attachment H and as noted in Section 3.1.2, the USEPA's CSO Guidance Document lists "Metals", "Nutrients", and "Toxics" as parameters of concern but does not provide any further definition of the individual parameters in these three categories. Tables 3-8, 3-9, and 3-10 below list the specific parameters that were added onto the initial Parameters Considered list for Nutrients, Metals, and Toxics and the reference source stating the reason for the inclusion of each of the parameters.

Table 3-8: Nutrients Included in the Initial List of Parameters Considered

Parameter (Nutrients)	Reference Source
Ammonia	NPDES Permit Required Sampling for CSO Discharges
Nitrate	NPDES Permit Required Sampling for Outfall #001
Nitrite	NPDES Permit Required Sampling for Outfall #001
Phosphate	Implied by EPA CSO Guidance for LTCP
TKN	NPDES Permit Required Sampling for Outfall #001
Total Nitrogen	Implied by EPA CSO Guidance for LTCP
Total Phosphorus	NPDES Permit Required Sampling for CSO Discharges

Table 3-9: Metals Included in the Initial List of Parameters Considered

Parameter (Metals)	Reference Source
Aluminum (Al)	Listed in DRBC WQRs Table 5
Arsenic (trivalent) (As III)	Listed in DRBC WQRs Table 5
Cadmium (Cd)	Listed in DRBC WQRs Table 5
Chromium (trivalent) (Cr III)	Listed in DRBC WQRs Table 5
Chromium (hexavalent) (Cr VI)	Listed in DRBC WQRs Table 5
Copper (Cu)	Listed in DRBC WQRs Table 5
Iron (Fe)	PA Code for TSF, WWF, and MF Critical Use
Lead (Pb)	Listed in DRBC WQRs Table 5
Mercury (Hg)	Listed in DRBC WQRs Table 5
Nickel (Ni)	Listed in DRBC WQRs Table 5
Selenium (Se)	Listed in DRBC WQRs Table 5
Silver (Ag)	Listed in DRBC WQRs Table 5
Zinc (Zn)	Listed in DRBC WQRs Table 5

Table 3-10: Toxics Included in the Initial List of Parameters Considered

Parameter (Toxics)	Reference Source
Phenols	Required by DRBC Zone 4 WQRs
Chlorodibromomethane	NPDES Permit Required Sampling for Outfall #001
Cyanide	NPDES Permit Required Sampling for Outfall #001
Dichlorobromomethane	NPDES Permit Required Sampling for Outfall #001

Once the initial list of Parameters Considered was developed, additional parameters were added onto the list if they had been detected during the historical sampling data of the influent to the WRTP (WRTP data), and in the existing CSO monitoring data (as required by the NPDES permit). One year's worth of DELCORA's plant influent historical sampling data from September 1, 2014 through September 1, 2015 was collected and analyzed to identify additional Parameters Considered.

It is important to state that that the historical sampling data noted above for the influent to the WRTP also included industrial wastewater from DELCORA's forty-five (45) Significant Industrial Users (SIUs). The industrial wastewater from forty-three (43) of DELCORA's SIUs is trucked directly to the WRTP and is discharged downstream of all CSOs into the combined sewer flow prior to the plant's influent sampling location. Consequently, the historical sampling data for the influent to the plant detected twenty-eight (28) industrial-type chemicals from these SIUs that are not normally associated with sanitary sewage or combined sewer overflows. Since the trucked-in industrial wastewater is discharged directly to the WRTP, it is not able to migrate back into the combined sewer system and, therefore, this industrial wastewater cannot be

discharged from any of DELCORA's CSOs. However, as part of the due diligence to address all possible POCs, the 28 industrial chemicals that were detected in the historical sampling of the plant influent were added onto an expanded list of Parameters Considered.

DELCORA actively maintains an Industrial Pretreatment program, and all of its industrial users are controlled by the sewer use regulations, Resolution No. 91-03, "The DELCORA Standards, Rules and Regulations," and the Local Limits, Resolution No. 95-11. In addition, all Significant and/or Categorical Industrial Users are further controlled by a permit, which is issued for not more than four (4) years. Each SIU is reviewed to determine how its wastewater is conveyed to the treatment plant. The only two (2) SIUs that discharge into the CSS, are commercial laundries with relatively benign wastewater compared to some of the truly industrial facilities that truck their wastewater to the WRTP. All of the parameters that are required to be analyzed by these commercial laundries in their wastewater based on their permit requirements were confirmed to be on the expanded list of the Parameters Considered. The two SIUs that discharge directly into DELCORA's combined sewer system are listed in Table 3-11 below.

Table 3-11: Industrial Users Discharging into DELCORA's Combined Sewer System

ID No	Permit #	Industry	Activity	Site Address	Discharge Route
W1	1DE-01-02	Ace Linen Service, Inc.	Laundry Service	3120 W. 6th St., Chester, PA 19013	Flows to Booth St. Interceptor to Delaware Interceptor to WRTP
W32	1DE-01-12	Delco Linen	Laundry Service	2626 W. 4th St., Chester, PA 19013	To 36-inch brick sewer on 4th St., to 48-inch brick sewer on Townsend St., to CSO Regulator #005, to Delaware River Interceptor, to WRTP

To help eliminate from the expanded list of the Parameters Considered the industrial chemicals that were detected as a result of the SIUs discharging to the WRTP, it was determined that additional wet weather sampling at the CSOs was required as noted in Section 3.4.2. The purpose of the additional sampling was to verify and confirm that the industrial-type chemicals not normally associated with CSOs that were detected in the historical sampling of the plant influent were in fact actually from the trucked-in industrial wastewater and not a part of the normal flow within the CSS that might overflow at a CSO. The CSO sampling results were used to screen non-detected parameters from the list of the Parameters Considered.

Review of the November 19th and December 1st, 2015 additional sampling results allows for shortening of the list of the Parameters Considered as possible POCs by screening those parameters that were introduced from the historical sampling of the plant influent that included the trucked-in industrial wastewater. The additional sampling results more accurately reflect the actual characteristics of the wastewater discharged at the CSOs, than does the historical data at the plant influent since the trucked-in industrial wastewater only goes into the plant and does not enter into the CSS. Therefore, if a parameter on the expanded Parameters Considered list was

not detected in the November and December 2015 wet weather sampling of the CSOs, those parameters were not considered further as POCs.

3.7 Methodology for Identification of the Pollutants of Concern List

Once the Parameters Considered list was narrowed using the November/December 2015 additional sampling results at the CSOs, the parameters remaining on the narrowed list of Parameters Considered were further evaluated to determine if they are Pollutants of Concern, or Parameters of Potential Concern (POPC). A parameter is considered a "Pollutant of Concern" for a water body if more than 10% of the samples exceeded the applicable water quality standard. This criteria is based on guidance provided by the USEPA, which recommends a "greater than 10% exceedance percentage" for determining that waters only partially meet their designated use for aquatic life support. A parameter is considered a "Parameter of Potential Concern" if 2 – 10% of the samples exceeded the water quality standard.

Water quality data for the parameters on the narrowed Parameters Considered list were collected from the STORET data repository for the one-year period from September 1, 2014 to September 1, 2015, from the water quality monitoring stations on each of the three receiving water bodies as noted in Section 3.5.1.

The segments of the Delaware River, Chester Creek and Ridley Creek have unique water quality standards that apply to them depending on the regulating authority, their designated uses, and the specific location within the waterbody. The maximum concentrations detected for each of the Parameters Considered were compared against the applicable surface water quality standards to determine which parameters were exceeding their standards. Attachment I in the List of Attachments provides a table with the final Parameters Considered list for each of the three receiving water bodies for which there is a water quality standard. The Delaware River was broken down into two tables; one for the Delaware River upstream of R.M 81.8 ("upper Delaware") and one for the Delaware River downstream of R.M 81.8 ("lower Delaware") based on the Water Contact Recreation designated use for the Delaware River below R.M. 81.8 and the more stringent requirements associated with primary contact.

The receiving stream water quality data from the USEPA STORET data warehouse was compared against the applicable WQS to check for exceedances. Both the acute and chronic conditions for the Parameters Considered were compared to the WQS, where applicable, to determine if there were exceedances. In addition to listing the Parameters Considered for each receiving water body, the table in Attachment I list the applicable water quality standards for each of the receiving water bodies, and identifies those parameters were the STORET sample data exceeded the water quality standards.

A flowchart was created to help illustrate the decision-making methodology used for developing the Pollutants of Concern list. The flowchart represents the process used for answering five (5) screening questions about the Parameters Considered in order to determine if a parameter is to be

considered a Pollutant of Concern, a Parameter of Potential Concern, or neither. The 5 screening questions for each Parameter Considered are:

1. Does a Water Quality Standard Exist for the parameter?
2. Do the available data indicate impairment exists and the impairment involves pollutants associated with CSOs?
3. Do greater than 10% of the samples for the receiving water body exceed the WQS?
4. Do 2% - 10% of the samples for the receiving water body exceed the WQS?
5. Was the parameter detected in the additional sampling of the CSOs?

Figure 3-3 presents the Methodology Flowchart used for developing the list of POCs and POPCs, and the following subsections provide additional details about the methodology used to answer the 5 screening questions.

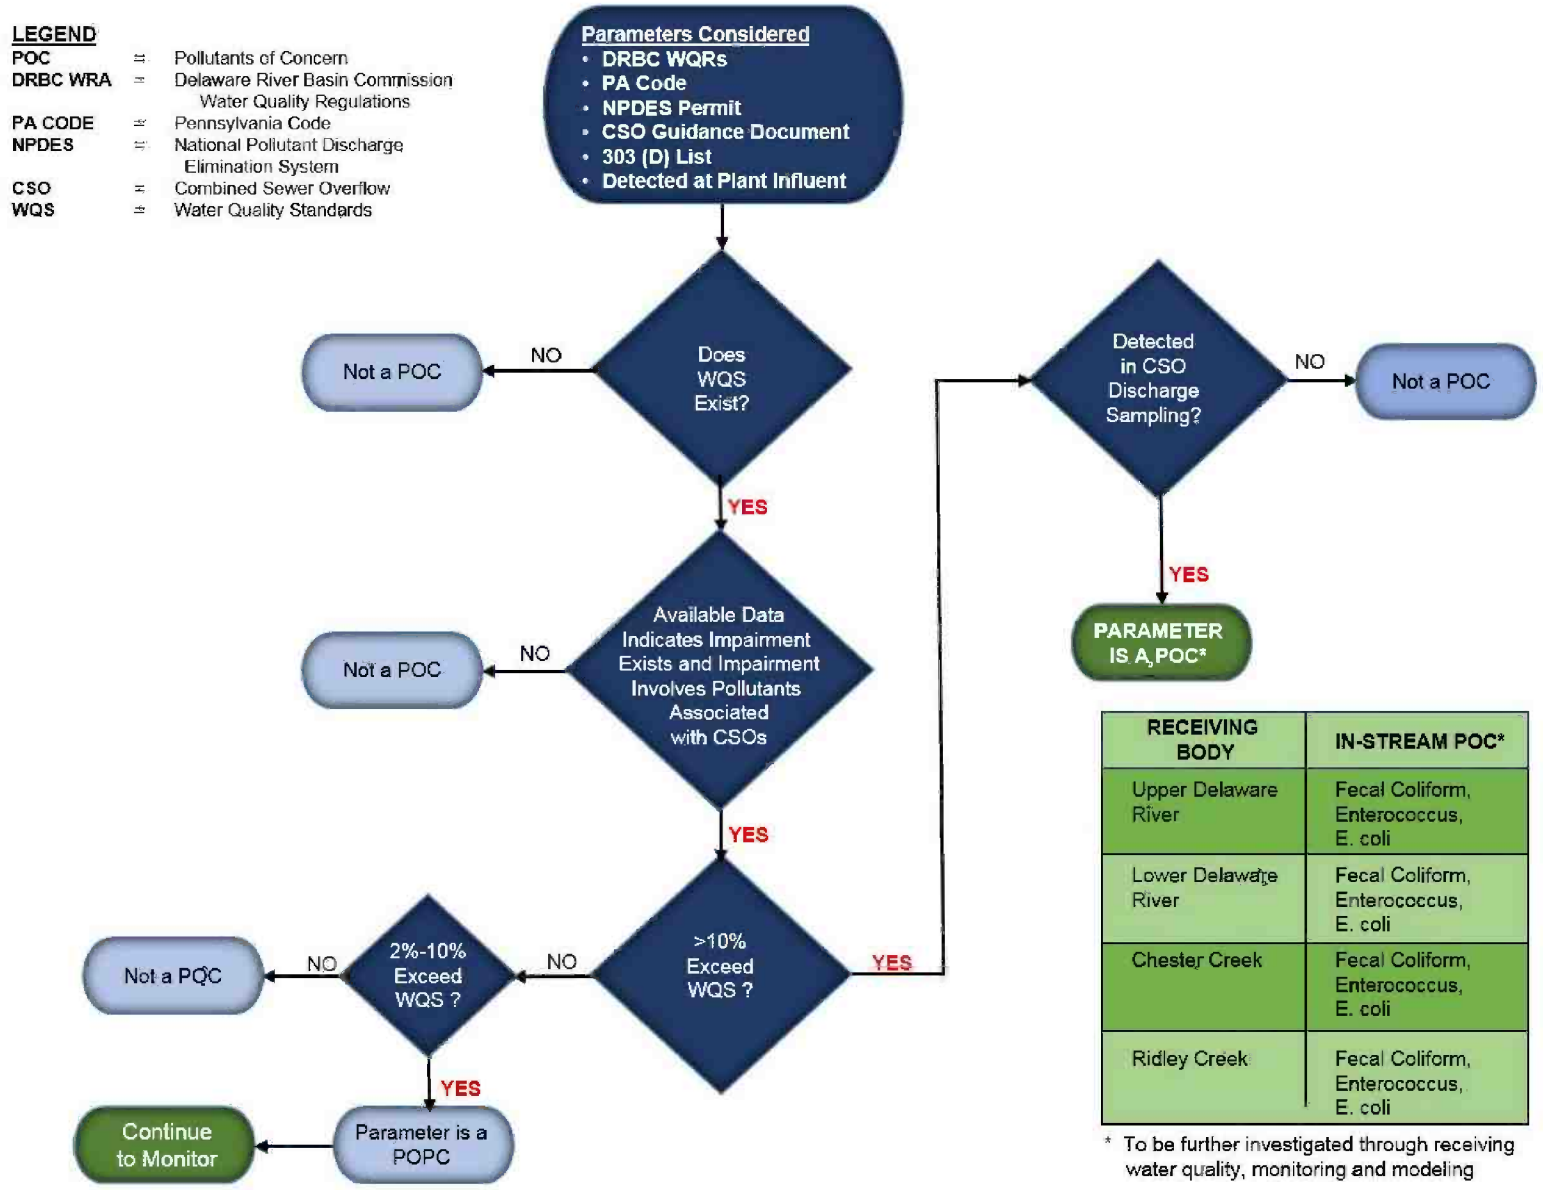
3.7.1 Screening of Parameters with No Water Quality Standard

The Methodology Flowchart for POC and POPC Determination shows that the first step is to determine if a Parameter Considered has an applicable PA State or DRBC water quality standard. If a parameter does not have an applicable water quality standard, there is no standard to exceed. Therefore, those parameters without a water quality standard are not considered further as a POC or a POPC. These include many of the Parameters Considered.

As noted previously in Section 3.1.2, the USEPA's CSO Guidance document states that receiving water monitoring should include identified parameters of concern and these typically include those previously identified for combined sewage and CSO monitoring:

- pH
- BOD
- TDS
- TSS
- Nutrients
- Metals
- Indicator bacteria

A number of the above listed parameters were screened as not a POC or POPC because they do not have an applicable surface water quality standard for the Delaware River, Chester Creek, or Ridley Creek. These include the parameters of BOD/CBOD, TDS and TSS, and the nutrients nitrate, nitrite, phosphorus, and TKN.



CSO Long-Term Control Plan
Delaware County Regional Water Quality Control Authority

GREELEY AND HANSEN

Figure 3-3
METHODOLOGY FLOWCHART FOR POC AND POPC DETERMINATION

The table of the final Parameters Considered in Attachment I shows in gray-highlighting those Parameters Considered that were screened-out as not being a POC because they do not have an applicable water quality standard. Of the 76 Parameters Considered, 25 were removed from further consideration because they do not have an applicable water quality standard.

3.7.2 Screening of Parameters Causing Impairment and that are Associated with CSOs

For the 51 Parameters Considered that do have an applicable water quality standard, the Methodology Flowchart shows that the second screening decision is to determine if existing water quality data indicate impairment of the receiving water bodies exists and the impairment involves pollutants associated with CSOs. The inclusion of this determination comes directly from the requirements of the Consent Decree as noted in Section 3.1.1.

"Impairment" of a receiving water body is "indicated" to exist in one of two ways. First, the receiving water body is considered impaired for a particular parameter if the parameter appears in the 2014 PA Integrated Water Quality & Assessment Report (303(d) List). The PA Integrated Report identifies surface water bodies that are not attaining their designated and existing uses as "impaired".

Secondly, for the purpose of this report, a receiving water body is also considered impaired for a parameter if any of the available sampling data for that parameter in the water body shows that there had been an exceedance of the applicable water quality standard. Those parameters that showed exceedances of the WQS and that may be associated with CSOs were evaluated further to determine if they should be considered as a POC.

The 2014 PA Integrated Water Quality & Assessment Report shows the Delaware River to be impaired for Fish Consumption by PCBs from an unknown source, and there is a PCB TMDL on the Delaware River stretching far upstream to Trenton, NJ. While the Delaware River is impaired from PCBs, the PCBs are not normally associated with CSOs. Given this reason, and the fact that the PCB impairment begins well upstream of DELCORA's service area – PCBs were screened as not being a POC. Furthermore, the additional CSO sampling results from November/December 2015 in Attachment I show that PCBs were found to be at a lower concentration than the Reporting Detection Limit (RDL). For this additional reason it was determined that PCBs are not associated with DELCORA's CSO discharges.

For the Chester Creek and Ridley Creeks, the 2014 PA Integrated Water Quality & Assessment Report shows that both of the creeks are impaired for Aquatic Life from siltation, with Urban Runoff/Storm Sewers identified as the source. The impairment of the Chester Creek and Ridley Creek by siltation primarily occurs upstream of DELCORA's service area as shown in Figure 3-1. The term "Siltation" is not defined in the 2014 PA Integrated Water Quality & Assessment Report, but through various sources could be defined as:

"the pollution of water by fine particulate terrestrial clastic material, with a particle size dominated by silt or clay. It refers both to the increased concentration of suspended sediments, and to the increased accumulation (temporary or permanent) of fine sediments on bottoms where they are undesirable. Siltation is most often caused by soil erosion or sediment spill."

There is not a water quality standard for "siltation", however, siltation can be considered as closely related to the widely used water quality parameter of "Turbidity", which is associated with CSO discharges. For this reason "Turbidity" was reviewed further as a surrogate for siltation to determine if it might be considered as a POC. Per available USEPA STORET data, the Turbidity concentrations on all of the three receiving water bodies were found to be below the WQS (see Attachment I) and therefore siltation was screened-out as not being a POC.

3.7.3 Screening of Parameters where > 10% of Observations Exceed WQS

The concentrations of those Parameters Considered that were detected within the receiving water bodies from USEPA's STORET data for the years 2010 - 2015 were compared to the applicable water quality standards to determine if a Parameter Considered should be viewed as a Pollutant of Concern.

If 10% or more of the total number of samples for a Parameter Considered listed in Attachment I exceeded the WQS, then the parameter was further evaluated to see if it was detected in the CSO discharges.

If 2% - 10% of the total number of samples for a Parameter Considered exceeded the WQS, then the parameter was considered a Parameter of Potential Concern. The concentrations of the Parameters of Potential Concern will continued to be monitored over time, and re-evaluated should the monitoring show their concentrations to increase over time.

Per the flowchart, if 2% - 10% of the total number of samples for a Parameter Considered do not exceed the WQS, then the parameter was not considered to be a POC or POPC.

3.7.4 Screening of Parameters Not Detected at CSO Discharges

The Methodology Flowchart shows that additional analysis is required for those parameters that exceeded the water quality standards for the receiving water bodies in more than 10% of the samples. For those parameters, the concentration of the parameter detected in the November/December 2015 sampling of the CSO discharges was reviewed.

If the parameter was "Not Detected (ND)" or was below the Reporting Detection Limit (see Attachment F) in the November/December 2015 CSO sampling results, it indicates that the parameter was not observed in DELCORA's CSO discharges. In this case, the parameter is not considered to be a POC. In this manner, the industrial-type chemicals that had been originally

detected in the historic sampling results from the influent to the WRTP were able to be removed from further consideration as a POC or POPC.

If the parameter was detected within the November/December 2015 CSO sampling results, it indicates that the parameter was in DELCORA's CSO discharge. In these cases the parameter is considered as a POC, and is to be further investigated through additional receiving water quality monitoring and modeling.

3.8 Discussion of the Pollutants of Concern and Parameters of Potential Concern

The Parameters Considered shown in Attachment I were analyzed against the WQS. The parameters that exceeded the WQS in the receiving bodies are shown in the summary table in Attachment J. The summary table also provides information on the number of observations for each parameter as well as the total number of exceedances for each parameter in all the receiving water bodies from 2010 to 2015. The POCs are shown in red highlight within the table, and POPCs are shown in yellow highlight.

The following discussion of the individual parameters is focused only on those parameters shown in the tables in Attachments I and J to be either a POC or a POPC.

3.8.1 Fecal Coliform Bacteria

Fecal coliform bacteria are the most common microbiological contaminants of natural waters, and are used to indicate contamination by human pathogens. Fecal coliform live in the digestive tracks of warm-blooded animals, including humans, and are excreted in the feces. The DRBC collects fecal coliform bacteria data at Stations 332049 and 892062 on the Delaware River. Additionally, DELCORA sampled the Chester and Ridley Creeks in 2010 for fecal coliform concentrations. The 2010 receiving water sampling results for the Chester and Ridley Creeks are presented in Attachment G.

There are no PA Code, Chapter 93 fecal coliform bacteria water quality standards for streams designated WWF, MF or TSF with no other qualifiers. However, the DRBC's Delaware River Zone 4 has a Stream Quality Objective for fecal coliform of no more than 770 CFU/100 mL for the section upstream of R.M. 81.8, which includes the tidal portions of the Chester and Ridley Creeks, and 200 CFU/100 mL for the section of the river downstream of R.M. 81.8. The tidal extent on Chester Creek and Ridley Creek is shown on Figure 3-1. Compliance with the DRBC Stream Quality Objectives for fecal coliform bacteria is based on a geometric average of samples taken at such frequency and location as to permit valid interpretation.

Of the six samples taken by DELCORA in 2010 on the Ridley Creek at RC1 (upstream) and RC3 (downstream), four show exceedances of the Stream Quality Objective for fecal coliform. These values indicate that the Ridley Creek was not meeting the DRBC Stream Quality Objective, however, more sampling is recommended to further confirm these results.

Of the six samples taken by DELCORA on the Chester Creek at CC1 (upstream) and CC3 (downstream), four show exceedances of the Stream Quality Objective for fecal coliform. These values indicate that the Chester Creek was also not meeting the DRBC WQS at that time, however as with the Ridley Creek, more sampling is recommended to further confirm these results.

The table in Attachment I shows that the available data indicates that there were no exceedances observed of fecal coliform in the Delaware River.

Given that more than 10% of the fecal coliform samples for both the Ridley and Chester Creeks exceeded the WQS, fecal coliform should be considered as a POC for the two creeks. However, although the existing data for the Delaware River has demonstrated that there were no exceedances observed of fecal coliform, since fecal coliform is a primary pollutant typically associated with CSO discharges it has been decided to also include it as a POC for the Delaware River in the interest of minimizing potential impacts to human health and the environment.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - Fecal Coliform considered to be a Pollutant of Concern.
- For the upper Delaware River (Upstream of R.M. 81.8)
  - Fecal Coliform considered to be a Pollutant of Concern.
- For the Chester Creek
  - Fecal Coliform considered to be a Pollutant of Concern.
- For the Ridley Creek
  - Fecal Coliform considered to be a Pollutant of Concern.

3.8.2 Enterococcus Bacteria

Enterococcus is a second bacteria genus that also resides in the digestive system of humans and animals, and that is used to indicate the presence of human pathogens. They have been long recognized as important human pathogens and are becoming increasingly so.

Unlike fecal coliform, the DRBC does not collect enterococcus bacteria data at Stations 332049 and 892062 on the Delaware River, and DELCORA did not collect samples for enterococcus bacteria in 2010 as it did for fecal coliform. Enterococcus are used as an indicator bacteria for marine waters.

As with fecal coliform, there are no PA Code, Chapter 93 water quality standards for enterococcus bacteria for streams designated WWF, MF or TSF with no other qualifiers. However, the DRBC's Delaware River Zone 4 has a WQS for enterococcus bacteria of no more

than 88 CFU/100 mL for the section upstream of R.M. 81.8, which includes tidal portions of the Chester and Ridley Creeks, and 33 CFU/100 mL for the section of the river downstream of R.M. 81.8. Compliance with the DRBC WQS for enterococcus bacteria is based on a geometric average of samples taken at such frequency and location as to permit valid interpretation.

Very little existing data was available for enterococcus bacteria concentrations in the Delaware River, Chester Creek and Ridley Creek in the area of DELCORA's CSO discharges. However, enterococcus bacteria and fecal coliform bacteria are similar to each other, they are both produced in the human digestive tract, and are both considered to be parameters typically associated with CSOs. For this reason it was decided to also include enterococcus bacteria as a POC at the same locations identified for fecal coliform bacteria, which includes all three of DELCORA's receiving water bodies.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - Enterococcus considered to be a Pollutant of Concern.
- For the upper Delaware River (Upstream of R.M. 81.8)
  - Enterococcus considered to be a Pollutant of Concern.
- For the Chester Creek
  - Enterococcus considered to be a Pollutant of Concern.
- For the Ridley Creek
  - Enterococcus considered to be a Pollutant of Concern.

3.8.3 Escherichia Coli Bacteria

Escherichia coli (also known as E. coli) is a facultative anaerobic, rod-shaped bacterium of the genus *Escherichia* that is commonly found in the lower intestine of warm-blooded organisms. E. coli is expelled into the environment within fecal matter. Fecal material can enter the environment from many sources including wastewater treatment plants, CSO discharges, livestock or poultry manure, sanitary landfills, septic systems, sewage sludge, pets and wildlife.

E. coli was not listed as an initial Parameter Considered because it is listed in the applicable reference sources from the PA Code or DRBC. However, in consultation with the PADEP it is understood that Enterococcus bacteria could be replaced with E. coli in future regulations (on the anticipation that national standards for E. coli will be adopted in Pennsylvania) and therefore E. coli is included as a POC for all the receiving water bodies.

- For the lower Delaware River (Downstream of R.M. 81.8)
  - E. coli considered to be a Pollutant of Concern.

- For the upper Delaware River (Upstream of R.M. 81.8)
  - E. coli considered to be a Pollutant of Concern.

- For the Chester Creek
  - E. coli considered to be a Pollutant of Concern.

- For the Ridley Creek
  - E. coli considered to be a Pollutant of Concern.

3.8.4 Metals

During the data analysis, it was detected that some metal concentrations, in the receiving water bodies, exceeded the water quality standards. These metals include Aluminum, Copper, Iron, Lead, and Mercury. The appropriate control measures for metals from CSO discharges are the continued implementation of and compliance with the Nine Minimum Controls (NMCs) as required by DELCORA's NPDES permit.

The NPDES permit requires DELCORA to submit an annual report each year to the PADEP, with appropriate documentation demonstrating the continued implantation of and compliance with the NMC required on a system wide basis.

Additionally, the USEPA's guidance document *Guidance for Nine Minimum Controls* states;

> *"…municipalities should immediately implement best available technology economically achievable (BAT) or best conventional pollutant control technology (BCT). At a minimum, BAT/BCT should include the nine minimum controls, which are determined on a best professional judgement (BPJ) basis by the NPDES permitting authority".*

For the removal of metals, the most applicable Nine Minimum Controls include the maximum use of the collection system for storage, the review and modification of pretreatment requirements to ensure that CSO impacts are minimized, maximization of flow to the POTW for treatment and pollution prevention programs (such as street sweeping) to reduce these contaminants in the CSOs.

Therefore, metals are not considered to be POCs.

3.9 Summary for Pollutants of Concern

In the effort to identify Pollutants of Concerns related to its CSO discharges, DELCORA has reviewed the 2014 PA Integrated Water Quality Monitoring and Assessment Report (303(d) List), the historic sampling data for the influent to the Western Regional Treatment Plant, the USEPA's STORET Data repository, historic water quality sampling data from the Chester and

Ridley Creeks, and additional sampling results from the CSOs from November and December of 2015.

Three (3) POCs were determined. These include Fecal Coliform bacteria, Enterococcus bacteria and E. coli bacteria. These three POCs are parameters typically associated with CSO discharges. The list of POCs is summarized in Table 3-12 with their respective exceedance percentage (%) for each of the receiving water bodies. The concentrations of these identified POCs in the Delaware River, Chester Creek and Ridley Creek will be further investigated through receiving water quality monitoring and modeling.

No Parameters of Potential Concern were identified at this time.

Table 3-12: List of Pollutants of Concern (POC)

No.	Upper Delaware River		Lower Delaware River		Chester Creek		Ridley Creek	
Pollutants of Concern (>10% of observed samples exceed WQS)								
1	Fecal Coliform[b]	100%	Fecal Coliform[b]	100%	Fecal Coliform[a],[b]	100%	Fecal Coliform[a],[b]	100%
2	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%	Enterococcus [b],[c]	100%
3	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%	E. coli[c]	100%

[a] Based on historical sampling conducted in 2010 upstream and downstream of CSO outfalls only on Chester and Ridley Creeks.

[b] Fecal Coliform and Enterococcus are listed as POCs due to both being parameters typically associated with CSOs.

[c] DRBC regulations are available for Enterococcus and it is typically associated with CSOs and therefore it is included as a POC. However, in consultation with PADEP Enterococcus could be replaced with E. coli bacteria in the future (based on the anticipation that national standards on E. coli will be adopted in Pennsylvania) and therefore E.coli is also included as a POC.

Subject: Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Sensitive Areas Study

Dear Ms. McCabe:

Greeley and Hansen is developing a Long Term Control Plan (LTCP) for the Delaware County Regional Water Quality Control Authority (DELCORA) located in Chester, PA. A map of the study area is provided as an attachment to this letter. The goal of this LTCP is to reduce the frequency, duration and intensity of combined sewer overflow events into the local waterbodies, including portions of the Delaware River, Chester Creek and Ridley Creek. As part of this evaluation, environmentally sensitive areas within the study area need to be identified so that appropriate considerations can be made to reduce combined sewer overflows to these areas.

Sensitive Areas are defined by the United States Environmental Protection Agency (USEPA) Federal Register Combined Sewer Overflow (CSO) Control Policy and the US EPA Guidance for Long Term Control Plan as follows:

- Outstanding National Resource Waters (ONRW)
- National Marine Sanctuaries
- Waters with threatened or endangered species and their habitat
- Waters with primary contact recreation (i.e. beaches, boat ramps, boat launches, etc.)
- Public drinking water intakes or their designated protection areas
- Shellfish beds

USEPA requirements indicate that sensitive areas are given the highest priority during the development of technical alternatives.

This letter is being submitted to your agency as a formal request for information that your agency may have on sensitive areas within Delaware County, PA. Specifically, we are interested in sensitive areas located within the area of study as shown in GREEN on the attached map. If portions of the study area meet the above sensitive area criteria, we request that you provide the following information:

- Complete list of identified Sensitive Areas;
- Narrative description of how the sensitive area criteria listed above applies to the study area;
- Map of specific locations within our study area identifying the specific sensitive areas; and
- Any additional information you deem appropriate.

DELCORA is under a Consent Decree to submit this study to USEPA in February 2016. In order to meet project milestones, we respectfully request you provide a response within 30 days of receipt of this letter, no later than November 23, 2015. We appreciate your cooperation and assistance in completing this study. Should you need any additional information, please feel free to contact me at (215) 553-7919 or Julia Spicher at (215) 553-7926.

Yours very truly,

Harrisburg, PA 17110-9797

Subject: Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Sensitive Areas Study

Dear Mr. Gregg:

Greeley and Hansen is developing a Long Term Control Plan (LTCP) for the Delaware County Regional Water Quality Control Authority (DELCORA) located in Chester, PA. A map of the study area is provided as an attachment to this letter. The goal of this LTCP is to reduce the frequency, duration and intensity of combined sewer overflow events into the local waterbodies, including portions of the Delaware River, Chester Creek and Ridley Creek. As part of this evaluation, environmentally sensitive areas within the study area need to be identified so that appropriate considerations can be made to reduce combined sewer overflows to these areas.

Sensitive Areas are defined by the United States Environmental Protection Agency (USEPA) Federal Register Combined Sewer Overflow (CSO) Control Policy and the US EPA Guidance for Long Term Control Plan as follows:

- Outstanding National Resource Waters (ONRW)
- National Marine Sanctuaries
- Waters with threatened or endangered species and their habitat
- Waters with primary contact recreation (i.e. beaches, boat ramps, boat launches, etc.)
- Public drinking water intakes or their designated protection areas
- Shellfish beds

USEPA requirements indicate that sensitive areas are given the highest priority during the development of technical alternatives.

This letter is being submitted to your agency as a formal request for information that your agency may have on sensitive areas within Delaware County, PA. Specifically, we are interested in sensitive areas located within the area of study as shown in GREEN on the attached map. If portions of the study area meet the above sensitive area criteria, we request that you provide the following information:

- Complete list of identified Sensitive Areas;
- Narrative description of how the sensitive area criteria listed above applies to the study area;
- Map of specific locations within our study area identifying the specific sensitive areas; and
- Any additional information you deem appropriate.

DELCORA is under a Consent Decree to submit this study to USEPA in February 2016. In order to meet project milestones, we respectfully request you provide a response within 30 days of receipt of this letter, no later than November 23, 2015. We appreciate your cooperation and assistance in completing this study. Should you need any additional information, please feel free to contact me at (215) 553-7919 or Julia Spicher at (215) 553-7926.

Yours very truly,

Greeley and Hansen LLC

RE: USFWS Project #2016-0026
PNDI Large Project

Dear Ms. Finizio:

This responds to your letter received on October 9, 2015, requesting information about federally listed and proposed endangered and threatened species within the area affected by the development of a Long Term Control Plan for the Delaware County Regional Authority. The project area is located in Delaware County, Pennsylvania. The following comments are provided pursuant to the Endangered Species Act of 1973 (Act, 87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.), the Migratory Bird Treaty Act (MBTA, 16 U.S.C. 703-712; Ch. 128; July 13, 1918; 40 Stat. 755, as amended), and the Bald and Golden Eagle Protection Act (BGEPA, 16 U.S.C. 668-668d).

Federally Listed Species

There are a number of federally listed species that are either known to occur, or have the potential to occur, in the proposed study area. We describe general information about these species, but without more specific project information and locations are not able to provide additional information regarding potential avoidance or conservation measures. We fully support your planning efforts and desires to protect sensitive areas and overall water quality. Let us know how we can be of additional assistance.

No critical habitat has been designated for any of the below listed species, at this time.

Bog turtle

The project is within the known range of the bog turtle (*Clemmys muhlenbergii*), a species that is federally listed as threatened. Bog turtles inhabit shallow, spring-fed fens, sphagnum bogs, swamps, marshy meadows, and pastures characterized by soft, muddy bottoms; clear, cool, slow-flowing water, often forming a network of rivulets; high humidity; and an open canopy. Bog

turtles usually occur in small, discrete populations occupying suitable wetland habitat dispersed along a watershed. The occupied "intermediate successional stage" wetland habitat is usually a mosaic of micro-habitats ranging from dry pockets, to areas that are saturated with water, to areas that are periodically flooded. Some wetlands occupied by bog turtles are located in agricultural areas and are subject to grazing by livestock. More information on this species can be found at: http://ecos.fws.gov/tess_public/profile/speciesProfile.action?spcode=C048

Indiana bat

The project area is within the range of the federally endangered Indiana bat (*Myotis sodalis*). Indiana bats hibernate in caves and abandoned mines during the winter months (November through March), and use a variety of forested upland and wetland habitats during the spring, summer, and fall. Indiana bats usually roost in dead or living trees with exfoliating bark, crevices or cavities. Female Indiana bats form nursery colonies under the exfoliating bark of dead or living trees, such as shagbark hickory, black birch, red oak, white oak, and sugar maple, in upland or riparian areas. More information on this species can be found at: http://www.fws.gov/MIDWEST/endangered/mammals/inba/index.html

Northern long-eared bat

The project is within the known range of the northern long-eared bat (*Myotis septentrionalis*), a species that is federally listed as threatened. Northern long-eared bats hibernate in caves and abandoned mines during the winter months, and use a variety of forested upland and wetland habitats during the spring, summer, and fall. More information on this species can be found at: http://www.fws.gov/midwest/endangered/mammals/nlba/index.html

Atlantic sturgeon

The project is within the known range of the Atlantic sturgeon (*Acipenser oxyrinchus oxyrinchus*), a species that is federally listed as threatened. The Atlantic sturgeon is a long-lived, estuarine dependent, anadromous fish. Adult sturgeon spawn in freshwater in the spring and early summer and migrate into "estuarine" and marine waters where they spend most of their lives. The Atlantic sturgeon is under the jurisdiction of the National Marine Fisheries Service (NMFS). Please contact NMFS regarding this species or visit their website at: http://www.nmfs.noaa.gov/pr/species/fish/atlanticsturgeon.htm#status

Shortnose sturgeon

The project is within the known range of the Shortnose sturgeon (*Acipenser brevirostrum*), a species that is federally listed as endangered. The shortnose sturgeon is the smallest of the three sturgeon species that occur in eastern North America. The shortnose sturgeon is anadromous, living mainly in the slower moving riverine waters or nearshore marine waters, and migrating periodically into faster moving fresh water areas to spawn. The shortnose sturgeon is under the jurisdiction of the NMFS. Please contact NMFS regarding this species or visit their website at: http://www.nmfs.noaa.gov/pr/species/fish/shortnosesturgeon.htm

In cases where adverse effects to federally listed species cannot be avoided, further consultation with the Service would be necessary to avoid potential violations of section 9 (prohibiting "take" of listed species) and/or section 7 (requiring federal agencies to consult) of the Endangered Species Act. Information about the section 7 and section 10 consultation processes (for federal and non-federal actions, respectively) can be obtained by contacting this office or accessing the Service's Endangered Species Home Page (http://endangered.fws.gov).

Bald and golden eagles

Bald eagles (*Haliaeetus leucocephalus*) are known to nest in the vicinity of the project area. While the bald eagle has been removed from the Federal list of threatened and endangered species (August 8, 2007; 72 FR 37346), the bald eagle along with the golden eagle (*Aquila chrysaetos*) continues to be protected under the BGEPA and MBTA. Both the BGEPA and the

MBTA prohibit take as defined as "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, destroy, molest, disturb, or otherwise harm eagles, their nests, or their eggs." Under the BGEPA, "disturb" means to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, based on the best scientific information available: (1) injury to an eagle; (2) decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior; or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior.

We recommend that you evaluate the project type, size, location and layout in light of the National *Bald Eagle Management Guidelines* to determine whether or not bald eagles might be disturbed as a direct or indirect result of this project. If it appears that disturbance may occur, we recommend that you consider modifying your project consistent with the Guidelines. These guidelines, as well as additional eagle information, are available at http://www.fws.gov/northeast/EcologicalServices/eagle.html To assist you in making a decision regarding impacts to bald eagles, a screening form can be found at http://www.fws.gov/northeast/pafo/bald_eagle.html.

Migratory Birds

The Service is the principal Federal agency charged with protecting and enhancing populations and habitat of migratory bird species. The MBTA prohibits the taking, killing, possession, transportation, and importation of migratory birds, their eggs, parts, and nests, except when specifically authorized by the Department of the Interior. While the MBTA has no provision for authorizing incidental take, the Service recognizes that some birds may be killed even if all reasonable measures to avoid take are implemented.

The potential exists for avian mortality if there is habitat destruction and alteration within the project boundaries. Site-specific factors that should be considered in project siting to avoid and minimize the risk to birds include avian abundance; the quality, quantity and type of habitat; geographic location; type and extent of bird use (e.g. breeding, foraging, migrating, etc.); and landscape features. Please review the enclosed information for general recommendations for avoiding and minimizing impacts to migratory birds within and around the project area. Please

be aware that since these are general guidelines, some of them may not be applicable to the current project design or they may have already been included in the project design.

The project area is located in the vicinity of the Important Bird Area (IBA) known as Upper Ridley-Crum Creek. IBAs are designated by the Pennsylvania Ornithological Technical Committee. They are the most critical regions in the Commonwealth for conserving bird diversity and abundance, and are the primary focus of Audubon Pennsylvania's conservation efforts. To find out more information about this IBA, including which bird species breed there, visit: http://netapp.audubon.org/IBA/State/US-PA

Please contact Brian Scofield of my staff at 814-234-4090 if you have any questions or require further assistance regarding this matter.

Sincerely,

Lora L. Zimmerman
Field Office Supervisor

Enclosure

Adaptive Management Practices for Conserving Migratory Birds

The Fish and Wildlife Service is the principal Federal agency charged with protecting and enhancing populations and habitat of migratory bird species. The Migratory Bird Treaty Act (MBTA, 16 U.S.C. 703-712; Ch. 128; July 13, 1918; 40 Stat. 755, as amended) prohibits the taking, killing, possession, transportation, and importation of migratory birds, their eggs, parts, and nests, except when specifically authorized by the Department of the Interior. While the MBTA has no provision for authorizing incidental take, the Service recognizes that some birds may be killed even if all reasonable measures to avoid take are implemented. Unless the take is authorized, it is not possible to absolve individuals, companies or agencies from liability (even if they implement avian mortality avoidance or similar conservation measures). However, the Office of Law Enforcement focuses on those individuals, companies, or agencies that take migratory birds with disregard for their actions and the law.

The potential exists for avian mortality from habitat destruction and alteration within the project boundaries. Site-specific factors that should be considered in project siting to avoid and minimize the risk to birds include avian abundance; the quality, quantity and type of habitat; geographic location; type and extent of bird use (*e.g.* breeding, foraging, migrating, etc.); and landscape features.

We offer the following recommendations to avoid and minimize impacts to migratory birds within and around the project area:

1. Where disturbance is necessary, clear natural or semi-natural habitats (*e.g.*, forests, woodlots, reverting fields, shrubby areas) and perform maintenance activities (*e.g.*, mowing) between September 1 and March 31, which is outside the nesting season for most native bird species. Without undertaking specific analysis of breeding species and their respective nesting seasons on the project site, implementation of this seasonal restriction will avoid take of most breeding birds, their nests, and their young (*i.e.*, eggs, hatchlings, fledglings).

2. Minimize land and vegetation disturbance during project design and construction. To reduce habitat fragmentation, co-locate roads, fences, lay down areas, staging areas, and other infrastructure in or immediately adjacent to already-disturbed areas (*e.g.*, existing roads, pipelines, agricultural fields) and cluster development features (*e.g.*, buildings, roads) as opposed to distributing them throughout land parcels. Where this is not possible, minimize roads, fences, and other infrastructure.

3. Avoid permanent habitat alterations in areas where birds are highly concentrated. Examples of high concentration areas for birds are wetlands, State or Federal refuges, Audubon Important Bird Areas, private duck clubs, staging areas, rookeries, leks, roosts, and riparian areas. Avoid establishing sizable structures along known bird migration pathways or known daily movement flyways (*e.g.,* between roosting and feeding areas).

4. To conserve area-sensitive species, avoid fragmenting large, contiguous tracts of wildlife habitat, especially if habitat cannot be fully restored after construction. Maintain

contiguous habitat corridors to facilitate wildlife dispersal. Where practicable, concentrate construction activities, infrastructure, and man-made structures (*e.g.*, buildings, cell towers, roads, parking lots) on lands already altered or cultivated, and away from areas of intact and healthy native habitats. If not feasible, select fragmented or degraded habitats over relatively intact areas.

5. Develop a habitat restoration plan for the proposed site that avoids or minimizes negative impacts to birds, and that creates functional habitat for a variety of bird species. Use only plant species that are native to the local area for revegetation of the project area.

If you have any questions regarding these measures, please contact Lora Zimmerman of the Pennsylvania Field Office located in State College, PA at 814-234-4090.

Mr. Brian Byrnes
Executive Director
Chester Ridley Crum Watersheds Association
38 Bishop Hollow Road
Newtown Square, PA 19073

Subject: Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Sensitive Areas Study

Dear Mr. Byrnes:

Greeley and Hansen is developing a Long Term Control Plan (LTCP) for the Delaware County Regional Water Quality Control Authority (DELCORA) located in Chester, PA. A map of the study area is provided as an attachment to this letter. The goal of this LTCP is to reduce the frequency, duration and intensity of combined sewer overflow events into the local waterbodies, including portions of the Delaware River, Chester Creek and Ridley Creek. As part of this evaluation, environmentally sensitive areas within the study area need to be identified so that appropriate considerations can be made to reduce combined sewer overflows to these areas.

Sensitive Areas are defined by the United States Environmental Protection Agency (USEPA) Federal Register Combined Sewer Overflow (CSO) Control Policy and the US EPA Guidance for Long Term Control Plan as follows:

- Outstanding National Resource Waters (ONRW)
- National Marine Sanctuaries
- Waters with threatened or endangered species and their habitat
- Waters with primary contact recreation (i.e. beaches, boat ramps, boat launches, etc.)
- Public drinking water intakes or their designated protection areas
- Shellfish beds

USEPA requirements indicate that sensitive areas are given the highest priority during the development of technical alternatives.

This letter is being submitted to your agency as a formal request for information that your agency may have on sensitive areas within Delaware County, PA. Specifically, we are interested in sensitive areas located within the area of study as shown in GREEN on the attached map. If portions of the study area meet the above sensitive area criteria, we request that you provide the following information:

- Complete list of identified Sensitive Areas;
- Narrative description of how the sensitive area criteria listed above applies to the study area;
- Map of specific locations within our study area identifying the specific sensitive areas; and
- Any additional information you deem appropriate.

DELCORA is under a Consent Decree to submit this study to USEPA in February 2016. In order to meet project milestones, we respectfully request you provide a response within 30 days of receipt of this letter, no later than November 23, 2015. We appreciate your cooperation and assistance in completing this study. Should you need any additional information, please feel free to contact me at (215) 553-7919 or Julia Spicher at (215) 553-7926.

Sensitive Areas Study

Partnership for the Delaware Estuary has identified sensitive areas within the study area which are listed and described below along with a visual representation on the provided map. Additional information on the study area is also presented.

Sensitive Areas

- **Ridley Creek watershed**
- **Schuylkill River watershed**
- **Darby Creek mouth / John Heinz National Wildlife Refuge at Tinicum**

Ridley Creek watershed

Ridley Creek begins north of Delaware County and flows through the county and into the Delaware River. Healthy freshwater mussel populations comprised of the Eastern elliptio (*Elliptio complanata*) exist throughout the creek which warrants protection. Additionally, there are long term freshwater mussel monitoring studies within the creek. Therefore, the Ridley Creek watershed should be considered a sensitive area.

Schuylkill River watershed

The northeast section of Delaware County drains into the Schuylkill River which flows just east of the county. Freshwater mussel beds have been qualitatively identified and quantitatively surveyed within the Schuylkill River and include multiple species including the eastern elliptio, the alewife floater (*Anodonta implicata*), and the tidewater mucket (*Leptodea ochracea*). Surveys have also identified juvenile mussels in the river indicating the population is successfully reproducing.

Darby Creek mouth / John Heinz National Wildlife Refuge at Tinicum

Access to Darby Creek is made possible via the Ridley Township Municipal Marina where boaters may access the Delaware River as well as the John Heinz National Wildlife Refuge at Tinicum. As well as serving as a primary contact for recreation, freshwater mussel surveys at the mouth of Darby Creek have yielded positive detections of the eastern elliptio and the alewife floater.

Although a few sensitive areas have been described above, it should be noted that Partnership for the Delaware Estuary and other organizations has only surveyed a portion of all streams in Delaware County. Historical data and museum records indicate that multiple species of freshwater mussels were found in Chester and Crum Creeks (Ortmann 1919). It is possible that additional freshwater mussel beds still exist in some streams that have not been properly surveyed. Attention should be paid to areas with hydrological connectivity to downstream sites that support freshwater mussels. In example, although outside of the highlighted study area, freshwater mussel populations as well as beds of submerged aquatic vegetation between Pennsylvania's coast and Little Tinicum Island may be impacted from waters draining the Darby Creek watershed.

Ortmann, A.E. 1919. A monograph of the naiades of Pennsylvania. Part III: Systematic account of the genera and species. Memoirs of the Carnegie Museum 8(1): xvi -385 + 21 plates.

Mr. John Buzzar
PA Fish and Boat Commission
1601 Elmerton Avenue
Harrisburg, PA 17110

Subject: Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Sensitive Areas Study

Dear Mr. Buzzar:

Greeley and Hansen is developing a Long Term Control Plan (LTCP) for the Delaware County Regional Water Quality Control Authority (DELCORA) located in Chester, PA. A map of the study area is provided as an attachment to this letter. The goal of this LTCP is to reduce the frequency, duration and intensity of combined sewer overflow events into the local waterbodies, including portions of the Delaware River, Chester Creek and Ridley Creek. As part of this evaluation, environmentally sensitive areas within the study area need to be identified so that appropriate considerations can be made to reduce combined sewer overflows to these areas.

Sensitive Areas are defined by the United States Environmental Protection Agency (USEPA) Federal Register Combined Sewer Overflow (CSO) Control Policy and the US EPA Guidance for Long Term Control Plan as follows:

- Outstanding National Resource Waters (ONRW)
- National Marine Sanctuaries
- Waters with threatened or endangered species and their habitat
- Waters with primary contact recreation (i.e. beaches, boat ramps, boat launches, etc.)
- Public drinking water intakes or their designated protection areas
- Shellfish beds

USEPA requirements indicate that sensitive areas are given the highest priority during the development of technical alternatives.

This letter is being submitted to your agency as a formal request for information that your agency may have on sensitive areas within Delaware County, PA. Specifically, we are interested in sensitive areas located within the area of study as shown in GREEN on the attached map. If portions of the study area meet the above sensitive area criteria, we request that you provide the following information:

- Complete list of identified Sensitive Areas;
- Narrative description of how the sensitive area criteria listed above applies to the study area;
- Map of specific locations within our study area identifying the specific sensitive areas; and
- Any additional information you deem appropriate.

DELCORA is under a Consent Decree to submit this study to USEPA in February 2016. In order to meet project milestones, we respectfully request you provide a response within 30 days of receipt of this letter, no later than November 23, 2015. We appreciate your cooperation and assistance in completing this study. Should you need any additional information, please feel free to contact me at (215) 553-7919 or Julia Spicher at (215) 553-7926.

RE: Species Impact Review (SIR) – Rare, Candidate, Threatened and Endangered Species
PNDI Search No.
Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Delaware County

Dear Ms. Finizio:

This responds to your inquiry about a Pennsylvania Natural Diversity Inventory (PNDI) Internet Database search "potential conflict" or a threatened and endangered species impact review. These projects are screened for potential conflicts with rare, candidate, threatened or endangered species under Pennsylvania Fish & Boat Commission jurisdiction (fish, reptiles, amphibians, aquatic invertebrates only) using the Pennsylvania Natural Diversity Inventory (PNDI) database and our own files. These species of special concern are listed under the Endangered Species Act of 1973, the Wild Resource Conservation Act, and the Pennsylvania Fish & Boat Code (Chapter 75), or the Wildlife Code.

Based on records maintained in the Pennsylvania Natural Diversity Inventory (PNDI) database and our own files, the following rare or protected species are known from the vicinity of the project site:

Common Name (Scientific Name, PA Status)
Atlantic Sturgeon (*Acipenser oxyrinchus*, Endangered)
Shortnose Sturgeon (*Acipenser brevirostrum*, Endangered)
Eastern Redbelly Turtle (*Pseudemys rubriventris*, Threatened)

The Shortnose and Atlantic Sturgeon, which are listed by both Pennsylvania and the U.S. Fish and Wildlife Service/National Marine Fisheries Service, occur in the Delaware River. They are especially vulnerable to physical (dredging, rip-rap, etc.) and chemical (pH, dissolved oxygen, temperature, heavy metals, and organic contaminants) changes to the aquatic environment. Although the mobile adults of these protected fish species may be capable of moving from the project area, their spawning grounds (including eggs, larvae, and immature fish) are vulnerable to burial, crushing by equipment, and siltation

from construction projects. In-stream activities during their spawning period may also disrupt the adults' reproductive behavior. Both Atlantic Sturgeon and Shortnose Sturgeon adults and juveniles may also forage and migrate through the proposed project area and could be adversely impacted by the proposed project.

The Eastern Redbelly Turtle is one of Pennsylvania's largest native aquatic turtles. This turtle species is known to inhabit relatively large, deep streams, rivers, ponds, lakes, and marshes with permanent water and ample basking sites. Redbelly turtles are documented in the Delaware River, Darby Creek, Crum Creek, Ridley Creek, and Chester Creek within the project area. They can be found in deep, slow water habitats in the creeks, as well as impoundments and nearby ponds and lakes. The existence of this turtle species is threatened by habitat destruction, poor water quality and competition with aggressive non-native turtle species that share its range and habitat (e.g. red-eared slider).

Additionally, in response to your request, we recommend that you access county information on our website, at http://fishandboat.com/county.htm for locations of public boat launches on Darby Creek and the Delaware River.

This response represents the most up-to-date summary of the PNDI data and our files and is valid for two (2) years from the date of this letter. An absence of recorded species information does not necessarily imply species absence. Our data files and the PNDI system are continuously being updated with species occurrence information. Should project plans change or additional information on listed or proposed species become available, this determination may be reconsidered, and consultation shall be re-initiated.

If you have any questions regarding this review, please contact Kathy Gipe at 814-359-5186 and refer to the SIR # 45340. Thank you for your cooperation and attention to this important matter of species conservation and habitat protection.

Sincerely,

Christopher A. Urban, Chief
Natural Diversity Section

Subject: Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Sensitive Areas Study
In Reply to SIR# 45340

Dear Ms. Gipe:

Greeley and Hansen is developing a Long Term Control Plan Update (LTCPU) for the Delaware County Regional Water Quality Control Authority (DELCORA) located in Chester, PA. As per our phone conversation on Wednesday, March 9, 2016, we are requesting additional information on the specific habitat location of the species listed in SIR #45340.

Two maps of the study area are provided as attachments to this letter including a map highlighting the specific focus area of Chester City and a second map showing the exact location of the combine sewer outfalls (CSOs). Per our telephone conversation, it is our understanding that a map of the specific habitat locations cannot be provided as this information is confidential. In order to properly determine if CSOs will impact these threatened and endangered species we need to better understand the species location within the focus project area. We request that you review the attached maps against your records and complete the table below.

CSO	Receiving Stream	Location	Distance Upstream to Nearest Species Habitat (miles)	Distance Downstream to Species Habitat (miles)	Above Tidal Boundary? (Yes or No)	Notes
2		Front & Booth				
3		Front & Highland				
4		Front & Hayes				
5		Front & Townsend				
7		Delaware & Reaney				
8		2nd & Tilghman				
9		2nd & Lloyd				
10		5th & Pusey				
11		2nd & Parker				
12		2nd & Edgmont				
13		2nd & Welsh				
14		3rd & Upland				
15		4th & Melrose				
16		8th & McDowell				
17		9th & Campbell				
18		Sun Drive & Hancock				
19		14th & Crozer				
20		Kerlin & Finland				
21		9th & Sproul				

CSO	Receiving Stream	Location	Distance Upstream to Nearest Species Habitat (miles)	Distance Downstream to Species Habitat (miles)	Above Tidal Boundary? (Yes or No)	Notes
22		6th & Sproul				
23		3rd & Edgmont				
24		3rd & Dock				
25		5th & Penn				

Additionally, information on the type of habitat (i.e. – spawning, nesting, siting) or other pertinent information would also be helpful. We appreciate your cooperation and assistance in completing this task. Should you need any additional information, please feel free to contact me at (215) 553-7919 or Julia Spicher at (215) 553-7926.

Yours very truly,

Mr. Matthew Fisher
Delaware Department of Natural Resources
and Environmental Control
89 Kings Highway
Dover, DE 19901

Subject: Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Sensitive Areas Study

Dear Mr. Fisher:

Greeley and Hansen is developing a Long Term Control Plan (LTCP) for the Delaware County Regional Water Quality Control Authority (DELCORA) located in Chester, PA. A map of the study area is provided as an attachment to this letter. The goal of this LTCP is to reduce the frequency, duration and intensity of combined sewer overflow events into the local waterbodies, including portions of the Delaware River, Chester Creek and Ridley Creek. As part of this evaluation, environmentally sensitive areas within the study area need to be identified so that appropriate considerations can be made to reduce combined sewer overflows to these areas.

Sensitive Areas are defined by the United States Environmental Protection Agency (USEPA) Federal Register Combined Sewer Overflow (CSO) Control Policy and the US EPA Guidance for Long Term Control Plan as follows:

- Outstanding National Resource Waters (ONRW)
- National Marine Sanctuaries
- Waters with threatened or endangered species and their habitat
- Waters with primary contact recreation (i.e. beaches, boat ramps, boat launches, etc.)
- Public drinking water intakes or their designated protection areas
- Shellfish beds

USEPA requirements indicate that sensitive areas are given the highest priority during the development of technical alternatives.

This letter is being submitted to your agency as a formal request for information that your agency may have on sensitive areas within Delaware County, PA. Specifically, we are interested in sensitive areas located within the area of study as shown in GREEN on the attached map. If portions of the study area meet the above sensitive area criteria, we request that you provide the following information:

- Complete list of identified Sensitive Areas;
- Narrative description of how the sensitive area criteria listed above applies to the study area;
- Map of specific locations within our study area identifying the specific sensitive areas; and
- Any additional information you deem appropriate.

DELCORA is under a Consent Decree to submit this study to USEPA in February 2016. In order to meet project milestones, we respectfully request you provide a response within 30 days of receipt of this letter, no later than November 23, 2015. We appreciate your cooperation and assistance in completing this study. Should you need any additional information, please feel free to contact me at (215) 553-7919 or Julia Spicher at (215) 553-7926.

Yours very truly,

Dear Marlene Finizio:

In response to your request to comment on the Long Term Control Plan for the Delaware County Regional Water Quality Control Authority the Delaware Department of Natural Resources and Environmental Control Division of Fish and Wildlife would like to notify you that the Delaware River adjacent to your study area is inhabited by both the Atlantic Sturgeon, and the Shortnose Sturgeon. Both species are considered endangered and are protected by the Endangered Species Act. In addition this area is utilized by several anadromous fish species including but not limited to Striped Bass and American Shad. In regards to your specific study site, or further information on species that can be found in the Delaware River you should contact the Pennsylvania Fish and Boat Commission.

Thank You,

Ian Park

Subject: Delaware County Regional Water Quality Authority
CSO Long Term Control Plan Update
Sensitive Areas Study

Dear Mr. Chanda:

Greeley and Hansen is developing a Long Term Control Plan (LTCP) for the Delaware County Regional Water Quality Control Authority (DELCORA) located in Chester, PA. A map of the study area is provided as an attachment to this letter. The goal of this LTCP is to reduce the frequency, duration and intensity of combined sewer overflow events into the local waterbodies, including portions of the Delaware River, Chester Creek and Ridley Creek. As part of this evaluation, environmentally sensitive areas within the study area need to be identified so that appropriate considerations can be made to reduce combined sewer overflows to these areas.

Sensitive Areas are defined by the United States Environmental Protection Agency (USEPA) Federal Register Combined Sewer Overflow (CSO) Control Policy and the US EPA Guidance for Long Term Control Plan as follows:

- Outstanding National Resource Waters (ONRW)
- National Marine Sanctuaries
- Waters with threatened or endangered species and their habitat
- Waters with primary contact recreation (i.e. beaches, boat ramps, boat launches, etc.)
- Public drinking water intakes or their designated protection areas
- Shellfish beds

USEPA requirements indicate that sensitive areas are given the highest priority during the development of technical alternatives.

This letter is being submitted to your agency as a formal request for information that your agency may have on sensitive areas within Delaware County, PA. Specifically, we are interested in sensitive areas located within the area of study as shown in GREEN on the attached map. If portions of the study area meet the above sensitive area criteria, we request that you provide the following information:

- Complete list of identified Sensitive Areas;
- Narrative description of how the sensitive area criteria listed above applies to the study area;
- Map of specific locations within our study area identifying the specific sensitive areas; and
- Any additional information you deem appropriate.

DELCORA is under a Consent Decree to submit this study to USEPA in February 2016. In order to meet project milestones, we respectfully request you provide a response within 30 days of receipt of this letter, no later than November 23, 2015. We appreciate your cooperation and assistance in completing this study. Should you need any additional information, please feel free to contact me at (215) 553-7919 or Julia Spicher at (215) 553-7926.

Public Survey Tally Sheet

CSO Long Term Control Plan
Delaware County Regional Water Quality Control Authority
River and Creeks Use Survey

The Delaware River, Chester Creek and Ridley Creek provide enjoyment through many recreational activities (i.e. boating, fishing). The Delaware County Regional Water Quality Control Authority (DELCORA) is committed to enhancing the quality of the River and Creeks to support these uses. To assist in planning water quality improvements, please let us know how you use the Delaware River, Chester Creek and Ridley Creek by completing this survey. You can also go online to www.DELCORA.org and click on River and Creeks Use Survey to complete the survey. This survey only pertains to specific areas along the Delaware River, Chester Creek and Ridley Creek as identified by the green area of interest on the attached map (see reverse side). Please fill out only one (1) survey per household. Please return survey in the enclosed self-addressed envelope by December 18, 2015.

1. Do you or anyone in your household use the Delaware River, Chester Creek and/or Ridley Creek for any recreational activities (i.e. boating, swimming, fishing etc)?

   YES | 72 | NO | 421 | (If no, skip questions 2 and 3)

2. Please check the appropriate water activities and how frequently you or members of your household participate in these activities along the Delaware River, Chester Creek and Ridley Creek, focusing only in the area indicated in GREEN on the map.4Participation of water activities along the river or creeks outside the green area should not be included.

Activities															
	Delaware River					***Chester Creek***					***Ridley Creek***				
	Frequency					Frequency					Frequency				
	Daily	1x week	1x month	1x year	Never	Daily	1x week	1x month	1x year	Never	Daily	1x week	1x month	1x year	Never

DELCORA CSO LTCPU - Applicable Water Quality Standards

Rev: 12-18-2015

Parameter	Source of Standard	Applicable Water Body	WQS Type	Water Quality Standard To Use	Standard Criterion (DRBC Zone 4 WQRs) *Applies to Delaware & Tidal Portions of Chester & Ridley*	Standard Criterion (25 PA Code Ch. 93 WQS, 93.7 Table 3 for TSF, WWF, MF & WC Critical Use Designations) *Applies to Delaware, Chester, Ridley*	Freshwater Objectives (DRBC WQRs Table 5 - Stream Quality Objectives for Toxic Pollutants for the Protection of Aquatic Life) *Applies to Delaware & Tidal Portions of Chester & Ridley*		Freshwater Objectives (DRBC WQRs Table 6 - Stream Quality Objectives for Carcinogens) *Applies to Delaware & Tidal Portions of Chester & Ridley*		Freshwater Objectives (DRBC WQRs Table 7 - Stream Quality Objectives for Systemic Toxicants) *Applies to Delaware & Tidal Portions of Chester & Ridley*		Fish & Aquatic Life Criteria (25 PA Code Ch. 93 WQS, 93.8c, Table 5) *Applies to Delaware, Chester, Ridley*		Human Criteria (25 PA Code Ch. 93 WQS, 93.8c, Table 5) *Applies to Delaware, Chester, Ridley*	US EPA National *Recommended* Water Quality Criteria Aquatic Life Criteria Table *Applies to Delaware, Chester, Ridley*		Units	Notes	Parameter
							Acute	Chronic	Fish & Water Ingestion	Fish Ingestion Only	Fish & Water Ingestion	Fish Ingestion Only	Criteria Continuous Concentrations	Criteria Maximum Concentrations	Health Criteria	Acute Criteria Maximum Concentration (CMC)	Chronic Criteria Continuous Concentration (CCC)			
Alkalinity	DRBC WQRs - for Zone 4 / PA Code (WWF, MF, TSF)	**Delaware River, Chester Creek, Ridley Creek**	**Minimum**	**20**	20	20	---	---	---	---	---	---	---	---	---	---	20	mg/L as $CaCO_3$	Can eliminate from POCs since it is naturally occurring	Alkalinity
Alkalinity	DRBC WQRs - for Zone 4	**Delaware River**	**Maximum**	**120**	120		---	---	---	---	---	---	---	---	---	---	---	mg/L as $CaCO_3$	Can eliminate from POCs since it is naturally occurring	Alkalinity
Alkalinity	DRBC WQRs - for Zone 4	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum**	**120**	120		---	---	---	---	---	---	---	---	---	---	---	mg/L as $CaCO_3$	Can eliminate from POCs since it is naturally occurring	Alkalinity
Aluminum	DRBC WQRs - Table 5 / PA Code - Table 5	**Delaware River, Chester Creek, Ridley Creek**	**Acute Maximum**	**750**	---	---	750	87	---	---	---	---	---	750	---	750	87	µg/L	Total recoverable, restricted to pH 6.5 - 9	Aluminum
Aluminum	DRBC WQRs - Table 5	**Delaware River**	**Chronic Maximum**	**87**	---	---	750	**87**	---	---	---	---	---	750	---	750	87	µg/L	Total recoverable, restricted to pH 6.5 - 9	Aluminum
Aluminum	DRBC WQRs - Table 5	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Chronic Maximum**	**87**	---	---	750	**87**	---	---	---	---	---	750	---	750	87	µg/L	Total recoverable, restricted to pH 6.5 - 9	Aluminum
Ammonia	PA Code (WWF, MF, TSF)	**Delaware River, Chester Creek, Ridley Creek**	**Maximum**	**$(NH_3 - N) \times (\log^{-1}[pK_T - pH] + 1)$**	---	$(NH_3 - N) \times (\log^{-1}[pK_T - pH] + 1)$	---	---	---	---	---	---	---	---	---	---	---	mg/L	pH dependent	Ammonia
Anthracene	DRBC WQRs - Table 7 / PA Code - Table 5	**Delaware River**	**Maximum**	**8,300**	---	---	---	---	---	---	8,300	40,000	---	---	8,300	---	---	µg/L		Anthracene
Anthracene	DRBC WQRs - Table 7	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum**	**8,300**	---	---	---	---	---	---	8,300	40,000	---	---	8,300	---	---	µg/L		Anthracene
Antimony	PA Code 25 - 93.8c, Table 5	**Chester Creek upstream of OF#20, & Ridley Creek upstream from OF#18**	**Acute Maximum**	**1,100**	---	---	---	---	---	---	5.6	640	220	1,100	5.6	---	---	µg/L		Antimony
Antimony	PA Code 25 - 93.8c, Table 5	**Chester Creek upstream of OF#20, & Ridley Creek upstream from OF#18**	**Chronic Maximum**	**200**	---	---	---	---	---	---	5.6	640	220	1,100	5.6	---	---	µg/L		Antimony
Antimony	DRBC WQRs - Table 7 / PA Code - Table 5	**Delaware River**	**Maximum**	**5.6**	---	---	---	---	---	---	5.6	640	220	1,100	5.6	---	---	µg/L		Antimony
Antimony	DRBC WQRs - Table 7	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum**	**5.6**	---	---	---	---	---	---	5.6	640	220	1,100	5.6	---	---	µg/L		Antimony
Arsenic (trivalent) (As III)	DRBC WQRs - Table 5 / PA Code - Table 5	**Chester Creek, Ridley Creek, Delaware Upstream of RM 81.8**	**Acute Maximum**	**340**	---	---	340	150	---	---	---	---	150	340	10	340	150	µg/L	Dissolved criteria	Arsenic (trivalent) (As III)
Arsenic (trivalent) (As III)	DRBC WQRs - Table 5 / PA Code - Table 5	**Chester Creek, Ridley Creek, Delaware Upstream of RM 81.8**	**Chronic Maximum**	**150**	---	---	340	150	---	---	---	---	150	340	10	340	150	µg/L	Dissolved criteria	Arsenic (trivalent) (As III)
Arsenic (trivalent) (As III)	PA Code 25 - 93.8c, Table 5	**Delaware River Downstream of RM 81.8**	**Maximum**	**10**	---	---	340	150	---	---	---	---	150	340	10	340	150	µg/L	Dissolved criteria	Arsenic (trivalent) (As III)
Bacteria - Enterococcus (Above R.M. 81.8)	DRBC WQRs - for Zone 4	**Delaware River Upstream of RM 81.8**	**Maximum Geometric Average**	**88**	88	---	---	---	---	---	---	---	---	---	---	---	---	CFU/100 mL		Bacteria - Enterococcus (Above R.M. 81.8)
Bacteria - Enterococcus (Below R.M. 81.8)	DRBC WQRs - for Zone 4	**Delaware River Downstream of RM 81.8**	**Maximum Geometric Average**	**33**	33	---	---	---	---	---	---	---	---	---	---	---	---	CFU/100 mL		Bacteria - Enterococcus (Below R.M. 81.8)
Bacteria - Enterococcus	DRBC WQRs - for Zone 4	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum Geometric Average**	**88**	88	---	---	---	---	---	---	---	---	---	---	---	---	CFU/100 mL		Bacteria - Enterococcus (Above R.M. 81.8)
Bacteria - Fecal Coliform (Above R.M. 81.8)	DRBC WQRs - for Zone 4	**Delaware River Upstream of RM 81.8**	**Maximum Geometric Average**	**770**	770	---	---	---	---	---	---	---	---	---	---	---	---	CFU/100 mL		Bacteria - Fecal Coliform (Above R.M. 81.8)

Parameter	Source of Standard	Applicable Water Body	WQS Type	Water Quality Standard To Use	Standard Criterion (DRBC Zone 4 WQRs) *Applies to Delaware & Tidal Portions of Chester & Ridley*	Standard Criterion (25 PA Code Ch. 93 WQS, 93.7 Table 3 for TSF, WWF, MF & WC Critical Use Designations) *Applies to Delaware, Chester, Ridley*	Freshwater Objectives (DRBC WQRs Table 5 - Stream Quality Objectives for Toxic Pollutants for the Protection of Aquatic Life) *Applies to Delaware & Tidal Portions of Chester & Ridley*		Freshwater Objectives (DRBC WQRs Table 6 - Stream Quality Objectives for Carcinogens) *Applies to Delaware & Tidal Portions of Chester & Ridley*		Freshwater Objectives (DRBC WQRs Table 7 - Stream Quality Objectives for Systemic Toxicants) *Applies to Delaware & Tidal Portions of Chester & Ridley*		Fish & Aquatic Life Criteria (25 PA Code Ch. 93 WQS, 93.8c, Table 5) *Applies to Delaware, Chester, Ridley*		Human Criteria (25 PA Code Ch. 93 WQS, 93.8c, Table 5) *Applies to Delaware, Chester, Ridley*	US EPA National *Recommended* Water Quality Criteria Aquatic Life Criteria Table *Applies to Delaware, Chester, Ridley*		Units	Notes	Parameter
							Acute	Chronic	Fish & Water Ingestion	Fish Ingestion Only	Fish & Water Ingestion	Fish Ingestion Only	Criteria Continuous Concentrations	Criteria Maximum Concentrations	Health Criteria	Acute Criteria Maximum Concentration (CMC)	Chronic Criteria Continuous Concentration (CCC)			
Bacteria - Fecal Coliform (Below R.M. 81.8)	DRBC WQRs - for Zone 4	**Delaware River Downstream of RM 81.8**	**Maximum Geometric Average**	**200**	200	---	---	---	---	---	---	---	---	---	---	---	---	---	CFU/100 mL	DRBC WQRs and PA Code PA Code for WC Critical Use agree from May 1 - Sept 30, but PA Code of 2000 CFU/100 mL from Oct. 1 - April 30 for WC exceeds that allowed by DRBC Zone 4.	Bacteria - Fecal Coliform (Below R.M. 81.8)
Bacteria - Fecal Coliform	DRBC WQRs - for Zone 4	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum Geometric Average**	**770**	770	---	---	---	---	---	---	---	---	---	---	---	---	---	CFU/100 mL		Bacteria - Fecal Coliform (Above R.M. 81.8)
Barium	PA Code 25 - 93.8c, Table 5	**Chester Creek, Ridley Creek, Delaware Upstream of RM 81.8**	**Acute Maximum**	**21,000**			---	---	---	---	---	---	4,100	21,000	2,400			µg/L		Barium
Barium	PA Code 25 - 93.8c, Table 5	**Chester Creek, Ridley Creek, Delaware Upstream of RM 81.8**	**Chronic Maximum**	**4,100**			---	---	---	---	---	---	4,100	21,000	2,400			µg/L		Barium
Barium	PA Code 25 - 93.8c, Table 5	**Delaware River Downstream of RM 81.8**	**Maximum**	**2,400**			---	---	---	---	---	---	4,100	21,000	2,400			µg/L		Barium
Benzene	PA Code 25 - 93.8c, Table 5	**Chester Creek upstream of OF#20, & Ridley Creek upstream from OF#18**	**Acute Maximum**	**640**	---	---	---	---	0.61	14	---	3,100	130	640	1.2			µg/L		Benzene
Benzene	PA Code 25 - 93.8c, Table 5	**Chester Creek upstream of OF#20, & Ridley Creek upstream from OF#18**	**Chronic Maximum**	**130**	---	---	---	---	0.61	14	---	3,100	130	640	1.2			µg/L		Benzene
Benzene	DRBC WQRs - Table 6	**Delaware River Upstream of RM 81.8**	**Maximum**	**14**	---	---	---	---	0.61	14	---	3,100	130	640	1.2			µg/L		Benzene
Benzene	DRBC WQRs - Table 6	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum**	**14**	---	---	---	---	0.61	14	---	3,100	130	640	1.2			µg/L		Benzene
Benzene	DRBC WQRs - Table 6	**Delaware River Downstream of RM 81.8**	**Maximum**	**0.61**	---	---	---	---	0.61	14	---	3,100	130	640	1.2			µg/L		Benzene
benzo (a) anthracene	PA Code 25 - 93.8c, Table 5	**Chester Creek, Ridley Creek, Delaware Upstream of RM 81.8**	**Acute Maximum**	**0.5**	---	---	---	---	---	---	---	---	0.1	0.5	0.0038			µg/L		benzo (a) anthracene
benzo (a) anthracene	PA Code 25 - 93.8c, Table 5	**Chester Creek, Ridley Creek, Delaware Upstream of RM 81.8**	**Chronic Maximum**	**0.1**	---	---	---	---	---	---	---	---	0.1	0.5	0.0038			µg/L		benzo (a) anthracene
benzo (a) anthracene	PA Code 25 - 93.8c, Table 5	**Delaware River Downstream of RM 81.8**	**Maximum**	**0.0038**	---	---	---	---	---	---	---	---	0.1	0.5	0.0038			µg/L		benzo (a) anthracene
Beryllium	DRBC WQRs - Table 7	**Delaware River**	**Maximum**	**420**							---	420	---	---				µg/L		Beryllium
Beryllium	DRBC WQRs - Table 7	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum**	**420**							---	420	---	---				µg/L		Beryllium
Biological Oxygen Demand (BOD)	No Standard						---	---	---	---	---	---	---	---	---					Biological Oxygen Demand (BOD)
Bis (2-ethylhexyl) phthalate	PA Code 25 - 93.8c, Table 5	**Chester Creek upstream of OF#20, & Ridley Creek upstream from OF#18**	**Acute Maximum**	**4,500**	---	---	---	---	1.2	2.2	---	620	910	4,500	1.2			µg/L		Bis (2-ethylhexyl) phthalate
Bis (2-ethylhexyl) phthalate	PA Code 25 - 93.8c, Table 5	**Chester Creek upstream of OF#20, & Ridley Creek upstream from OF#18**	**Chronic Maximum**	**910**	---	---	---	---	1.2	2.2	---	620	910	4,500	1.2			µg/L		Bis (2-ethylhexyl) phthalate
Bis (2-ethylhexyl) phthalate	DRBC WQRs - Table 6	**Delaware River Upstream of RM 81.8**	**Maximum**	**2.2**	---	---	---	---	1.2	2.2	---	620	910	4,500	1.2			µg/L		Bis (2-ethylhexyl) phthalate
Bis (2-ethylhexyl) phthalate	DRBC WQRs - Table 6	**Chester Creek - Mouth to OF#20 (Tidal limit), & Ridley Creek - Mouth to OF#18 (Tidal limit)**	**Maximum**	**2.2**	---	---	---	---	1.2	2.2	---	620	910	4,500	1.2			µg/L		Bis (2-ethylhexyl) phthalate
Bis (2-ethylhexyl) phthalate	DRBC WQRs - Table 6	**Delaware River Downstream of RM 81.8**	**Maximum**	**1.2**	---	---	---	---	1.2	2.2	---	620	910	4,500	1.2			µg/L		Bis (2-ethylhexyl) phthalate
Bromodichloromethane (aka Dichlorobromomethane)	DRBC WQRs - Table 6	**Delaware River Upstream of RM 81.8**	**Maximum**	**17**					0.55	17	680	---	---	---	0.55			µg/L		Bromodichloromethane (aka Dichlorobromomethane)

(A) Temperature shall not exceed 5 °F (2.8 °C) above the average 24-hour temperature gradient displayed during the 1961-66 period, or a maximum of 86 °F (30.0 °C) - whichever is less.

(B) Using M.B.A.S assay, with a maximum 30-day average of 1.0 mg/L.

(C) Unless exceeded due to natural conditions.

NOTES:

DRBC standards in their WQRs are referred to as "Stream Quality Objectives". DRBC's Stream Quality Objectives have primacy over the PA Code standards for the Delaware River.

PA CODE refers to the standards as "Water Quality Standards".

Ridley Creek is "TSF & MF" Critical Use from Rt. 320 Bridge upstream to the Media Water Intake. Ridley Creek is "WWF & MF" downstream from the Rt. 320 Bridge to mouth.

Chester Creek has a "TSF" Critical Use designation as well, but this is well upstream of the CSO discharge furthest upstream on Chester Creek and does not apply for this analysis.

Certificate of Analysis

Project Name:	**Annual Stormwaters**	Workorder:	**2031197**
Purchase Order:		Workorder ID:	**CSO Sampling**

Dear Mike Krause:

Enclosed are the analytical results for samples received by the laboratory on Thursday, September 25, 2014.

The ALS Environmental laboratory in Middletown, Pennsylvania is a National Environmental Laboratory Accreditation Program (NELAP) accredited laboratory and as such, certifies that all applicable test results meet the requirements of NELAP.

If you have any questions regarding this certificate of analysis, please contact Mrs. Vanessa N Badman (Project Coordinator) at (717) 944-5541.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program and any applicable state requirements. The test results meet requirements of the current NELAP standards or state requirements, where applicable. For a specific list of accredited analytes, refer to the certifications section of the ALS website at www.alsglobal.com/en/Our-Services/Life-Sciences/Environmental/Downloads.

This laboratory report may not be reproduced, except in full, without the written approval of ALS Environmental.

2031197006	Sun & Hancock	Water	9/25/2014 09:50	9/25/2014 16:10	Mike Krause

Notes

-- Samples collected by ALS personnel are done so in accordance with the procedures set forth in the ALS Field Sampling Plan (20 - Field Services Sampling Plan).
-- All Waste Water analyses comply with methodology requirements of 40 CFR Part 136.
-- All Drinking Water analyses comply with methodology requirements of 40 CFR Part 141.
-- Unless otherwise noted, all quantitative results for soils are reported on a dry weight basis.
-- The Chain of Custody document is included as part of this report.
-- All Library Search analytes should be regarded as tentative identifications based on the presumptive evidence of the mass spectra. Concentrations reported are estimated values.
-- Parameters identified as "analyze immediately" require analysis within 15 minutes of collection. Any "analyze immediately" parameters not listed under the header "Field Parameters" are preformed in the laboratory and are therefore analyzed out of hold time.
-- Method references listed on this report beginning with the prefix “S” followed by a method number (such as S2310B-97) refer to methods from “Standard Methods for the Examination of Water and Wastewater”.

Standard Acronyms/Flags

J	Indicates an estimated value between the Method Detection Limit (MDL) and the Practical Quantitation Limit (PQL) for the analyte
U	Indicates that the analyte was Not Detected (ND)
N	Indicates presumptive evidence of the presence of a compound
MDL	Method Detection Limit
PQL	Practical Quantitation Limit
RDL	Reporting Detection Limit
ND	Not Detected - indicates that the analyte was Not Detected at the RDL
Cntr	Analysis was performed using this container
RegLmt	Regulatory Limit
LCS	Laboratory Control Sample
MS	Matrix Spike
MSD	Matrix Spike Duplicate
DUP	Sample Duplicate
%Rec	Percent Recovery
RPD	Relative Percent Difference
LOD	DoD Limit of Detection
LOQ	DoD Limit of Quantitation
DL	DoD Detection Limit

Received Date/Time/Temp 10/31/12 07:45pm 1.1 C Iced (Y/N): Y

Parameter	Method	Result	RLs	Test Date, Time, Analyst
GENERAL CHEMISTRY				
AMMONIA NITROGEN AS N	SM 4500NH3 B,D	1.79 mg/l	0.100 mg/l	11/08/12 03:55PM MRP
PHOSPHORUS TOTAL	SM 4500P B.5 E	0.813 mg/l	0.0600 mg/l	11/01/12 09:00AM NM
TOTAL SUSPENDED SOLIDS	SM 2540D	47.0 mg/l	2.00 mg/l	11/01/12 12:21PM LMB

Notes:

A result of "ND" indicates that the analyte tested was either not detected or the concentration was below the RLs.
Definitions: NEG=negative; POS=positive; COL=colonies; RLs=laboratory reporting limits; L/A=laboratory accident; TNTC= Too numerous to count; pres=presumptive
A result marked with "DRY" indicates that the result was calculated and reported on a dry weight basis.
MCL= EPA recommended "maximum contaminant level", PLs = Customer-specific permit limits.
The test results meet all requirements of NELAC unless otherwise specified.
The report shall not be reproduced except in full without the written consent of the laboratory.
Unless otherwise specified, the Environmental and Food Chemistry testing except Field Parameters were performed by QC Inc. located at 1205 Industrial Blvd., Southampton, PA 18966; Pharmaceutical, Dairy and Food Microbiological tests were performed by QC Inc. located at 702 Electronic Dr., Horsham, PA 19044.
QCL Accreditations: Southampton Div: EPA ID PA00018; NELAP ID's: PA 09-00131, NJ PA166, NY 11223

Certificate of Analysis

Project Name:	**2015-LOWER DELAWARE TESTING**	Workorder:	**2107040**
Purchase Order:		Workorder ID:	**CSO WW LTCP**

Dear Ms. Fitzgerald:

Enclosed are the analytical results for samples received by the laboratory on Tuesday, November 10, 2015.

The ALS Environmental laboratory in Middletown, Pennsylvania is a National Environmental Laboratory Accreditation Program (NELAP) accredited laboratory and as such, certifies that all applicable test results meet the requirements of NELAP.

If you have any questions regarding this certificate of analysis, please contact Mr. Brad W Kintzer (Project Coordinator) at (717) 944-5541.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program and any applicable state requirements. The test results meet requirements of the current NELAP standards or state requirements, where applicable. For a specific list of accredited analytes, refer to the certifications section of the ALS website at www.alsglobal.com/en/Our-Services/Life-Sciences/Environmental/Downloads.

This laboratory report may not be reproduced, except in full, without the written approval of ALS Environmental.

ALS Spring City: 10 Riverside Drive, Spring City, PA 19475 610-948-4903

CC: Mr. Ray Rios , Mr. Mike Krause

This page is included as part of the Analytical Report and must be retained as a permanent record thereof.

Brad W. Kintzer

SAMPLE SUMMARY

Workorder: 2107040 CSO WW LTCP

Lab ID	Sample ID	Matrix	Date Collected	Date Received	Collected By
2107040001	CPS/EPS1 (74/26)	Water	11/10/2015 05:00	11/10/2015 12:05	Collected by Client

Notes

-- Samples collected by ALS personnel are done so in accordance with the procedures set forth in the ALS Field Sampling Plan (20 - Field Services Sampling Plan).
-- All Waste Water analyses comply with methodology requirements of 40 CFR Part 136.
-- All Drinking Water analyses comply with methodology requirements of 40 CFR Part 141.
-- Unless otherwise noted, all quantitative results for soils are reported on a dry weight basis.
-- The Chain of Custody document is included as part of this report.
-- All Library Search analytes should be regarded as tentative identifications based on the presumptive evidence of the mass spectra. Concentrations reported are estimated values.
-- Parameters identified as "analyze immediately" require analysis within 15 minutes of collection. Any "analyze immediately" parameters not listed under the header "Field Parameters" are preformed in the laboratory and are therefore analyzed out of hold time.
-- Method references listed on this report beginning with the prefix “S” followed by a method number (such as S2310B-97) refer to methods from “Standard Methods for the Examination of Water and Wastewater”.

Standard Acronyms/Flags

J	Indicates an estimated value between the Method Detection Limit (MDL) and the Practical Quantitation Limit (PQL) for the analyte
U	Indicates that the analyte was Not Detected (ND)
N	Indicates presumptive evidence of the presence of a compound
MDL	Method Detection Limit
PQL	Practical Quantitation Limit
RDL	Reporting Detection Limit
ND	Not Detected - indicates that the analyte was Not Detected at the RDL
Cntr	Analysis was performed using this container
RegLmt	Regulatory Limit
LCS	Laboratory Control Sample
MS	Matrix Spike
MSD	Matrix Spike Duplicate
DUP	Sample Duplicate
%Rec	Percent Recovery
RPD	Relative Percent Difference
LOD	DoD Limit of Detection
LOQ	DoD Limit of Quantitation
DL	DoD Detection Limit
I	Indicates reported value is greater than or equal to the Method Detection Limit (MDL) but less than the Report Detection Limit (RDL)
(S)	Surrogate Compound
NC	Not Calculated
*	Result outside of QC limits

PROJECT SUMMARY

Workorder: 2107040 CSO WW LTCP

Workorder Comments

See attached subcontracted radiological results from ALS-Ft. Collins. VLF 12/1/15

Sample Comments

Lab ID: 2107040001 **Sample ID:** CPS/EPS1 (74/26) **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Re: ALS Workorder: 1511233
Project Name:
Project Number: 2107040

Dear Mr. Kintzer:

One water sample was received from ALS Environmental, on 11/12/2015. The sample was scheduled for the following analysis:

Gross Alpha/Beta

The results for these analyses are contained in the enclosed reports.

The data contained in the following report have been reviewed and approved by the personnel listed below. In addition, ALS certifies that the analyses reported herein are true, complete and correct within the limits of the methods employed.

Thank you for your confidence in ALS Environmental. Should you have any questions, please call.

Sincerely,

ALS Environmental
Jeff R. Kujawa
Project Manager

ALS Environmental – Fort Collins is accredited by the following accreditation bodies for various testing scopes in accordance with requirements of each accreditation body. All testing is performed under the laboratory management system, which is maintained to meet these requirement and regulations. Please contact the laboratory or accreditation body for the current scope testing parameters.

ALS Environmental

1511233

Gross Alpha/Beta:
The samples were analyzed for gross alpha and beta activity by gas flow proportional counting according to the current revision of SOP 724. Gross alpha results are referenced to ^{241}Am. Gross beta results are referenced to $^{90}Sr/Y$.

All acceptance criteria were met.

Analyses	Result	Qual	Report Limit	Units	Dilution Factor	Date Analyzed

Explanation of Qualifiers

Radiochemistry:

U or ND - Result is less than the sample specific MDC.

Y1 - Chemical Yield is in control at 100-110%. Quantitative yield is assumed.

Y2 - Chemical Yield outside default limits.

W - DER is greater than Warning Limit of 1.42

* - Aliquot Basis is 'As Received' while the Report Basis is 'Dry Weight',

- Aliquot Basis is 'Dry Weight' while the Report Basis is 'As Received',

G - Sample density differs by more than 15% of LCS density.

D - DER is greater than Control Limit

M - Requested MDC not met.

LT - Result is less than requested MDC but greater than achieved MDC.

M3 - The requested MDC was not met, but the reported activity is greater than the reported MDC.

L - LCS Recovery below lower control limit.

H - LCS Recovery above upper control limit.

P - LCS, Matrix Spike Recovery within control limits.

N - Matrix Spike Recovery outside control limits

NC - Not Calculated for duplicate results less than 5 times MDC

B - Analyte concentration greater than MDC.

B3 - Analyte concentration greater than MDC but less than Requested MDC.

Inorganics:

B - Result is less than the requested reporting limit but greater than the instrument method detection limit (MDL).

U or ND - Indicates that the compound was analyzed for but not detected.

E - The reported value is estimated because of the presence of interference. An explanatory note may be included in the narrative.

M - Duplicate injection precision was not met.

N - Spiked sample recovery not within control limits. A post spike is analyzed for all ICP analyses when the matrix spike and or spike duplicate fail and the native sample concentration is less than four times the spike added concentration.

Z - Spiked recovery not within control limits. An explanatory note may be included in the narrative.

* - Duplicate analysis (relative percent difference) not within control limits.

S - SAR value is estimated as one or more analytes used in the calculation were not detected above the detection limit.

Organics:

U or ND - Indicates that the compound was analyzed for but not detected.

B - Analyte is detected in the associated method blank as well as in the sample. It indicates probable blank contamination and warns the data user.

E - Analyte concentration exceeds the upper level of the calibration range.

J - Estimated value. The result is less than the reporting limit but greater than the instrument method detection limit (MDL).

A - A tentatively identified compound is a suspected aldol-condensation product.

X - The analyte was diluted below an accurate quantitation level.

* - The spike recovery is equal to or outside the control criteria used.

+ - The relative percent difference (RPD) equals or exceeds the control criteria.

G - A pattern resembling gasoline was detected in this sample.

D - A pattern resembling diesel was detected in this sample.

M - A pattern resembling motor oil was detected in this sample.

C - A pattern resembling crude oil was detected in this sample.

4 - A pattern resembling JP-4 was detected in this sample.

5 - A pattern resembling JP-5 was detected in this sample.

H - Indicates that the fuel pattern was in the heavier end of the retention time window for the analyte of interest.

L - Indicates that the fuel pattern was in the lighter end of the retention time window for the analyte of interest.

Z - This flag indicates that a significant fraction of the reported result did not resemble the patterns of any of the following petroleum hydrocarbon products:
- gasoline
- JP-8
- diesel
- mineral spirits
- motor oil
- Stoddard solvent
- bunker C

Certificate of Analysis

Project Name:	**2015-LOWER DELAWARE TESTING**	Workorder:	**2109302**
Purchase Order:		Workorder ID:	**2015-LOWER DELAWARE TESTING**

Dear Ms. Fitzgerald:

Enclosed are the analytical results for samples received by the laboratory on Thursday, November 19, 2015.

The ALS Environmental laboratory in Middletown, Pennsylvania is a National Environmental Laboratory Accreditation Program (NELAP) accredited laboratory and as such, certifies that all applicable test results meet the requirements of NELAP.

If you have any questions regarding this certificate of analysis, please contact Mr. Brad W Kintzer (Project Coordinator) at (717) 944-5541.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program and any applicable state requirements. The test results meet requirements of the current NELAP standards or state requirements, where applicable. For a specific list of accredited analytes, refer to the certifications section of the ALS website at www.alsglobal.com/en/Our-Services/Life-Sciences/Environmental/Downloads.

This laboratory report may not be reproduced, except in full, without the written approval of ALS Environmental.

ALS Spring City: 10 Riverside Drive, Spring City, PA 19475 610-948-4903

CC: Mr. Ray Rios , Mr. Mike Krause

This page is included as part of the Analytical Report and must be retained as a permanent record thereof.

Brad W. Kintzer

Notes

-- Samples collected by ALS personnel are done so in accordance with the procedures set forth in the ALS Field Sampling Plan (20 - Field Services Sampling Plan).
-- All Waste Water analyses comply with methodology requirements of 40 CFR Part 136.
-- All Drinking Water analyses comply with methodology requirements of 40 CFR Part 141.
-- Unless otherwise noted, all quantitative results for soils are reported on a dry weight basis.
-- The Chain of Custody document is included as part of this report.
-- All Library Search analytes should be regarded as tentative identifications based on the presumptive evidence of the mass spectra. Concentrations reported are estimated values.
-- Parameters identified as "analyze immediately" require analysis within 15 minutes of collection. Any "analyze immediately" parameters not listed under the header "Field Parameters" are preformed in the laboratory and are therefore analyzed out of hold time.
-- Method references listed on this report beginning with the prefix “S” followed by a method number (such as S2310B-97) refer to methods from “Standard Methods for the Examination of Water and Wastewater”.

Standard Acronyms/Flags

J	Indicates an estimated value between the Method Detection Limit (MDL) and the Practical Quantitation Limit (PQL) for the analyte
U	Indicates that the analyte was Not Detected (ND)
N	Indicates presumptive evidence of the presence of a compound
MDL	Method Detection Limit
PQL	Practical Quantitation Limit
RDL	Reporting Detection Limit
ND	Not Detected - indicates that the analyte was Not Detected at the RDL
Cntr	Analysis was performed using this container
RegLmt	Regulatory Limit
LCS	Laboratory Control Sample
MS	Matrix Spike
MSD	Matrix Spike Duplicate
DUP	Sample Duplicate
%Rec	Percent Recovery
RPD	Relative Percent Difference
LOD	DoD Limit of Detection
LOQ	DoD Limit of Quantitation
DL	DoD Detection Limit
I	Indicates reported value is greater than or equal to the Method Detection Limit (MDL) but less than the Report Detection Limit (RDL)
(S)	Surrogate Compound
NC	Not Calculated
*	Result outside of QC limits

Sample Comments

Lab ID: 2109302001 **Sample ID:** CPS/EPS1 (72/28) **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Lab ID: 2109302002 **Sample ID:** CPS1 **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Lab ID: 2109302003 **Sample ID:** 14th **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Lab ID: 2109302004 **Sample ID:** Sun **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Mr. Brad W Kintzer
Project Coordinator

PARAMETER QUALIFIERS

Lab ID	#	Sample ID	Analytical Method	Analyte
2109302001	1	CPS/EPS1 (72/28)	S5210B-11	Biochemical Oxygen Demand
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.26 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302001	2	CPS/EPS1 (72/28)	S5210B-11	Carbonaceous BOD
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.22 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302001	3	CPS/EPS1 (72/28)	S2540D-11	Total Suspended Solids
This sample was analyzed after the 7 day holding time for total suspended solids had expired.				
2109302002	1	CPS1	S5210B-11	Biochemical Oxygen Demand
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.26 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302002	2	CPS1	S5210B-11	Carbonaceous BOD
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.22 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302002	3	CPS1	S2540D-11	Total Suspended Solids
This sample was analyzed after the 7 day holding time for total suspended solids had expired.				
2109302002	4	CPS1	EPA 608	Decachlorobiphenyls
The surrogate Decachlorobiphenyls for method EPA 608 was outside of control limits. The % Recovery was reported as 29.1 and the control limits were 30 to 150. This result was reported at a dilution of 1.				
2109302003	1	14th & Crozer	S5210B-11	Biochemical Oxygen Demand
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.26 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302003	2	14th & Crozer	S5210B-11	Carbonaceous BOD
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.22 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302003	3	14th & Crozer	S2540D-11	Total Suspended Solids
This sample was analyzed after the 7 day holding time for total suspended solids had expired.				
2109302004	1	Sun & Hancock	S5210B-11	Biochemical Oxygen Demand
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.26 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302004	2	Sun & Hancock	S5210B-11	Carbonaceous BOD
The dilution water blank associated with this analyte had a dissolved oxygen depletion of 0.22 mg/l. Criteria states that the depletion should be at a maximum 0.2 mg/l.				
2109302004	3	Sun & Hancock	S2540D-11	Total Suspended Solids
This sample was analyzed after the 7 day holding time for total suspended solids had expired.				
2109302004	4	Sun & Hancock	S4500NH3G-11	Total Kjeldahl Nitrogen
The recovery of the Matrix Spike (MS) associated to this analyte was outside of the established control limits.

Re: ALS Workorder: 1511447
Project Name:
Project Number: 2109302

Dear Mr. Kintzer:

Four water samples were received from ALS Environmental, on 11/24/2015. The samples were scheduled for the following analysis:

Gross Alpha/Beta

The results for these analyses are contained in the enclosed reports.

The data contained in the following report have been reviewed and approved by the personnel listed below. In addition, ALS certifies that the analyses reported herein are true, complete and correct within the limits of the methods employed.

Thank you for your confidence in ALS Environmental. Should you have any questions, please call.

Sincerely,

ALS Environmental
Jeff R. Kujawa
Project Manager

ALS Environmental – Fort Collins is accredited by the following accreditation bodies for various testing scopes in accordance with requirements of each accreditation body. All testing is performed under the laboratory management system, which is maintained to meet these requirement and regulations. Please contact the laboratory or accreditation body for the current scope testing parameters.

ALS Environmental – Fort Collins

ALS Environmental

1511451

Gross Alpha/Beta:
The sample was analyzed for gross alpha and beta activity by gas flow proportional counting according to the current revision of SOP 724. Gross alpha results are referenced to ^{241}Am. Gross beta results are referenced to $^{90}Sr/Y$.

All acceptance criteria were met.

After printing this label:
1. Use the 'Print' button on this page to print your label to your laser or inkjet printer.
2. Fold the printed page along the horizontal line.
3. Place label in shipping pouch and affix it to your shipment so that the barcode portion of the label can be read and scanned.

Warning: Use only the printed original label for shipping. Using a photocopy of this label for shipping purposes is fraudulent and could result in additional billing charges, along with the cancellation of your FedEx account number.
Use of this system constitutes your agreement to the service conditions in the current FedEx Service Guide, available on fedex.com.FedEx will not be responsible for any claim in excess of $100 per package,-whether the result of loss, damage, delay, non-delivery,misdelivery,or misinformation, unless you declare a higher value, pay an additional charge, document your actual loss and file a timely claim.Limitations found in the current FedEx Service Guide apply. Your right to recover from FedEx for any loss, including intrinsic value of the package, loss of sales, income interest, profit, attorney's fees, costs, and other forms of damage whether direct, incidental,consequential, or special is limited to the greater of $100 or the authorized declared value. Recovery cannot exceed actual documented loss.Maximum for items of extraordinary value is $1,000, e.g. jewelry, precious metals, negotiable instruments and other items listed in our ServiceGuide. Written claims must be filed within strict time limits, see current FedEx Service Guide.

Analyses	Result	Qual	Report Limit	Units	Dilution Factor	Date Analyzed

Explanation of Qualifiers

Radiochemistry:

U or ND - Result is less than the sample specific MDC.

Y1 - Chemical Yield is in control at 100-110%. Quantitative yield is assumed.

Y2 - Chemical Yield outside default limits.

W - DER is greater than Warning Limit of 1.42

" - Aliquot Basis is 'As Received' while the Report Basis is 'Dry Weight'.

- Aliquot Basis is 'Dry Weight' while the Report Basis is 'As Received'.

G - Sample density differs by more than 15% of LCS density.

D - DER is greater than Control Limit

M - Requested MDC not met.

LT - Result is less than requested MDC but greater than achieved MDC.

M3 - The requested MDC was not met, but the reported activity is greater than the reported MDC.

L - LCS Recovery below lower control limit.

H - LCS Recovery above upper control limit.

P - LCS, Matrix Spike Recovery within control limits.

N - Matrix Spike Recovery outside control limits

NC - Not Calculated for duplicate results less than 5 times MDC

B - Analyte concentration greater than MDC.

B3 - Analyte concentration greater than MDC but less than Requested MDC.

Inorganics:

B - Result is less than the requested reporting limit but greater than the instrument method detection limit (MDL).

U or ND - Indicates that the compound was analyzed for but not detected.

E - The reported value is estimated because of the presence of interference. An explanatory note may be included in the narrative.

M - Duplicate injection precision was not met.

N - Spiked sample recovery not within control limits. A post spike is analyzed for all ICP analyses when the matrix spike and or spike duplicate fail and the native sample concentration is less than four times the spike added concentration.

Z - Spiked recovery not within control limits. An explanatory note may be included in the narrative.

* - Duplicate analysis (relative percent difference) not within control limits.

S - SAR value is estimated as one or more analytes used in the calculation were not detected above the detection limit.

Organics:

U or ND - Indicates that the compound was analyzed for but not detected.

B - Analyte is detected in the associated method blank as well as in the sample. It indicates probable blank contamination and warns the data user.

E - Analyte concentration exceeds the upper level of the calibration range.

J - Estimated value. The result is less than the reporting limit but greater than the instrument method detection limit (MDL).

A - A tentatively identified compound is a suspected aldol-condensation product.

X - The analyte was diluted below an accurate quantitation level.

* - The spike recovery is equal to or outside the control criteria used.

+ - The relative percent difference (RPD) equals or exceeds the control criteria.

G - A pattern resembling gasoline was detected in this sample.

D - A pattern resembling diesel was detected in this sample.

M - A pattern resembling motor oil was detected in this sample.

C - A pattern resembling crude oil was detected in this sample.

4 - A pattern resembling JP-4 was detected in this sample.

5 - A pattern resembling JP-5 was detected in this sample.

H - Indicates that the fuel pattern was in the heavier end of the retention time window for the analyte of interest.

L - Indicates that the fuel pattern was in the lighter end of the retention time window for the analyte of interest.

Z - This flag indicates that a significant fraction of the reported result did not resemble the patterns of any of the following petroleum hydrocarbon products:
- gasoline
- JP-8
- diesel
- mineral spirits
- motor oil
- Stoddard solvent
- bunker C

Certificate of Analysis

Revised Report - 1/7/2016 6:17:18 AM - See workorder comment section for explanation

Project Name:	**2015-LOWER DELAWARE TESTING**	Workorder:	**2110770**
Purchase Order:		Workorder ID:	**2015-LOWER DELAWARE TESTING**

Dear Ms. Fitzgerald:

Enclosed are the analytical results for samples received by the laboratory on Tuesday, December 1, 2015.

The ALS Environmental laboratory in Middletown, Pennsylvania is a National Environmental Laboratory Accreditation Program (NELAP) accredited laboratory and as such, certifies that all applicable test results meet the requirements of NELAP.

If you have any questions regarding this certificate of analysis, please contact Mr. Brad W Kintzer (Project Coordinator) at (717) 944-5541.

Analyses were performed according to our laboratory's NELAP-approved quality assurance program and any applicable state requirements. The test results meet requirements of the current NELAP standards or state requirements, where applicable. For a specific list of accredited analytes, refer to the certifications section of the ALS website at www.alsglobal.com/en/Our-Services/Life-Sciences/Environmental/Downloads.

This laboratory report may not be reproduced, except in full, without the written approval of ALS Environmental.

Notes

-- Samples collected by ALS personnel are done so in accordance with the procedures set forth in the ALS Field Sampling Plan (20 - Field Services Sampling Plan).
-- All Waste Water analyses comply with methodology requirements of 40 CFR Part 136.
-- All Drinking Water analyses comply with methodology requirements of 40 CFR Part 141.
-- Unless otherwise noted, all quantitative results for soils are reported on a dry weight basis.
-- The Chain of Custody document is included as part of this report.
-- All Library Search analytes should be regarded as tentative identifications based on the presumptive evidence of the mass spectra. Concentrations reported are estimated values.
-- Parameters identified as "analyze immediately" require analysis within 15 minutes of collection. Any "analyze immediately" parameters not listed under the header "Field Parameters" are preformed in the laboratory and are therefore analyzed out of hold time.
-- Method references listed on this report beginning with the prefix “S” followed by a method number (such as S2310B-97) refer to methods from “Standard Methods for the Examination of Water and Wastewater”.

Standard Acronyms/Flags

J	Indicates an estimated value between the Method Detection Limit (MDL) and the Practical Quantitation Limit (PQL) for the analyte
U	Indicates that the analyte was Not Detected (ND)
N	Indicates presumptive evidence of the presence of a compound
MDL	Method Detection Limit
PQL	Practical Quantitation Limit
RDL	Reporting Detection Limit
ND	Not Detected - indicates that the analyte was Not Detected at the RDL
Cntr	Analysis was performed using this container
RegLmt	Regulatory Limit
LCS	Laboratory Control Sample
MS	Matrix Spike
MSD	Matrix Spike Duplicate
DUP	Sample Duplicate
%Rec	Percent Recovery
RPD	Relative Percent Difference
LOD	DoD Limit of Detection
LOQ	DoD Limit of Quantitation
DL	DoD Detection Limit
I	Indicates reported value is greater than or equal to the Method Detection Limit (MDL) but less than the Report Detection Limit (RDL)
(S)	Surrogate Compound
NC	Not Calculated
*	Result outside of QC limits

PROJECT SUMMARY

Workorder: 2110770 2015-LOWER DELAWARE TESTING

Workorder Comments

See attached subcontracted radiological results from ALS-Ft. Collins. VLF 12/23/15

This report was modified on 1/6/16 to add Total Nitogen to all samples. BWK

Sample Comments

Lab ID: 2110770001 **Sample ID:** CPS/EPS1 (72/28) LTCPWWCSO **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Lab ID: 2110770002 **Sample ID:** CPS1 **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Lab ID: 2110770003 **Sample ID:** 14th **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Lab ID: 2110770004 **Sample ID:** Sun **Sample Type:** SAMPLE

MBAS calculated as LAS molecular weight 342 g/mol.

The reporting limits for GCMS volatile analytes were raised due to the dilution of the sample caused by matrix.

Re: ALS Workorder: 1512056
Project Name:
Project Number: 2110770

Dear Mr. Kintzer:

Four water samples were received from ALS Environmental, on 12/3/2015. The samples were scheduled for the following analysis:

Gross Alpha/Beta

The results for these analyses are contained in the enclosed reports.

The data contained in the following report have been reviewed and approved by the personnel listed below. In addition, ALS certifies that the analyses reported herein are true, complete and correct within the limits of the methods employed.

Thank you for your confidence in ALS Environmental. Should you have any questions, please call.

Sincerely,

ALS Environmental
Jeff R. Kujawa
Project Manager

ALS Environmental – Fort Collins is accredited by the following accreditation bodies for various testing scopes in accordance with requirements of each accreditation body. All testing is performed under the laboratory management system, which is maintained to meet these requirement and regulations. Please contact the laboratory or accreditation body for the current scope testing parameters.

ALS Environmental – Fort Collins

ALS Environmental

1512056

Gross Alpha/Beta:
The samples were analyzed for gross alpha and beta activity by gas flow proportional counting according to the current revision of SOP 724. Gross alpha results are referenced to ^{241}Am. Gross beta results are referenced to $^{90}Sr/Y$.

All acceptance criteria were met.

After printing this label:
1. Use the 'Print' button on this page to print your label to your laser or inkjet printer.
2. Fold the printed page along the horizontal line.
3. Place label in shipping pouch and affix it to your shipment so that the barcode portion of the label can be read and scanned.

Warning: Use only the printed original label for shipping. Using a photocopy of this label for shipping purposes is fraudulent and could result in additional billing charges, along with the cancellation of your FedEx account number.
Use of this system constitutes your agreement to the service conditions in the current FedEx Service Guide, available on fedex.com.FedEx will not be responsible for any claim in excess of $100 per package, whether the result of loss, damage, delay, non-delivery,misdelivery,or misinformation, unless you declare a higher value, pay an additional charge, document your actual loss and file a timely claim.Limitations found in the current FedEx Service Guide apply. Your right to recover from FedEx for any loss, including intrinsic value of the package, loss of sales, income interest, profit, attorney's fees, costs, and other forms of damage whether direct, incidental,consequential, or special is limited to the greater of $100 or the authorized declared value. Recovery cannot exceed actual documented loss.Maximum for items of extraordinary value is $1,000, e.g. jewelry, precious metals, negotiable instruments and other items listed in our ServiceGuide. Written claims must be filed within strict time limits, see current FedEx Service Guide.

Analyses	Result	Qual	Report Limit	Units	Dilution Factor	Date Analyzed

Explanation of Qualifiers

Radiochemistry:

U or ND - Result is less than the sample specific MDC.

Y1 - Chemical Yield is in control at 100-110%. Quantitative yield is assumed.

Y2 - Chemical Yield outside default limits.

W - DER is greater than Warning Limit of 1.42

' - Aliquot Basis is 'As Received' while the Report Basis is 'Dry Weight'.

- Aliquot Basis is 'Dry Weight' while the Report Basis is 'As Received'.

G - Sample density differs by more than 15% of LCS density.

D - DER is greater than Control Limit

M - Requested MDC not met.

LT - Result is less than requested MDC but greater than achieved MDC.

M3 - The requested MDC was not met, but the reported activity is greater than the reported MDC.

L - LCS Recovery below lower control limit.

H - LCS Recovery above upper control limit.

P - LCS, Matrix Spike Recovery within control limits.

N - Matrix Spike Recovery outside control limits

NC - Not Calculated for duplicate results less than 5 times MDC

B - Analyte concentration greater than MDC.

B3 - Analyte concentration greater than MDC but less than Requested MDC.

Inorganics:

B - Result is less than the requested reporting limit but greater than the instrument method detection limit (MDL).

U or ND - Indicates that the compound was analyzed for but not detected.

E - The reported value is estimated because of the presence of interference. An explanatory note may be included in the narrative.

M - Duplicate injection precision was not met.

N - Spiked sample recovery not within control limits. A post spike is analyzed for all ICP analytes when the matrix spike and or spike duplicate fail and the native sample concentration is less than four times the spike added concentration.

Z - Spiked recovery not within control limits. An explanatory note may be included in the narrative.

* - Duplicate analysis (relative percent difference) not within control limits.

-S - SAR value is estimated as one or more analytes used in the calculation were not detected above the detection limit.

Organics:

U or ND - Indicates that the compound was analyzed for but not detected.

B - Analyte is detected in the associated method blank as well as in the sample. It indicates probable blank contamination and warns the data user.

E - Analyte concentration exceeds the upper level of the calibration range.

J - Estimated value. The result is less than the reporting limit but greater than the instrument method detection limit (MDL).

A - A tentatively identified compound is a suspected aldol-condensation product.

X - The analyte was diluted below an accurate quantitation level.

* - The spike recovery is equal to or outside the control criteria used.

+ - The relative percent difference (RPD) equals or exceeds the control criteria.

G - A pattern resembling gasoline was detected in this sample.

D - A pattern resembling diesel was detected in this sample.

M - A pattern resembling motor oil was detected in this sample.

C - A pattern resembling crude oil was detected in this sample.

4 - A pattern resembling JP-4 was detected in this sample.

5 - A pattern resembling JP-5 was detected in this sample.

H - Indicates that the fuel pattern was in the heavier end of the retention time window for the analyte of interest.

L - Indicates that the fuel pattern was in the lighter end of the retention time window for the analyte of interest.

Z - This flag indicates that a significant fraction of the reported result did not resemble the patterns of any of the following petroleum hydrocarbon products:
- gasoline
- JP-8
- diesel
- mineral spirits
- motor oil
- Stoddard solvent
- bunker C

*Fecal Coliform was identified as a parameter exceeding water quality standards (WQS) for Chester and Ridley Creeks based on historical data from 2010 (see Attachment J). Sufficient historical data indicating WQS exceedance for all receiving waterbodies was unavailable, however Enterococcus and Fecal Coliform are considered typical parameters associated with CSOs and for this reason are included as POCs.

Biological information shown on the maps represents known concentration areas or occurrences, but does not necessarily represent the full distribution or range of each species. DNREC, NJDEP ENSP, and PGC provided information for some of the federally and state listed species and species of conservation concern for display in the ESI atlas and accompanying digital data in 2013-2014. These data represent existing information known to these agencies at the time of the request and should never be substituted for consultation with these agencies. This atlas was developed using NJDEP GIS digital data for archaeological and historic sites, but this secondary product has not been verified by NJDEP and is not state-authorized. Archaeological and historical site information for Delaware was provided by DE Division of Historical and Cultural Affairs.

Biological information shown on the maps represents known concentration areas or occurrences, but does not necessarily represent the full distribution or range of each species. DNREC, NJDEP ENSP, and PGC provided information for some of the federally and state listed species and species of conservation concern for display in the ESI atlas and accompanying digital data in 2013-2014. These data represent existing information known to these agencies at the time of the request and should never be substituted for consultation with these agencies. This atlas was developed using NJDEP GIS digital data for archaeological and historic sites, but this secondary product has not been verified by NJDEP and is not state-authorized. Archaeological and historical site information for Delaware was provided by DE Division of Historical and Cultural Affairs.

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Revised Identification of Sensitive Area Analysis (RISAA) dated May 13, 2016. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). EPA hereby approves the RISAA.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

Section 1 Introduction

1.1 DELCORA's System

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the safe collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in **Figure 1-1**. The total service area served by DELCORA is approximately 82,977 acres, as shown on **Figure 1-2,** which illustrates that DELCORA serves a significant and widespread portion of Delaware County. The combined sewer area simulated in the original model, also shown in **Figure 1-2**, is located within the Chester City. It comprises approximately 49% of the Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows.

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western service area discharges to the Western Regional Treatment Plant (WRTP). The Eastern service area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWD-SWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are to be directed to the PWD-SWPCP. As such, dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

Under National Pollutant Discharge Elimination System (NPDES) Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall 001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow (CSO) outfalls (002-026, 032, 033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

There are a total of 26 combined sewer overflow (CSO) outfalls listed with 25 discharge points (Outfalls 009 and 010 both discharge at Outfall 009) in DELCORA's existing NPDES Permit.

1.2 DELCORA's Consent Decree

DELCORA prepared and submitted their original Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) to the PADEP in 1999. This LTCP was subsequently approved by the PADEP, and DELCORA had started to implement the CSO control elements selected in the LTCP. In 2009, the United States Environmental Protection Agency (USEPA) informed DELCORA that the original LTCP was not in compliance with the requirements of the USEPA's CSO Policy. As such, DELCORA prepared and submitted a revised LTCP in April 2012. Subsequent to the receipt of the revised LTCP, DELCORA and the USEPA had corresponded various times including requests for additional information from the USEPA in accordance with Section 308 of the Clean Water Act. A Consent Decree was issued by the USEPA to DELCORA in June 2015. The Consent Decree requires a new LTCP to be prepared based on an agreed upon schedule, which will include interim deliverables and milestones that must be met.

According to the Consent Decree between the US EPA, PADEP, and DELCORA, DELCORA's Hydrologic and Hydraulic Model (H&H Model) will be updated to meet the requirements in Section V.A.14 of the Consent Decree. A detailed plan to update, calibrate and validate the H&H model shall be submitted not later than sixty (60) days after August 17, 2015, the lodging date.

1.3 Contents in This Plan

This Model Update and Calibration Plan (Plan) was prepared based on the requirements listed in the Consent Decree. **Table 1-1** lists individual sections of the Plan and contents.

Table 1-1 DELCORA H&H Model Update and Calibration Plan

Section	Description
Section 1 Introduction	This section introduces DELCORA's system and Consent Decree, as well as individual sections of the Plan.
Section 2 Review of the Original H&H Model	This section summarizes review of the original H&H model, assesses the model's adequacy for use in DELCORA's Long Term Control Plan Update (LTCPU), identifies gaps with the original model in meeting the requirements in the Consent Decree, and determines refinement needs for the model update.
Section 3 DELCORA H&H Model Update	This section describes general methodology used in model update, and provides detail model update needs for service area delineation, combined area delineation, model network extension, regulator, and model inputs.
Section 4 Additional Rainfall and Flow Monitoring	This section provides an overview of the existing rain gauge and flow meter conditions, describes the additional rain gauges and flow monitoring needs and a monitoring work plan.

Section	Description
Section 5 DELCORA H&H Model Calibration and Validation	This section provides detailed data analysis needed for model calibration and validation, lists criteria for dry weather and wet weather calibration, and illustrates calibration and validation results.
Section 6 Model Development and Implementation Schedule.	This section provides a schedule for model development and implementation, including integration into LTCP development consistent with other dates required pursuant to the Consent Decree.

Section 2 Review of the Original H&H Model

The original DELCORA H&H model was developed and calibrated for the 1999 LTCP. The model was updated and expanded over the years to account for changes in the CSO system, but it was not re-calibrated during the development of the 2012 LTCP.

The project team will update the model as needed to reflect current hydrologic and hydraulic conditions of DELCORA's collection system. The updated model will then be calibrated and validated with the additional rainfall and flow monitoring data before being applied to evaluate CSO control alternatives for DELCORA's Long Term Control Plan Update.

In order to appropriately update the original H&H model, it has been reviewed to address the following

- Assess adequacy of the original model for use in DELCORA's LTCPU,
- Identify gaps with the original model in meeting the requirements in the Consent Decree, and
- Determine refinements needed for the model update.

2.1 General Observation

The original H&H model was built with EPASWMM Version 5. It includes one (1) rain gage, 67 subcatchments, 29 outfall nodes, 736 storage nodes, 735 conduit links, and 34 orifice links. The detail layout of the model is shown in **Figure 2-1**. The model was set up to simulate monthly CSO discharges with reasonable continuity error in EPASWMM 5.0.

Major observations of the original model and comments are summarized in **Table 2-1**.

Figure 2-1 The Original Model Layout

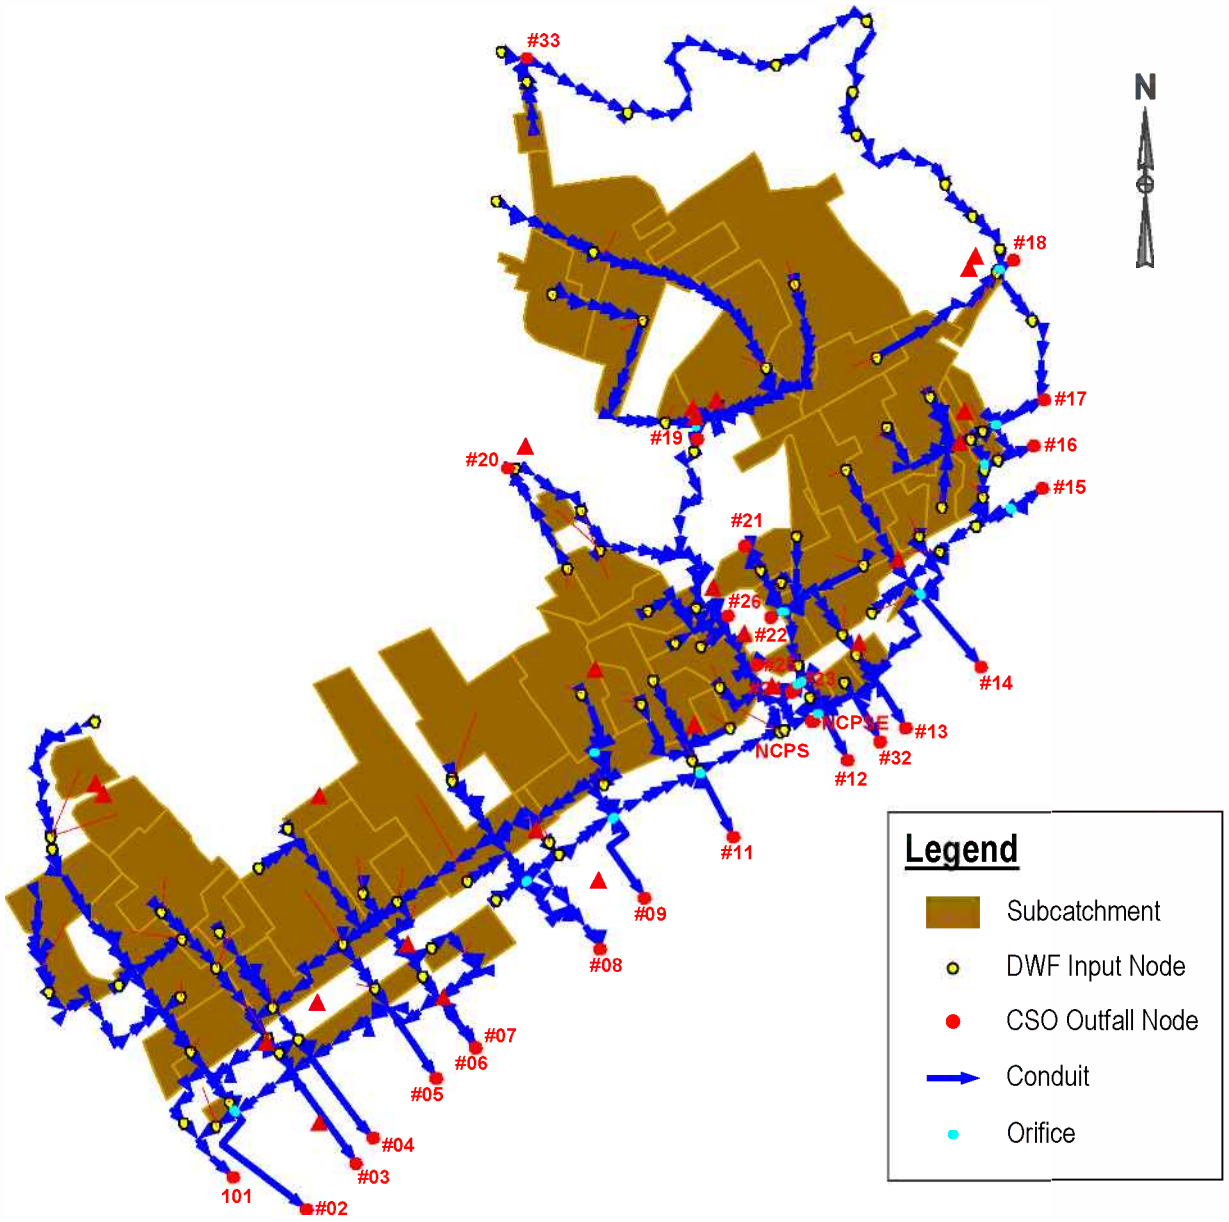

Table 2-1 Review Summary of the Original Model

Review Item	Observation	Comments
Model Software	- EPA SWMM 5.0	
Vertical Datum	- NAVD 88	- To be verified
General Sub Models	- EPASWMM for the runoff model - Horton Equation for the infiltration model - Hydrodynamic wave for the flow routing model	- All these choices are commonly seen in collection system modeling practices
Rain Gauge	- One (1) rain gage, located at the Western Regional Treatment Plant (WRTP)	- One rain gauge is not sufficient for the entire service area in the model
Service Area	- 67 subcatchments, all for combined area - One set of Horton infiltration parameters are applied to most of the subcatchments (66 out of 67 subcatchments) - The infiltration parameters applied in the model is equivalent to infiltration parameters for soil type C/D	- All service area including separated area that contribute flow to the DELCORA collection system should be included in the model - Combined area delineation will be checked to include any changes along the years - Soil type need to be checked to verify Horton infiltration parameters in all subcatchments
Sewer Manhole	- 736 storage nodes. - All sewer manholes are simulated as storage units in the model. - The majority of the storage units (732 out of the 736) have a diameter of 4-ft, and the rest (4 units) have a surface area of 100 square feet (sf.) (equivalent to 10'x10'). - All storage units are set-up with a ponding area of 9,999 sf. to allow excess water to collect atop of the nodes and be re-introduced into the system as conditions permit.	- Sewer manholes will be simulated as common junction node - This will help with SSO evaluation in the collection system
CSO Outfall	- 29 outfall nodes - All CSO outfalls are free outfall	- All outfalls are located in the Delaware River in the tidal reach, a tidal stage instead of free outfall should be assigned to the outfalls - Outfall ID 101 has dry weather input of 1.76 cfs, it represents WRTP in the model

Review Item	Observation	Comments
Sewer Mains	- 735 conduit links. - Negative slopes at Nodes 73803 and 70709 not matching the GIS. - Pipe connectivity is not consistent with the GIS in Subcatchment EA1, 25A. - Pipe size and connectivity is not consistent with the GIS around Node: 5201242, 5201234. - Pipe size is not consistent with the GIS around Node: 52018-52015. - Pipe size is not consistent with the GIS around Node: 531-527, 522-517, 516-513, 510020301-5100202, 403-NCPS, 40801-40801A, 32405-32404, and 1110402-11103. - Pipe size and slope are not consistent with the GIS around Node: 422-4140. - NREG06 outfall pipe direction is opposite.	- All the negative slopes and inconsistencies need to be checked with the most updated GIS and record drawings during the model update
CSO Regulators	- 34 orifice links. - All CSO regulators are simulated using orifices to intercept dry weather flows and partial wet weather flows to the collection system, and with elevated conduits to convey extra flows to the CSO outfalls. - Approximately 75% of the orifices (25 out of 34) are modeled with Real Time Control (RTC) to mimic regulator gate opening based on level. - None of the regulator diverting weir structures is simulated in the model.	- Diverting weir structures need to be added in the model - The slopes of all overflow pipes connected to the CSO outfalls need to verified - All orifice opening dimensions verified will be verified - All the RTC rules regulating orifice opening will be verified with actual operation
Pump Station	- No pump station is included in the model	- All pump stations that contribute flow to the DELCORA collection system should be added to the model, with related force mains
Dry Weather Flow	- 94 dry weather flow (DWF) inputs - Total DWF is 7.01 MGD - No diurnal curve - DWF does not include all the separated service areas that contribute to the DELCORA system -	- DWF should be updated to include all the service areas that contribute to the DELCORA system - Weekday and weekend diurnal curve should be included in the model to effectively simulate dry weather diurnal pattern
RDII	- No rainfall-derived infiltration/inflow (RDII) element was found in the model	- RDII should be included in the model to estimate reasonable wet weather inflow from RDII

2.2 Limitation of the Original Model and Update Needs

A thorough review of the original model reveals major gaps in its ability to meet the requirements in the Consent Decree, including the following:

- The model was created to estimate CSO overflows from the combined area, but some of the communities that contribute Rainfall Derived Infiltration and Inflow (RDII) from the separated areas to the DELCORA collection system were not included in the model. To accurately reflect the collection system, all service areas should be included in the simulation. As such, the model network will need to be expanded to the separated service areas.
- Based on discussions with Weston, the roofs are not connected to the sewer system in the separated area. Therefore, the wet weather flow from the separated areas is RDII instead of surface runoff as in the combined area. However, the RDII can contribute a significant portion of wet weather flow to a collection system, especially from areas with old/leaky sewers. The RDII component should be evaluated and included in the model for all individual sewer service areas.
- The model does not include any pump stations. All related pump stations and force mains that convey flows to the DELCORA system will need to be included in the model, with appropriate pump curves and pump operating rules.
- All CSO regulators and outfall pipes need to be revisited in the model. The regulator simulated in the original model does not include any flow diverting weirs, and the invert of the outfall pipes were adjusted to match the diverting weir crest level. The regulators will be set-up in the model based on the real configuration, including regulating gates, overflow weirs, and overflow pipes with correct slopes. This will be done by a review of the record drawings for the regulators, as well as field survey, if needed.
- The dry weather input in the model will need to be updated with additional rainfall and flow monitoring data that covers the entire service area. Weekday and weekend diurnal curves will need to be included in the model to accurately reflect dry weather peaks and valleys.
- Sewer manhole will be simulated as a junction node instead of a storage node, with a proper surcharge level to reflect actual manhole cover type. Storage nodes will only be used for actual storage facilities such as pump station wet wells or any storage unit proposed in the CSO control alternatives.

Section 3 DELCORA H&H Model Update

The original H&H Model will be updated based on the review results and current collection system conditions. The updated model will be calibrated and applied to evaluate CSO control alternatives for DELCORA's LTCPU.

The purpose of this section is to introduce the model update methodology and detail model refinement needs.

3.1 Model Update Methodology

3.1.1 Hydrologic Representation

Per Section V.A.14b of the Consent Decree (Page 15), " *The updated H&H Model shall specifically include hydrologic representation of all areas tributary to the entire Collection System, as well as all areas tributary to all municipal wastewater collection and transmission systems that are, as of the date the LTCP is submitted, hydraulically connected to, or that directly or indirectly influence flow to, the CSOs and/or the WRTP, regardless of who owns or operates the system(s), including but not limited to the entire "Western Service Area" and "Eastern Service Area" depicted on Figure 1-2 of the Long-Term Control Plan submitted by DELCORA in April 2012.*"

Instead of including only the combined area for the subcatchments as in the original model, the updated model will have subcatchments for both combined and separated service areas. All the areas that contribute dry weather flow and/or wet weather flow to DELCORA's CSOs and/or the WRTP will be included in the service area for the model.

Wet weather flows generated from both surface runoff from the combined area and RDII will be simulated in the updated model.

3.1.2 Hydraulic Representation

Per Section V.A.14c of the Consent Decree (Page 16), " *The H&H Model shall accurately represent the response of the Model Area to wet weather events, including the flows that result from wet weather events to and from DELCORA's CSOs and to the WRTP. To accomplish this, the model shall explicitly include all interceptors, diversion structures, CSOs, pump stations and major trunk sewers within the Collection System, as well as such pipes and appurtenances within the areas outside the Collection System that are needed to ensure adequate H&H Model accuracy. The H&H Model shall also include all sewers required for model continuity and/or that hydraulically impact or are downstream of known chronic unpermitted releases. DELCORA shall investigate and collect current system attribute information as necessary to update the H&H Model.*"

Pipe network in the updated model will be extended to the updated service areas for both the combined and separated areas. All hydraulic structures that control flows in the collection system, including pump stations, regulator orifices and weirs, and their operating rules, will be simulated in the updated model.

3.2 Model Refinement

The updated DELCORA H&H model will be created based on NAVD 88 datum. InfoSWMM will be used during the model developing and the calibration phase and the final model can be submitted with either the InfoSWMM or EPASWMM platform.

The model update will be based on information obtained from a variety of sources including DELCORA's input, GIS, Sewer Atlas, record drawings, and field survey. Other documents including flow agreements between DELCORA and individual communities, pump discharge curves, standard/actual operating procedures for CSO regulators, pump station and WRTP, etc. will also be used to set up real time control in the model.

3.2.1 Delineation of Service Area and Combined Area

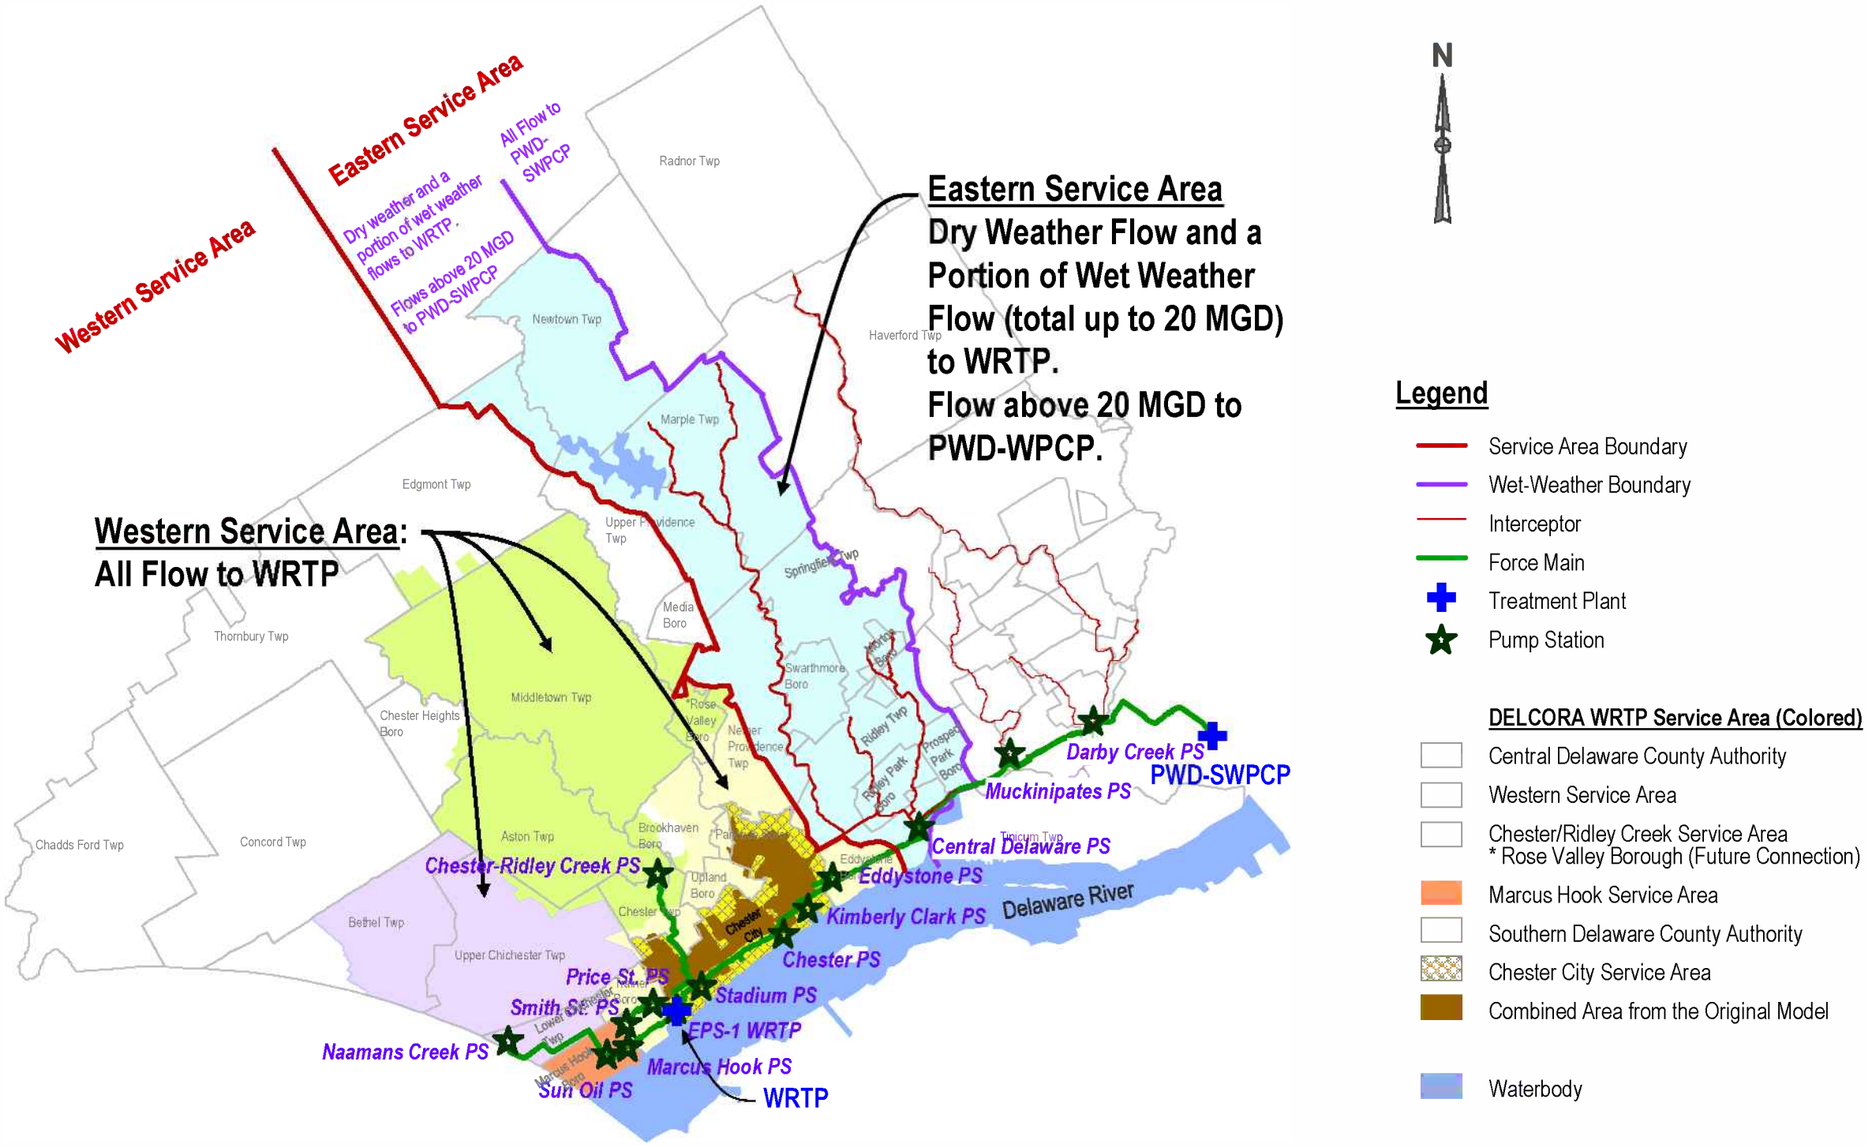
3.2.1.1 Delineation of Service Area

DELCORA serves a significant and widespread portion of Delaware County. Historically, DELCORA Western Regional Treatment Plant (WRTP) received both dry and wet weather flows from the Western Service Area only. In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are directed to the PWD-SWPCP. As such, dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority (CDCA) in the Eastern Service Area also discharge to the WRTP.

Historically, municipalities in the Central Delaware County Authority that contribute flows to the WRTP include Marple Township, Morton Borough, Nether Providence Township, Newtown Township, Prospect Park Borough, Ridley Park Borough, Rutledge Borough, Springfield Township, Swarthmore Borough, Ridley Township, and Upper Providence Township. In October 2012, DELCORA signed an agreement with Edgmont Township to provide sewer service to the eastern portion of the Township. The sanitary sewage of the Township will be collected and transported using the Crum Creek Sewer District System through the CDCA collection and conveyance facilities to the DELCORA System for treatment and ultimate disposal and discharge.

Figure 3-1 shows the entire service area for the WRTP, including the updated Eastern Service Area. Facilities and conveyance schematic is shown in **Figure 1-1**.

Figure 3-1 DELCORA's Western Regional Treatment Plant (WRTP) Service Area



Eastern Service Area

The DELCORA Eastern Service Area is composed of four subareas that are served by conveyance authorities: Radnor Haverford Marple (RHM) Authority, Darby Creek Joint Authority (DCJA), Muckinipates Authority (MA), and Central Delaware County Authority (CDCA) and are delineated in **Figure 1-2**. Each of these authorities has a legal agreement with their member municipalities to dispose of their wastewater. In turn, DELCORA has legal agreements with each of the authorities, except RHM, to receive, treat, and dispose of the collected wastewater. RHM discharges to the DCJA. DELCORA owns and operates three large pump stations that serve DELCORA's Eastern service area; they are the Central Delaware Pump Station, the Muckinipates Pump Station, and the Darby Creek Pump Station. These pump stations were originally designed to pump the wastewater from DELCORA's Eastern Service Area to PWD-SWPCP for treatment.

The Central Delaware Pump Station (serving CDCA) is rated for 40 MGD. It was constructed in the 1970s to discharge all flow through a force main that is routed northeast toward the Muckinipates Pump Station. The operation of the pump station had been modified in 2002 to allow for flow from the CDPS to be discharged to the WRTP. Currently the wastewater flows above 20 MGD are conveyed to PWD-SWPCP. The next pump station is the 24-MGD Muckinipates Pump Station (serving MA). Here, the force main increases to 48 inches in diameter and continues approximately 1.65 miles northeast to the Darby Creek Pump Station. Upon reaching the 60-MGD Darby Creek Pump Station (serving DCJA and RHM), the force main increases in diameter to 66 inches and continues approximately 2.5 miles for ultimate discharge at PWD-SWPCP.

Western Service Area

The DELCORA Western Service Area is shown in **Figure 3-1**. DELCORA owns and operates the collection system in the following communities in the Western Service Area.

- Chester City
- Chester Township (parts of)*
- Marcus Hook Borough
- Parkside Borough
- Rose Valley Borough *
- Upland Borough
- Trainer Borough

*Note:

- DELCORA owns only a portion of Chester Township's collection system, but all flow comes to WRTP as some goes through the CRC PS service area.
- Rose Valley Borough collection system discharges to its own treatment plant (this portion will be discharged to the CRC PS service area in future) and the remaining portion is discharged to the Western Service Area to the WRTP.

DELCORA does not own or operate the collection system in the following communities in the

Western Service Area, however, these communities will be included as part of the service areas in the updated H&H model because they contribute flows to the WRTP.

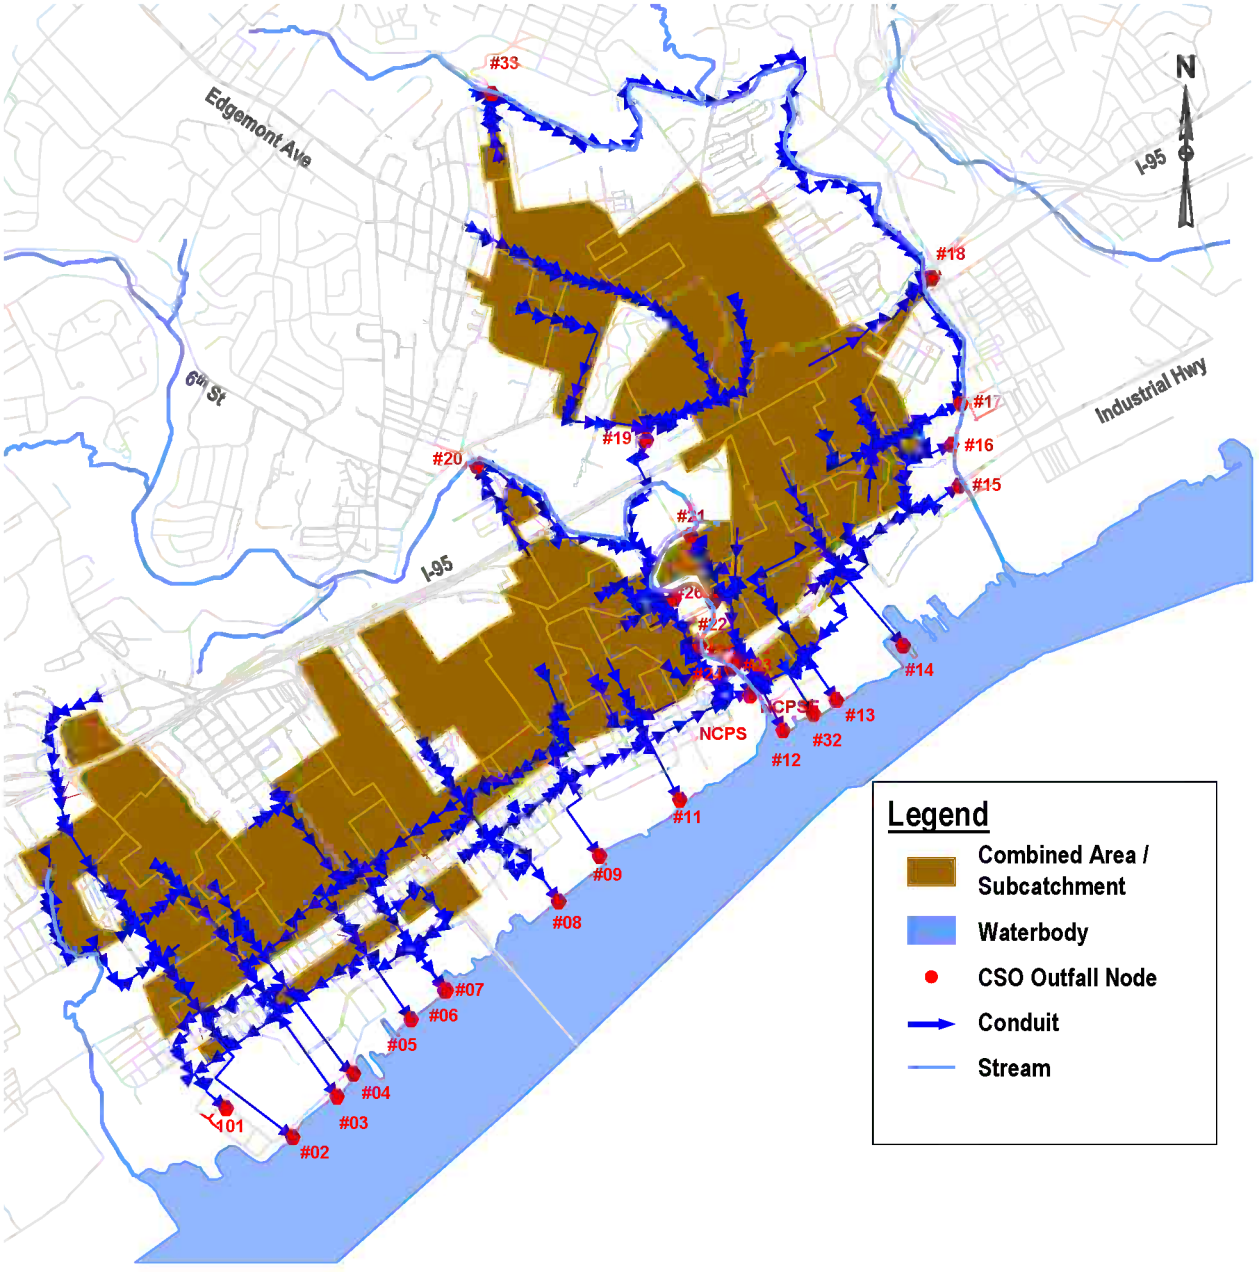
- Brookhaven Borough
- Lower Chichester Township
- Nether Providence Township
- Eddystone Borough

3.2.1.2 Delineation of Combined Area

The entire combined area of DELCORA's collection system is located in the City of Chester. The combined sewer area is shown in **Figure 3-1**. The combined area according to the original model is shown in in **Figure 3-2**.

The combined area delineation will be updated with separation projects completed in recent years. The latest GIS database, survey, and record drawings will be used to perform the desktop combined sewer area check. Field verifications will be conducted as necessary to verify the boundaries and to generate an accurate representation of the combined areas for the updated model.

Figure 3-2 Combined Area Delineation in the Original Model



3.2.2 Model Network

The collection system network in the original model (**Figure 3-2**) will be updated with the following.

- To extend sewers to the updated delineation of the combined and separated areas,
- To include all pump stations that control flows in the DELCORA collection system, and
- To reflect actual configuration of the CSO regulators.

DELCORA's WRTP treats all wastewater from the Southern Delaware County Authority, Marcus Hook Borough, Trainer Borough, Upland Borough, Parkside Borough, Eddystone Borough, Chester Township, the City of Chester, a portion of the wastewater from Brookhaven Borough and Nether Providence Township, as well as the dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority.

A flow diagram presented in **Figure 1-2** shows all the connections on DELCORA's system and related facilities including interceptors, force mains, pump stations and treatment plants. The interconnectivity coupled with the legal agreements that DELCORA maintains with the municipalities and conveyance authorities in Delaware County creates the complicated legal/financial framework under which DELCORA operates.

3.2.2.1 Sewer Lines and Manholes

3.2.2.2 Regulators

Since the approval of the first LTCP in 1999, DELCORA has under-taken a program to replace and/or rehabilitate CSO regulators and tide gates in the City of Chester CSO system. As indicated in **Table 3-1**, the majority of the City's CSO regulators are Brown & Brown type regulators. The operation of the CSO regulators has been changed from being controlled by the level in the trunk sewer entering the CSO regulator chamber to being controlled by the level in the interceptor. This change is being implemented as part of the CSO regulator replacement program. This ensures that the flow sent to the WRTP for treatment is maximized.

During dry-weather operations, the sewage flow levels entering the CSO regulator chamber are below the top of the diversion weir and will pass through the CSO regulator gate. Once through the CSO regulator gate, the flow will be sent to the WRTP via the interceptors. During wet-weather events, the level in the combined sewer will begin to rise thus raising the float assembly and beginning to close the CSO regulator gate.

Regulator gates, diversion weirs, and operating rules will be simulated in the updated model.

Table 3-1 CSO Regulator Information

CSO Regulator No.	CSO Regulator Location	CSO Receiving Water	CSO Regulator Type
002	Front & Booth	Delaware River	Brown & Brown
003	Front & Highland	Delaware River	Brown & Brown
004	Front & Hayes	Delaware River	McNulty
005	Front & Townsend	Delaware River	Brown & Brown
006	Delaware & Jeffrey	Delaware River	Separated, CSO Outfall removed.
007	Delaware & Reaney	Delaware River	Brown & Brown
008	2nd & Tilghman	Delaware River	Brown & Brown
009	2nd & Lloyd	Delaware River	Brown & Brown
010*	5th & Pusey	Delaware River	Brown & Brown
011	2nd & Parker	Delaware River	Brown & Brown
012	2nd & Edgmont	Delaware River	Brown & Brown
013	2nd & Welsh	Delaware River	Brown & Brown
014	3rd & Upland	Delaware River	Brown & Brown
015	4th & Melrose	Ridley Creek	Brown & Brown
016	8th & McDowell	Ridley Creek	Brown & Brown
017	9th & Campbell	Ridley Creek	Brown & Brown
018	Sun Dr. & Hancock	Ridley Creek	Brown & Brown
019	14th & Crozer Hospital	Chester Creek	Brown & Brown
020	Kerlin & Finland	Chester Creek	Brown & Brown
021	9th & Sproul	Chester Creek	Brown & Brown
022	6th & Sproul	Chester Creek	Brown & Brown
023	3rd & Edgmont	Chester Creek	Brown & Brown
024	3rd & Dock	Chester Creek	Brown & Brown
025	5th & Penn	Chester Creek	Brown & Brown
026	7th & Penn	Chester Creek	Brown & Brown
027	2nd & Dock Pump Station	Chester Creek	Overflow pump removed.
032	2nd & Avenue of the States	Delaware River	No CSO Regulator
033	Elkington Blvd. and Ridley Creek	Ridley Creek	No CSO Regulator

Note: CSO 010 discharges at Outfall 009.

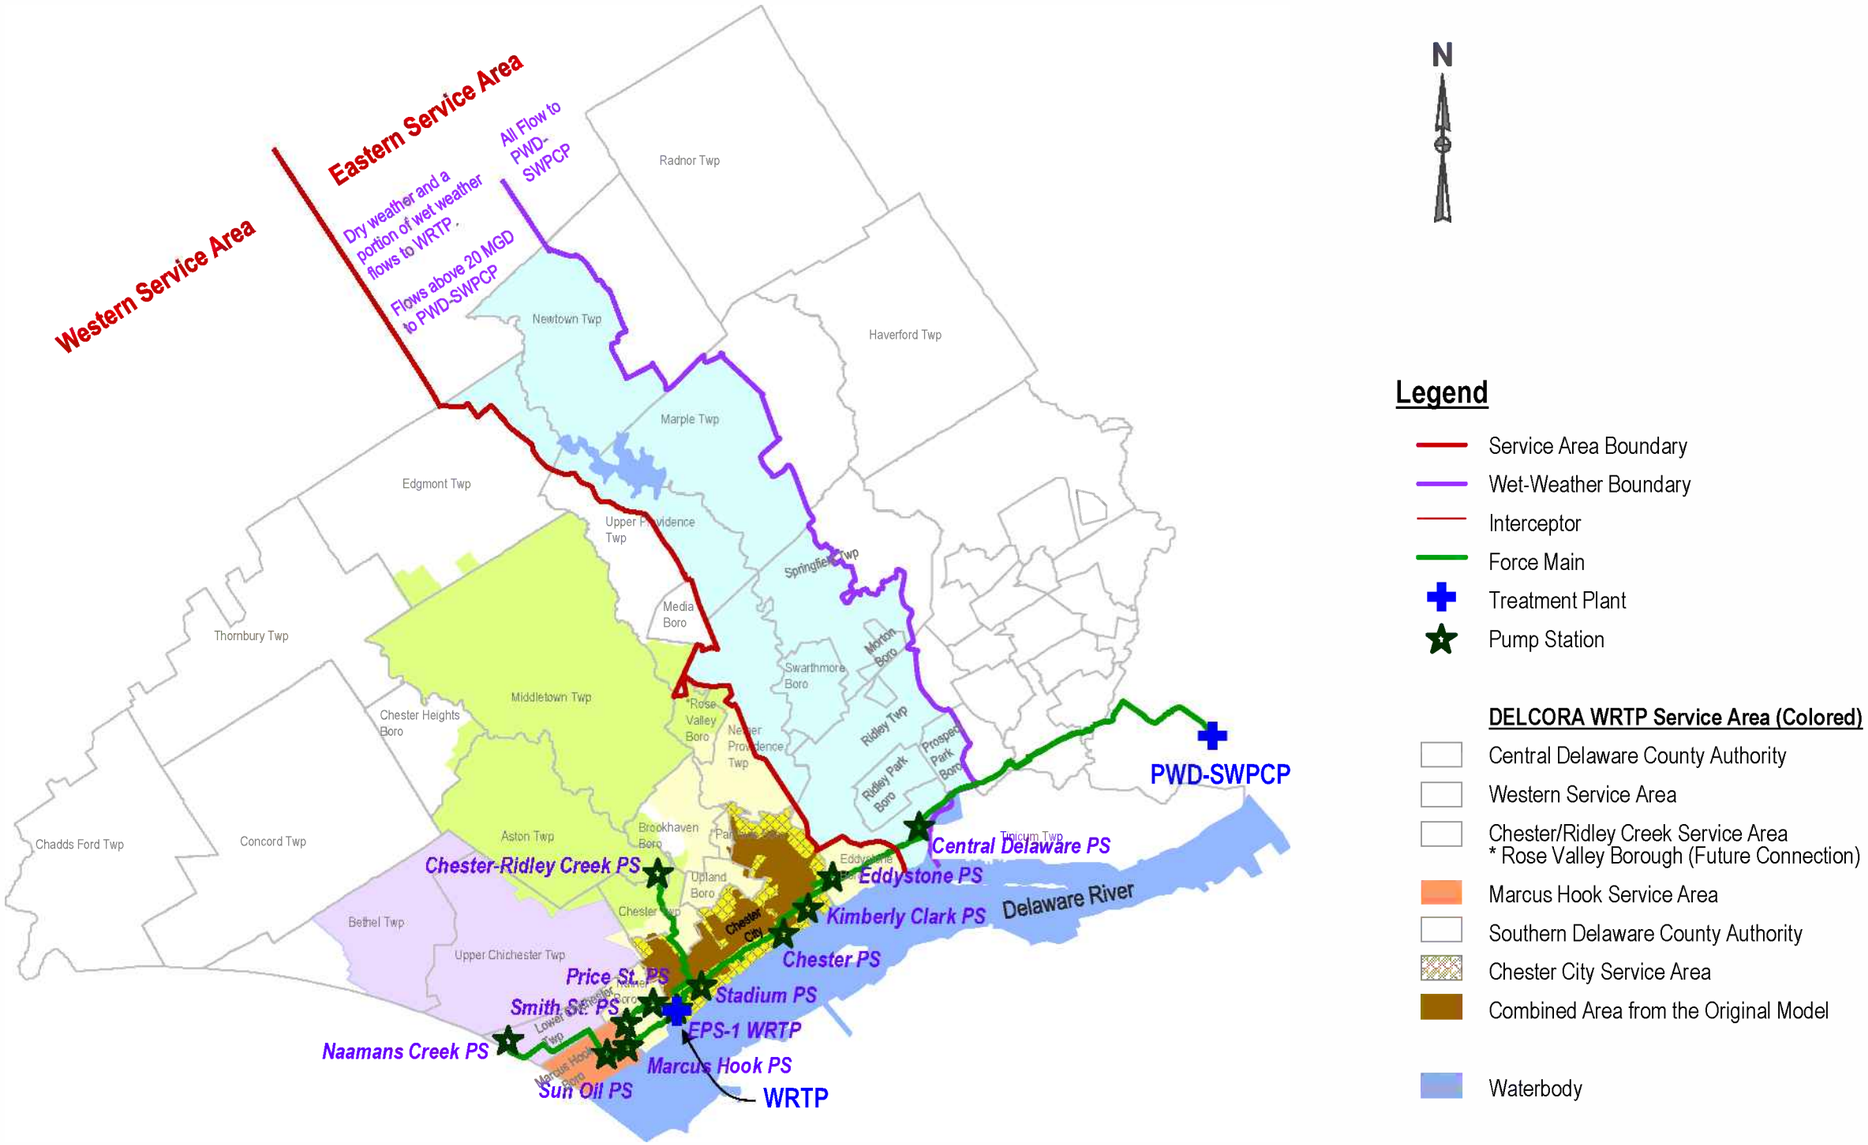
3.2.2.3 Pump Stations

All major pump stations in the Western Service Area and CDPS in the Eastern Service Area will be added in the updated model, as well as force mains connecting the pump stations to the interceptor/WRTP. The list of the pump stations include (**Figure 3-3**):

- Chester PS
- Existing PS-1 WRTP
- Price & Smith Street Trainer PS
- Marcus Hook PS
- Naamans Creek PS
- Sun Oil PS (Owned by Sunoco)
- Kimberly Clark PS (Owned by KC)
- Eddystone PS
- Central Delaware PS
- Chester Ridley Creek PS
- Stadium PS

DELCORA owns or operates a number of lift stations that contribute to the Western Service Area and whose flows are handled by the above list of pumps stations. These lift stations will also be evaluated during the model updating process and included only if they have significant impact on DELCORA's system hydraulics.

Figure 3-3 Pump Stations to be Included in the Updated Model



3.2.3 Model Input

3.2.3.1 Subcatchments

The following subcatchment information is required by the model:

- Area
- Percent of directly connected impervious area (effective impervious area)
- Width
- Slope
- Manning's roughness coefficient (n) for both pervious and impervious areas
- Depression storage for both pervious and impervious areas (initial subtraction)
- Soil and soil infiltration parameters
- Rainfall dependent inflow and infiltration (RDII) parameters
- Base flow

Area
Area of the combined sewer subcatchment is the geographical area of the subcatchment. It will be estimated from the GIS by geometry calculation of the area of the subcatchment.

Percent of Directly Connected Impervious Area
Directly connected impervious area means the impervious area that is effectively connected to the sewer collection system. As a result, runoff from these areas is completely captured by the collection system. Runoff from the rest of the impervious area is deemed not to be captured by the system due to various potential reasons, including drains to pervious area/creek/streams, limited number and capacity of stormwater inlets, and bypassing etc. For model construction, the percent imperviousness calculated based on GIS shapefiles will be used as the initial input and then adjusted during the model calibration process to best simulate the observed hydrologic response over a range of precipitation events.

The initial percent imperviousness for the combined area will be calculated based on the impervious coverage shape file and zoning shape file. An example of percent imperviousness applied to different land uses are shown in **Table 3-2**. This table will be modified with specific land use types observed in the combined area and it will provide the basis of calculating the initial percent imperviousness inputs in a combined sewer subcatchment.

Table 3-2 Percent Imperviousness Applied for Different Land Use Types

Land Use Type	% Imperviousness
Driveway	100%
Parking_Paved	100%
Parking_Unpaved	90%
Roadway	100%
Sidewalk	100%
Building - Connected Rooftops	100%
Building - Commercial and Industrial	80%
Building - Residential; with Disconnected Rooftop	50%

For the separated area, the initial percent imperviousness will be set at 0% because the impervious area in the separated area is not contributing runoff to the sewer collection system, therefore it is not effectively connected. *Subcatchment parameters mentioned hereafter will be set at default values for the separated subcatchments.*

Width

The width of a subcatchment relates to sheet flow path and affects time of concentration and the shape of the runoff hydrograph. The initial estimate of the width will be estimated by the subcatchment area divided by the representative overland flow length. Width is one of the calibration parameters for runoff.

Slope

The slope of a subcatchment should reflect the average slope along the pathway of overland flow to inlet locations. For the combined sewer subcatchments, the slopes will be determined by the elevation difference divided by the length of flow path. GIS contours will be used to estimate elevations.

Manning's roughness coefficient (n)

Manning's roughness coefficient (n) will be estimated for both pervious and impervious overland flow. The initial values will be set to 0.013 for impervious surfaces and 0.15 for pervious surface. A typical range of Manning's n suggested by the SWMM is 0.011-0.024 for impervious area and 0.06-0.80 for pervious area. Roughness is an empirical value and may be treated as a calibration parameter if necessary.

Depression Storage

Depression storage is the rainfall abstraction volume that must be filled prior to the occurrence of runoff. It represents the loss (initial abstraction) caused by surface ponding, surface wetting, etc. The initial values of depression storage will be set to 0.05 for impervious surface and 0.15 for pervious surface. Typical depression storage values are 0.05-0.10 for impervious surfaces and 0.10-0.30 for pervious surfaces. Depression storage is an empirical value and may be treated as a calibration parameter, especially to adjust runoff volumes.

In the model, the subcatchment is divided into three subareas: pervious area with depression storage, impervious area with depression storage, and impervious area without depression storage. The initial percent of the impervious area without depression storage will be set to 0.10.

Soil and Soil Infiltration Parameters
Soil information is needed to estimate infiltration in the pervious area. The rate of infiltration is a function of soil properties and antecedent soil conditions. Three infiltration methods are available in the software: Horton method, Green-Ampt method, or NRCS Curve Number method. The Horton method has been extensively used for similar type of modeling work and it will be used in this modeling effort to estimate infiltration. The required soil parameters for Horton method include:

- Maximum Infiltration rate (in/hr)
- Minimum Infiltration Rate (in/hr)
- Decay Constant (/hr)
- Drying time (d)
- Maximum Infiltration Volume Possible (inch)

Horton's infiltration parameters for Soil B and C will be estimated based on typical values from literature, shown in **Table 3-3**.

Table 3-3 Horton Infiltration Parameters

Horton Infiltration Parameter	Soil B	Soil C
Max Infiltration Rate (in/hr)	3	2
Min Infiltration Rate (in/hr)	0.43	0.13
Decay Constant (1/hr)	4	4
Drying Time (d)	3	8
Max Volume (in)	13.2	12.5

3.2.3.2 Manhole

Sewer manholes will be simulated as junction nodes in the model. The following information is required:

- Node ID
- Invert
- Maximum Depth (approximated as the difference from manhole rim and manhole invert)
- Surcharge Depth

Manhole ID will be inherited from the name of the manhole in the sewer GIS. Manhole input information will be updated based on the latest available GIS information.

Most of the manhole input parameters, including invert and rim will be found or estimated from record drawings, design drawings, and the sewer manhole shape file. If information is not available, then estimations will be made based on city topography and sewer connectivity. Ground elevation estimated from contours will be used as the manhole rim elevation, and manhole inverts will be estimated assuming constant pipe slope as the upstream or downstream pipes.

For water tight manholes or manholes with bolted down covers, a surcharge depth of 50-ft will be applied.

3.2.3.3 Sewer Mains

Sewer mains are the conveyance element and will be simulated as conduits in the model. The following input information is needed:

- Conduit ID
- Shape
- Number of barrels
- Upstream and downstream nodes
- Upstream and downstream offset
- Dimension (length, diameter/depth)
- Manning's roughness coefficient
- Minor loss coefficient (entry loss, exit loss, average loss)
- Flap gate installed or not (set at no flap gate for most of the sewer mains)

Conduit ID will be inherited from the sewer GIS. Manhole input information will be updated based on the latest available GIS information.

Most of the pipe input parameters, including upstream and downstream nodes, dimension, shape, number of barrels, and flap gate information, will be found or estimated from record drawings, design drawings and sewer gravity main GIS shape file. For pipes that do not begin or end at the invert of the upstream or downstream node, an offset value will be provided to describe the difference from the invert of the pipe to the invert of the upstream or downstream node.

Manning's roughness coefficient is related to the pipe material. The initial input of the Manning's n for different materials is summarized in **Table 3-4**. The Manning's n may be changed during calibration to account for minor loss or additional sediment depositions in the pipe.

The initial minor loss for pipe will be set at zero for most pipes. For those pipes with sharp turns, a higher minor loss will be applied.

If sewer main information is not available, sewer length will be estimated in GIS geometry measurement; sewer size will be assumed based on upstream and downstream sewers; sewer upstream and downstream offsets will be estimated based on sewer connectivity assuming constant slope.

Table 3-4 Manning's Roughness Coefficient for Sewer Mains

Pipe Material	Manning's N
Polyvinyl Chloride (PVC)	0.011
Reinforced Concrete Pipe (RCP)	0.013
Ductile Iron (DI)	0.013
Cast Iron (CI)	0.013
Corrugated Metal Pipe (CMP)	0.020
Masonry	0.025
Unknown	0.013

3.2.3.4 CSO Outfalls

CSO outfalls will be simulated as outfall nodes in the model. The following information is required:

- Outfall ID
- Type (free, normal, fixed stage, tidal stage, time series, stage-flow, flap gate)
- Invert
- Boundary conditions

Outfalls are the discharge points in the model. The outfalls can either be free outfalls without any boundary conditions or the outfalls can have a boundary condition that the head needs to overcome for outflow to occur. The outfalls in the DELCORA's collection system are mostly in the tidal river reach. Therefore, appropriate tidal stages will be needed to set boundary conditions. Outfalls can have a flap gate at the end to prevent backflow.

Outfall ID will be named according to the CSO overflow points. For example, the outfall for CSO 02 will be named "Outfall_02". The inverts of outfalls will be estimated based on record drawings and design drawings, and will be confirmed/adjusted from the field survey, if necessary.

3.2.3.5 Flow Diversion Structure

Orifices

Regulator gates will be simulated as orifices in the updated model. The following information is required to model an orifice in the model:

- Orifice ID
- Upstream and downstream nodes
- Type (two types: side, bottom)
- Shape (two shapes: circle, rectangular)
- Dimension (Height, Width, Crest Height)

- Discharge Coefficient
- Flap gate

Orifice ID will be named according to the CSO overflow points. For example, the orifice for CSO 03 will be named "Ori_03". All orifices in the collection system are side orifices. The dimensions will be based on record drawings and will be field verified, if necessary.

Weirs
Diversion weirs will be simulated as weirs in the model. The following information is required to model a weir in the model:

- Weir ID
- Upstream and downstream nodes
- Type (four types: transverse, sideflow, V-notch, trapezoidal)
- Dimension (Height, Weir Length, Weir Crest Height)
- Coefficient of Discharge
- Flap gate
- Number of End Contractions

Weir ID will be named according to the CSO overflow points. For example, the weir for CSO 03 will be named "Weir_03". Weir information will be obtained from record drawings and will be field verified, if necessary.

3.2.3.6 Pump Stations

The wet well in the pump stations will be simulated as storage nodes, and pumps will be simulated as pumps in the model. Dimensions of the storage will be based on record drawings. For pumps, the following information is required:

- Pump ID
- Upstream and downstream nodes
- Pump Type
- Pump Curve
- Startup Depth
- Shutoff Depth

Pump startup depth and shutoff depth will be set up in the model according to the typical pump operation. Pump head-discharge curves will be based on the manufacturer's performance curve. Pump curves at different speeds can be developed based on the Affinity Laws.

3.2.3.7 Dry Weather Flow (DWF)

Average day dry weather flows (DWF) will be allocated to each sewershed based on the flow monitoring data and land use. A dry weather flow diurnal curve will be developed for each meter's service area and applied to all sewersheds within that metershed. The total daily average DWF from all sewersheds add up to the DWF measured at the influent to the WRTP. DWF analysis is described in detail in Section 5.

For simulation of CSO control scenarios, the DWF projection will be performed to account for the future development and population growth in the service area. The future land use map (FLUM) and development densities will be used to project future DWF.

3.2.3.8 Rainfall Derived Infiltration and Inflow (RDII)

The model will use the RTK unit hydrograph (UH) to estimate RDII into the sewer system. A RTK UH set contains up to three hydrographs (**Figure 3-4**): one for a short-term response (UH1), one for an intermediate-term response (UH2), and one for a long-term response (UH3). UH1 represents the most rapidly responding inflow component and has a short T value, UH2 includes both inflow and infiltration and has a longer T value, and UH3 includes infiltration that may continue long after the storm event has ended and has the longest T value. The unit hydrograph is defined by the following three parameters:

- R: the fraction of rainfall volume that enters the sewer system and equals to the volume under the hydrograph,
- T: the time from the onset of rainfall event to the peak of the unit hydrograph in hours, and
- K: the ratio of time to recession of the unit hydrograph to the time to peak.

The same set of RDII parameters will be applied in the same metershed because of the availability of the flow hydrograph for model calibration. The initial values of RTK will be estimated using the RDII Analyst tool in the InfoSWMM. The RTK values are calibration parameters to be refined during model calibration.

Rainfall and sewershed area information will be needed for RDII calculation. Sewershed area will be estimated based on areas of the parcels with wastewater services and the areas along the sewer pipes outside parcel areas.

Section 4 Additional Rainfall and Flow Monitoring

4.1 Existing Rainfall and Flow Monitoring Data Review

4.1.1 Existing Rainfall Monitoring Data Review

DELCORA operates and maintains four (4) rainfall gauges in Delaware County that record precipitation in 15-minute increments. The gauges are located at the following DELCORA owned facilities:

- Western Regional Treatment Plant (WRTP)
- Central Delaware County Pump Station (CDPS)
- Muckinipates Pump Station (MPS)
- Darby Creek Pump Station (DCPS)

The three rain gauges located at the pump stations were installed in January 2009 and are a tipping bucket style gauge (Texas Electronics, Inc. TR-525I Rainfall Sensor with a six-inch diameter funnel). The accuracy of the gauges are 1.0% up to 2"/hr or less and each tip represents 0.01" of precipitation. The rainfall gauges are connected to a Telog RU-33 units which sums the number of tips in a 5 minute interval and then logs the total. Data is downloaded daily.

The rain gauge located at the WRTP has been in operation since the mid-1990s. The current gauge is a BlueBugBox Weather Station from WeatherBug.

In addition to these four gauges, precipitation records are available from the National Oceanic and Atmospheric Administration (NOAA) station located at the Philadelphia International Airport. Precipitation records for this station go back to 1/1/1900. This data has been obtained and will be used to select the typical year.

The data from the four DELCORA gauges, the NOAA station and other available gauges will also be used as part of the process.

4.1.2 Existing Flow Monitoring Data Review

DELCORA owns and operates a flow monitoring network across Delaware County. The monitoring network includes various types of flow meters located throughout DELCORA's Eastern Service Area and Western Service Area, at the WRTP, in each of the Pump Stations, and at the tie-in points where other municipal collection systems tie-into the CSO system.

At the pump stations, DELCORA uses magnetic flow meters due to their high accuracy (±1%) and repeatability. In the collection system, area-velocity type meters are used due to the number of locations and the ability to install them without collection system retrofit. Typically these meters are accurate to ±5-7%. The metered flow in the collection system meters is read and recorded once every 15 minutes.

Figure 4-1 shows all the existing flow meters in the DELCORA collection system. A description of the flow monitoring system for each of the defined areas is as follows:

- Eastern Service Area – In the Eastern Service Area, there are a total of 117 flow meters deployed in the collection system to record flow data from the contributing municipalities. These flow meters capture approximately 75% of the EDUs in this service area. The data from these flow meters are used to generate an apportionment percentage assigned to each member municipality in the CDCA, MA, and DCJA. The apportionment percentage is used to distribute the treatment and O&M costs of DELCORA and each of the authorities. The majority of the flow meters, one hundred thirteen (113), are area-velocity type meters installed in the collection system pipes and or manholes at key locations. The remaining flow meters are magnetic flow meters and are located at small pump stations in Upper Providence Township and Newtown Township. Flow from all these meter locations eventually passed through one of DELCORA's primary pump stations (CDPS, MPS, and DCPS) which are equipped with magnetic type flow meters to record flow data. The flow meters in the collection system were installed in 2006. The magnetic flow meters located at the pump stations measure and record flow on a continuous basis. The installation dates area listed in **Table 4-1**.

Table 4-1 Installation Date of the Existing Magnetic Flow Meters at Pump Stations

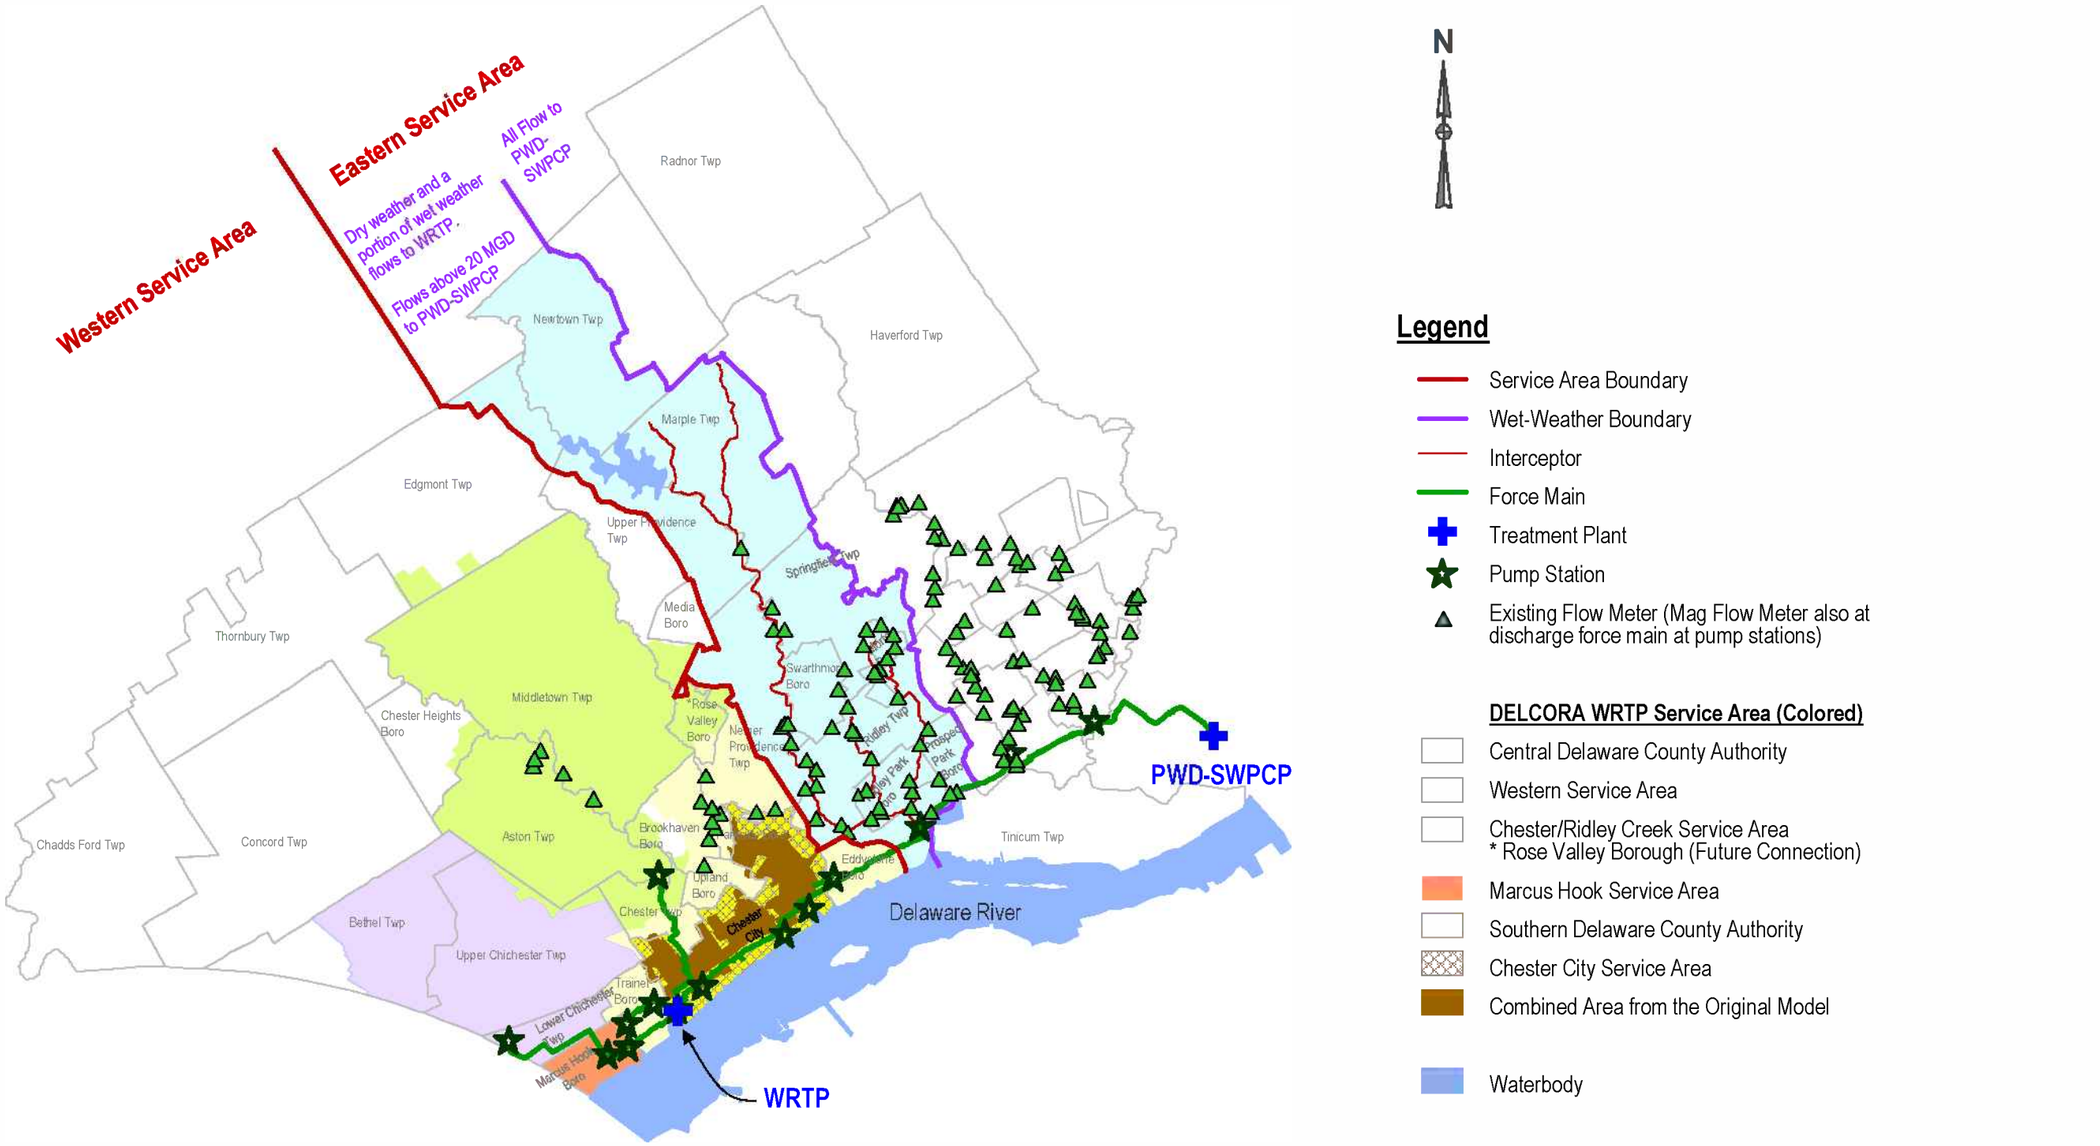
Pump Station	Magnetic Flow Meter Installation Date
Darby Creek PS	1/2008
Muckinipates PS	1/2004
Central Delaware PS	12/2002
WRTP Main Influent PS	1/1998
Chester PS	6/2004
EPS-1	7/2007

- Western Service Area – In the Western Service Area there are a total of eighteen (18) flow meters deployed throughout the collection system that record the flow. All of these meters are area-velocity type flow meters. Ten (10) flow meters are located in the portions of Brookhaven Borough and Nether Providence Township that are connected directly to interceptors in the Chester Collection System and were installed in 2008. The remaining seven (7) meters, located in Rose Valley Borough, Aston Township, and Middletown Township, are located upstream of pump stations with magnetic flow meters.
- Pump Stations – At each of the pump stations shown on **Figure 1-1**, DELCORA has a magnetic flow meter installed on the discharge force main to record flow data. At the CDPS there are two (2) flow meters, one (1) on the force main tributary to the Western Regional Treatment Plant and one (1) on the force main to the City of Philadelphia treatment plant. All of the pump station flow meters measure and record flow on a continuous basis.

- WRTP – There is one flow meter located in the influent pipe line into the WRTP. This flow meter is a magnetic type meter and measures all of the flow to the treatment plant. The flow is recorded continuously.

Data from the pump station magnetic meters, the 10 collection system meters in the Western Service Area, and 61 meters in the Central Delaware County Authority (CDCA) will be used as direct input to the H&H model.

Figure 4-1 DELCORA Existing Flow Meters



4.2 Additional Rainfall and Flow Monitoring Locations

4.2.1 Proposed Rainfall Monitoring Locations

The existing rain gauges in the WRTP service area, including one in the combined area at the WRTP and one in the separated area at the CDCA Pump Station (rain gauges at the Muckinipates PS and Darby Creek PS are out of the WRTP service area), are not sufficient to provide effective spatial coverage of the entire service area. Additional rain gauge is needed for the additional rainfall and flow monitoring program if rain gauge is used as the only source of precipitation data.

Rain gauge network density can be determined from watershed area by the following equation. The number of gauges, N, is,

$N=A^{0.33}$ (U.S. Army Corps of Engineers, 1996)
where A is the watershed area in mi^2

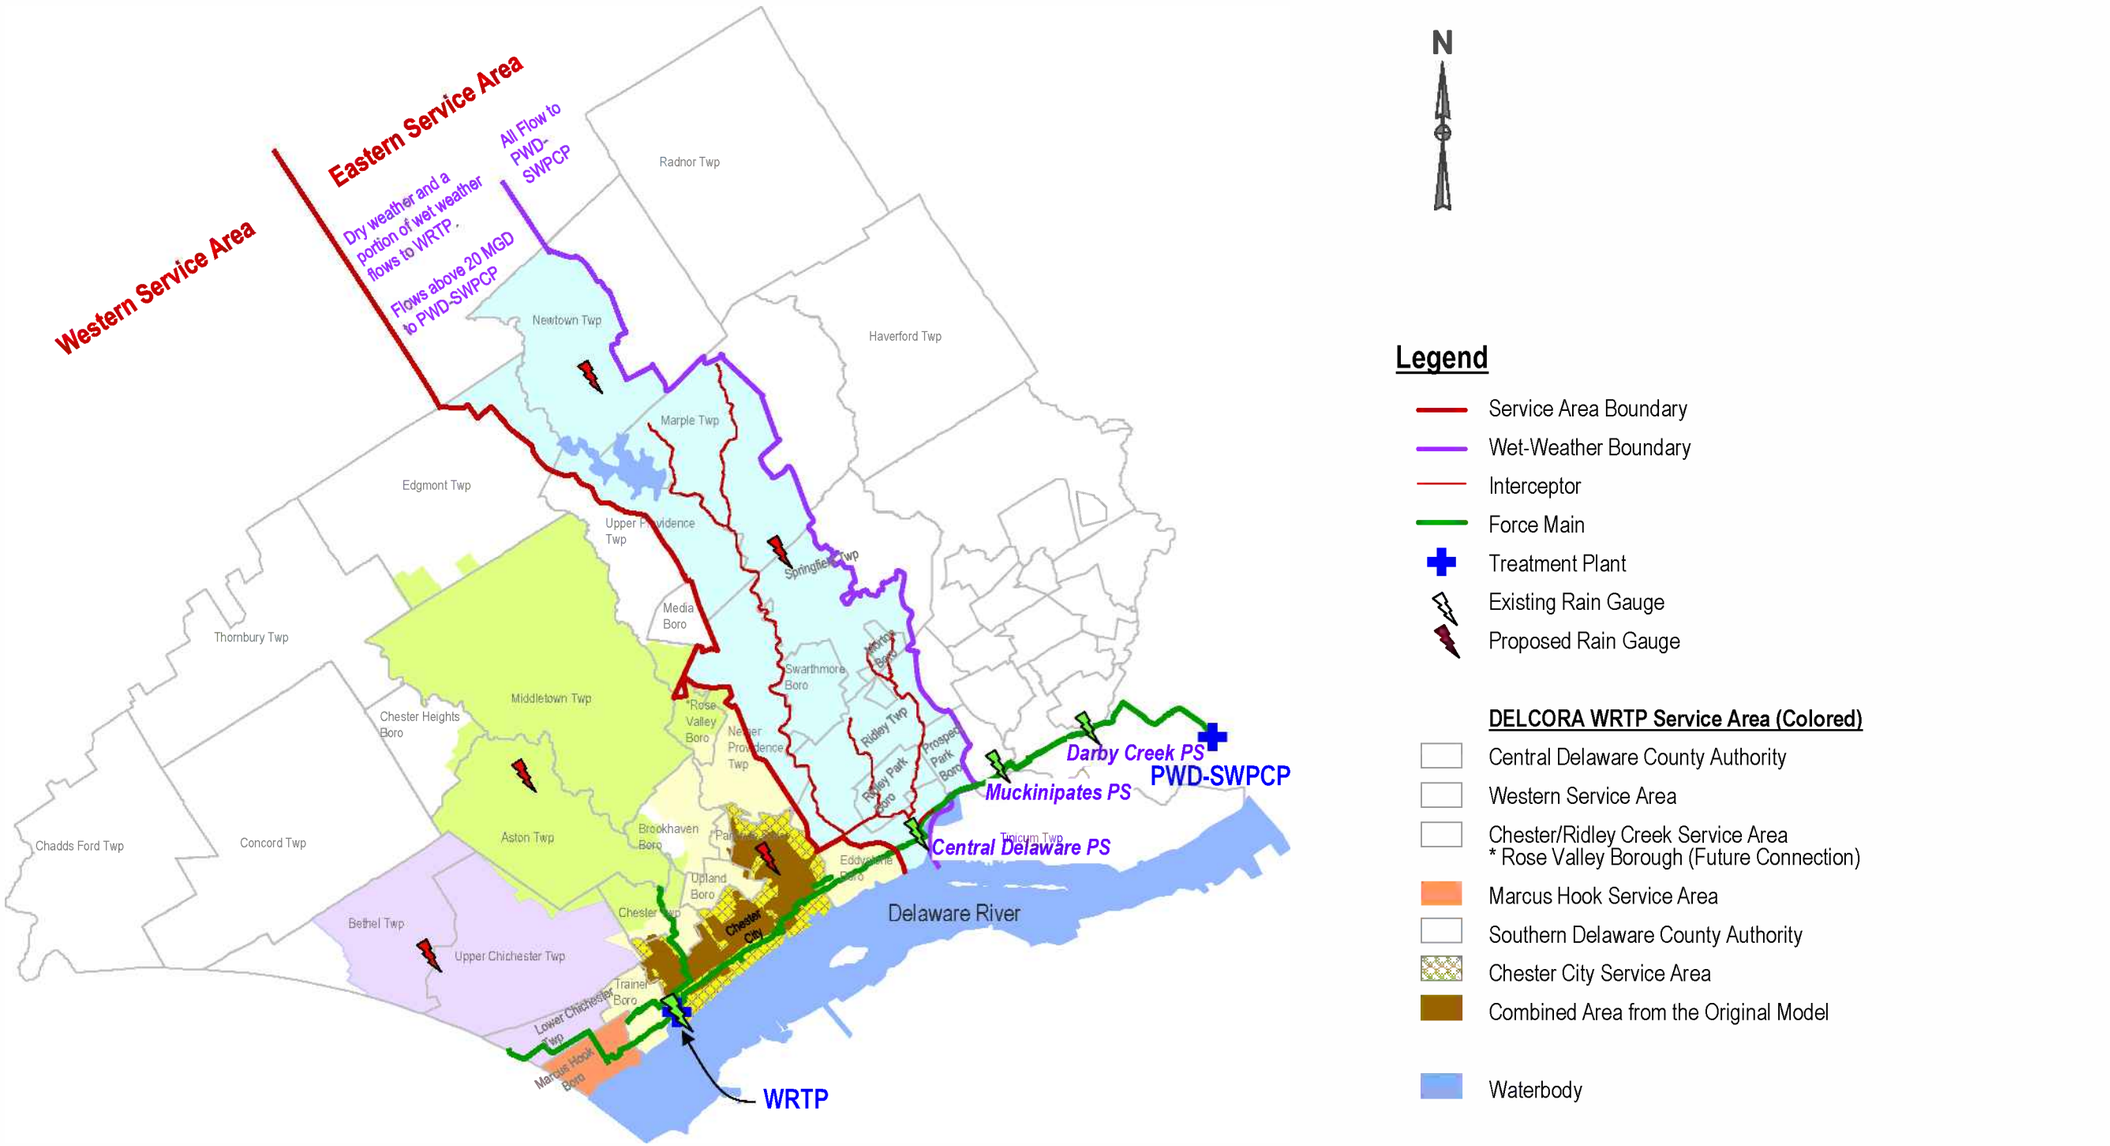
The number of gauges recommended by the Equation is quite small when compared to typical urban rain gauge networks where densities may be as great as one gauge per 10 to 20 km^2.

In this Plan, rain gauge intensity is estimated based on one gauge per 3 km^2 for the combined area and based on the Equation for the separated area. With this, the DELCORA System requires one (1) additional rain gauges in the combined areas and four (4) additional rain gauges in the separated areas.

Figure 4-2 shows the potential locations for the additional rain gauges, locations of the existing rain gauges are also shown.

Another approach of rainfall monitoring is to use the Gauge-Adjusted Radar Rainfall (GARR). A detail comparison of these two approaches will be evaluated during preparation of the Rainfall and Flow Monitoring Work Plan.

Figure 4-2 Proposed Rain Gauge Locations



4.2.2 Proposed Flow Monitoring Locations

In addition to the existing flow meters in the separated area measuring flows from individual contributing municipalities and pump stations, additional flow meters are needed, mainly in the combined area, to characterize surface runoff from the combined area and CSO discharges, meters in the separated area are also needed to characterize RDII from the Western Service Area.

Proposed flow meter locations can be categorized into the following four types: (**Table 4-2**):

- Located on the influent pipe to CSO regulators, this is to measure the influent flow to CSO regulators and for combined area runoff calibration. 15 meters are proposed for this category.
- Located on the overflow pipe, this is to measure the CSO overflows and calibrate CSO regulator parameters. Five (5) meters are proposed with four (4) for four largest CSO overflow points, including CSO 19, CSO 08, CSO 05, and CSO 02, and one (1) for a small overflow point CSO 14.
- Located on the side-line from the combined areas (flows from the combined area tie into interceptor instead of CSO regulator). This is to measure flows from the combined area and to calibrate combined area runoff parameters. Two (2) meters are proposed for this category.
- Located upstream of the combined area, this is to measure flows from the upstream separated area for RDII characterization. Four (4) meters are proposed for this category.

In total, 26 additional flow meters are proposed. **Table 4-2** lists approximate flow meter locations and location categories. **Figure 4-3** shows a map of the proposed additional flow meters, with zoom into the combined area in **Figure 4-4**.

Table 4-2 Proposed Additional Flow Meters

Proposed Flow Meter	Approximate Location	Type
In-02	Influent pipe to CSO 02 Regulator	On the influent pipe to regulator
In-03	Influent pipe to CSO 03 Regulator	On the influent pipe to regulator

Figure 4-3 Proposed Flow Meters

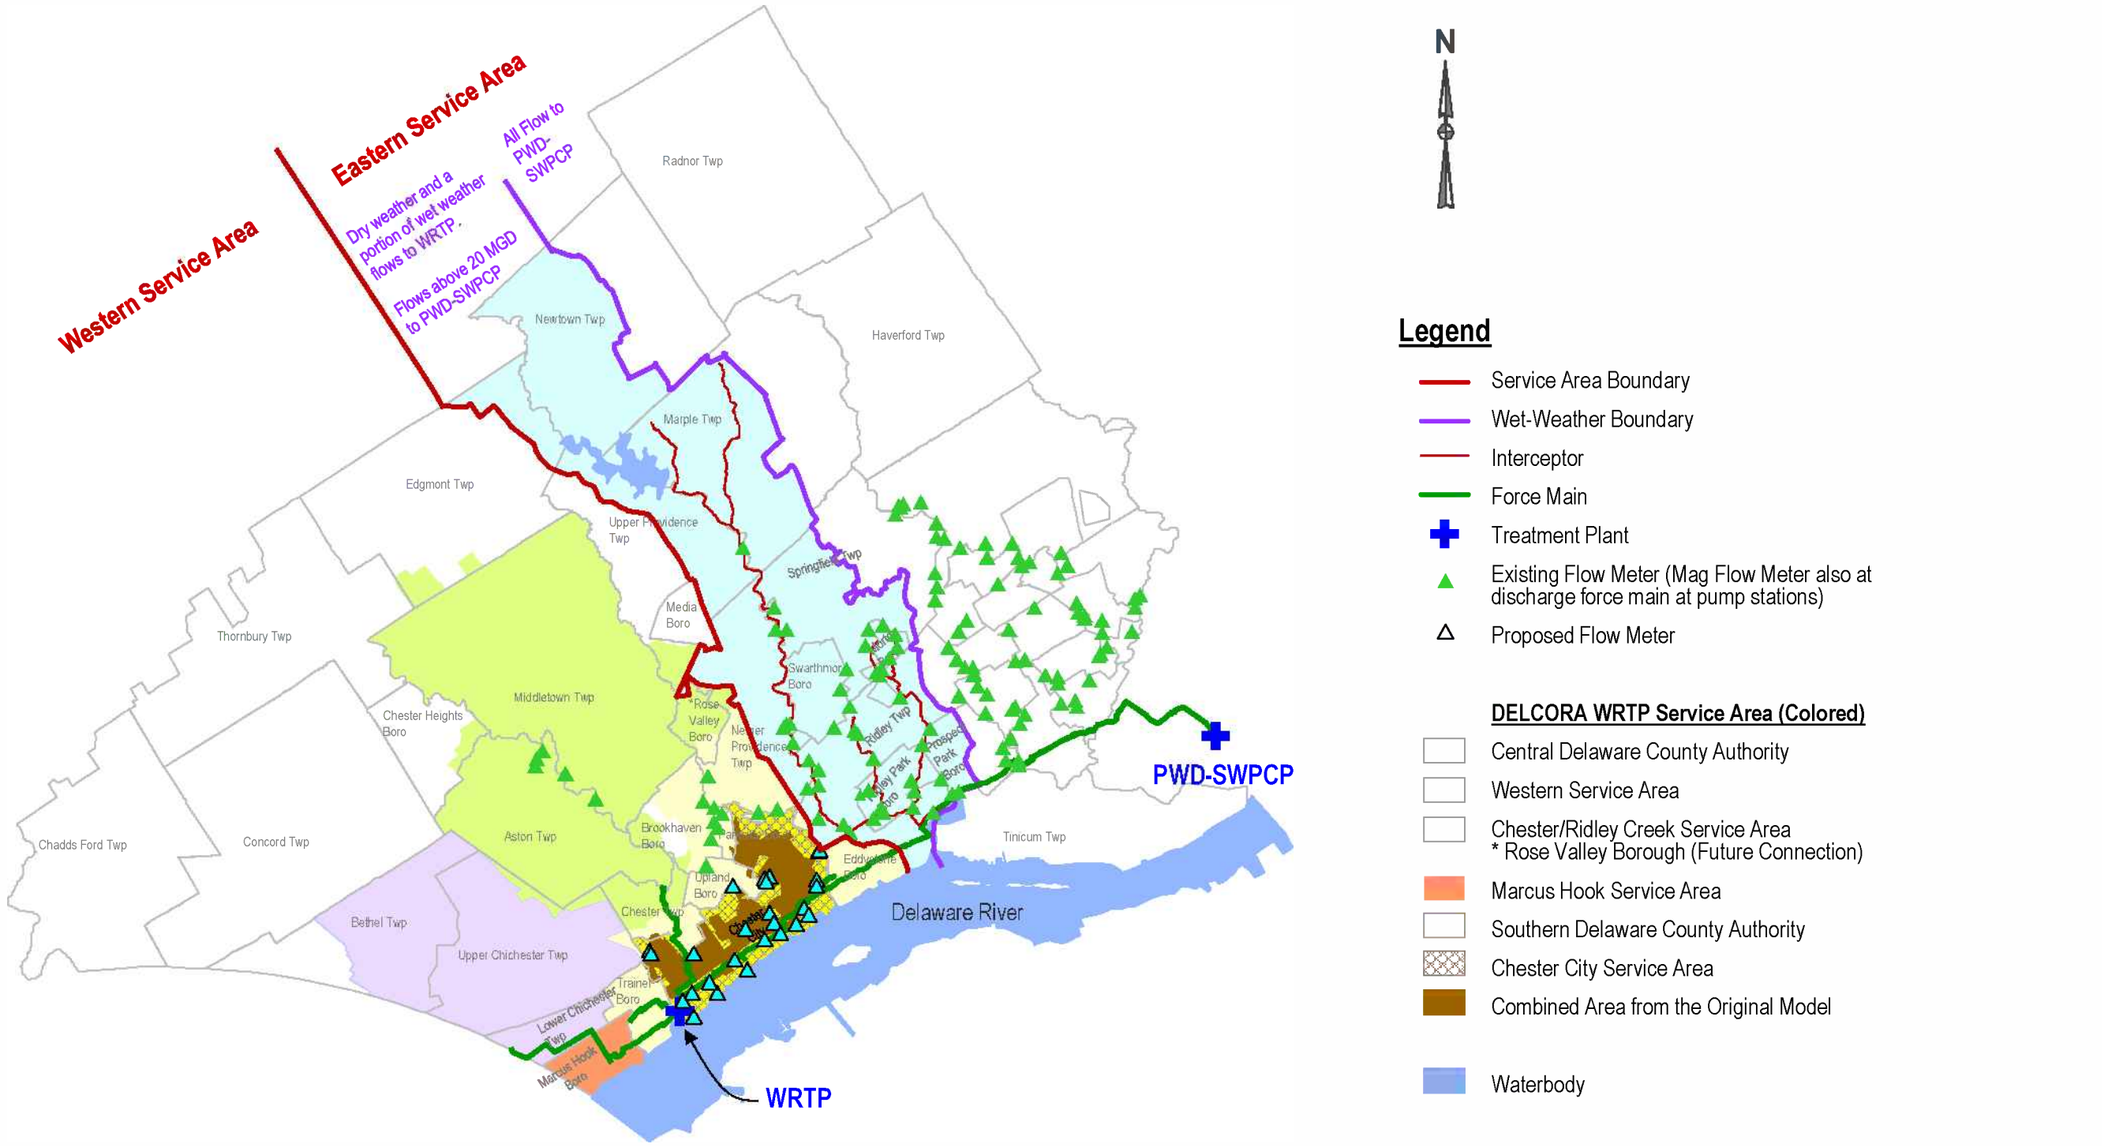

Figure 4-4 Additional Flow Meters (Zoom into the Combined Area)

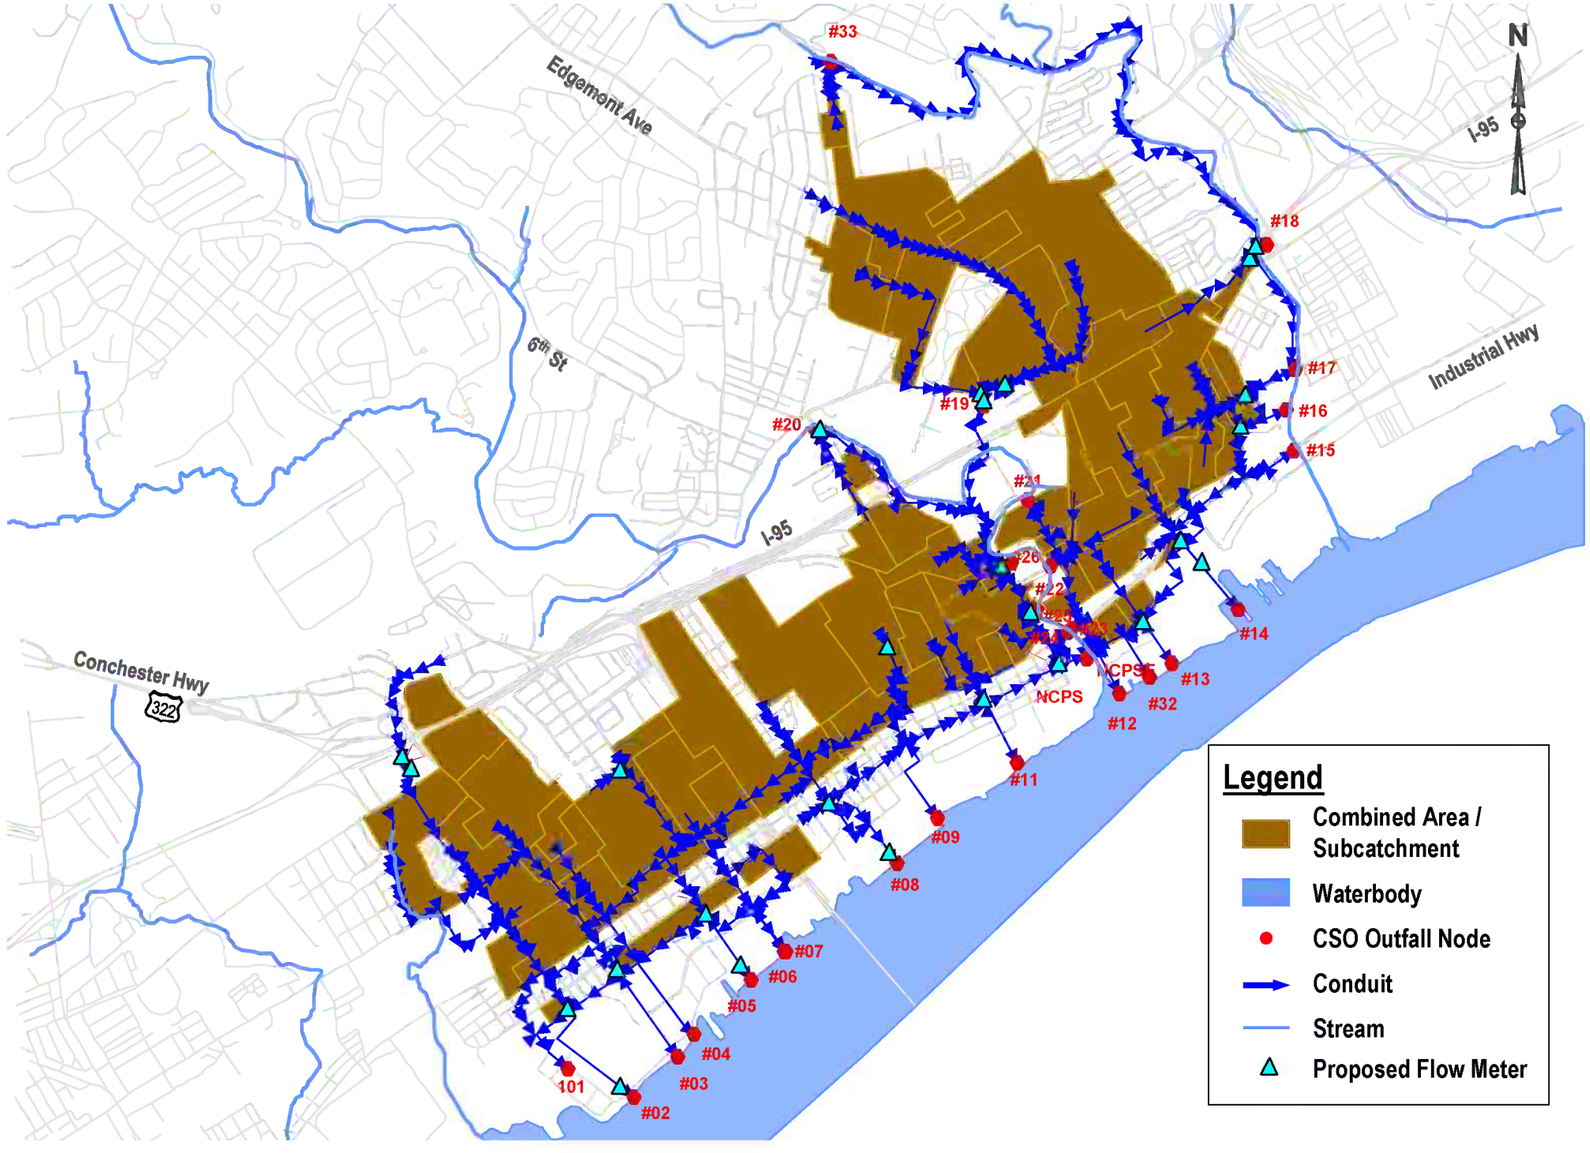


4.3 Rainfall and Flow Monitoring Work Plan

Per the Consent Decree, the additional rainfall and flow monitoring need to be carried out at least for 12 months. Key tasks of the monitoring program include the following. A detail work plan will be prepared during the first Task (Prepare Rainfall and Flow Monitoring Work Plan).

- Prepare Rainfall and Flow Monitoring Work Plan in October 2015, exact locations of the proposed rain gauge and flow meter will be field verified and finalized during plan development,
- Procure Flow Metering and Rain Gauge Services in November 2015,
- Install and Calibrate Rain Gauge and Flow Meters for Official Data Gathering in November through December 2015,
- Conduct Rainfall and Flow Monitoring continuously for 12-month through Year 2016.
- Monitoring data collection and analysis, within two months after the monitoring program is completed.

Section 5 DELCORA H&H Model Calibration and Validation

5.1 Rainfall and Flow Monitoring Data Analysis

A rainfall and flow monitoring data analysis will be performed for the data collected from the additional rainfall and flow monitoring program listed in Section 4. The purposes of this data analysis are to:

- document rainfall and flow monitoring locations,
- overview monitoring data quality,
- analyze rainfall data to identify dry weather and wet weather conditions and to characterize individual rainfall event for precipitation depth, duration, maximum intensity, and return frequency,
- analyze flow data to determine dry weather flow and diurnal pattern, wet weather flow and peak factor, and system response to wet weather events, and
- determine wet weather events for H&H model calibration and validation.

5.1.1 Rainfall Monitoring Data Analysis

A rain gauge location map will be prepared, together with a Thiessen polygon. A system-wide area-weighted average rainfall will be calculated based on the Thiessen polygons.

Monthly rainfall depth and total rainfall depth will be calculated for each rain gauge to characterize geographical rainfall distribution throughout the collection system.

An inter-event time of 6 hours will be used to identify individual rainfall event. The inter-event time specifies the minimum duration in which precipitation does not occur. Based on this criterion, a dry weather time period and the number of total rainfall events will be identified. The rainfall events during the flow monitoring periods should have a wide variation in terms of total depth, intensity, duration, and antecedent conditions to provide a large dataset for balanced model calibration and validation.

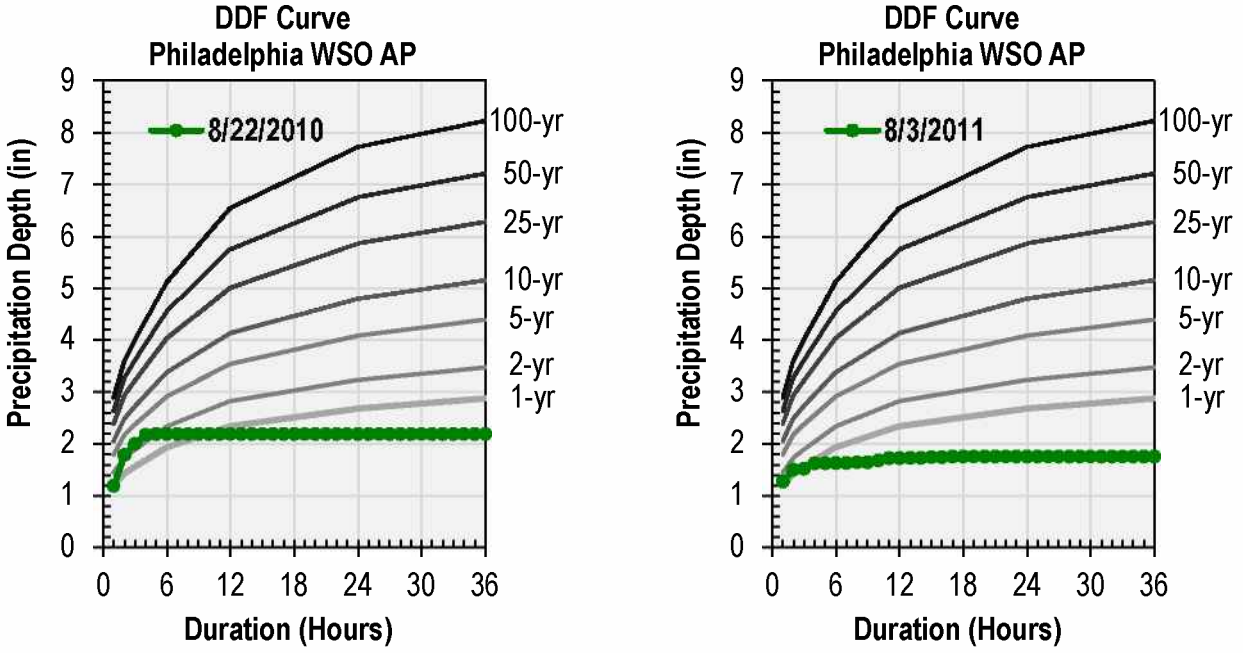
Table 5-1 shows NOAA precipitation frequency estimates for the Philadelphia International Airport. The original NOAA table contains rainfall data for 1-year to 1000-year return frequencies. A regression model can be used to derive the data for once per 3 months (four times a year) and once per 6 months (twice a year) storms. Based on **Table 5-1**, a Depth-Duration-Frequency (DDF) curve can be developed for individual rainfall event. For example, **Figure 5-1** shows the August 22, 2010 rainfall event as a 2-year storm and the August 3, 2011 rainfall event as a 1-yr storm.

All the rainfall events will be characterized by event start time, event end time, rainfall depth, duration, maximum intensity, and return frequency in a summary table. Top 10 rainfall events will be identified as candidate events for model calibration and validation.

Table 5-1 NOAA Philadelphia Precipitation Frequency Estimates

Duration	Precipitation Frequency Estimates (rainfall: in)						
	1	2	5	10	25	50	100
5-min	0.347	0.414	0.486	0.537	0.598	0.64	0.681
10-min	0.555	0.661	0.778	0.858	0.954	1.02	1.08
15-min	0.694	0.831	0.984	1.08	1.21	1.29	1.37
30-min	0.951	1.15	1.4	1.57	1.79	1.94	2.1
1-hr	1.19	1.44	1.79	2.05	2.38	2.63	2.89
2-hr	1.43	1.73	2.17	2.49	2.93	3.27	3.6
3-hr	1.56	1.89	2.37	2.73	3.22	3.61	4.01
6-hr	1.93	2.33	2.91	3.38	4.03	4.56	5.12
12-hr	2.34	2.82	3.54	4.13	5.01	5.75	6.55
24-hr	2.68	3.23	4.08	4.8	5.86	6.75	7.72
2-day	3.07	3.71	4.7	5.51	6.69	7.67	8.73
3-day	3.26	3.93	4.96	5.81	7.03	8.05	9.14
4-day	3.44	4.15	5.22	6.1	7.37	8.42	9.54

Figure 5-1 Rainfall with 1-yr and 2-yr Return Frequency

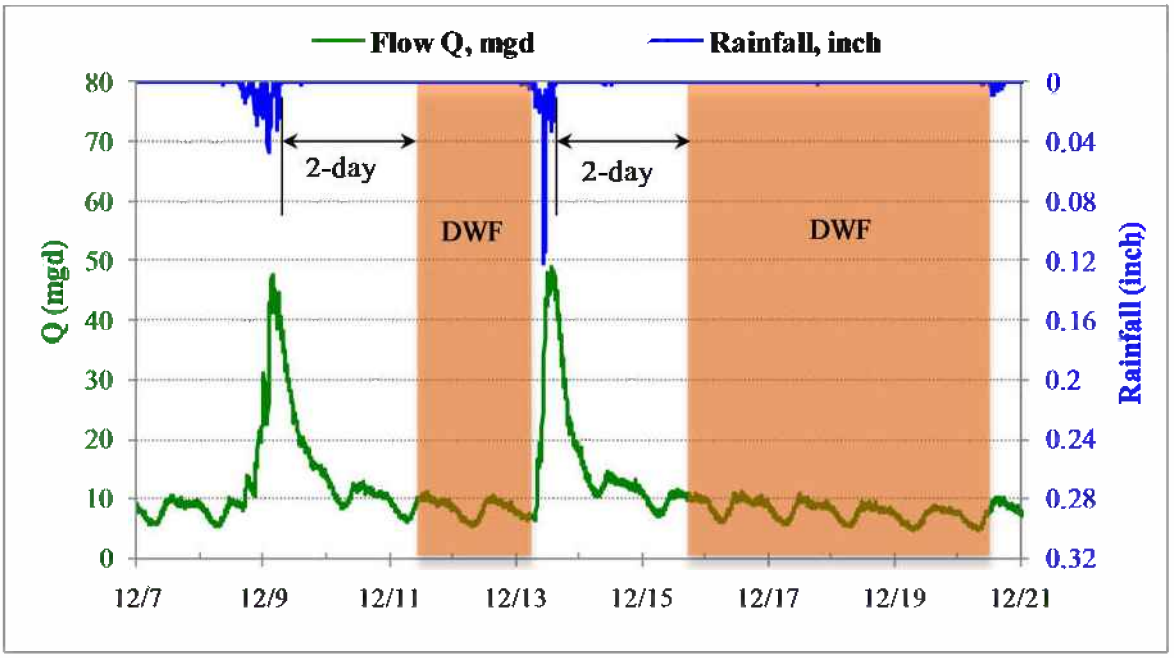


5.1.2 Flow Monitoring Data Analysis

5.1.2.1 Dry Weather Flow (DWF) Analysis

A "dry weather" condition was defined as a period with no precipitation that begins two days after the last wet weather event and lasts until the beginning of the next precipitation event. **Figure 5-2** is an example plot showing both rainfall data and a flow hydrograph. Periods of dry weather flow are also shown in the plot based on the definition. Flow hydrographs will be screened for each metering site to confirm that the data used for the DWF calculation was appropriate. **Figure 5-3** shows an example that some portion of the flow data measured needs to be exempted from the DWF calculation because the data was not consistent with other dry weather flows measured during the monitoring periods.

Figure 5-2 Hydrograph to Show Dry Weather Flow (Example Plot)



Average dry weather flow will be calculated by averaging the monitored flows from the dry weather periods identified in the rainfall data analysis. The overall and monthly DWFs for all monitoring sites will be analyzed.

The dry weather flows vary throughout the day, with the highest flows normally occurring around noon and the lowest rates between midnight and early morning. Flow data from the dry weather periods will be used to develop a flow diurnal pattern for each flow meter site. Diurnal patterns will be analyzed for both weekdays and weekends because they are usually different. In the example plot shown on **Figure 5-4**, the weekend DWF peak and valley have a 3-hour lag compared to the weekday pattern.

Figure 5-3 Data Screening for Dry Weather Flow Calculation (Example Plot)

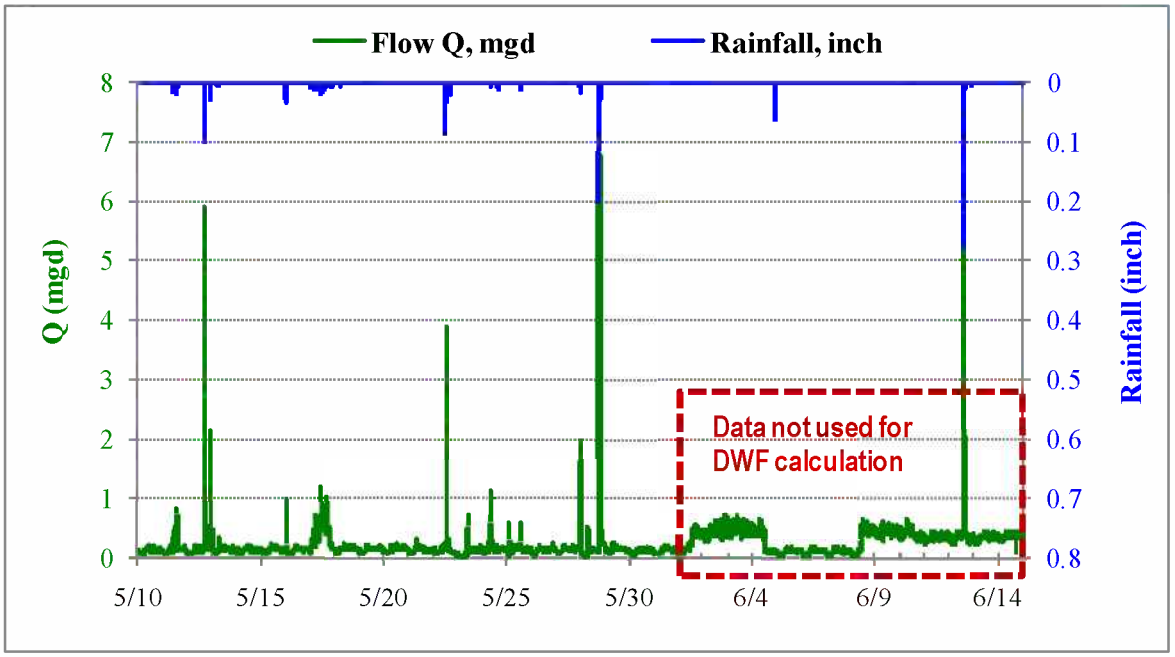


Figure 5-4 Weekday and Weekend Dry Weather Flow Diurnal Pattern (Example Plot)

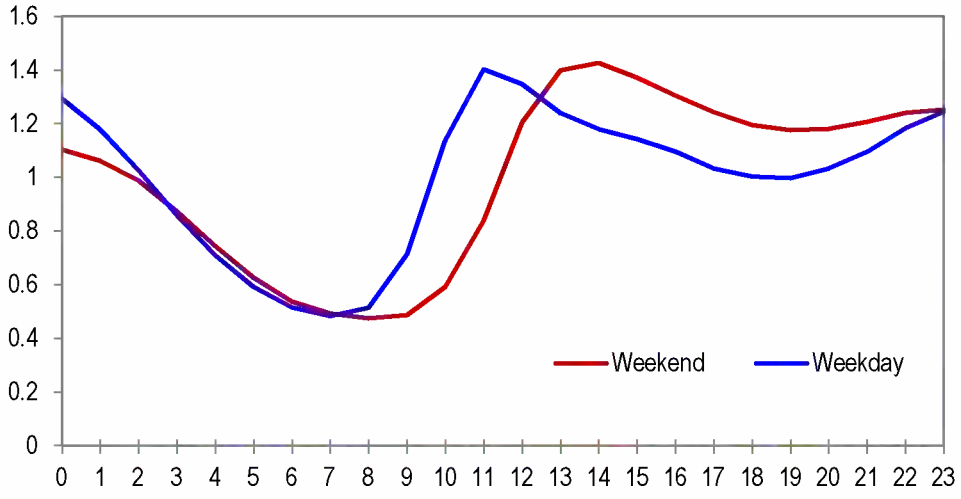


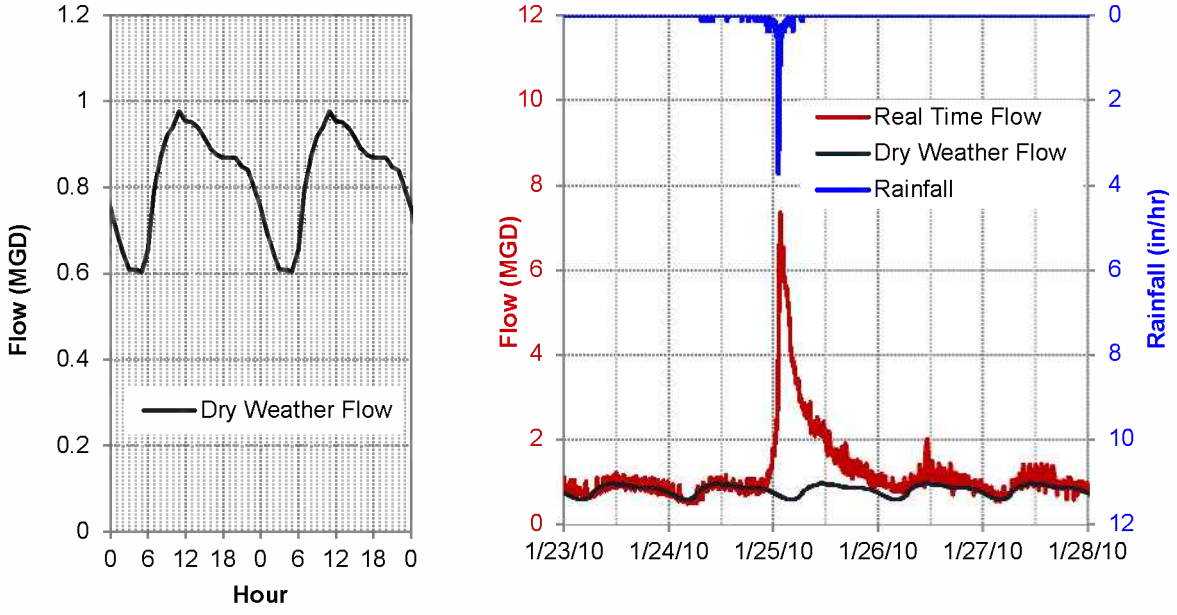
5.1.2.2 Wet Weather Flow Analysis

Wet weather flows are the combination of dry weather flows and additional flows that enter the system during wet weather conditions. The additional flows are from combined area surface runoff and RDII.

Inflow normally occurs when rainfall enters the system through direct connections such as roof leaders, yard drains, catch basins, sump pumps, manhole covers and frame seals or indirect connections with storm sewers. Inflow is usually recognized graphically by large magnitude, short duration spikes immediately following a rain event. Infiltration occurs during wet weather conditions when water enters a sewer system from the ground through means which include, but not limited to, deteriorated pipes, pipe joints, connections, or manholes. It is significantly influenced by the size and duration of the rainfall event. Infiltration is often recognized graphically by a gradual increase in flow after a wet weather event. The increased flow typically sustains for a short period after rainfall has stopped and then gradually drops off.

The peaking factor represents the ratio of the peak wet weather flow to the average dry weather flow. Usually, an hourly peaking factor is used to represent the wet weather peaking factor. Peaking factors will be analyzed for each flow monitoring site. The peaking factors in the separated area can be used to determine the extent of the RDII within a particular basin. **Figure 5-5** is an example flow hydrograph plot showing an hourly peaking factor of approximately 9 for the monitoring site. This high peaking factor indicates that a significant amount of RDII enters the collection system. The immediate flow increase shortly after the rainfall indicates significant inflow into the collection pipes, and the long tail back to the base flow indicates infiltration occurrence at the site as well.

Figure 5-5 Hydrographs of Flow Meters in Separated Area (Example Plot)



5.1.3 Wet Weather Event Selection for Model Calibration and Validation

Based on the rainfall and flow monitoring data analysis, four to six rainfall events will be selected for model calibration. The event selection should cover wide variation in terms of rainfall return frequency, rainfall depth, intensity, duration, antecedent conditions, and back-to-back storms. With this, the calibrated model can be reasonably applied for various hydrologic conditions. The selected calibrating period shall have good wet weather response from most of the flow monitoring locations.

One to two other rainfall events will be selected for model validation.

5.2 Model Calibration and Validation

Model credibility is developed through model calibration and validation. Model calibration involves application of the model to known external inputs (e.g., rainfall), evaluation of the model's ability to replicate monitored conditions (e.g., flow and volume), and adjustment of key model parameters as needed until an acceptable level of agreement is reached between simulated and monitored conditions.

After the model is satisfactorily calibrated it must be validated by running known storms with known flow results and having the model replicate the known events. Storms used in model validation should be independent from the storms used in the model calibration.

5.2.1 Calibration/Validation Criteria

5.2.1.1 Dry Weather Flow Calibration Criteria

A dry weather flow (DWF) analysis will be conducted based on the rainfall and flow monitoring results. DWF distribution in the collection system will be based on land use or water consumption data.

Weekday and weekend diurnal factor will be analyzed and applied for each flow meter service area and a monthly factor will be used, if necessary.

DWF calibration will adhere to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be within 1 hour of the observed,
- The simulated peak flow will be within 10% of the observed flow, and
- The simulated flow volume over 24 hours will be within 10% of observed flow.

5.2.1.2 Wet Weather Flow Calibration Criteria

Wet weather flow (WWF) includes surface runoff from the combined area, RDII from the entire service area, and connected rooftops, if any, from the separated area. RDII parameters will be developed based on the separated area, and surface runoff parameters will be adjusted for the combined area to calibrate the system response to the wet weather conditions.

Four (4) to six (6) wet weather events will be selected for wet weather calibration, depending on the rainfall and flow monitoring results, and various rainfall intensities and volume should also be considered.

WWF calibration will adhere to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be within 1 hour of the observed,
- The simulated peak flow will be within 10% of the observed flow, and
- The simulated flow volume over 24 hours will be within 10% of observed flow.

5.2.2 Model Calibration Approach

The runoff calibration for the combined sewer area is achieved by primarily adjusting width and percent imperviousness. The RDII calibration is achieved by adjusting RTK values. The calibration of hydraulic control structures (weirs and orifices) is achieved by adjustment the discharge coefficients. The conduit hydraulics calibration is achieved by adjusting Manning's n and head loss coefficients. Flow depth, as well as flow rate, is checked while calibrating the hydraulic model.

Once the model is calibrated, different sets of flow monitoring data are used to validate the model calibration. Model calibration and validation is an iterative process.

Percent Imperviousness
The percent imperviousness for combined sewer subcatchment is the key parameter to be adjusted to calibrate runoff to the observed wet weather flow volumes. Site visits of the combined sewer areas may be needed to verify real connectivity. If runoff from a large portion of the impervious surface could not be captured by the combined sewers due to a limited number and size of storm inlets, the percent imperviousness will need to be reduced significantly from its initial value calculated based on impervious land cover. This is done to represent a more reasonable "effectively connected area" and to achieve a satisfactory calibration for runoff volume.

Width
The width for the combined sewer sub catchments, in conjunction with percent imperviousness, will be adjusted to calibrate to the observed wet weather flow peaks.

Depression Storage
The depression storage is another hydrologic parameter for wet weather volume calibration. It can also be adjusted to achieve a satisfactory calibration for the wet weather flow start timing.

RDII Parameters
RDII parameters are to be adjusted to calibrate to the observed wet weather volumes and flow hydrograph shape for the separate sewer areas. The RDII parameters for the combined sewer areas will use the same as those for the immediate upstream separate sewer areas. Then, the runoff parameters will be adjusted to calibrate to the observed data.

Pipe Roughness
Pipe roughness will be adjusted to calibrate to the observed flow depths and velocities at the meter locations.

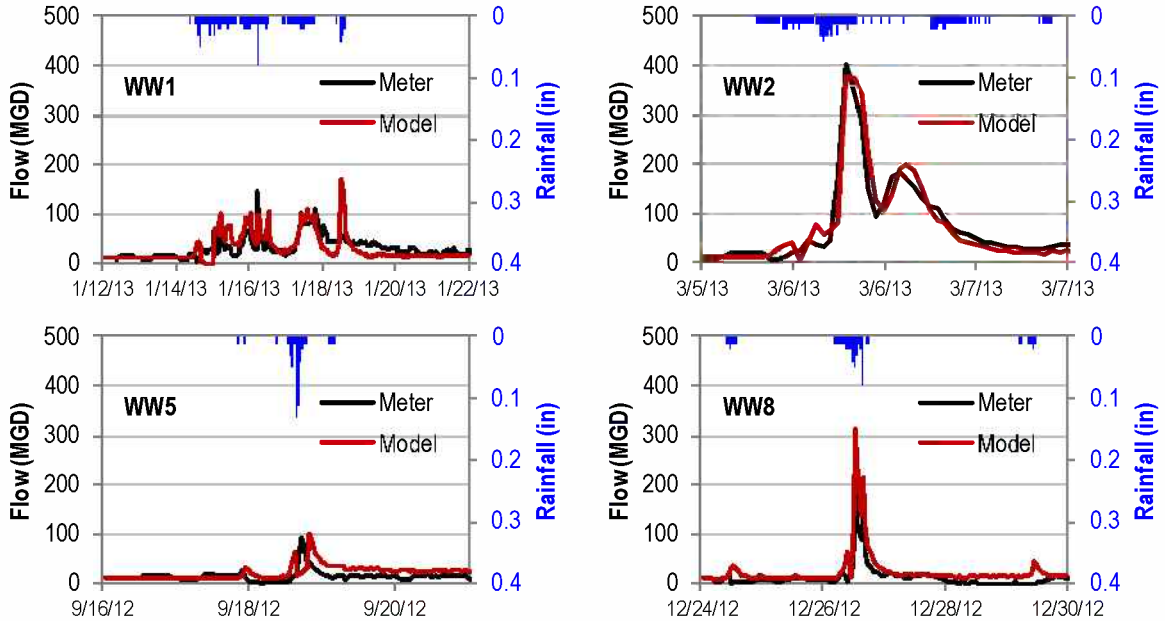
Orifice and Weir
Orifice and weir parameters discharge coefficients will be adjusted to calibrate to the observed overflows at the outfall meter locations.

Minor Loss
Minor loss values will be applied in the model where necessary to refine observed flow/depth relationships at the meter locations.

5.2.3 Model Calibration Results

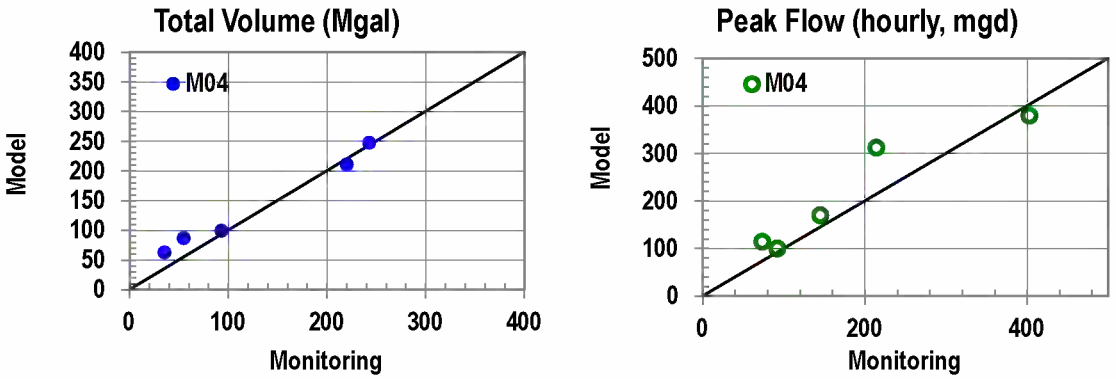
Generally, the model predictions should be in great agreement with the metering data. **Figure 5-6** is an example plot showing metered and modeled flow at one monitoring site for four wet weather events (WW1, WW2, WW5, and WW8). A great agreement between metered and modeled data may not be achievable for each individual wet weather event. The larger storm events will have more weighting factor in the calibration process because the large events are the ones that dominate the total overflow volume.

Figure 5-6 Model Calibration Hydrograph (Example Plot)



Comparisons of the predicted total volume against the monitoring total volume and predicted peak flow against monitoring peak flow will be analyzed and shown in 1:1 ratio plots for all calibrated meters (see example **Figure 5-7**). This is to evaluate the overall calibration and validation from all the events. The event points in **Figure 5-7** are distributed close to the 1:1 ratio line, which means that the model predicted peak flow and wet weather event volume are in a great agreement with the metered data.

Figure 5-7 Model Calibration Hydrograph (Example Plot)



Section 6 Model Development and Implementation Schedule

The schedule for model development and implementation is shown in **Figure 6-1**. All LTCPU tasks related to the H&H model construction, application, and implementation are included in the schedule. The schedule is integrated into LTCP development consistent with other dates required pursuant to the Consent Decree.

Figure 6-1 Schedule for H&H Model Development and Implementation

	Tasks of DELCORA H&H Model Development and Implementation	Start	Finish
	Lodging date of Consent Decree (8/17/15)		
	DELCORA Long Term Control Plan Update	8/17/15	2/14/19
	TASK 3 - Typical Year Rainfall Record (90 days)	8/18/15	10/31/15
1	Develop criteria for determination of typical hydrologic period		
2	Review available historic rainfall and flow data		
3	Obtain rainfall data from the Philadelphia National Airport.		
4	Review with DELCORA		
5	Select the typical hydrologic period and document the selection process		
6	Draft Report		
7	Final Report		
	TASK 5 - Hydrologic & Hydraulic Model	8/18/15	10/31/17
1	Initial assessment of GIS Model		
2	Initial assessment of H&H Model		
3	Report summarizing Initial Assessment		
4	Develop an H&H Model Update and Calibration Plan (60 days)	8/18/15	10/14/15
5	Develop Schedule for Model Development and implementation		
6	H&H Model Update		
7	Flow Monitoring Data Analysis		
8	H&H Model Calibration		
9	H&H Model Report		
	TASK 6 - Rainfall and Flow Monitoring	10/15/15	1/31/17
1	Prepare Rainfall and Flow Monitoring Work Plan (from Task 5)		
2	Procure Flow Metering and Rain Gauge Services		
3	Install and Calibrate Rain Gauge and Flow Meters for Official Data Gathering		
4	Conduct Rainfall and Flow Monitoring		
	TASK 7 - Existing Service Area Characterization	9/15/15	12/31/17
1	GIS Mapping Review and Update		
2	Refine Service Area Delineation (Combined and Separated)		
3	Investigate Existing CSO Facilities		
4	Investigate Service Agreements		
5	Perform H&H Modeling of Existing System		
6	Documentation		
	Evaluation of CSO Alternatives (Part of Task 11)	5/1/17	1/31/18
1	Develop Future DWF and Service Area		
2	Develop CSO Alternatives		
3	Evaluate CSO Alternatives using H&H Model

GREELEY AND HANSEN

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION III
1650 Arch Street
Philadelphia, Pennsylvania 19103-2029

MAR 01 2016

Mr. Robert Willert, Executive Director
Delaware County Regional Quality Control Authority
100 East Fifth Street
Chester, PA 19013

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Hydrologic and Hydraulic Model Update and Calibration Plan. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP).

EPA hereby approves the plan with the understanding that the term "two days" as stated in paragraph 5.1.2.1 (Dry Weather Overflow Analysis) shall mean 48 hours.

Thank you for your continued cooperation with this matter. Please do not hesitate to contact me at (215)814-2097 if you have any questions.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

Section 1 Introduction

1.1 DELCORA's Consent Decree

DELCORA prepared and submitted their original Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) to the PADEP in 1999. This LTCP was subsequently approved by the PADEP, and DELCORA had started to implement the CSO control elements selected in the LTCP. In 2009, the United States Environmental Protection Agency (USEPA) informed DELCORA that the original LTCP was not in compliance with the requirements of the USEPA's CSO Policy. As such, DELCORA prepared and submitted a revised LTCP in April 2012. Subsequent to the receipt of the revised LTCP, DELCORA and the USEPA had corresponded various times including requests for additional information from the USEPA in accordance with Section 308 of the Clean Water Act. A Consent Decree was issued by the USEPA to DELCORA in June 2015. The Consent Decree requires a new LTCP to be prepared based on an agreed upon schedule, which will include interim deliverables and milestones that must be met.

According to the Consent Decree between the US EPA, PADEP, and DELCORA, within ninety (90) days after August 17, 2015 (the lodging date), DELCORA shall submit to Plaintiffs a report or technical memorandum describing DELCORA's statistical evaluation of long-term local rainfall patterns and the identification of an appropriate typical period for LTCP development purposes.

The statistical evaluation in this study utilizes local long-term rainfall record from the Philadelphia International Airport. It considers various appropriate rain year characteristics, including distributions of event rainfall totals, event durations, and peak and average rainfall intensities.

1.2 Typical Year for CSO LTCP Development

Precipitation generates urban storm water, combined sewer overflows (CSOs), and increased wet weather flows to the wastewater treatment plant. These will contribute bacteria and pollutants to the Delaware River and its tributaries. The effect of these contributors on the Delaware River mainly depends on the magnitude and duration of rainfall events and on the prevailing ambient river conditions controlling dilution and transport of the pollutants. This variability and complexity poses a significant challenge for assessing the performance of wet weather and CSO control alternatives.

In accordance with the USEPA CSO Control Policy (CSO Policy), dated April 19, 1994, the CSO control alternatives should be assessed on a "system-wide, annual average basis". This is accomplished by continuous simulation using a typical hydrologic period for the combined sewer system (CSS) and receiving water quality modeling applications. The CSO Policy supports continuous simulation modeling, i.e., using long-term rainfall records rather than records for individual storms. Long-term continuous rainfall records enable simulations to be based on a sequence of storms so that the additive effect of storms occurring close together can be examined. They also enable storms with a range of characteristics to be included.

Typically, a 3- to 5-year period is evaluated to balance between manageable model simulation time and representation of various rainfall/river conditions. In this study, a 3-year period is deemed most appropriate considering the modeling complexity. The representative three-year period is intended to

contain a relatively wet year, a dry year and an average year. Average year conditions are defined as the arithmetic average of the predictions for the selected period.

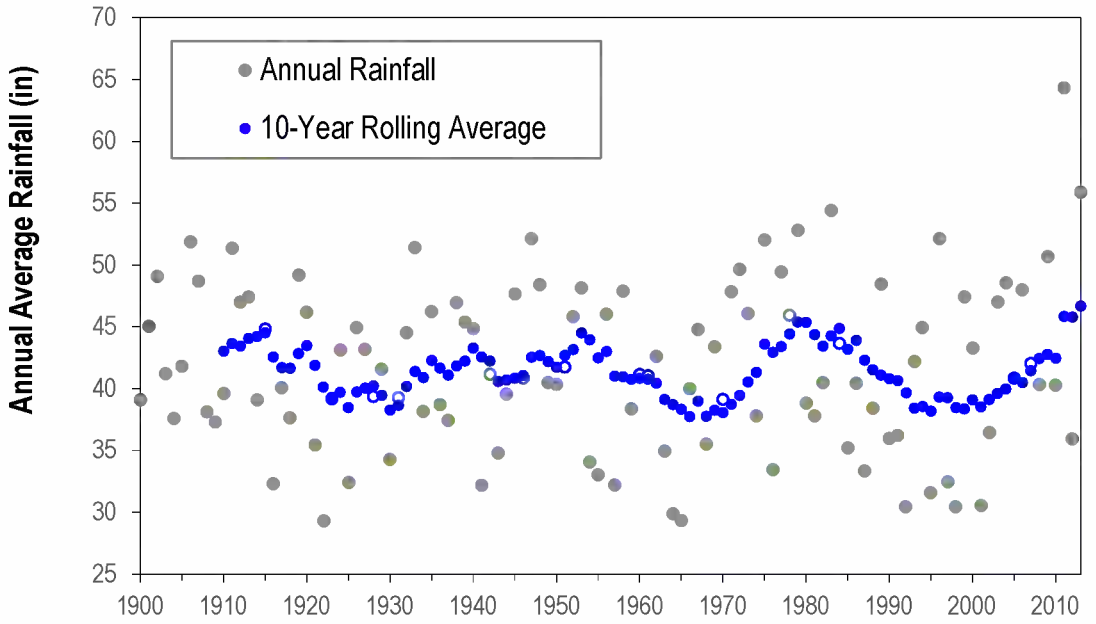
1.3 Climate Change Considerations

Average U.S. precipitation has increased since 1900, but there are regional differences, with some areas having larger increases, and others, decreases. Local climate change should be considered when selecting appropriate data records for the typical period analysis.

Rainfall data from the Philadelphia International Airport were obtained from the National Oceanic and Atmospheric Administration (NOAA). Hourly rainfall data is available from 1900 through 2013. This provides sufficient data to evaluate climate change in the area. **Figure 1-1** shows annual rainfall from 1900 to 2013. A 10-year rolling average trend line is also shown in the figure for characterizing long-term precipitation pattern. In the past 114 years, annual rainfall ranges from 29.3 to 64.33 inches, with the wettest year in 2011. The 10-year rolling average rainfall indicates that precipitation in the area runs through various dry and wet cycles, however with more extreme conditions (dry and wet) in recent years.

Considering the climate change, it is determined that the typical period for the LTCPU be selected based on statistical analysis of rainfall records in recent 30 years (i.e., 1984-2013).

Figure 1-1 Historical Annual Rainfall at Philadelphia International Airport



1.4 Methodology of Typical Year Selection

The typical hydrologic period is selected to provide representative and unbiased approximations of expected future conditions in terms of both averages and historical variability. Representativeness is

assessed using objective criteria for each of the ambient factors (i.e., river flow and rainfall). As indicated in the previous section, the selection of the typical hydrologic period is based on the historical records in the past 30 years from 1984 through 2013.

The following datasets are used for the analysis of the typical hydrologic period:

- Hourly precipitation data for the National Climate Data Center gauge at Philadelphia International Airport for 1984 - 2013.
- Daily Delaware River stream flow data from the U.S. Geological Survey gauge at Trenton, NJ (USGS 01463500) for 1984 - 2013. This is the closest USGS gauge that with daily river flow available.

Key criteria parameters used in the evaluation are listed in **Table 1-1**. Each parameter is given a weighting factor to describe the individual importance on the averageness of the analyzed time period. The parameters that are given the highest impact weighting include the following:

- The total annual rainfall depth, which drives the total runoff volume.
- The maximum peak intensity, which usually defines the biggest overflow event.
- The median Delaware River flow; the impact of sewer overflows on the water quality of the receiving water is dependent on the magnitude of the flows in river, and in the project area, intense local rainfall events are typically independent from watershed wide high flow events.

Table 1-1 Hydrologic Period Ranking Parameters

Key Parameter	Weighting Factor	Comments
Annual rainfall depth	25.0%	Important for evaluating annual overflow volume
Number of events > 0.1" rainfall depth	2.5%	Typically storms over 0.1" would start to cause surface runoff
Number of events > 0.25" rainfall depth	2.5%	Previous model indicates system overflows at storms over 0.25"
Number of events > 1.5" rainfall depth	7.5%	Storms to be controlled to meet potential presumption approach
Number of back-to-back events	5.0%	Important for evaluating the antecedent conditions
Maximum peak intensity	20.0%	Storms with high intensity causes overflows
Average rainfall duration	2.5%	Important for evaluating wet weather durations
Average rainfall intensity	5.0%	Important for evaluating overall rainfall intensity
Delaware River flow - 25th percentile	2.5%	Important for evaluating dilution power of the Delaware River flow for water quality
Delaware River flow - 50th percentile	25.0%	
Delaware River flow - 75th percentile	2.5%	

Section 2 Typical Year Selection for DELCORA

2.1 Annual Rainfall and River Flow Statistics

30-year hourly precipitation data (1984 - 2013) from the Philadelphia International Airport was analyzed to evaluate all individual rainfall events in the period. An inter-event time (IET) of 6 hours (i.e. minimum dry time of 6 hours between rainfall events was used to differentiate between individual events. Precipitation periods with a total rainfall volume of greater than 0.1 inch were counted as rainfall events. If the next rainfall event's starting time is within one day of the previous rainfall event's ending time, these two rainfall events are considered as back-to-back rainfall events. All rainfall events for the data period were analyzed for duration, inter-event duration, total rainfall amount, as well as maximum and average rainfall intensities.

A total of 1,934 rainfall events were counted for the period of 1984 - 2013. **Table 2-1** summarizes rainfall events on an annual basis for rainfall volume, max rainfall intensity, average intensity, average rainfall duration, quantities of rainfall events above 0.1 inch and 0.25 inch, and back-to-back rainfall event number. Statistical river flow information is also included in **Table 2-1**.

2.3 Ranking Analysis

From **Table 2-2** the relative deviation for each parameter was calculated for individual 3-year period. With the weighting factors listed in **Table 1-1**, a deviation score was developed for each individual period. The 3-year periods were then ranked based on the deviation score. The lower the deviation score (**Figure 2-1** Y-axis), the higher the rank for the hydrologic period (i.e., the closer it is to the average condition). **Table 2-3** and **Figure 2-1** shows the ranking results of the 28 hydrologic periods, with a ranking of 1 being the highest and a ranking of 28 being the lowest ranked hydrologic period. Hydrologic period 1994-1996 is ranked No.1 because it has the lowest deviation score of 0.047.

Table 2-3 Typical Period Ranking Analysis

Year	Rainfall								Delaware River Flow			Deviation Score	Rank
	Annual Rainfall	Max Rainfall Intensity	Average Rainfall Intensity	Average Rainfall Duration	Events ≥0.10 in	Events ≥0.25 in	Events ≥1.5 in.	Back-to-Back Event	25th Pct	50th Pct	75th Pct

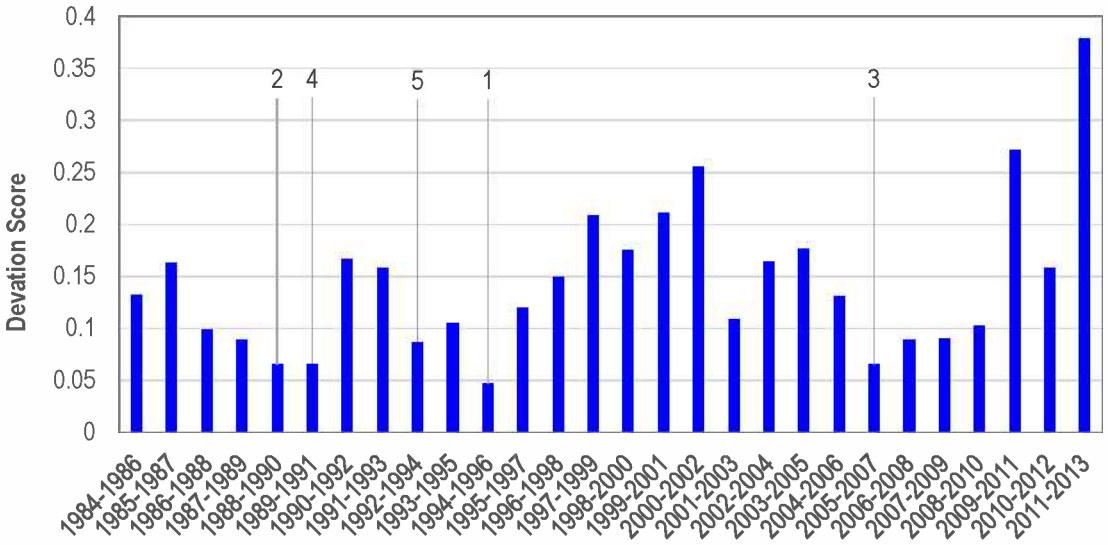
Figure 2-1 Ranking Score of 3-year Period, 1984-2013



2.4 Top 5 Ranked 3-year Hydrologic Periods

Based on the ranking analysis, the top 5 ranked hydrologic periods are:

- Rank 1: 1994-1996
- Rank 2: 1988-1990
- Rank 3: 2005-2007
- Rank 4: 1989-1991
- Rank 5: 1992-1994

Table 2-4 shows rainfall and river flow statistics for these top ranked hydrologic periods.

Table 2-4 Top 5 Ranked Hydrologic Periods

Rank	Year	Rainfall								Delaware River Flow (cfs)		
		Annual Rainfall (in)	Max Rainfall Intensity (in/hr)	Average Rainfall Intensity (in/hr)	Average Rainfall Duration (hr)	Events ≥0.10 in.	Events ≥0.25 in.	Events ≥1.5 in.	Back-to-Back Event	25th Percentile	50th Percentile	75th Percentile
1	1994-1996	42.9	1.50	0.08	10.1	65	47	5	7	5,611	9,710	16,775
2	1988-1990	41.0	1.69	0.08	10.5	63	44	5	10	5,598	8,338	13,925
3	2005-2007	43.6	1.55	0.09	10.6	61	45	6	10	6,030	10,450	17,533
4	1989-1991	40.2	1.50	0.08	10.8	63	45	5	10	5,187	8,043	14,467
5	1992-1994	39.2	1.50	0.08	10.6	64	41	5	8	5,070	7,760	13,167
Average 1984-2013		41.3	1.53	0.08	10.7	62	44	5	9	5,540	9,325	15,770

Figure 2-2(a) shows the max rainfall day for each month from 1988 through 2013. Max rainfall day in the month is determined by analyzing the daily rainfall amount and the day with the maximum rainfall amount is selected as the max rainfall day for the month. Max rainfall day in the month is probably the precipitation day that causes the maximum wet weather inflow to the collection system and CSO overflows in the month. **Figure 2-2(b)** shows the river flow and flow statistics for the max rainfall day in the month. The selected typical hydrologic period must ensure that large storm events do not occur under the extremely low river flow conditions. **Figure 2-2** indicates that all the top 5 ranked hydrologic periods meet this criteria.

Rainfall return frequency during 1988 through 2013 was analyzed to understand the distribution of the large rainfall events with return frequencies above 1-year. Rainfall return frequency is shown for each month in **Figure 2-2** (the number in the parentheses indicates the quantity of rain events at the return frequency). **Table 2-5** summarizes quantity of large rainfall events with return frequencies for the top 5 ranked hydrologic periods.

- All of the top 5 hydrologic periods have a 25-yr storm.
- Hydrologic period 1994-1996 (Rank 1) contains one 25-yr storm, one 10-yr storm and three 1-year storm. Hydrologic period 1988-1990 (Rank 2) contains one 25-yr storm, one 10-yr storm, three 2-year storm and one 1-year storm.
- Hydrologic period 1994-1996 (Rank 1) is more conservative because its annual average rainfall amount of 42.9" is slightly greater than the 30-yr average. It is considered a better option than hydrologic period 1988-1990 (Rank 2), which has a slightly less annual rainfall than the average.

Table 2-5 Rainfall Return Frequency Summary for the Top 5 Ranked Hydrologic Periods

Rank	Year	Quantity of Rainfall Events with Return Frequency above				
		25-yr	10-yr	5-yr	2-yr	1-yr
1	1994-1996	1	1			3
2	1988-1990	1	1		3	1
3	2005-2007	1	1		2	4
4	1989-1991	1			2	3
5	1992-1994	1	1			3

The analysis was also conducted with an IET of 12 hours, and the top five ranked hydrologic periods were shown in **Table 2-6**. The top four hydrologic periods based on the IET of 12 hours are the same as the analysis based on the IET of 6 hours, which include the 3-year period 1994 - 1996 remaining as Rank 1.

Table 2-6 Top 5 Ranked Hydrologic Periods (IET = 12 hr)

Rank	Year	Rainfall								Delaware River Flow (cfs)		
		Annual Rainfall (in)	Max Rainfall Intensity (in/hr)	Average Rainfall Intensity (in/hr)	Average Rainfall Duration (hr)	Events ≥0.10 in.	Events ≥0.25 in.	Events ≥1.5 in.	Back-to-Back Event	25th Percentile	50th Percentile	75th Percentile
1	1994-1996	42.9	1.50	0.08	12.5	62	47	6	4	5,611	9,710	16,775
2	1988-1990	41.0	1.69	0.07	13.9	59	43	6	5	5,598	8,338	13,925
3	2005-2007	43.6	1.55	0.08	14.3	55	43	6	5	6,030	10,450	17,533

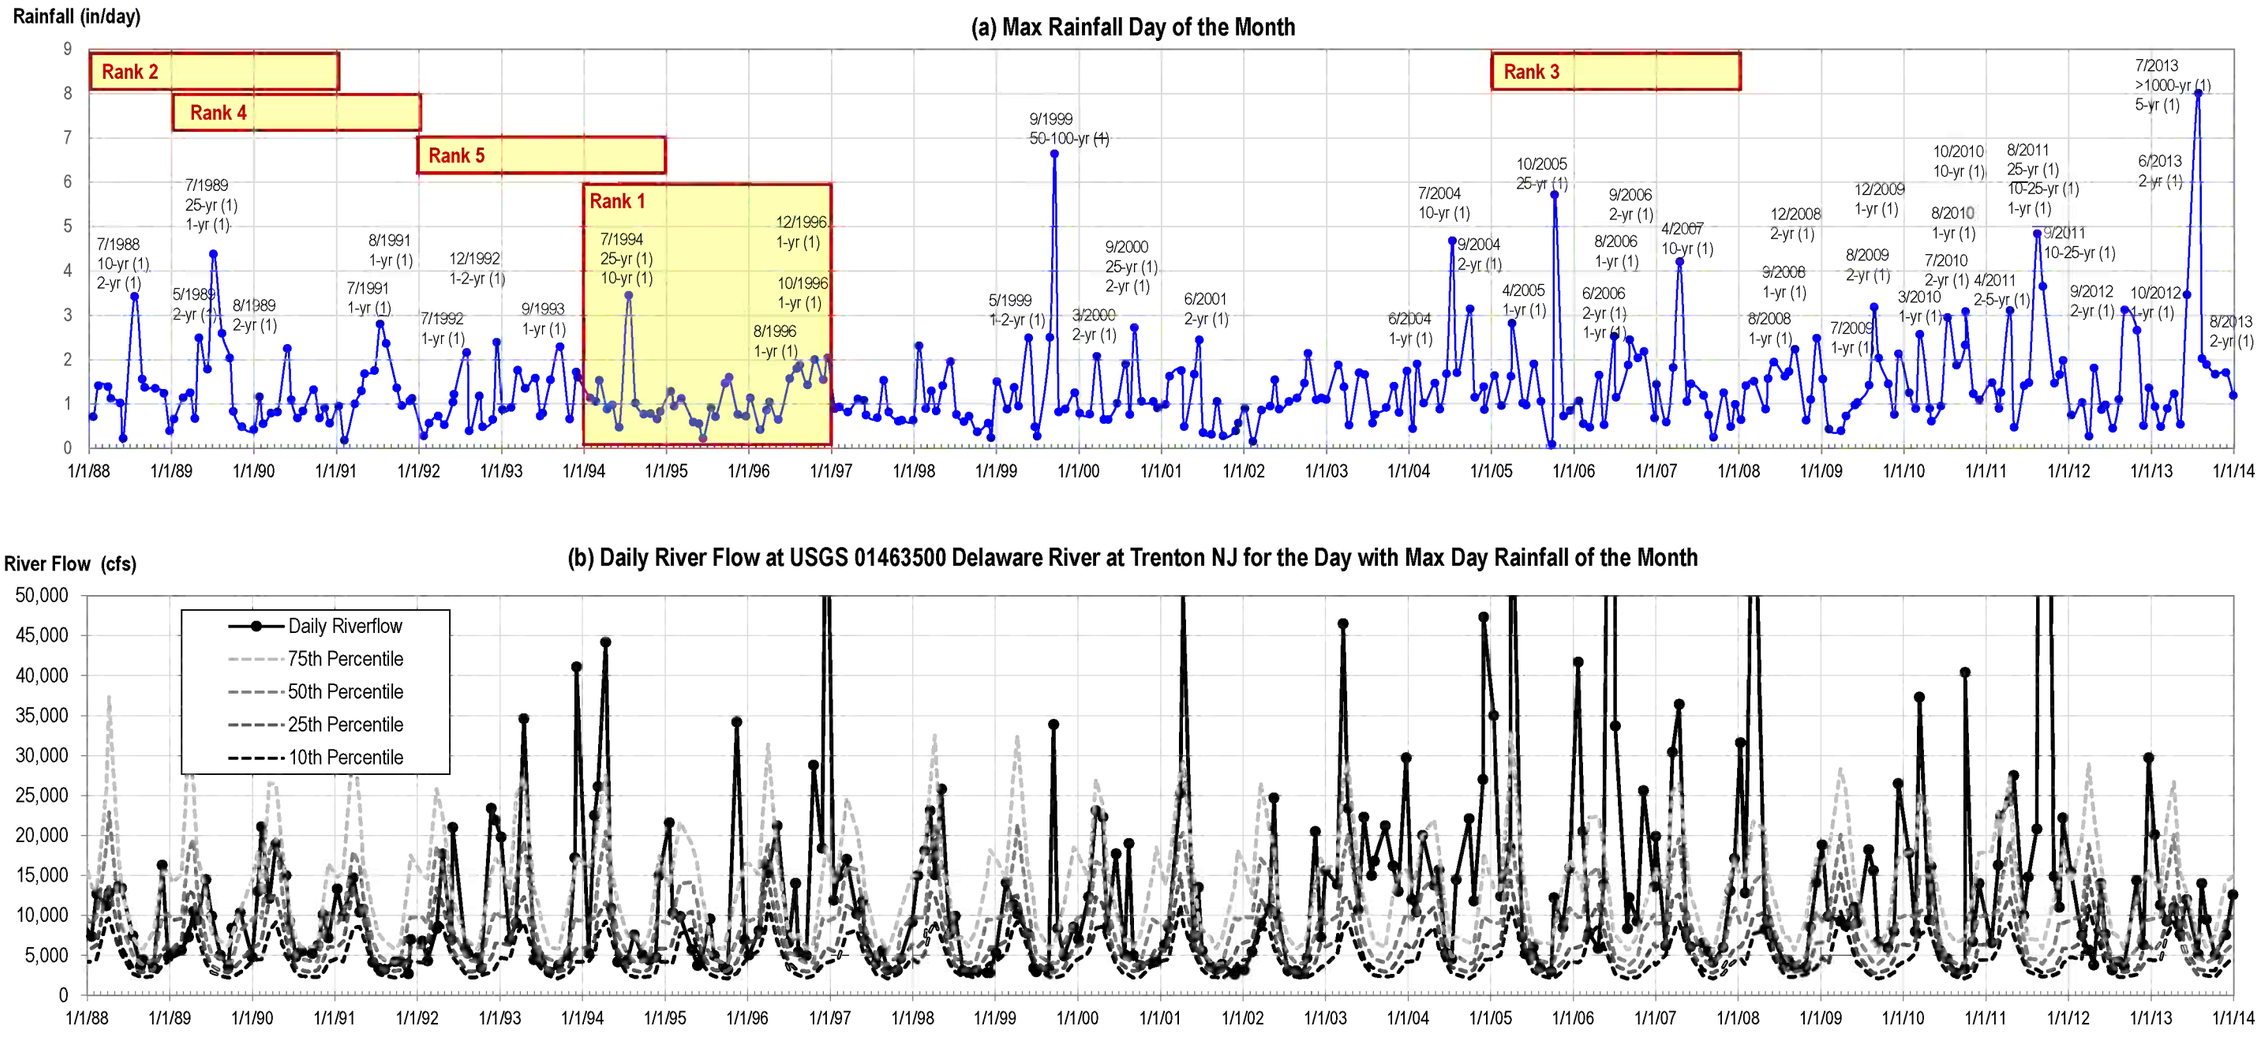
5	2007-2009	44.3	1.42	0.08	14.6	60	42	8	6	6,277	9,625	17,733
Average 1984-2013		41.3	1.53	0.07	14.1	58	43	6	5	5,540	9,325	15,770

Figure 2-2 Max Day Rainfall in the Month and Delaware River Daily Flows 1988-2013



2.5 Recommendation

It is recommended the 3-year period 1994-1996 (Rank 1) be selected as the typical hydrologic period for the CSO LTCPU. This period contains a wide range of storms and antecedent conditions. The hydrologic period of 1994-1996 is also evaluated for longer historical rainfall records up to 100 years. It is ranked No. 1 for the 50-years record and No.2 for the 100-year records (**Table 2-7**).

Table 2-7 Rank of Hydrologic Period 1994-1996 from Various Rainfall Data Set

	30-year Rainfall Records, 1984-2013	50-year Rainfall Records, 1964-2013	100-year Rainfall Records, 1914-2013
Rank of 1994-1996	1	1	2 (1925-1927 as Rank 1)

2.6 Additional Information on Statistical Analysis of Rainfall and River Flow Data

Figure 2-3 shows annual rainfall and average annual rainfall for years 1983-2013. The hydrologic period 1994-1996 contains a relatively wet year (1996 with 52.1 inches), a dry year (1995 with 31.6 inches) and a year close to average conditions (1994 with 44.9 inches).

Figure 2-4 shows annual average Delaware River flow and average flow for years 1983-2013. The hydrologic period 1994-1996 contains a relatively high flow year (1996 with 19,000 cfs), a low flow year (1995 with 9,000 cfs) and a year close to average conditions (1994 with 13,500 cfs).

Figure 2-3 Annual Rainfall 1983 - 2013

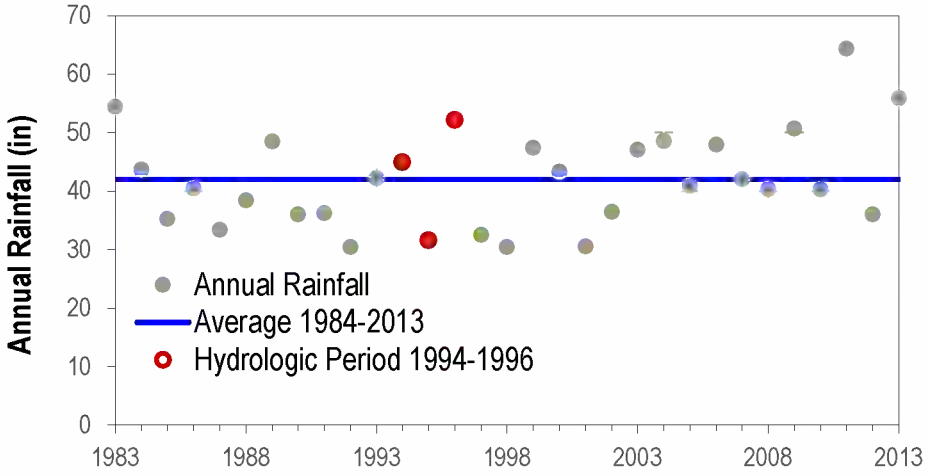


Figure 2-4 Annual Average Delaware River Flow 1983 - 2013

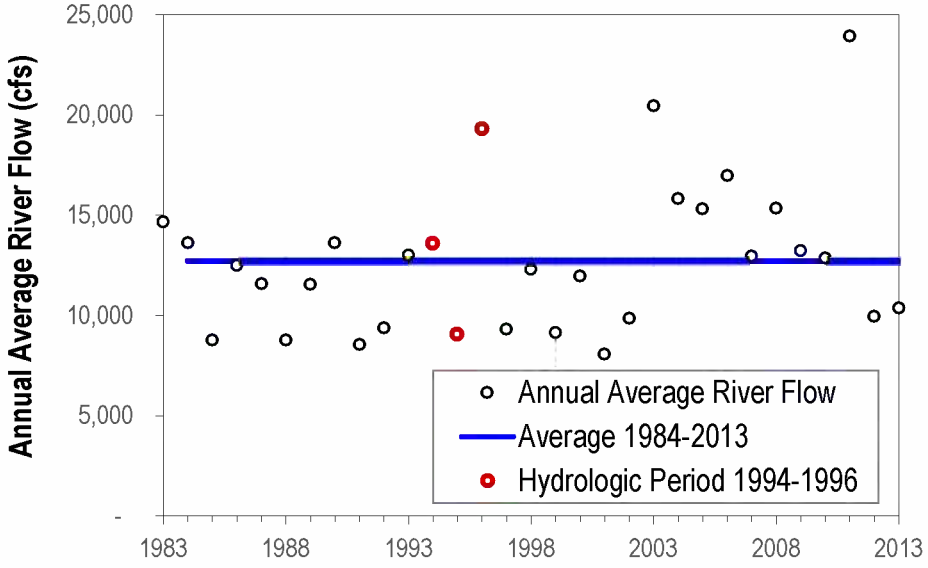

Delaware River flow distribution was developed for each calendar day using 100 years of records from 1913 to 2013, as shown in **Figure 2-5**. The River flow varies through the year with high flow season around March-April, and low flow season around June-August. **Figure 2-6** shows the Delaware River flow distribution during rainfall events at and above 1-year return frequency. Each dot on the plot represents an individual day during the storm events. It is observed that the river flows have a wide range of distribution during rainfall events below 2-yr return frequency. During larger storm events (greater than 5-year storms), the river flows tend to be relatively higher, as indicated by more dots with higher distribution percentiles on the plot. For example, during most of the 10-year storm events, the river flows are above the 35th percentile. In rare cases, large storm events occurred during a relatively low flow condition (e.g., the lowest dot for the 10-year storm), which is not a typical condition.

Figure 2-5 Delaware River Daily Flow Distribution

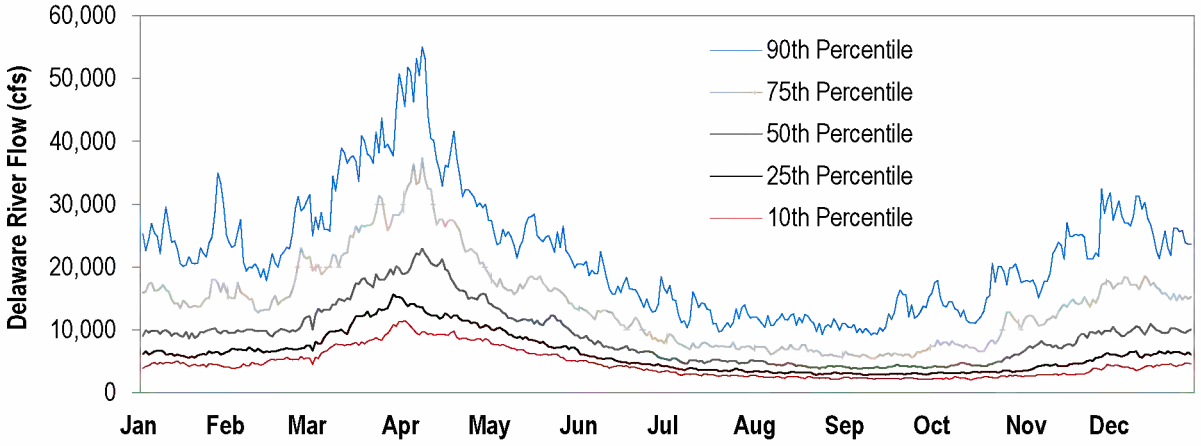

Figure 2-6 River Flow Distribution during Rainfall Events Greater Than 1-year Return Frequency

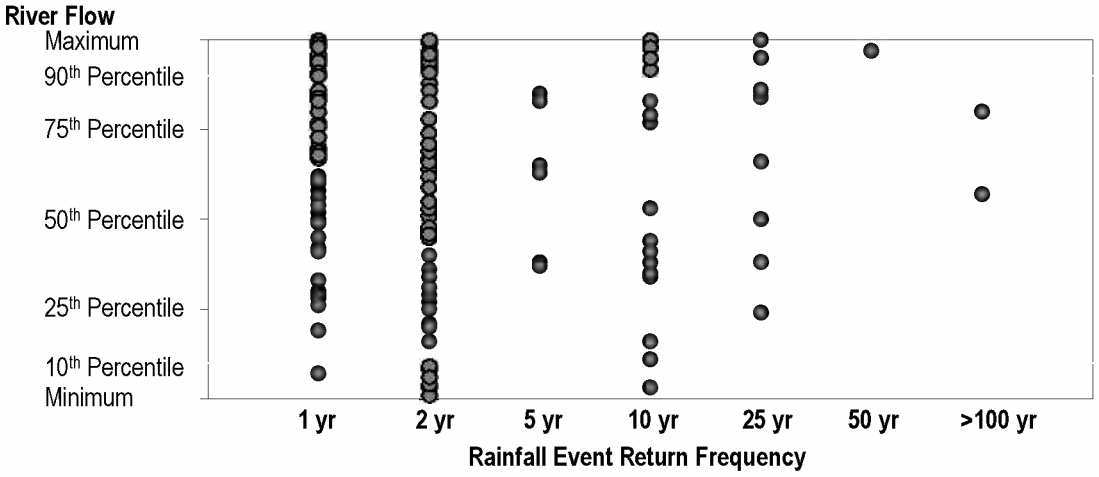

Figure 2-7 shows the daily rainfall profile and daily Delaware River flow hydrograph for the hydrologic period 1994-1996. This period includes two large storm events in July 1994 (a 10-year storm in July 14, 1994 and a 25-year storm in July 18, 1994). During these large storm events, the River flows were around 40th to 50th percentile (**Figure 2-8**). This is consistent with the typical trend shown in **Figure 2-6**. **Figure 2-9** shows Chester Creek and Ridley Creek flows in July 1994, it is obvious that creek flows are highly influenced by local precipitation and the big storms in July 1994 resulted in high creek flows.

Characteristics of the top 10 storms (by rainfall depth) in each year of the hydrologic period 1994-1996 are shown in **Table 2-8**, **Table 2-9**, and **Table 2-10**.

Figure 2-7 Daily Rainfall and River Flow Conditions 1994-1996

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Disantis:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Typical Hydrologic Period Report (Updated April 2016). EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). EPA hereby approves the subject plan.

Thank you for your continued cooperation with this matter. Please do not hesitate to contact me at (215) 814-2097 if you have any questions.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

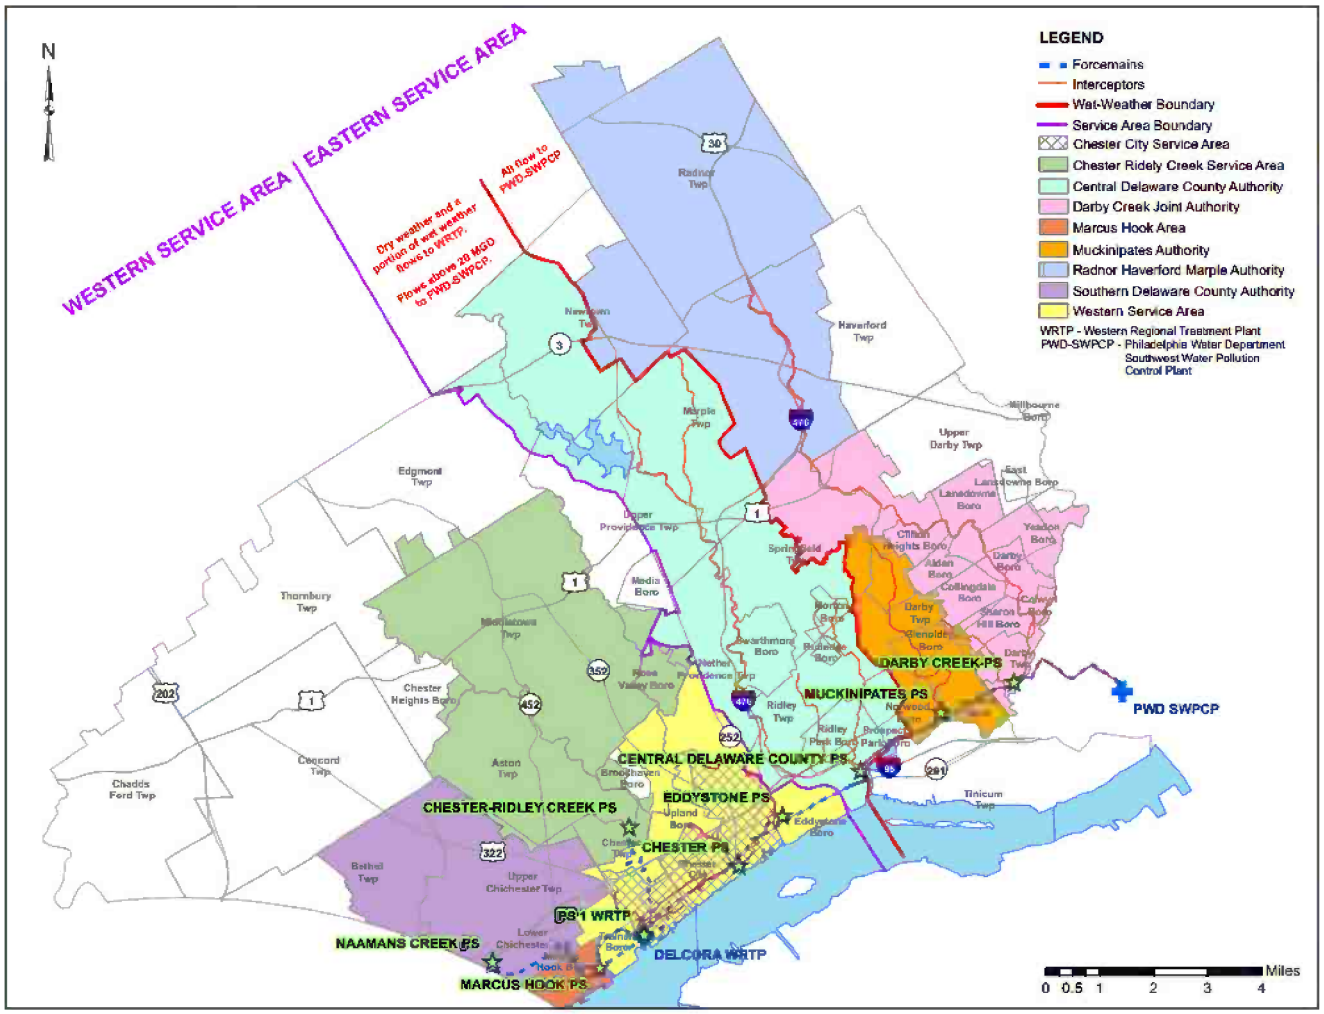
Section 1 Introduction

1.1 DELCORA's Service Area

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the safe collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1. The interconnectivity coupled with the legal agreements that DELCORA maintains with the municipalities and conveyance authorities in Delaware County creates the complicated legal/financial framework under which DELCORA operates. The total service area served by DELCORA is approximately 82,977 acres, as shown on Figure 1-2: DELCORA'S Service Area



, which illustrates that DELCORA serves a significant and widespread portion of Delaware County. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows. The combined sewer area simulated in the model, also shown in Figure 1-2, is located within the Chester City. It comprises approximately 49% of the Chester City's serviced area.

DELCORA has characterized its service areas as "Eastern" and "Western." Historically, the Eastern service area discharged to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWD-SWPCP) while the Western Service Area discharged to DELCORA's Western Regional Treatment Plant (WRTP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Dry weather flow and a portion of the wet weather flow from the Central Delaware County Authority in the Eastern Service Area now discharges to the WRTP while only those CDPS flows above 20 MGD are to be directed to the PWD-SWPCP.

Eastern Service Area

The DELCORA Eastern Service Area is composed of four subareas that are served by conveyance authorities: Radnor Haverford Marple (RHM) Authority, Darby Creek Joint Authority (DCJA), Muckinipates Authority (MA), and Central Delaware County Authority (CDCA) and are delineated in Figure 1-2. Each of these authorities has a legal agreement with their member municipalities to dispose of their wastewater. In turn, DELCORA has legal agreements with each of the authorities, except RHM, to receive, treat, and dispose of the collected wastewater. RHM discharges to the DCJA. DELCORA owns and operates three large pump stations that serve DELCORA's Eastern service area; they are the Central Delaware Pump Station, the Muckinipates Pump Station, and the Darby Creek Pump Station. These pump stations were originally designed to pump the wastewater from DELCORA's Eastern Service Area to PWD-SWPCP for treatment.

The Central Delaware Pump Station (serving CDCA) is rated for 40 MGD. It was constructed in the 1970s to discharge all flow through a force main that is routed northeast toward the Muckinipates Pump Station. The operation of the pump station had been modified in 2002 to allow for flow from the CDPS to be discharged to the WRTP. Currently the wastewater flows above 20 MGD are conveyed to PWD-SWPCP. The next pump station is the 24-MGD Muckinipates Pump Station (serving MA). Here, the force main increases to 48 inches in diameter and continues approximately 1.65 miles northeast to the Darby Creek Pump Station. Upon reaching the 60-MGD Darby Creek Pump Station (serving DCJA and RHM), the force main increases in diameter to 66 inches and continues approximately 2.5 miles for ultimate discharge at PWD-SWPCP.

Under National Pollutant Discharge Elimination System (NPDES) Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall 001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow (CSO) outfalls (002-026, 032, 033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

There are a total of 26 combined sewer overflow (CSO) outfalls listed with 25 discharge points (Outfalls 009 and 010 both discharge at Outfall 009) in DELCORA's existing NPDES Permit.

1.2 DELCORA's Consent Decree

DELCORA prepared and submitted their original Combined Sewer Overflow (CSO) Long Term Control Plan (LTCP) to the PADEP in 1999. This LTCP was subsequently approved by the PADEP, and DELCORA had started to implement the CSO control elements selected in the LTCP. In 2009, the United States Environmental Protection Agency (USEPA) informed DELCORA that the original LTCP was not in compliance with the requirements of the USEPA's CSO Policy. As such, DELCORA prepared and submitted a revised LTCP in April 2012. Subsequent to the receipt of the revised LTCP, DELCORA and the USEPA had corresponded various times including requests for additional information from the USEPA in accordance with Section 308 of the Clean Water Act. A Consent Decree was issued by the USEPA to DELCORA in June 2015. A Consent Decree was ultimately executed between DELCORA, the Pennsylvania Department of Environmental Protection (PADEP) and USEPA, was lodged on August 17, 2015 and was approved by the Federal District Court on November 10, 2015. The final Consent Decree requires that a new LTCP be prepared based on a 42-month schedule from the date of lodging (August 17, 2015), which includes interim deliverables and milestones that must be met.

DELCORA's original Hydrologic and Hydraulic Model (H&H Model) was updated to meet the requirements in Section V.A.14.a-f of the Consent Decree. These requirements along with a description of submissions made to comply with these requirements appear in Table 1-1.

Figure 1-1: DELCORA's Conveyance System

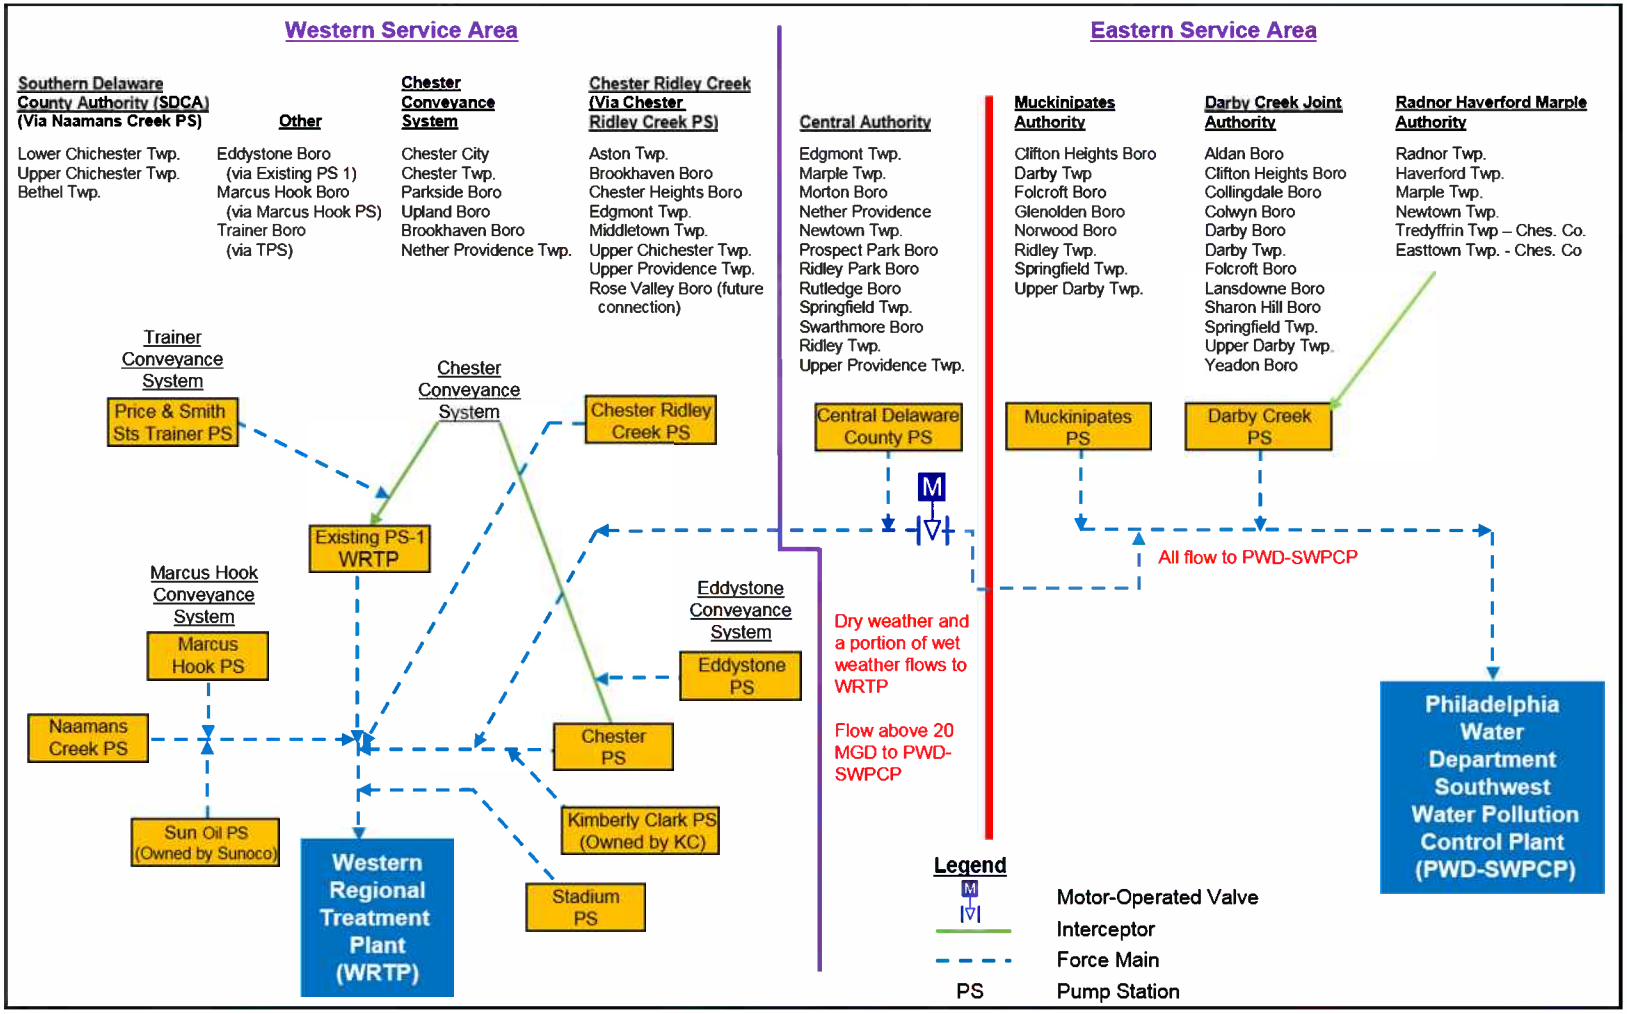


Figure 1-2: DELCORA'S Service Area

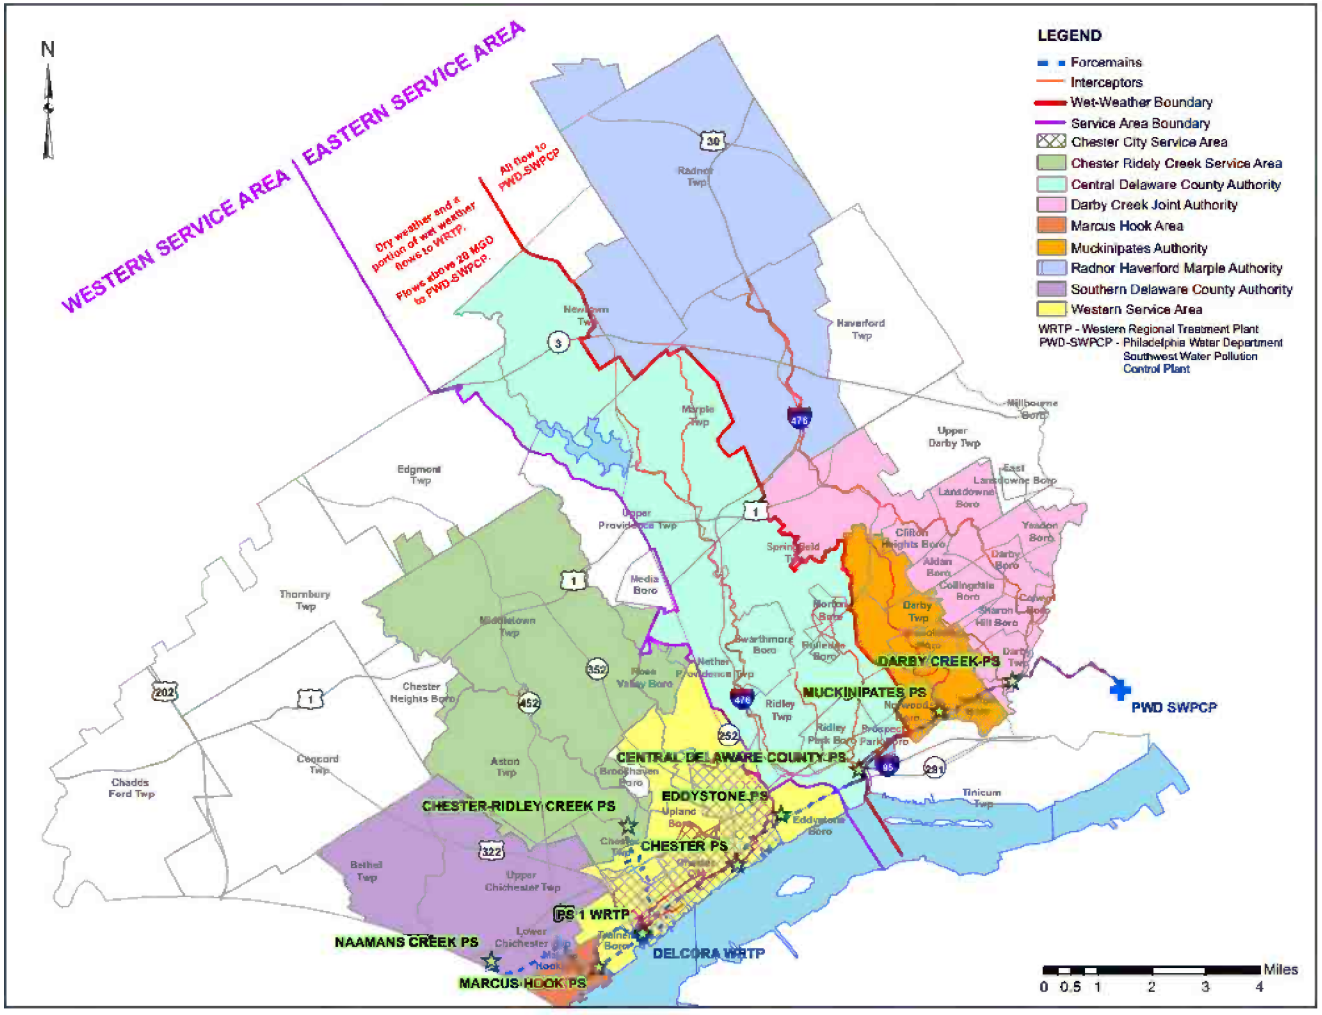

Table 1-1: Summary of Consent Decree Section V.A.14

Consent Decree Requirement	Submission Addressing Consent Decree Requirement
§V.A.14.a *a. Not later than sixty (60) Days after the Date of Lodging of this Consent Decree, DELCORA shall submit a detailed plan to update, calibrate, and validate the H&H Model to Plaintiffs for review and approval pursuant to Section VI (Review and Approval of Submittals). The plan shall address:* *(i) Model Update Methodology.* *(ii) Hydrologic and Hydraulic Model Refinement.* *(iii) Flow Data Assessment, and additional Rainfall and Flow Monitoring to be Carried Out.* *(iv) Dry Weather Flow Calibration, including quantitative and qualitative calibration criteria.* *(v) Wet Weather Flow Calibration, including quantitative and qualitative calibration criteria.* *(vi) Model Validation; and* *(vii) Schedule for model development and implementation, including integration into LTCP development consistent with other dates required pursuant to this Consent Decree.",*	Addressed through submission of the *Hydrologic and Hydraulic Model Update and Calibration Plan* (Greeley and Hansen, 2015) submitted on October 15, 2015 USEPA approved the plan on March 1, 2016. Schedule revised on July 28, 2016. Revised schedule can be found in Appendix A.
§V.A.14.b *b. The updated H&H Model shall specifically include hydrologic representation of all areas tributary to the entire Collection System, as well as all areas tributary to all municipal wastewater collection and transmission systems that are, as of the date the LTCP is submitted, hydraulically connected to, or that directly or indirectly influence flow to, the CSOs and/or the WRTP, regardless of who owns or operates the system(s), including but not limited to the entire "Western Service Area" and "Eastern Service Area" depicted on Figure 1-2 of the Long-Term Control Plan submitted by DELCORA in April 2012, and attached as Appendix A hereto (collectively, the "Model Area")."*	

Consent Decree Requirement	Submission Addressing Consent Decree Requirement
§V.A.14.c *c. The H&H Model shall accurately represent the response of the Model Area to wet weather events, including the flows that result from wet weather events to and from DELCORA's CSOs and to the WRTP. To accomplish this, the model shall explicitly include all interceptors, diversion structures, CSOs, pump stations and major trunk sewers within the Collection System, as well as such pipes and appurtenances within the areas outside the Collection System that are needed to ensure adequate H&H Model accuracy. The H&H Model shall also include all sewers required for model continuity and/or that hydraulically impact or are downstream of known chronic unpermitted releases. DELCORA shall investigate and collect current system attribute information as necessary to update the H&H Model.",*	Revisions to H&H model characterization of the system described in Section 3 of this report. Calibration and verification of model described in Section 4 of this report.
§V.A.14.d *d. Rainfall and flow monitoring shall be carried out in accordance with current good industry practice for a period of at least twelve (12) months, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization of dry and wet weather flows from the entire Model Area, and the response of each CSO to wet weather flows.*	Rainfall and flow monitoring approach described in Section 2 of this report Rainfall and flow monitoring data described in prior quarterly reports (see below) Minimum effective density of 1 gauge/virtual radar based gauge per square km was obtained as described in Section 2 of this report.
§V.A.14.e *e. For all rainfall and flow monitoring carried out in support of efforts to update and calibrate the H&H Model, DELCORA shall prepare and submit to Plaintiffs for review and comment in accordance with the requirements of Section VI (Review and Approval of Submittals) quarterly technical memoranda documenting the results and quality of the rainfall and flow monitoring data.*	Addressed through submission of the *Rainfall and Flow Monitoring Quarterly reports.* 1st Quarter: August 08, 2016 2nd Quarter: November 01, 2016 3rd Quarter: February 01, 2017 4th Quarter: May 01, 2017

Consent Decree Requirement	Submission Addressing Consent Decree Requirement
§V.A.14.f *Within 30 Days after the H&H Model is revised, calibrated, and validated in accordance with the schedule set forth in the plan, DELCORA shall submit a Sewer System H&H Model Report to Plaintiffs for review and approval in accordance with the requirements of Section VI (Review and Approval of Submittals). The Sewer System H&H Model Report shall specifically address each item set forth in Subparagraphs 14(a)(i)-(vii) hereof."*	Addressed through submission of the *Sewer System H&H Model Report*.

In order to comply with Sections V.A.14.d.and e of the Consent Decree, the 12-month rainfall and flow monitoring period was completed on March 31, 2017 and quarterly rainfall and flow monitoring memoranda were submitted.

The outstanding requirements described in Sections V.A.14b, c and f will be addressed in this Sewer System H&H Model Report (hereinafter referred to as Report). This Report will evaluate the Model Area comprising those areas hydraulically connected to the WRTP. Section V.A.14.b of the Consent Decree describes the Model Area as follows:

> *"b. The updated H&H Model shall specifically include hydrologic representation of all areas tributary to the entire Collection System, as well as all areas tributary to all municipal wastewater collection and transmission systems that are, as of the date the LTCP is submitted, hydraulically connected to, or that directly or indirectly influence flow to, the CSOs and/or the WRTP, regardless of who owns or operates the system(s), including but not limited to the entire "Western Service Area" and "Eastern Service Area" depicted on Figure 1-2 of the Long-Term Control Plan submitted by DELCORA in April 2012, and attached as Appendix A hereto (collectively, the "Model Area")."*

As shown in the schematic of DELCORA's conveyance system (see Figure 1-1), the conveyance system is divided into the Western Service Area and the Eastern Service Area. The Western Service Area discharges to DELCORA's WRTP and is therefore included in the Model Area. The Eastern Service Area is served by three pumps stations: the Central Delaware Pump Station, the Muckinipates Pump Station and the Darby Creek Pump Station. Up to 20 MGD (which includes both dry and wet weather flows) from the Central Delaware Pump Station can be pumped to, and thus is hydraulically connected to, DELCORA's WRTP. Therefore, municipalities connected to the Central Delaware Pump Station are considered part of the Model Area. Sewage from the Muckinipates Pump Station and the Darby Creek Pump Station flows to the PWD-SWPCP and cannot pump flow to the WRTP. Therefore, municipalities connected to these pump stations are not hydraulically connected to the WRTP and do not directly or indirectly influence CSOs or flow to the WRTP, and, therefore, are not considered part of the Model Area. In summary, the Model Area includes the municipalities in the Western Service Area plus those municipalities that are connected to the Central Delaware Pump Station, as described in Table 1-2.

Table 1-2: Model Area

Municipality ID No.	Municipality	Service Area
1	Aston Township	Western
2	Bethel Township	Western
3	Brookhaven Borough	Western
4	Chester City	Western
5	Chester Township	Western
6	Eddystone Borough	Western
7	Edgmont Township	Eastern
8	Lower Chichester Township	Western
9	Marcus Hook Borough	Western
10	Marple	Eastern
11	Middletown Township	Western
12	Morton	Eastern
13	Nether Providence*	Eastern and Western
14	Newtown Township	Eastern
15	Parkside Borough	Western
16	Prospect Park	Eastern
17	Ridley Park Borough	Eastern
18	Ridley Township	Eastern
19	Rose Valley Borough	Western
20	Rutledge	Eastern
21	Springfield	Eastern
22	Swarthmore	Eastern
23	Trainer Borough	Western
24	Upland Borough	Western
25	Upper Chichester Township	Western
26	Upper Providence Township	Eastern and Western

As outlined in the *Hydrologic and Hydraulic Model Update and Calibration Plan* (Greeley and Hansen, 2015) and in conformance with Section V.A.14.c, the original H&H model was evaluated and updated as necessary to ensure inclusion of necessary components of the collection and conveyance system.

In addition, this Report includes results of the gauge-adjusted rainfall analysis (GARR) to demonstrate compliance with the requirement of Sections V.A.14.d that "…*Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area.*"

1.3 Contents in This Report

This report was prepared based on the requirements listed in the Consent Decree. The purpose of this document is to describe the development, calibration and validation of the updated sewer collection system H&H model. The 2012 H&H model was expanded to the Model Area and updated as needed to reflect current hydrologic and hydraulic conditions of DELCORA's collection system. After updating, the revised model was calibrated and validated with the additional rainfall and flow monitoring data so it can then be used to assist the Delaware County Regional Water Authority (DELCORA) throughout its combined sewer overflow (CSO) long-term control plan (LTCP) update process. Table 1-3 lists individual sections of this Report and their contents.

Table 1-3: DELCORA Sewer System H&H Model Report

Section	Description
Section 1 Introduction	Section 1 introduces DELCORA's system, Consent Decree requirements and the purpose of this report.
Section 2 Rainfall and Flow Monitoring	Section 2 provides an overview of the rain gauge and flow monitoring program and data analysis process for model input.
Section 3 DELCORA H&H Model Update	Section 3 summarizes the review of the original H&H model, describes general methodology used in the model update, and details the model updates made to the service area delineation, combined and separated area delineation, model network extension, regulator, and model inputs.
Section 4 DELCORA H&H Model Calibration and Validation	Section 4 provides a description of calibration and validation, lists criteria for dry weather and wet weather calibration, and illustrates calibration and validation method and results.
Section 5 Conclusion	Section 5 provides a short summary of the H&H Model Update, including model calibration results.

Section 2 Rainfall and Flow Monitoring

As per the Consent Decree, DELCORA was required to perform a Rainfall and Flow Monitoring program for at least 12 months and submit quarterly reports to document the findings of the program. This program started on March 18, 2016 and was completed on April 4, 2017. The rainfall and flow monitoring data were collected on a monthly basis. This section will discuss the network of rainfall and flow monitoring instrumentation, outline the monitoring program, and describe how the data collected for the Rainfall and Flow Monitoring Program was analyzed for use in the H&H Model calibration and validation.

2.1 Rainfall Monitoring and Analysis

A total of six (6) rain gauges were used for the monitoring program. As shown in Figure 2-1, the gauges are stationed at the following locations:

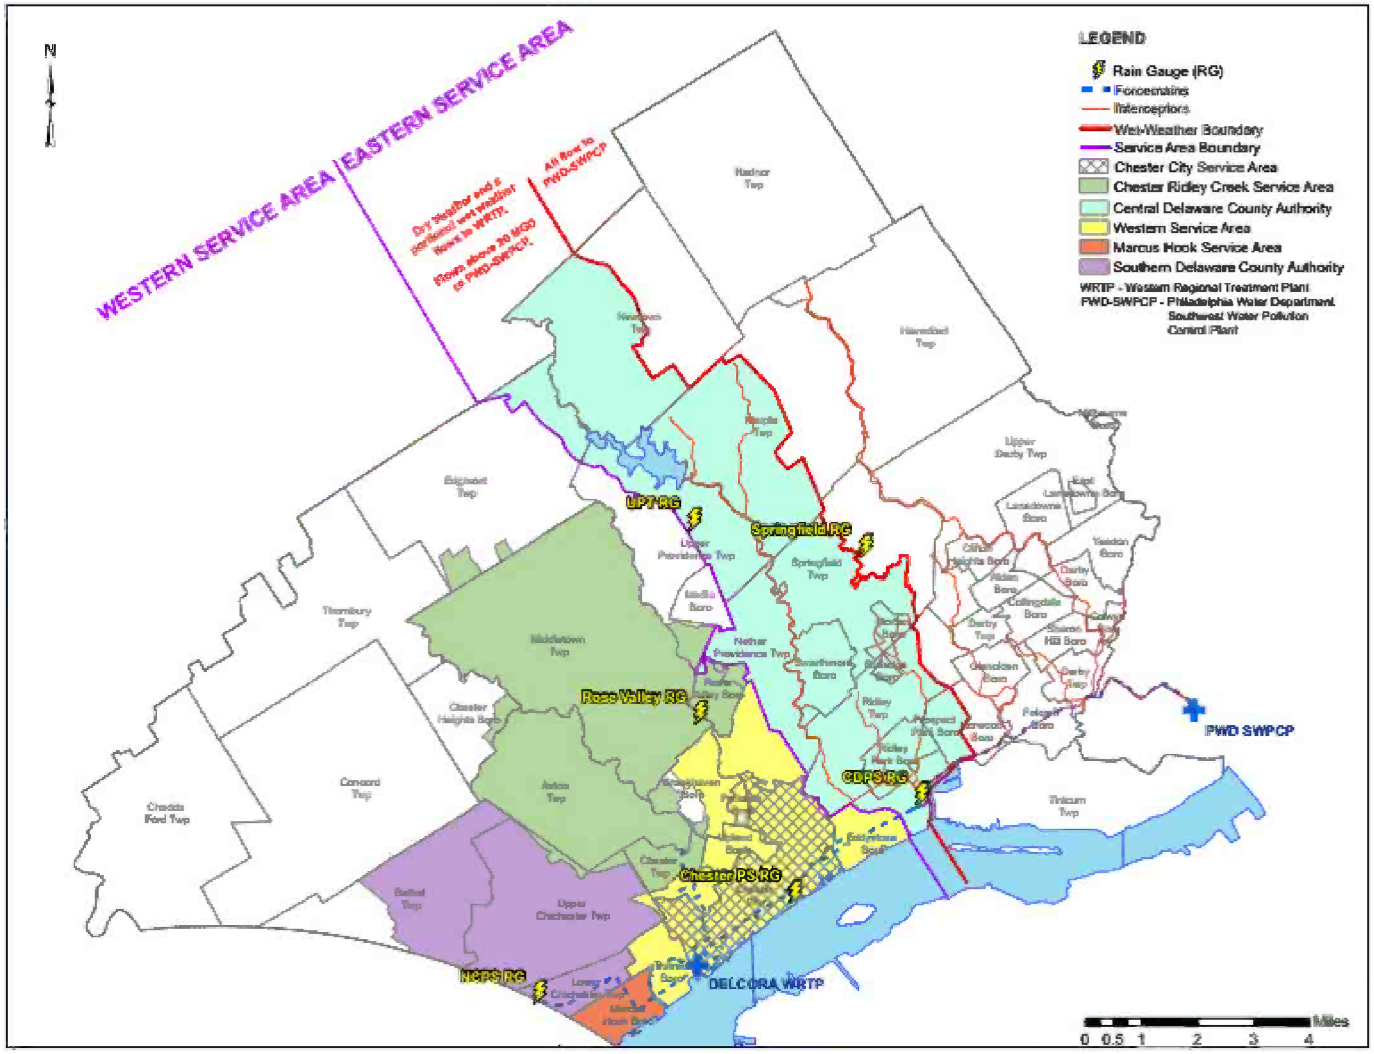
- Rose Valley
- Chester Pump Station (CPS)
- Naaman's Creek Pump Station (NCPS)
- Springfield
- Upper Providence Township (UPT)
- Central Delaware County Pump Station (CDPS)

Five out of six of the gauges provided data at 5 minute intervals. One rain gauge provided data on 15-minute intervals. According to the Consent Decree, rainfall data to be used for calibration and validation of the model *"…shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per kilometer"*. In order to achieve this density, Gauge-Adjusted Radar Rainfall (GARR) was employed. The rain gauges used to complete the flow monitoring program and choose the wet weather events used in calibration and validation were also used in the GARR analysis which provided effective spatial coverage of the entire Model Area. The gauge rainfall data from the six rain gauges installed throughout the DELCORA service area was analyzed and used to:

- Document rainfall and flow monitoring locations,
- Overview flow monitoring data quality,
- Analyze rainfall data to identify dry weather and wet weather conditions and to characterize individual rainfall event for precipitation depth, duration, maximum intensity, and return frequency,
- Analyze flow data to determine dry weather flow and diurnal pattern, wet weather flow and peak factor, and system response to wet weather events, and
- Determine the wet weather events for H&H Model calibration and validation.

An inter-event time of 48 hours was used to identify individual rainfall events. The inter-event time specifies the minimum duration in which precipitation does not occur. Based on this criterion, a dry weather time period and the number of total rainfall events were identified. The rainfall events during the

Figure 2-1: Rain Gauge Locations



flow monitoring periods had a wide variation in terms of total depth, intensity, duration, and antecedent conditions to provide a large dataset for balanced model calibration and validation.

The rainfall events were characterized by event start time, event end time, rainfall depth, duration, maximum intensity, and return frequency. As an initial screening criterion, rainfall events with a minimum of 0.9 inches of rainfall were identified. Further screening based on requiring at least two dry days prior to the event resulted in an initial list of ten (10) candidate events for calibration and validation (see Table 2-1).

Table 2-1: Top 10 Rainfall Events

Event	Event Start	Event End	Chester-PS Rainfall (in)	Duration (hr)	Max Intensity (in/hr)
E1	5/29/16 19:00	5/30/16 5:00	1.82	11.00	0.78
E2	9/28/16 12:00	9/30/16 10:00	2.36	47.00	0.37
E3	11/29/16 7:00	11/29/16 20:00	1.08	14.00	0.21
E4	3/30/17 21:00	4/1/17 3:00	1.83	31.00	0.25
E5	5/21/16 11:00	5/22/16 21:00	1.71	35.00	0.33
E6	7/28/16 15:00	7/29/16 9:00	1.26	19.00	0.74
E7	9/19/16 8:00	9/19/16 16:00	0.96	9.00	0.42
E8	3/13/16 18:00	3/14/16 14:00	1.08	21.00	0.25
E9	5/6/16 4:00	5/7/16 11:00	1.18	32.00	0.24
E10	10/8/16 14:00	10/9/16 11:00	1.00	22.00	0.15

2.2 Flow Monitoring

DELCORA owns and operates a flow monitoring network across the DELCORA Service Area. The monitoring network includes various types of flow meters located throughout DELCORA's Eastern Service Area and Western Service Area, at the WRTP, in each of the Pump Stations, and at the tie-in points where other municipal collection systems tie-into the collection system. Seven existing flow meters in the separated area (outside the CSO area), eight existing flow meters at pump stations and one existing flow meter at WRTP were used for the calibration and validation of the H&H Model. In addition, temporary flow meters were installed at 38 new locations to characterize surface runoff from the combined area and CSO discharges. The locations of flow meters installed specifically for the flow monitoring program and the H&H Model calibration and validation can be categorized into the following five categories:

1. Located on the influent pipe to CSO regulators, this is to measure the influent flow to CSO regulators and for combined area runoff calibration. Sixteen (16) meters were installed for this category.
2. Located on the effluent pipe and overflow pipe of CSO regulators, this is to measure the CSO overflows and calibrate CSO regulator parameters. Twelve (12) meters were installed for this category. They are on the effluent and overflow pipe of CSOs 02, 03, 05, 08, 14, & 19.
3. Located on the side-line from the combined areas (flows from the combined area tie into interceptor instead of CSO regulator). This is to measure flows from the combined area and to calibrate combined area runoff parameters. Two (2) meters were installed for this category.

4. Located upstream of the combined area, this is to measure flows from the upstream separated area for RDII characterization. Three (3) meters were installed for this category.
5. Located in the main interceptors to measure level and flows in the major interceptors. Five (5) meters were installed for this category.

Table 2-2 lists the flow meter locations and location categories of the meters. Figures 2-2 and 2-3 show the locations of the flow meters that were used for H&H Model calibration and validation. After initial installation of the new temporary flow meters, difficulties were encountered at Manhole MH3029. The site was severely surcharged during field investigation. Meanwhile it was found that at Manhole MH3002 (four manholes upstream of MH3029, approximately 800 feet upstream) another existing flow meter (Ridley Creek MH-28) was already installed for DELCORA. Instead of installing a new temporary flow meter around the site, the existing meter Ridley Creek MH-28 was used for the flow monitoring program. Data was gathered from a total of 55 flow meters, 38 of which were newly installed as part of the flow monitoring program.

The network of flowmeters can be grouped to define metersheds where flow from a given area discharges through a common flowmeter. Subcatchments associated with each metershed are shown in Table 2-3 along with the associated metershed acreage. Rainfall and flow data gathered for each metershed will be used to calibrate the associated subcatchments in the H&H Model.

2.3 Dry Weather Flow (DWF) Analysis

A "dry weather" condition was defined as a period with no precipitation that begins 48 hours after the last wet weather event and lasts until the beginning of the next precipitation event. Dry weather flow periods based on this definition are illustrated in the hydrograph shown in Figure 2-4.

Average dry weather flow was calculated by averaging the monitored flows from the dry weather periods identified in the rainfall data analysis. The overall and monthly DWFs for all monitoring sites were analyzed and used as inputs in the H&H Model.

Table 2-2: Flow Monitoring Locations

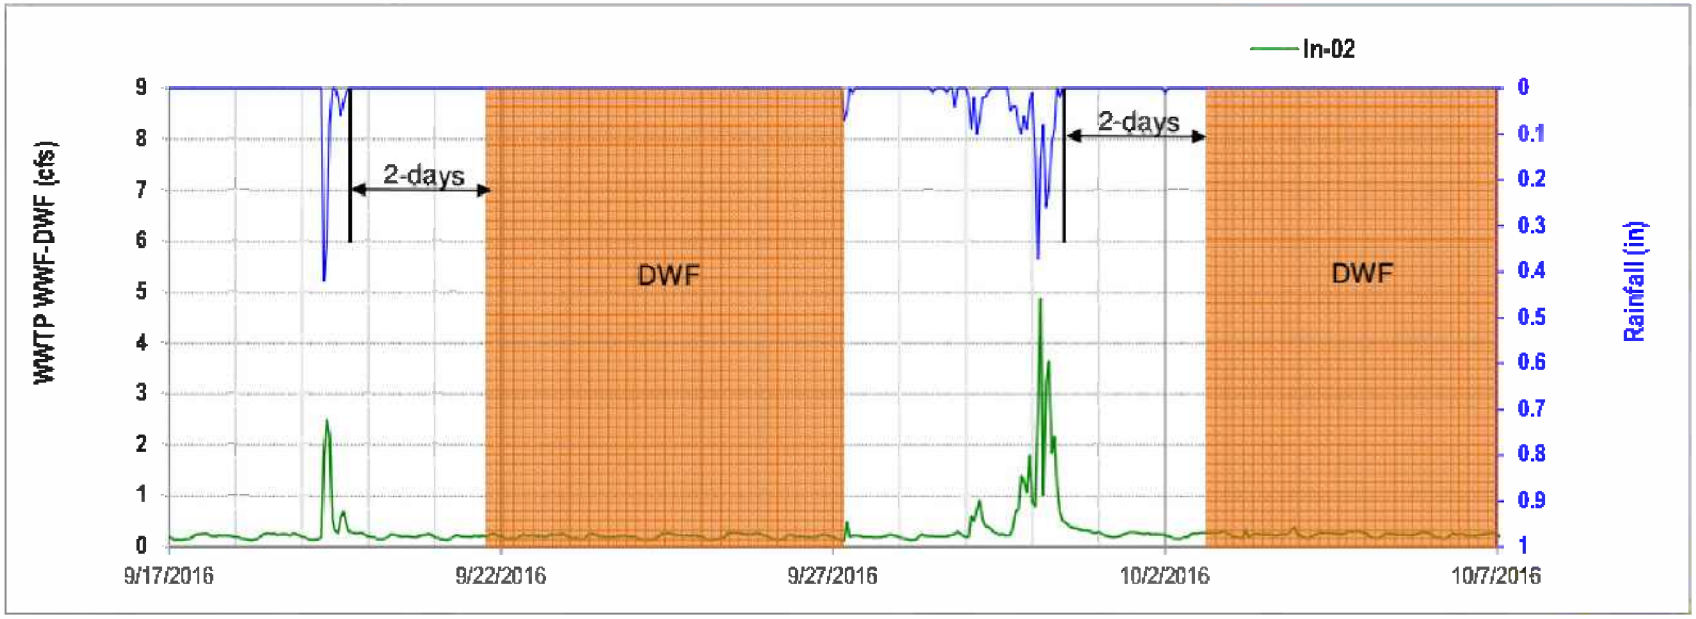
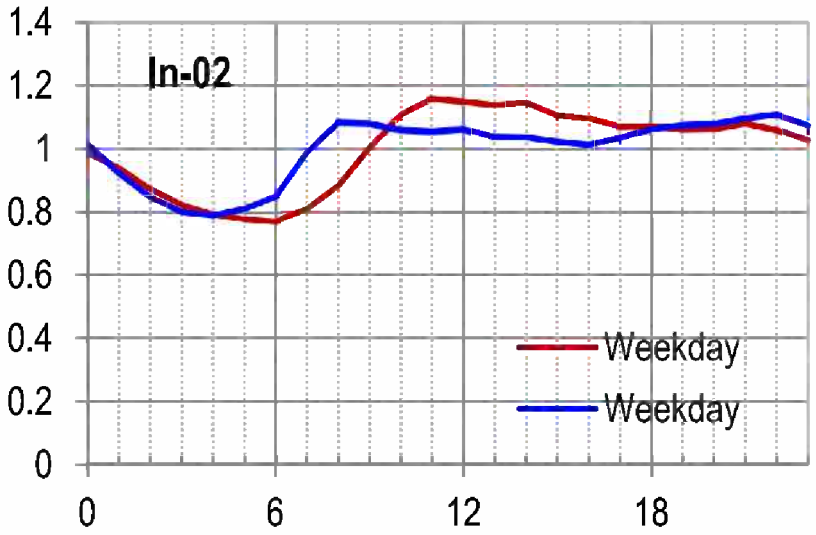
Figure 2-4: Hydrograph to Show Dry Weather Flow



The dry weather flows vary throughout the day, with the highest flows normally occurring around noon and the lowest rates between midnight and early morning. Flow data from the dry weather periods were used to develop a flow diurnal pattern for each flow meter site. Diurnal patterns were analyzed for both weekdays and weekends. In the plot shown on Figure 2-5, the weekend DWF peak and valley have a 3-hour lag compared to the weekday pattern.

Figure 2-5: Weekday and Weekend Dry Weather Flow Diurnal Pattern (Example Plot)

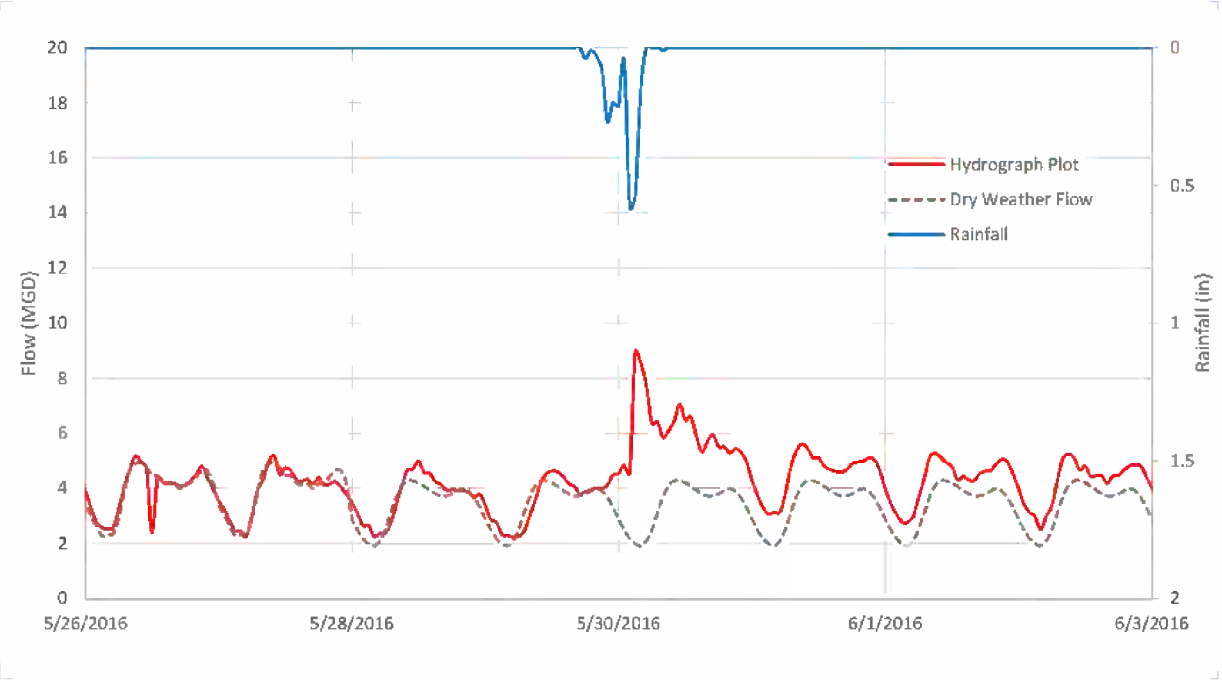


2.4 Wet Weather Flow Analysis

Wet weather flows are the combination of dry weather flows and additional flows that enter the system during wet weather conditions. The additional flows are from combined area surface runoff and RDII. Inflow normally occurs when rainfall enters the system through direct connections such as roof leaders, yard drains, catch basins, sump pumps, manhole covers and frame seals or indirect connections with storm sewers. Inflow is usually recognized graphically by large magnitude, short duration spikes immediately following a rain event. Infiltration occurs during wet weather conditions when water enters a sewer system from the ground through means which include, but not limited to, deteriorated pipes, pipe joints, connections, or manholes. It is significantly influenced by the size and duration of the rainfall event. Infiltration is often recognized graphically by a gradual increase in flow after a wet weather event. The increased flow typically sustains for a short period after rainfall has stopped and then gradually drops off.

The peaking factor represents the ratio of the peak wet weather flow to the average dry weather flow. Usually, an hourly peaking factor is used to represent the wet weather peaking factor. Peaking factors were analyzed for each flow monitoring site. The peaking factors in the separated area can be used to determine the extent of the RDII within a particular basin. Figure 2-6 is a flow hydrograph plot showing an hourly peaking factor of approximately 4.5 for the monitoring site. This high peaking factor indicates that a significant amount of RDII enters the collection system. The immediate flow increase shortly after the rainfall indicates significant inflow into the collection pipes, and the long tail back to the base flow indicates infiltration occurrence at the site as well.

Figure 2-6: Hydrographs of Flow Meters in Separated Area (Example Plot)



2.5 Wet Weather Event Selection for Model Calibration and Validation Flow Analysis

Based on the rainfall and flow monitoring data analysis, the rainfall events shown in Table 2-4 were selected for model calibration and validation. The events were selected to cover variations in terms of rainfall depth, intensity, duration and antecedent conditions. .

Table 2-4: Calibration and Validation Rainfall Events

Section 3 DELCORA H&H Model Update

The original DELCORA H&H model was developed and calibrated for the 1999 LTCP. The model was updated and expanded over the years to account for changes in the CSO system, but it was not re-calibrated during the development of the 2012 LTCP (Weston, 2012). The project team reviewed the 2012 model in order to:

- Assess adequacy of the original model for use in DELCORA's LTCPU,
- Identify gaps with the original model in meeting the requirements in the Consent Decree,
- Identify updates required to reflect current hydrologic and hydraulic conditions of DELCORA's collection system, and
- Determine refinements needed for the model update.

Results from the review of the 2012 H&H Model were presented in the *Hydrologic and Hydraulic Model Update and Calibration Plan* (Greeley and Hansen, 2015). The purpose of this section of the Report is to describe the model update methodology and summarize the revisions incorporated into the updated model.

3.1 Model Update Methodology

3.1.1 Hydrologic Representation

Instead of including only the combined area for the subcatchments as in the original model, the updated model has subcatchments for both combined and separated service areas. All the areas that contribute dry weather flow and/or wet weather flow to DELCORA's CSOs and/or the WRTP were included in the service area for the model. Wet weather flows generated from surface runoff in the combined area and RDII in the separated areas were simulated in the updated model.

3.1.2 Hydraulic Representation

The 2012 H&H model included only the combined sewer system (CSS) area of DELCORA's collection system, which is located within the boundaries of the City of Chester. The CSS area is shown in Figure 3-1. The combined CSS area according to the original model is shown in in Figure 3-2. Per the requirements of the Consent Decree, the H&H model was updated to include the Model Area. Pipe networks in the updated model were extended to the updated service areas for both the combined and separated areas. All hydraulic structures that control flows in the collection system, including pump stations, regulator orifices and weirs, and their operating rules, were simulated in the updated model.

3.2 Model Refinement

A number of hydraulic modeling software packages are available, including EPA SWMM5, InfoSWMM, InfoWorks, Mike Urban and PCSWMM. For this H&H Model update, EPA SWMM, Version 5.0, Build 5.0.022 and Innovyze InfoSWMM Version 14.5 Update 4 were selected as the modeling software. EPA

SWMM5 is a fully dynamic model and has been used extensively throughout the United States and abroad to assess CSO, flooding and water quality issues. It can be applied to simulate single events or long periods of time in a continuous mode. InfoSWMM uses the current EPA SWMM 5 engine as its computational solution and is fully integrated with ArcGIS which provides greater flexibility of importing model network from existing GIS database and preparing initial model inputs from existing datasheets. InfoSWMM was used during the model development and the calibration phase.

The model update is based on information obtained from a variety of sources including DELCORA's input, GIS, record drawings and field survey. Other documents pertaining to standard/actual operating procedures for CSO regulators, pump stations and the WRTP were also used to set up real time controls in the model. The model network consists of all major interceptors and force mains and extends to all active overflow points. The datum for the model is NGVD 29.

3.2.1 Delineation of Model Area and Combined Area

DELCORA's latest GIS database, survey and record drawings were used to perform the desktop CSS delineation to verify the boundaries. The total acreage of the model area is approximately 50,000 acres and the updated combined sewer area is approximately 1,460 acres as of May 2017.

Metersheds were delineated for the purpose of dry weather flow allocation and model calibration. A metershed means the geographical area served by a system of sanitary drains, storm drains, private interceptor, main sewers, and public sewers that drain to a common monitoring point (flow meter location). Metershed delineation was performed based on the location of flow meter, sewer connectivity, and city contours. A listing of metersheds, their acreage and their associated subcatchments can be found in Table 2-3.

Sewersheds (subcatchment) are delineated based on the drainage network, area characteristics, and flow monitor locations. Each sewershed has a dry weather and a wet weather flow input to the model network. The model network comprises 111 sewersheds (subcatchments), including 54 combined and 57 separated subcatchments.

3.2.1.1 Delineation of Model Area

The updated H&H model will evaluate the Model Area comprising those areas hydraulically connected to the WRTP. As shown in the schematic of DELCORA's conveyance system (see Figure 1-1), the conveyance system is divided into the Western Service Area and the Eastern Service Area. The Western Service Area discharges to DELCORA's WRTP and is therefore included in the Model Area. The Eastern Service Area is served by three pumps stations: the Central Delaware Pump Station, the Muckinipates Pump Station and the Darby Creek Pump Station. Up to 20 MGD (which includes both dry and wet weather flows) from the Central Delaware Pump Station can be pumped to, and thus is hydraulically connected to, DELCORA's WRTP. Therefore, municipalities connected to the Central Delaware Pump Station are considered part of the Model Area. Sewage from the Muckinipates Pump Station and the Darby Creek Pump Station flows to the PWD-SWPCP rather than to the WRTP. Therefore, municipalities connected to these pump stations are not hydraulically connected to the WRTP and do not directly or indirectly influence CSOs or flow to the WRTP, and, therefore, are not considered part of the Model Area.

Eastern Service Area

Within the Eastern Service Area, only the municipalities in the Central Delaware County Authority contribute flows to the WRTP and are, therefore, only these municipalities are included in the Model Area. These municipalities include Marple Township, Morton Borough, Nether Providence Township, Newtown Township, Prospect Park Borough, Ridley Park Borough, Rutledge Borough, Springfield Township, Swarthmore Borough, Ridley Township, and Upper Providence Township. In October 2012, DELCORA signed an agreement with Edgmont Township to provide sewer service to the eastern portion of the Township. The sanitary sewage of the Township will be collected and transported using the Crum Creek Sewer District System through the CDCA collection and conveyance facilities to the DELCORA System for treatment and ultimate disposal and discharge.

Western Service Area

DELCORA's Western Service Area (shown in Figure 3-1) contributes flow to their WRTP and is therefore considered part of the Model Area. DELCORA owns and operates the collection system in the following communities in the Western Service Area.

- Chester City
- Chester Township (parts of)[1]
- Marcus Hook Borough
- Parkside Borough
- Rose Valley Borough[1]
- Upland Borough
- Trainer Borough

DELCORA does not own or operate the collection system in the following communities in the Western Service Area, however, these communities will be included as part of the service areas in the updated H&H model because they contribute flows to the WRTP.

- Brookhaven Borough
- Lower Chichester Township
- Nether Providence Township
- Eddystone Borough

Model Area Summary

In summary, the Model Area includes the municipalities in the Western Service Area plus those municipalities in the Eastern Service Area that are connected to the Central Delaware Pump Station, as described in Table 3-1. The Model Area is illustrated in Figure 3-1. A schematic of the facilities and conveyance network are shown in Figure 1-1.

---

[1] - DELCORA owns only a portion of Chester Township's collection system, but all flow comes to WRTP as some goes through the CRC PS service area.
- Rose Valley Borough collection system discharges to its own treatment plant (this portion will be discharged to the CRC PS service area in future) and the remaining portion is discharged to the Western Service Area to the WRTP.

3.2.1.2 Delineation of Combined Sewer System Area

The entire combined sewer system (CSS) area of DELCORA's collection system is located in the City of Chester and consists of a drainage area of approximately 1,460 acres. It comprises approximately half of Chester City's serviced area. To support this service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five[2] (25) combined sewer outfall regulators controlling storm

[2] DELCORA's NPDES permit includes 26 regulators. After the NPDES permit was issued, CSO regulator 033 was disconnected from the CSS.

overflows. The location of the CSS area is shown in Figure 3-1. An enlarged view of the CSS area according to the 2012 H&H model is shown in Figure 3-2.

The CSS area delineation was updated with separation projects completed in recent years. The latest GIS database, survey, and record drawings were used to perform the desktop combined sewer area check. Some areas have separated systems with trunk sewers that subsequently connect to the CSS. For this situation, these particular separate sewer system areas were included within the delineation of the CSS. The revised CSS delineation is illustrated in Figure 3-3.

3.2.2 Model Network Extension

The collection system network in the original model has been updated with the following.

- Extended sewers to the updated delineation of the combined and separated areas
- Included all pump stations that control flows in the DELCORA collection system, and
- Reflect actual configuration of the CSO regulators.

3.2.2.1 Sewer Lines and Manholes

3.2.2.2 Regulators

Since the approval of the first LTCP in 1999, DELCORA has under-taken a program to replace and/or rehabilitate CSO regulators and tide gates in the City of Chester CSO system. In some cases, regulators have been eliminated. The updated model includes twenty-five[2] (25) CSO regulators, which were modeled as weirs and orifices. The configuration of CSO regulators was obtained from both record drawings and field surveys.

As indicated in Table 3-2, the majority of the City's CSO regulators are Brown & Brown type regulators. The operation of the CSO regulators has been changed from being controlled by the level in the trunk sewer entering the CSO regulator chamber to being controlled by the level in the interceptor. This change is being implemented as part of the CSO regulator replacement program. This ensures that the flow sent to the WRTP for treatment is maximized.

During dry-weather operations, the sewage flow levels entering the CSO regulator chamber are below the top of the diversion weir and will pass through the CSO regulator gate. Once through the CSO regulator gate, the flow typically passes through an orifice plate and then will be sent to the WRTP via the interceptors. During wet-weather events, the level in the combined sewer (Type A regulator) or in the interceptor (Type B regulator) will begin to rise thus raising the float assembly and beginning to close the CSO regulator gate. For cases where the regulator float and gate have been removed, dry weather flow and some portion of the wet weather flow will pass through the opening previously covered by the now removed gate. Flow through this opening will be modeled as an orifice. When weather flow exceeds the

- CSO Regulators 006 ad 007 have been disconnected from CSS and removed from NPDES permit
- CSO Regulator 033 has been disconnected from the CSS but had not been removed from NPDES permit at the date of this Report

Figure 3-2: CSS Area Delineation in the Original Model

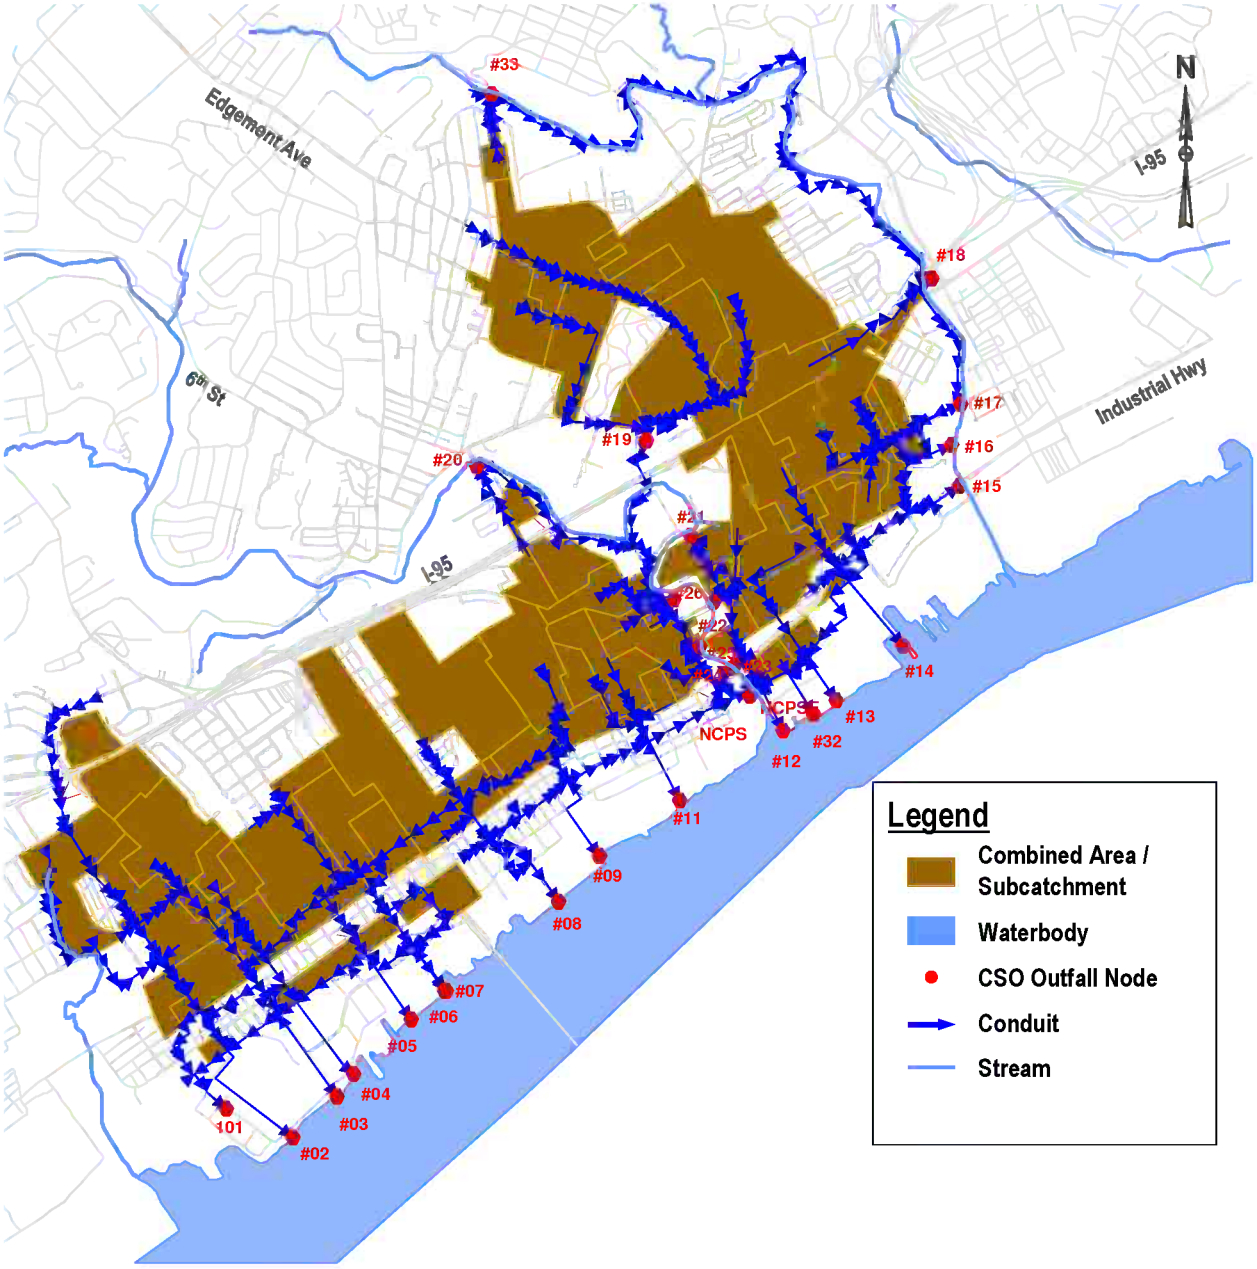

Figure 3-3: CSS Area Delineation in the Revised Model

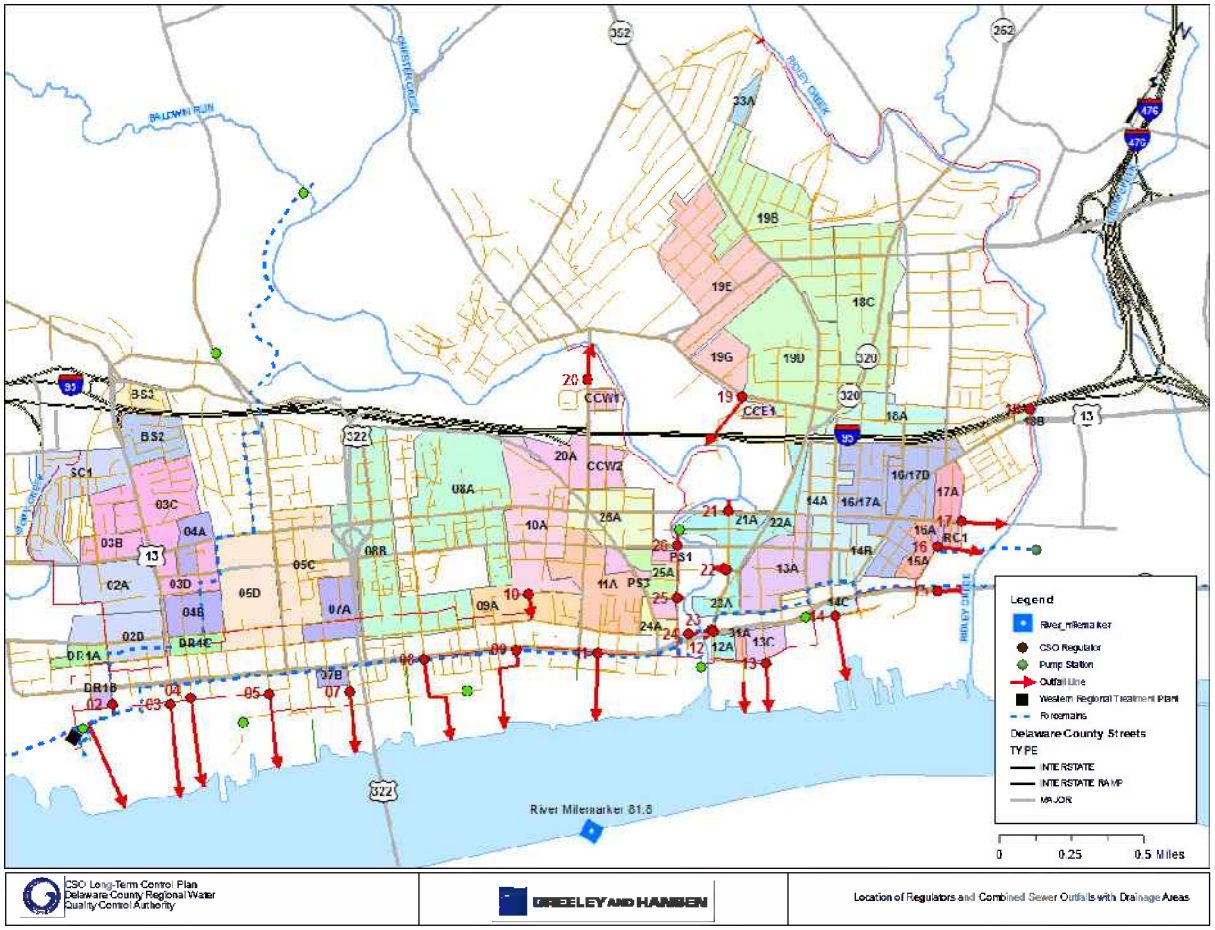

capacity of the orifice, the level in the sewer will continue to rise until it is high enough for a portion of the flow to pass over the weir be discharge through the associated outfall.

Regulator gates, diversion weirs, and operating rules are simulated in the updated model.

3.2.3 Pump Stations

Major pump stations in the Western Service Area and the Central Delaware Pump Station in the Eastern Service Area were added to the updated model, as well as force mains connecting the pump stations to the interceptor/WRTP. The list of the pump stations includes (Figure 3-4):

- Chester PS
- Existing PS-1 WRTP
- Marcus Hook PS
- Naamans Creek PS

- Eddystone PS
- Central Delaware PS
- Chester Ridley Creek PS

The following pump stations were excluded from the H&H Model:

- Price & Smith Street Trainer PS
- Sun Oil PS (Owned by Sunoco)
- Kimberly Clark PS (Owned by KC)
- Stadium PS

Flow from the Price & Smith Street Trainer PS discharges to the downstream existing PS-1 Pump Station (EPS-1) where it is re-pumped. The updated H&H model assumes that all flow from subcatchments associated with the Price and Smith Street Trainer PS can be treated as an input to EPS-1.

Flow from the Stadium PS is sanitary sewage with no wet weather flow. The Stadium PS discharges flow only during events held at the stadium. Due to the limited flow, its sporadic nature and the lack of wet weather flow, the Stadium PS is expected to have negligible effect on the wet weather capacity of the CSS. Therefore, the Stadium PS was not included in the H&H Model.

DELCORA owns or operates a number of lift stations that contribute to the Western Service Area and whose flows are handled by the above list of pumps stations. It was determined that the behavior of these lift stations would not require modeling and that inflow can be assumed to equal outflow to the downstream conduit.

3.2.4 Model Input

3.2.4.1 Subcatchments

The following subcatchment information is required by the model:

- Area
- Percent of directly connected impervious area (effective impervious area)
- Width
- Slope
- Manning's roughness coefficient (n) for both pervious and impervious areas
- Depression storage for both pervious and impervious areas (initial abstraction)
- Soil and soil infiltration parameters
- Rainfall dependent inflow and infiltration (RDII) parameters
- Base flow

Area

Area of the combined sewer subcatchment is the geographical area of the subcatchment. It was estimated from the GIS by geometry calculation of the area of the subcatchment. Subcatchment areas for the updated H&H model are depicted in Figure 3-3.

Percent of Directly Connected Impervious Area

Directly connected impervious area means the impervious area that is effectively connected to the sewer collection system. As a result, runoff from these areas is completely captured by the collection system. Runoff from the rest of the impervious area is deemed not to be captured by the system due to various potential reasons including, but not limited to, drains to pervious areas/creeks/streams, limited number and capacity of stormwater inlets, and bypassing. For model construction, the percent imperviousness was calculated using the high resolution land cover raster published by the Chesapeake Conservancy (Chesapeake Conservancy, 2017) as well as the land use shapefile published in 2015 by the Delaware Valley Regional Planning Commission as the initial inputs. Then, the impervious percentage values were adjusted during the model calibration process (see Section 4) to best simulate the observed hydrologic response over the selection of precipitation events.

The initial percent imperviousness for the combined area was calculated based on the impervious coverage shape file and the subcatchment shape file. The subcatchment delineations were overlaid on the land cover designation and the percent impervious within each subcatchment was evaluated with the results presented in Table 3-3.

For the separated area, the initial percent imperviousness will be set at 0% because the impervious area in the separated area is not contributing runoff to the CSS, therefore it is not effectively connected. *Subcatchment parameters mentioned hereafter will be set at default values for the separated subcatchments.*

Width

The width of a subcatchment relates to sheet flow path and affects time of concentration and the shape of the runoff hydrograph. The initial estimate of the width was made by dividing the subcatchment area by the representative overland flow length. Width is one of the calibration parameters for runoff.

Slope

The slope of a subcatchment should reflect the average slope along the pathway of overland flow to inlet locations. For the combined sewer subcatchments, slopes from the 2012 H&H model were retained for use in the updated model.

CCE1	1%

Manning's roughness coefficient (n)

Manning's roughness coefficient (n) was estimated for both pervious and impervious overland flow. The initial values were set to 0.013 for impervious surfaces and 0.15 for pervious surfaces. A typical range of Manning's n suggested by the SWMM is 0.011-0.024 for impervious area and 0.06-0.80 for pervious area. Roughness is an empirical value and may be treated as a calibration parameter if necessary.

Depression Storage

Depression storage is the rainfall abstraction volume that must be filled prior to the occurrence of runoff. It represents the loss (initial abstraction) caused by surface ponding, surface wetting, etc. The initial values of depression storage were set to 0.05 for impervious surfaces and 0.15 for pervious surfaces. Typical depression storage values are 0.05-0.10 for impervious surfaces and 0.10-0.30 for pervious surfaces. Depression storage is an empirical value and may be treated as a calibration parameter, especially to adjust runoff volumes.

In the model, the subcatchment was divided into three subareas: pervious area with depression storage, impervious area with depression storage, and impervious area without depression storage. The initial percent of the impervious area without depression storage was set to 0.10.

Soil and Soil Infiltration Parameters

Soil information was obtained to estimate infiltration in the pervious areas of the CSS. The rate of infiltration is a function of soil properties and antecedent soil conditions. Three infiltration methods are available in the software: Horton method, Green-Ampt method, or National Resources Conservation Service (NRCS) Curve Number method. The Horton method has been extensively used for similar type of modeling work and it was used in this modeling effort to estimate infiltration. The required soil parameters for Horton method include:

- Maximum Infiltration rate (in/hr)
- Minimum Infiltration Rate (in/hr)
- Decay Constant (/hr)
- Drying time (d)
- Maximum Infiltration Volume Possible (inch)

To determine the Horton infiltration parameters, a soil map was first obtained from the NRCS (USDA, 2017). The soil types were then correlated to standard hydrologic soil groups.[3] A map of the hydrologic soil groups found in the CSS is presented in Figure 3-5. Hydrologic soil groups found in DELCORA's CSS are groups A, B, C, B/D and C/D. Horton's infiltration parameters for these soil groups were estimated based on typical values from literature and are shown in Table 3-4.

Table 3-4: Horton Infiltration Parameters

Horton Infiltration Parameter	Soil A	Soil B	Soil C	Soil B/D	Soil C/D
Max Infiltration Rate (in/hr)	5	3	2	2	1.5
Min Infiltration Rate (in/hr)	1.18	0.43	0.2	0.22	0.06
Decay Constant (1/hr)	4	4	4	4	4
Drying Time (d)	2	3	8	8	10.5
Max Volume (in)	14	13.2	12.5	9.8	7.0

3.2.4.2 Manhole

Sewer manholes were simulated as junction nodes in the model. The following information is required:

- Node ID
- Invert
- Maximum Depth (approximated as the difference from manhole rim and manhole invert)
- Surcharge Depth

Manhole ID was inherited from the name of the manhole in the sewer GIS. The naming convention is "MH_XXXX". Manhole input information was updated based on the latest available GIS information.

Manhole input parameters, including invert and rim were found or estimated from record drawings, design drawings, and the sewer manhole shape file. For water tight manholes or manholes with bolted down covers, a surcharge depth of 50-ft will be applied.

[3] Soil types can be categorized into standard hydrologic soil groups A, B, C and D, with group A having the lowest runoff potential and group D having the highest runoff potential. Dual rated groups are group D in their natural state, but can behave according to the first letter if the area is drained. Additional information regarding hydrologic soil group descriptions can be found in the Appendix.

3.2.4.3 Sewer Mains

Sewer mains are the conveyance element and were simulated as conduits in the model. The following input information was needed:

- Conduit ID
- Shape
- Number of barrels
- Upstream and downstream nodes
- Upstream and downstream offset
- Dimension (length, diameter/depth)
- Manning's roughness coefficient
- Minor loss coefficient (entry loss, exit loss, average loss)
- Flap gate installed or not (set at no flap gate for most of the sewer mains)

Conduit ID was inherited from the 2012 H&H Model.

Most of the pipe input parameters, including upstream and downstream nodes, dimension, shape, number of barrels, and flap gate information, were found or estimated from record drawings, design drawings and sewer gravity main GIS shapefiles. For pipes that do not begin or end at the invert of the upstream or downstream node, an offset value was provided to describe the difference from the invert of the pipe to the invert of the upstream or downstream node.

Manning's roughness coefficient is related to the pipe material. The initial input of the Manning's n for different materials is summarized in Table 3-5. The Manning's n may be changed during calibration to account for minor loss or additional sediment depositions in the pipe.

The initial minor loss for pipe will be set at zero for most pipes. For those pipes with sharp turns, a higher minor loss was applied.

If sewer main information was not available, sewer length was estimated in GIS geometry measurement; sewer size were assumed based on upstream and downstream sewers; sewer upstream and downstream offsets were estimated based on sewer connectivity assuming constant slope.

Figure 3-5: Hydrologic Soil Groups for CSS Area

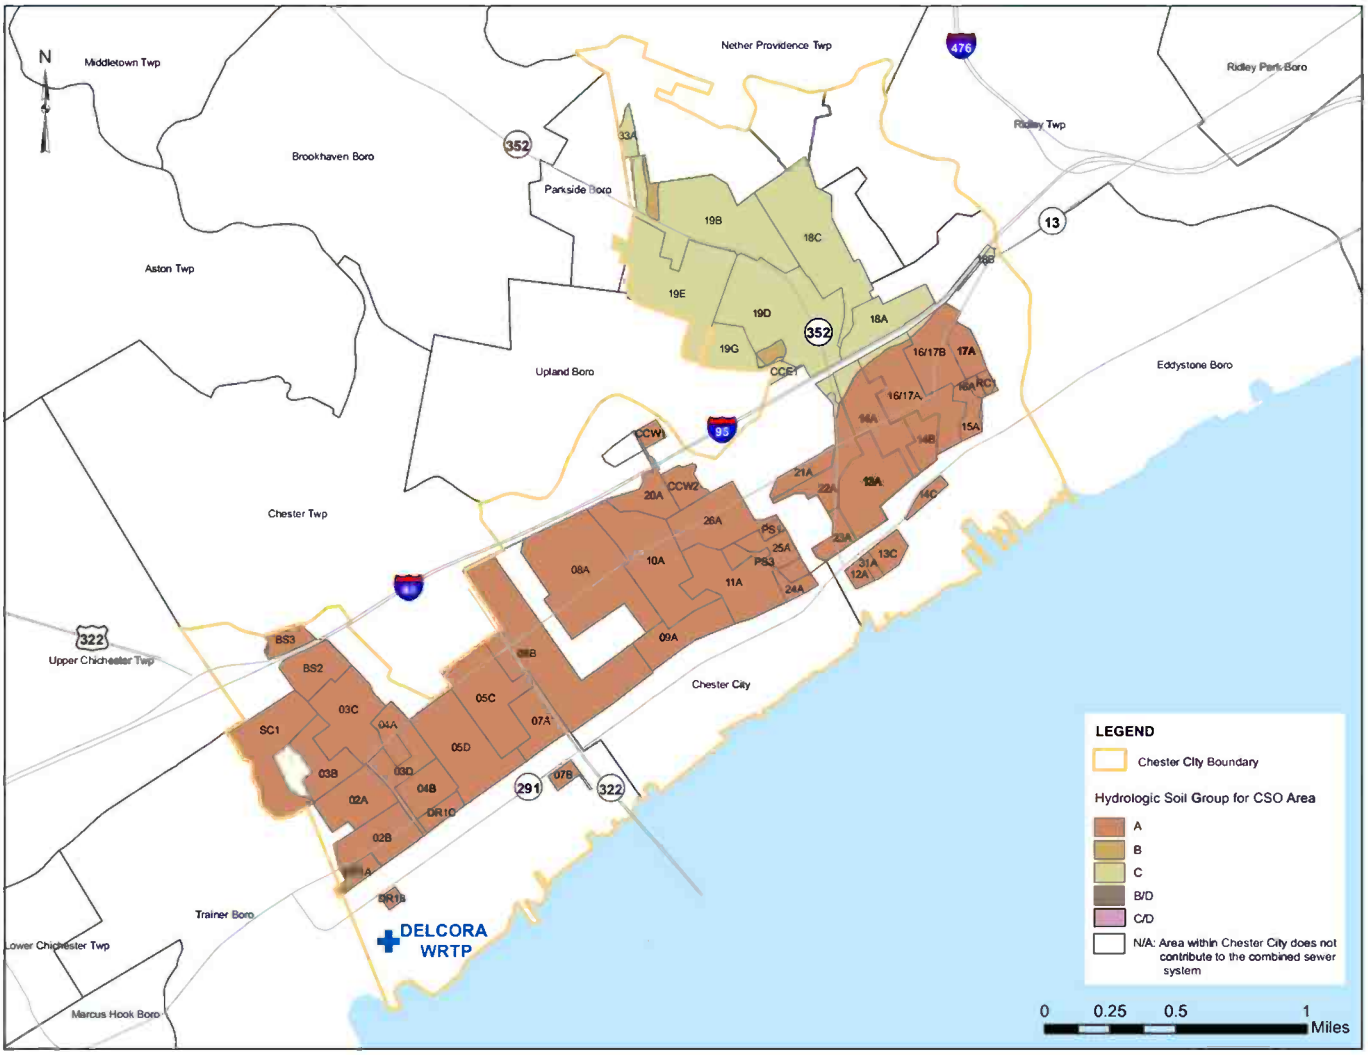

Table 3-5: Manning's Roughness Coefficient for Sewer Mains

Pipe Material	Manning's N
Polyvinyl Chloride (PVC)	0.011
Reinforced Concrete Pipe (RCP)	0.013
Ductile Iron (DI)	0.013
Cast Iron (CI)	0.013
Corrugated Metal Pipe (CMP)	0.020
Masonry	0.025
Unknown	0.013

3.2.4.4 CSO Outfalls

CSO outfalls will be simulated as outfall nodes in the model. The following information is required:

- Outfall ID
- Type (free, normal, fixed stage, tidal stage, time series, stage-flow, flap gate)
- Invert
- Boundary conditions

Outfalls are the discharge points in the model. The outfalls can either be free outfalls without any boundary conditions or the outfalls can have a boundary condition that the head needs to overcome for outflow to occur. The outfalls in the DELCORA's collection system are mostly in the tidal river reach. Therefore, appropriate tidal stages from NOAA data were used to set boundary conditions. Outfalls can have a flap gate at the end to prevent backflow.

Outfall ID will be named according to the CSO regulator overflow points. For example, the outfall for CSO regulator 002 will be named "NREG-002". The inverts of outfalls will be estimated based on record drawings and design drawings, and will be confirmed/adjusted from the field survey, if necessary.

A summary of the outfall data used in the model is contained in Table 3-6. One regulator (Regulator 010) does not have its own outfall, but rather discharges through the same outfall (Outfall 009) as Regulator 009. Also, Regulator 033 has been disconnected from the CSS and, therefore, its outfall is not included in the updated H&H model. As a result, there are a total of 24 CSO outfalls in the updated H&H model.

Table 3-6: CSO Outfall Characteristics Summary

Outfall No.	CSO Receiving Water	Invert at Regulator	Invert at Receiving Stream
002	Delaware River	7.00	-3.5
003	Delaware River	7.98	-3.5
004	Delaware River	8.80	-3.5
005	Delaware River	4.74	-4.5
007	Delaware River	0.81	0.21
008	Delaware River	2.79	0.01
009	Delaware River	2.61	-4
010*	Delaware River	22.5	*
011	Delaware River	7.09	-4
012	Delaware River	1.46	-2
013	Delaware River	1.86	-4
014	Delaware River	-1.09	-4
015	Ridley Creek	0.52	-3
016	Ridley Creek	0.11	-5
017	Ridley Creek	0.09	0.09
018	Ridley Creek	6.28	-5.0
019	Chester Creek	18.00	12.28
020	Chester Creek	8.78	-4
021	Chester Creek	5.78	-1.5
022	Chester Creek	11.5	-3.5
023	Chester Creek	1.33	-3.0
024	Chester Creek	1.21	-4.0

026	Chester Creek	9.00	-4.0
032	Delaware River	1.00	-4.0
033	Ridley Creek	N/A	N/A

Notes:
*CSO regulator 010 discharges at Outfall 009.
N/A: Not Applicable

3.2.4.5 Flow Diversion Structure

As described in Section 3.2.2.2, most of the flow diversion structures are similar to Brown and Brown type regulators. The key components required for modeling these structures include float-operated gates, orifice plates and diversion weirs. Schematic representations of the flow diversion structures are shown in Figure 3-6.

Regulator Gates

Regulator gates will be simulated as orifices in the updated model. The following information is required to model a regulator gate in the model:

- Regulator Gate ID
- Upstream and downstream nodes
- Type
- Shape (two shapes: circle, rectangular)
- Dimension (Height, Width)
- Discharge Coefficient

Regulator gate ID is named according to the CSO regulator points. For example, the regulator gate for CSO regulator 003 is named "REG_003_Gate." All regulator gates are modeled as side-type orifices and have been assigned a discharge coefficient of 0.65. All regulator gates are modeled as rectangular except for REG_004_Gate which is modeled as a circular orifice. The updated model includes real time control rules for opening and closing of the gates based on levels in the float chamber and regulator limit settings. A summary of regulator gate characteristics is shown in Table 3-7.

Orifices

The following information is required to model an orifice in the model:

- Orifice ID
- Upstream and downstream nodes
- Type (two types: side, bottom)
- Shape (two shapes: circle, rectangular)
- Dimension (Height, Width, Crest Height)
- Discharge Coefficient

Orifice ID will be named according to the CSO overflow points. For example, the orifice for CSO 03 will be named "REG_03_Orifplate". All orifices in the collection system are side orifice type, rectangular in shape and were assigned a discharge coefficient of 0.65. The dimensions are based on record drawings.

A summary of the orifice data used in the model is contained in Table 3-8. The update H&H model has 20 orifices. All orifices are side type and are rectangular in shape. Regulators 004, 015, 017 018 and 032 do not have an orifice plate. Regulators 006, 027 and 033 are no longer connected to the CSS and therefore do not have any orifices, weirs or outfalls included in the H&H model.

Weirs

Diversion weirs will be simulated as weirs in the model. The following information is required to model a weir in the model:

- Weir ID
- Upstream and downstream nodes
- Type (four potential weir types: transverse, sideflow, V-notch, trapezoidal)
- Dimension (Height, Weir Length, Weir Crest Height)
- Coefficient of Discharge
- Number of End Contractions

Weir ID will be named according to the CSO overflow points. For example, the weir for CSO 03 will be named "Weir_03". Weir information will be obtained from record drawings and will be field verified, if necessary. All weirs were found to be of the transverse type with no end contractions. All weirs are assigned a discharge coefficient of 3.33.

A summary of the weir data used in the model is contained in Table 3-9.

3.2.4.6 Pump Stations

The wet wells in the pump stations were simulated as storage nodes, and pumps were simulated as ideal pumps in the model. Dimensions of the storage nodes were based on record drawings. For pumps, the following information is required:

- Pump ID
- Startup Depth
- Shutoff Depth

Pump startup depth and shutoff depth will be set up in the model according to the typical pump operation.

Table 3-9: Weir Characteristics

Weir ID No.	Dimensions		
	Height	Length	Crest Height
002	2.50 ft.	2.24 ft.	1.21 in.
003	2.50 ft.	2.24 ft.	1.30 in.

3.2.4.7 Modeling of Separated Areas - Rainfall Derived Infiltration and Inflow (RDII)

The model will use the RTK unit hydrograph (UH) to estimate RDII into the separated area sewer systems. As shown in Figure 3-7 (Muleta & Boulos, 2008), a RTK UH set contains up to three hydrographs: one for a short-term response (UH1), one for an intermediate-term response (UH2), and one for a long-term response (UH3). UH1 represents the most rapidly responding inflow component and has a short T value, UH2 includes both inflow and infiltration and has a longer T value, and UH3 includes infiltration that may continue long after the storm event has ended and has the longest T value. The unit hydrograph is defined by the following three parameters:

- R: the fraction of rainfall volume that enters the sewer system and equals to the volume under the hydrograph,
- T: the time from the onset of rainfall event to the peak of the unit hydrograph in hours, and
- K: the ratio of time to recession of the unit hydrograph to the time to peak.

The same set of RDII parameters will be applied in the same metershed because of the availability of the flow hydrograph for model calibration. The initial values of RTK will be estimated using the RDII Analyst tool in the InfoSWMM. The RTK values are calibration parameters to be refined during model calibration.

Figure 3-7: RTK Unit Hydrographs

3.3 Summary

The 2012 H&H model was updated as described above. A summary of the key revisions is presented in Table 3-10. The detailed layout of the updated model is shown in Figure 3-8 and Figure 3-9.

Table 3-10: Summary of Revised H&H Model

Review Item	2012 Model Review Observation	Comments	Updated Model
Model Software	- EPA SWMM 5.0		Innovyze InfoSWMM version 14.5
Vertical Datum	- NAVD 88	- To be verified	- NGVD29
General Sub Models	- EPASWMM for the runoff model - Horton Equation for the infiltration model - Hydrodynamic wave for the flow routing model	- All these choices are commonly seen in collection system modeling practices	
Rain Gauge	- One (1) rain gage, located at the Western Regional Treatment Plant (WRTP)	- One rain gauge is not sufficient for the entire service area in the model	- Seven (7) rain gauges, as shown in Section 2 - Additional GARR analysis performed
Service Area	- 67 subcatchments, all for combined area - One set of Horton infiltration parameters are applied to most of the subcatchments (66 out of 67 subcatchments) - The infiltration parameters applied in the model is equivalent to infiltration parameters for soil type C/D	- All service area including separated area that contribute flow to the DELCORA collection system should be included in the model - Combined area delineation will be checked to include any changes along the years - Soil type need to be checked to verify Horton infiltration parameters in all subcatchments	- 111 subcatchments, 54 for combined area and 57 for separated areas - Combined area was modified to include newly separated areas. - Horton infiltration parameters applied to 54 out of 111 subcatchments - Horton infiltration parameters varied based on identified soil types -

Review Item	2012 Model Review Observation	Comments	Updated Model
Sewer Manhole	- 736 storage nodes. - All sewer manholes are simulated as storage units in the model. - The majority of the storage units (732 out of the 736) have a diameter of 4-ft, and the rest (4 units) have a surface area of 100 square feet (sf.) (equivalent to 10'x10'). - All storage units are set-up with a ponding area of 9,999 sf. to allow excess water to collect atop of the nodes and be re-introduced into the system as conditions permit.	- Sewer manholes will be simulated as common junction node - This will help with SSO evaluation in the collection system	- 860 common junction nodes. - The majority of the common junction nodes (836 out of the 860) have a diameter of 4-ft, and the rest (4 units) have a surface area of 100 square feet (sf.) (equivalent to 10'x10'). - There are 35 imaginary junctions created to receive flow from the subcatchments gravity network not included in the model network
CSO Outfall	- 29 outfall nodes - All CSO outfalls are free outfall	- All outfalls are located in the Delaware River in the tidal reach, a tidal stage instead of free outfall should be assigned to the outfalls - Outfall ID 101 has dry weather input of 1.76 cfs, it represents WRTP in the model	- 24 CSO outfall nodes - Tidal data is assigned to 24 outfalls using time series - Wherever tide gates are installed, a real time control is applied

Review Item	2012 Model Review Observation	Comments	Updated Model
Sewer Mains	- 735 conduit links. - Negative slopes at Nodes 73803 and 70709 not matching the GIS. - Pipe connectivity is not consistent with the GIS in Subcatchment EA1, 25A. - Pipe size and connectivity is not consistent with the GIS around Node: 5201242, 5201234. - Pipe size is not consistent with the GIS around Node: 52018-52015. - Pipe size is not consistent with the GIS around Node: 531-527, 522-517, 516-513, 510020301-5100202, 403-NCPS, 40801-40801A, 32405-32404, and 1110402-11103. - Pipe size and slope are not consistent with the GIS around Node: 422-4140. - NREG06 outfall pipe direction is opposite.	- All the negative slopes and inconsistencies need to be checked with the most updated GIS and record drawings during the model update	- 817 conduit links. - 45 imaginary conduit links created to receive flows from subcatchment gravity network not included in the model

Review Item	2012 Model Review Observation	Comments	Updated Model
CSO Regulators	- 34 orifice links. - All CSO regulators are simulated using orifices to intercept dry weather flows and partial wet weather flows to the collection system, and with elevated conduits to convey extra flows to the CSO outfalls. - Approximately 75% of the orifices (25 out of 34) are modeled with Real Time Control (RTC) to mimic regulator gate opening based on level. - None of the regulator diverting weir structures is simulated in the model.	- Diverting weir structures need to be added in the model - The slopes of all overflow pipes connected to the CSO outfalls need to verified - All orifice opening dimensions verified will be verified - All the RTC rules regulating orifice opening will be verified with actual operation	- 44 orifice links. - CSO regulators are simulated using orifices and float-operated gates to intercept dry weather flows and partial wet weather flows to the collection system, and with conduits set a verified inverts to convey extra flows to the CSO outfalls. Exceptions occur at several regulators where orifices have been removed and at one regulator where the float and gate have been removed. - Approximately 57% of the orifices (25 out of 45) are modeled with Real Time Control (RTC) to mimic regulator gate opening based on level. - Regulator diverting weir structures added to the model. - All orifice opening dimensions were verified using record drawings excepting Orifice 024 which was field verified.
Pump Station	- No pump station is included in the model	- All pump stations that contribute flow to the DELCORA collection system should be added to the model, with related force mains	- Pump stations added to model. - Related force mains added to model

Review Item	2012 Model Review Observation	Comments	Updated Model
Dry Weather Flow	- 94 dry weather flow (DWF) inputs - Total DWF is 7.01 MGD - No diurnal curve - DWF does not include all the separated service areas that contribute to the DELCORA system -	- DWF should be updated to include all the service areas that contribute to the DELCORA system - Weekday and weekend diurnal curve should be included in the model to effectively simulate dry weather diurnal pattern	- 111 dry weather flow (DWF) inputs - Total DWF is 24.6 MGD - DWF analysis was performed on all flow meters in separated and combined areas as well as pump stations - Weekday and weekend diurnal curves were generated as well as overall, weekday, weekend and monthly DWF factors.
RDII	- No rainfall-derived infiltration/inflow (RDII) element was found in the model	- RDII should be included in the model to estimate reasonable wet weather inflow from RDII	- RDII was included in the model to estimate reasonable wet weather inflow from RDII

Figure 3-8: Updated H&H Model Layout

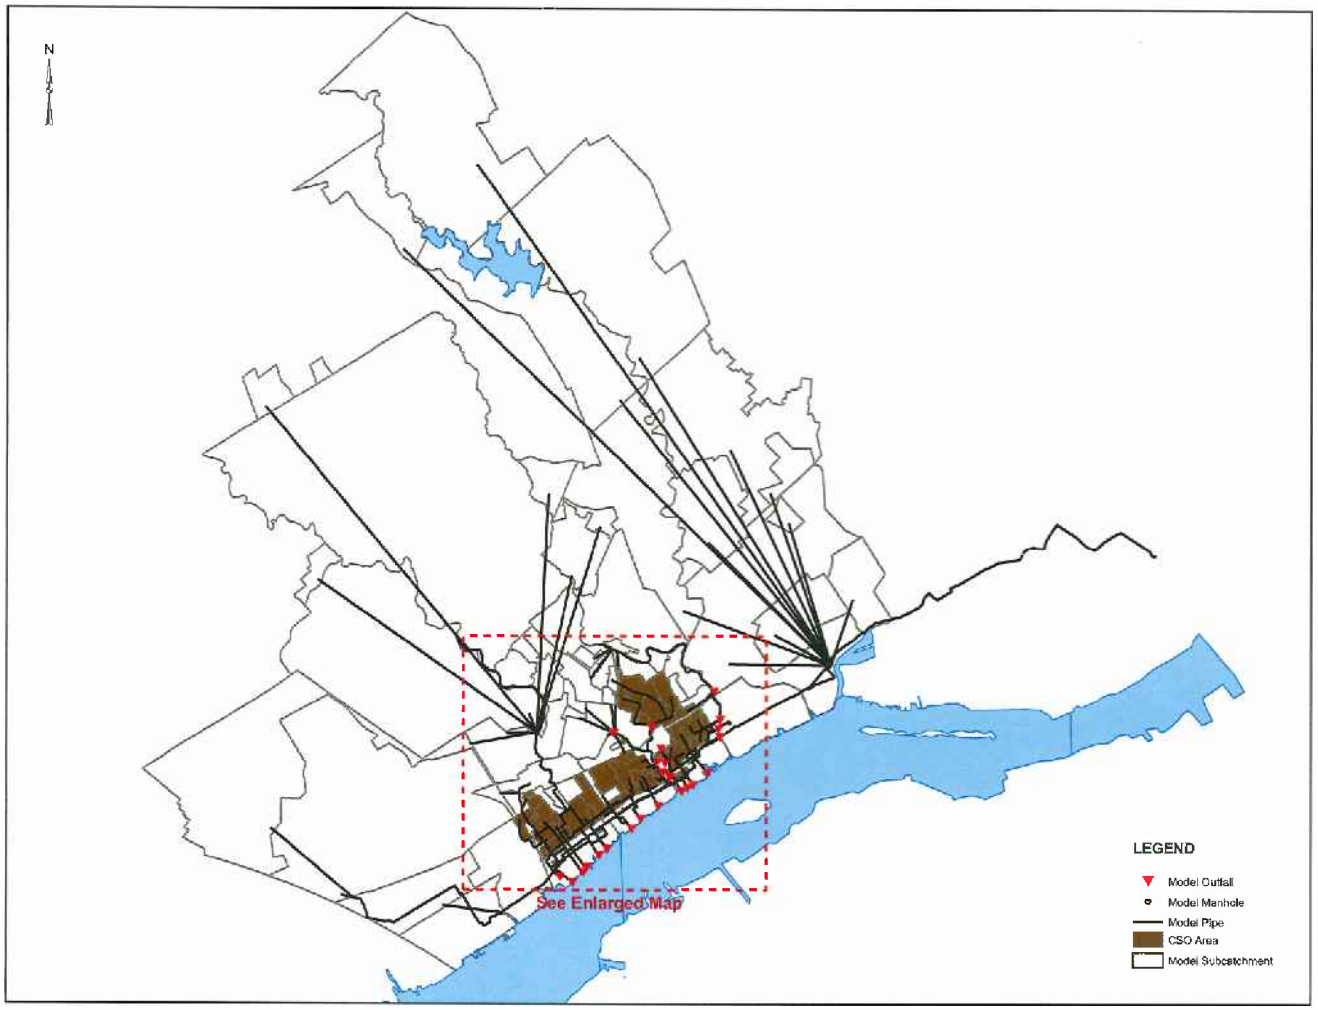

Figure 3-9: Updated H&H Model Layout – CSS Area

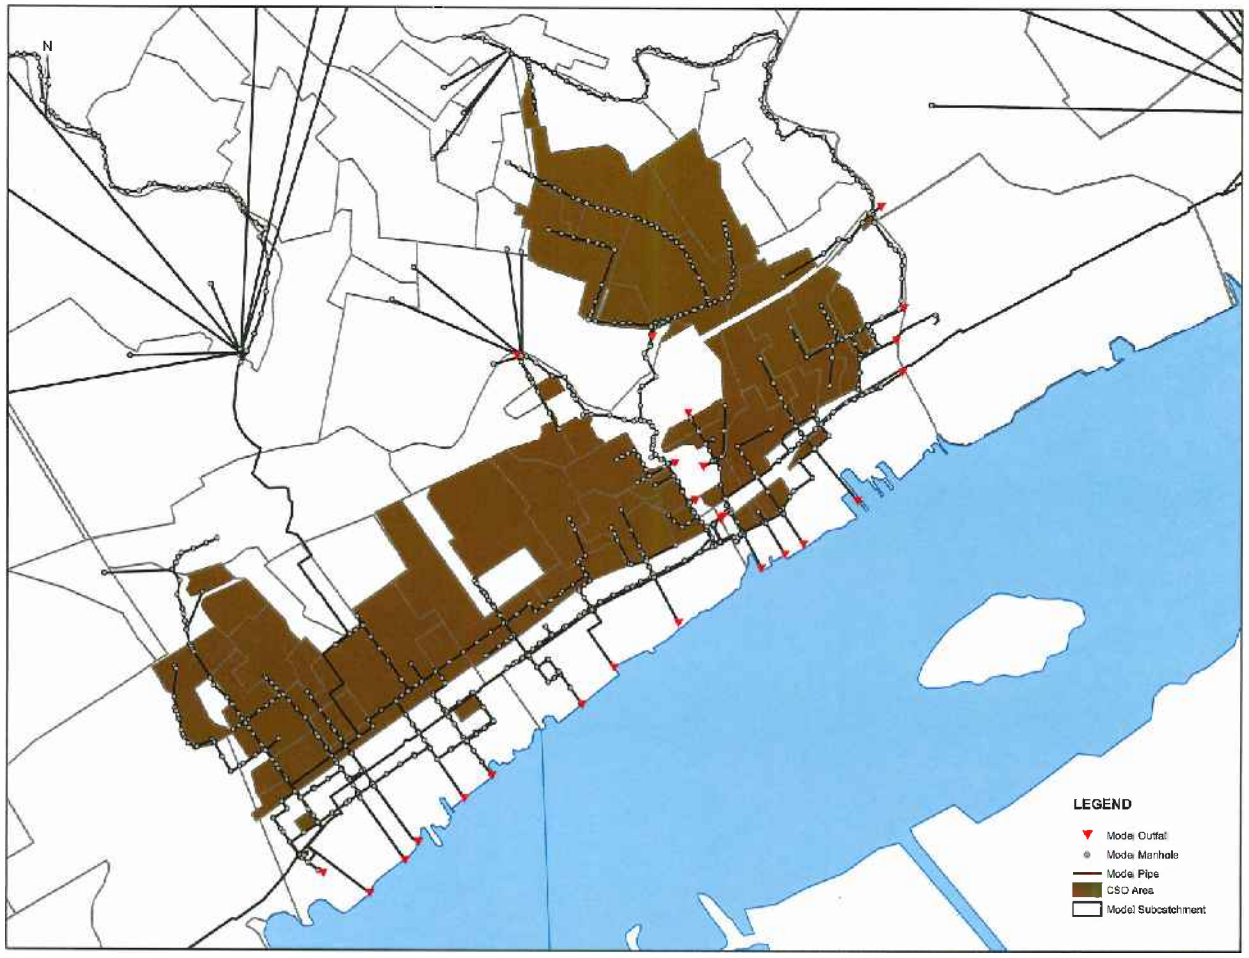


Section 4 DELCORA H&H Model Calibration and Validation

4.1 Model Calibration and Validation

Model credibility is developed through model calibration and validation. Model calibration involves application of the model to known external inputs (e.g., rainfall), evaluation of the model's ability to replicate monitored conditions (e.g., flow and volume), and adjustment of key model parameters as needed until an acceptable level of agreement is reached between simulated and monitored conditions.

After the model is satisfactorily calibrated it must be validated by running known storms with known flow results and having the model replicate the known events. Storms used in model validation should be independent from the storms used in the model calibration.

4.1.1 Calibration/Validation Criteria

4.1.1.1 Dry Weather Flow Calibration Criteria

Dry weather flow (DWF) analysis was based on the rainfall and flow monitoring results. DWF distribution in the collection system was based on land use data. Weekday, weekend and monthly diurnal factors from the DWF analysis were applied for each flow meter service area. Upstream meters in the system were calibrated first, then flows through the system to the pumps stations and to the WRTP were balanced. Figure 4-1 shows the arrangement of the meters in the system and meter identification.

DWF calibration will adhere to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be within 1 hour of the observed,
- The simulated peak flow will be within 10% of the observed flow, and
- The simulated flow volume over 24 hours will be within 10% of observed flow.

4.1.1.2 Wet Weather Flow Calibration Criteria

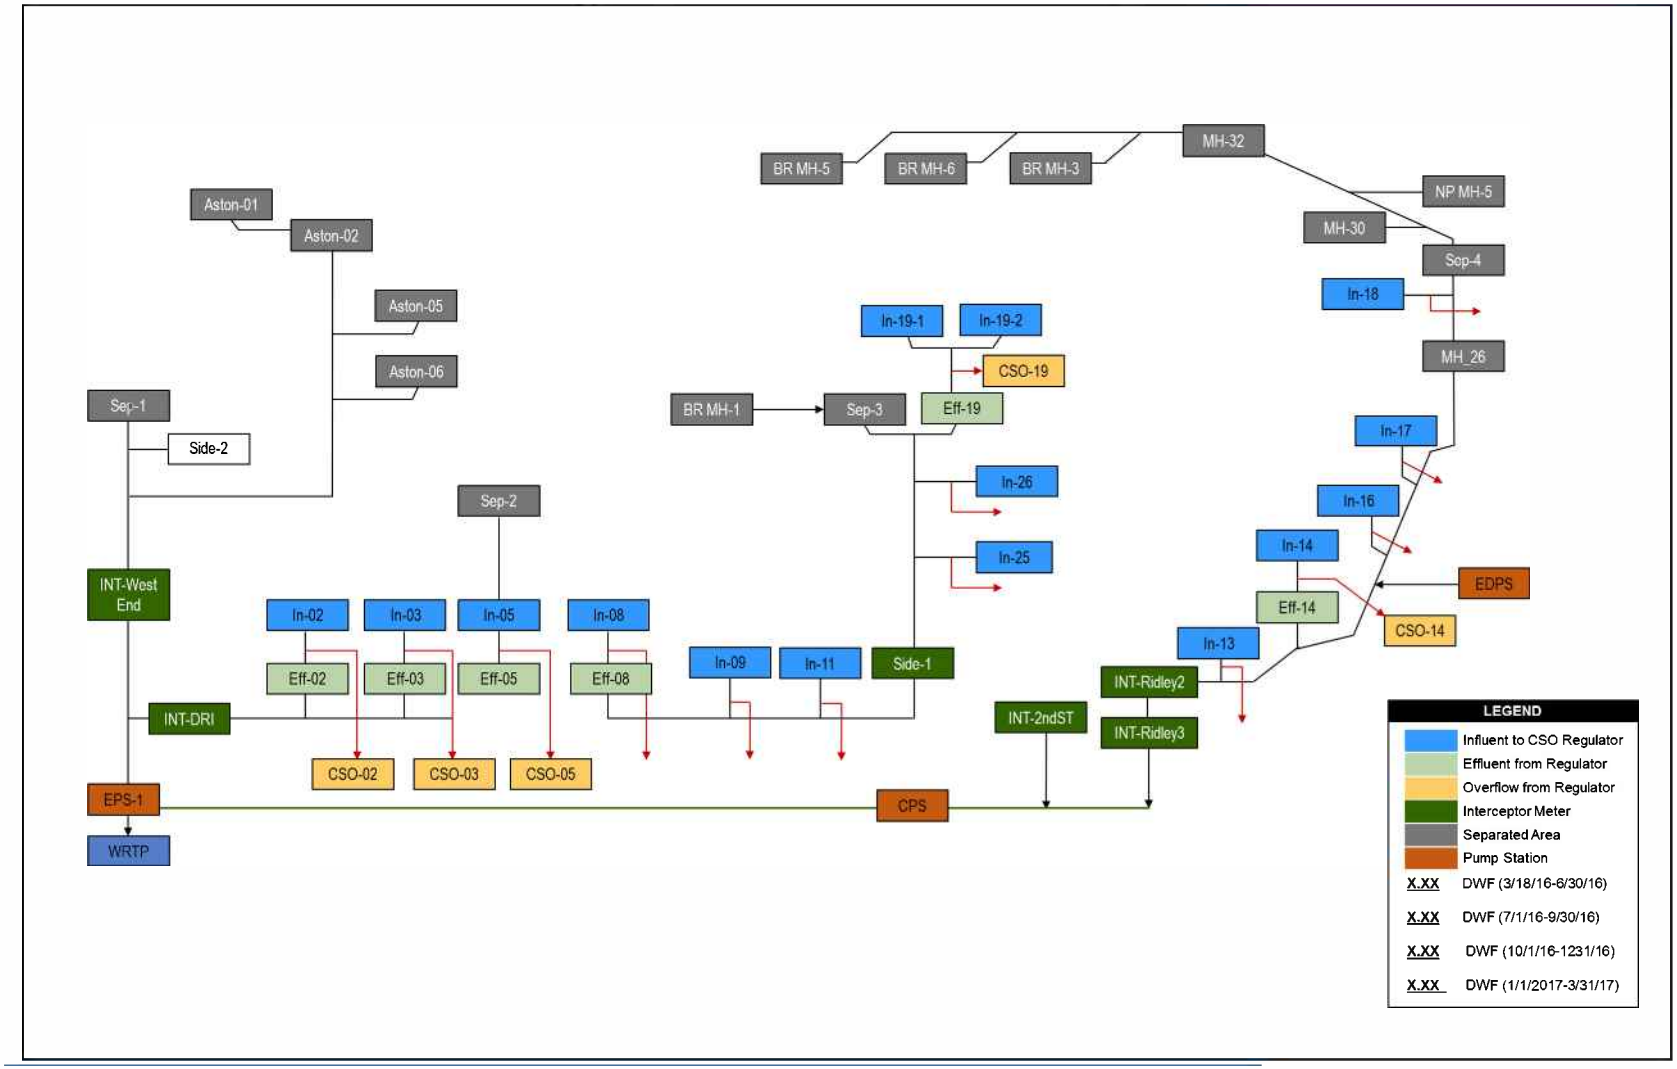
Wet weather flow (WWF) includes surface runoff from the combined area, RDII from the entire service area, and connected rooftops, if any, from the separated area. RDII parameters will be developed based on the separated area, and surface runoff parameters will be adjusted for the combined area to calibrate the system response to the wet weather conditions.

Four (4) wet weather events were selected for wet weather calibration. Final selections include wet weather events with various rainfall intensities and volume.

WWF calibration will adhere to industry standards and the criteria below:

- The simulated hydrograph should match the general observed hydrograph shape,
- The simulated time of peaks and troughs will be similar having regard to the duration of the event,

Figure 4-1: Flow Meter Schematic



- The simulated peak flow for significant peaks will be within the range of -15% to +25%,
- The simulated flow volume will be within the range of -10% to +20%,
- The depth of surcharge will be in the range of -0.1 m to +0.5 m, and
- At key points such as CSOs, the unsurcharged depth will be within ± 100 mm (± 0.33 ft.)

4.1.2 Model Calibration Approach

The runoff calibration for the combined sewer area is achieved by primarily adjusting width and percent imperviousness. The RDII calibration for separated areas was achieved by adjusting RTK values. The calibration of hydraulic control structures (weirs and orifices) is achieved by adjustment the discharge coefficients. The conduit hydraulics calibration is achieved by adjusting Manning's n and head loss coefficients. Flow depth, as well as flow rate, is checked while calibrating the hydraulic model.

After calibration, a different set of flow monitoring data was used to validate the model calibration. Model calibration and validation is an iterative process.

Percent Imperviousness

The percent imperviousness for combined sewer subcatchment is the key parameter to be adjusted to calibrate runoff to the observed wet weather flow volumes. If runoff from a large portion of the impervious surface could not be captured by the combined sewers due to a limited number and size of storm inlets, the percent imperviousness will need to be reduced significantly from its initial value calculated based on impervious land cover. This is done to represent a more reasonable "effectively connected area" and to achieve a satisfactory calibration for runoff volume.

Width

The width for the combined sewer sub catchments, in conjunction with percent imperviousness, will be adjusted to calibrate to the observed wet weather flow peaks.

Depression Storage

The depression storage is another hydrologic parameter for wet weather volume calibration. It can also be adjusted to achieve a satisfactory calibration for the wet weather flow start timing.

RDII Parameters

RDII parameters are to be adjusted to calibrate to the observed wet weather volumes and flow hydrograph shape for the separate sewer areas. Then, the runoff parameters will be adjusted to calibrate to the observed data.

Pipe Roughness

Pipe roughness was adjusted to calibrate to the observed flow depths and velocities at the meter locations.

Orifice and Weir

Orifice and weir parameters discharge coefficients were adjusted to calibrate to the observed overflows at the outfall meter locations.

Minor Loss

Minor loss values were applied in the model where necessary to refine observed flow/depth relationships at the meter locations.

4.1.3 Model Calibration Results

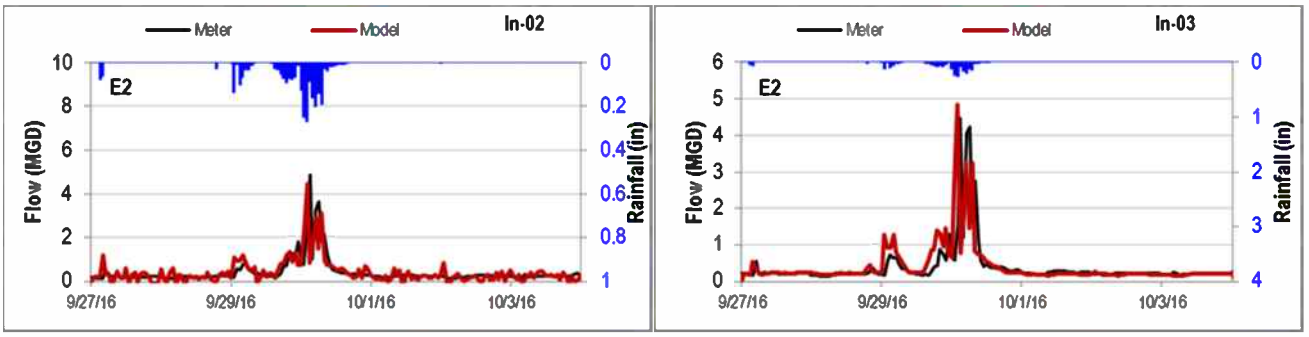
Successful calibration is indicated by satisfying agreements between the model prediction and the flow monitoring data in terms of shape of hydrograph, wet weather volume and peak flow. The calibration was performed and evaluated for various sizes of storms and different antecedent conditions so that the calibrated model can be reasonably applied for various hydrologic conditions. Wet weather events used for model calibration and validation are summarized in listed in Table 4-1. The larger storm events will have more weighting factor in the calibration process because the large events are the ones that dominate the total overflow volume.

Table 4-1: Wet Weather Events for Model Calibration and Validation

Event ID	Start Time	Stop Time	Rainfall Depth* (inches)	Used in Calibration	Used in Validation
E1	5/29/16 19:00	5/30/16 5:00	1.82	C	
E2	9/28/16 12:00	9/30/16 10:00	2.36	C	
E3	11/29/16 7:00	11/29/16 20:00	1.08	C	
E5	5/21/16 11:00	5/22/16 21:00	1.71		V
E6	7/28/16 15:00	7/29/16 9:00	1.26	C	
*At Chester PS rain gauge					

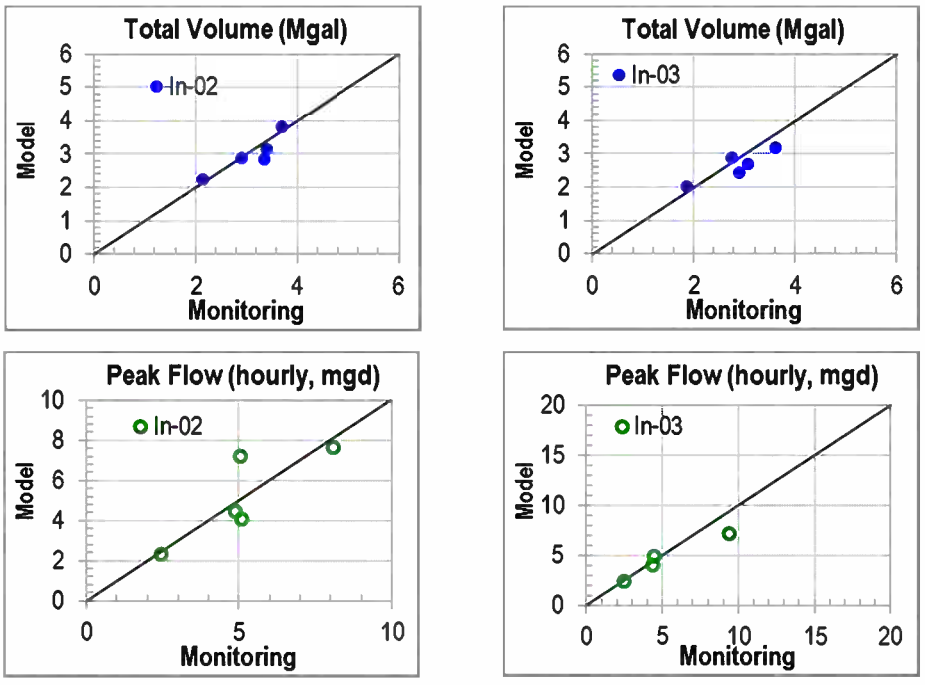
Examples of model calibration results are shown in Figure 4-2. Additional figures for all meters installed at different locations, including meters installed at major trunk interceptor, overflow pipes, influent pipe to overflow control structure, intercepting pipes, previous CSO areas, separate sewer areas and boundaries can be found in Appendix C.

Figure 4-2: Model Calibration Hydrograph (Example Plot)



Comparisons of the predicted total volume against the monitoring total volume and predicted peak flow against monitoring peak flow were analyzed and shown in 1:1 ratio plots for all calibrated meters. This is to evaluate the overall calibration and validation from all the events. The event points in Figure 4-3 are distributed close to the 1:1 ratio line, which means that the model predicted peak flow and wet weather event volume are in good agreement with the metered data. Additional figures for all model calibration plots can be found in Appendix C.

Figure 4-3: Model Calibration Hydrograph (Example Plot)



Section 5 Conclusion

The H&H model from the 2012 DELCORA LTCP Update was reviewed and updated. Data from the rainfall and flow monitoring program was used to calibrate and validate the updated H&H model. The calibrated H&H model will be used to assist DELCORA throughout the remaining steps in the CSO LTCP update process.

In a previous report (Greeley and Hansen, 2016), a typical hydrologic period was selected to represent the average conditions in terms of rainfalls, river flows and combined sewer system response across the DELCORA service area. Subsequent reports will apply the selected typical hydrologic period to the calibrated H&H model to evaluate existing CSO discharge frequency and volume and to evaluate the impacts of proposed LTCP control alternatives on CSO discharges.

Appendix A H&H Model Update and Calibration Schedule

Figure 6-1 Schedule for H&H Model Development and Implementation (Updated July 28, 2016)

	Tasks of DELCORA H&H Model Development and Implementation	Start	Finish
	Lodging date of Consent Decree (8/17/15)		
	DELCORA Long Term Control Plan Update	8/17/15	2/14/19
	TASK 3 - Typical Year Rainfall Record (90 days)	8/18/15	10/31/15
1	Develop criteria for determination of typical hydrologic period		
2	Review available historic rainfall and flow data		
3	Obtain rainfall data from the Philadelphia National Airport.		
4	Review with DELCORA		
5	Select the typical hydrologic period and document the selection process		
6	Draft Report		
7	Final Report		
	TASK 5 - Hydrologic & Hydraulic Model	8/18/15	8/17/17
1	Initial assessment of GIS Model		
2	Initial assessment of H&H Model		
3	Report summarizing Initial Assessment		
4	Develop an H&H Model Update and Calibration Plan (60 days)	8/18/15	10/14/15
5	Develop Schedule for Model Development and implementation		
6	H&H Model Update		
7	Flow Monitoring Data Analysis		
8	H&H Model Calibration		
9	H&H Model Report		
	TASK 6 - Rainfall and Flow Monitoring	10/15/15	3/31/17
1	Prepare Rainfall and Flow Monitoring Work Plan (from Task 5)		
2	Procure Flow Metering and Rain Gauge Services		
3	Install and Calibrate Rain Gauge and Flow Meters for Official Data Gathering		
4	Conduct Rainfall and Flow Monitoring		
	TASK 7 - Existing Service Area Characterization	9/15/15	8/17/17
1	GIS Mapping Review and Update		
2	Refine Service Area Delineation (Combined and Separated)		
3	Investigate Existing CSO Facilities		
4	Investigate Service Agreements		
5	Perform H&H Modeling of Existing System		
6	Documentation		
	Evaluation of CSO Alternatives (Part of Task 11)	5/1/17	3/31/18
1	Develop Future DWF and Service Area		
2	Develop CSO Alternatives		
3	Evaluate CSO Alternatives using H&H Model

- Consent Order Deadline
- Draft and Final submittals

Appendix B Description of Hydrologic Soil Groups

Hydrologic Soil Groups (USDA, 2017a)

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.

Statistical Evaluation: Nash-Sutcliffe Efficiencies

The Nash-Sutcliffe efficiency (NSE) was selected as an appropriate statistical measure of the goodness-of-fit for model calibration. It has been widely applied in hydrologic models (Moriasi et al., 2007) and thus can be used to assess the event volume predictions of the hydrologic component of the model. Although interpretation of NSE values may be subjective, model calibration is generally considered satisfactory for values greater than 0.5, with values greater than 0.75 being considered very good (Moriasi et al., 2007).

For this application the values were calculated as shown in following equation:

$$NSE = 1 - \left[\frac{\sum_{i=1}^{n}\left(Y_i^{obs} - Y_i^{sim}\right)^2}{\sum_{i=1}^{n}\left(Y_i^{obs} - Y^{mean}\right)^2}\right]$$

where,
Y_i^{obs}: the i^{th} metered event volume
Y_i^{sim}: the i^{th} modeled event volume
Y^{mean}: the mean metered volume
n: the total number of events

NSE values were calculated for all flow meter calibration and the results are shown in **Figure C-1** for the wet weather events**.** According to the above mentioned criteria wet weather calibration of over 82% of meters are above good condition and over 76% of the meters are above very good condition.

E3	5.00	5.46	-15% to +25%	9%	1.32	1.53	-10% to +20%	15%
E4	7.05	6.37	-15% to +25%	-10%	4.00	3.17	-10% to +20%	-21%
E5	7.54	7.97	-15% to +25%	6%	2.25	1.91	-10% to +20%	-15%
E6	6.81	21.65	-15% to +25%	218%	1.01	1.18	-10% to +20%	17%

Note: Four of the six wet weather events are calibrated well within the industry criteria. Flow meter data recorded for Events E1 and E6 is not consistent with the recorded rainfall intensity. These events are expected to have the highest peak flow. This is most likely a result of a malfunctioning flow meter. However, based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

E6	1.20	1.17	-15% to +25%	-2%	0.49	0.57	-10% to +20%	17%

Note: Four of the six wet weather events are calibrated well within the industry criteria. The EFF-02 meter is the effluent meter from Regulator 02. The calibration of Regulator 02 meters (which include the IN-02, EFF-02 and CSO-02 meters) are more focused on the influent IN-02 meter and the overflow CSO-02 meter when the total metered influent flow (IN-02) is not balanced with the total metered effluent flow (EFF-02 plus CSO-02). Based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

E5	7.71	3.20	-15% to +25%	-58%	3.99	3.41	-10% to +20%	-15%
E6	4.18	4.39	-15% to +25%	5%	1.44	2.15	-10% to +20%	49%

Note: Four of the six wet weather events are calibrated well within the industry criteria. The EFF-08 meter is the effluent meter from Regulator 08. The calibration of Regulator 08 meters (which include the IN-08, EFF-08 and CSO-08 meters) are more focused on the influent IN-08 meter and the overflow CSO-08 meter when the total metered influent flow (IN-08) is not balanced with the total metered effluent flow (EFF-08 plus CSO-08). Based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

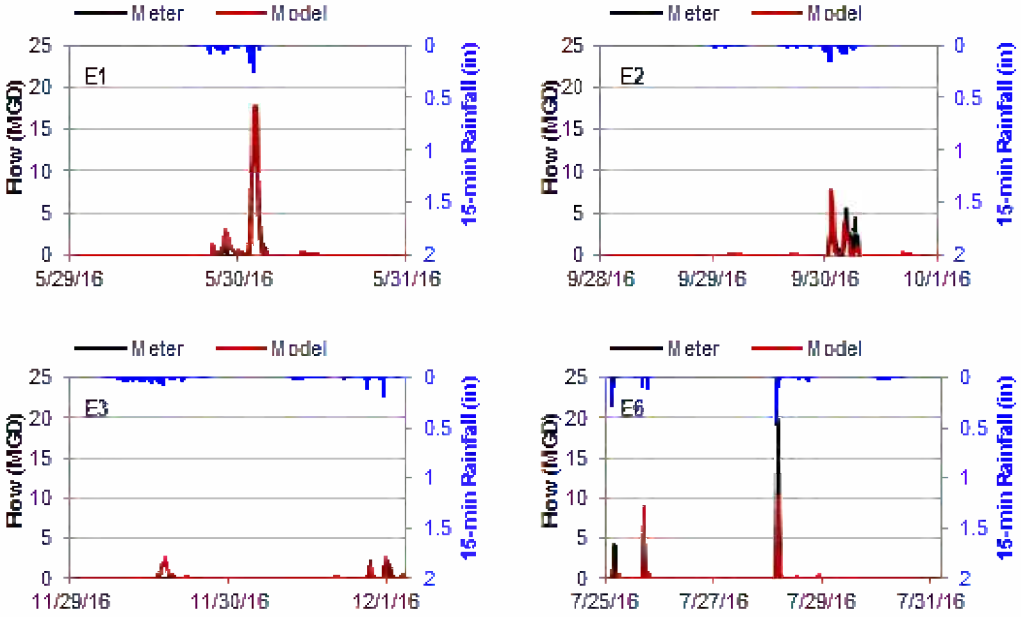
E6	7.32	3.42	-15% to +25%	-53%	1.05	1.05	-10% to +20%	0%

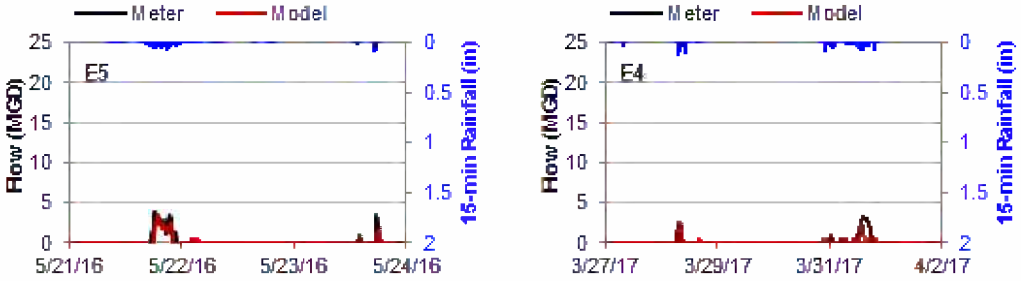
Note: Four of the six wet weather events are calibrated well within the industry criteria. The EFF-14 meter is the effluent meter from Regulator 14. The calibration of Regulator 14 meters (which include the IN-14, EFF-14 and CSO-14 meters) are more focused on the influent IN-14 meter and the overflow CSO-14 meter when the total metered influent flow (IN-14) is not balanced with the total metered effluent flow (EFF-14 plus CSO-14). Based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

FLOW METER CSO-14 MODEL CALIBRATION AND VALIDATION RESULTS_Wet Weather Events

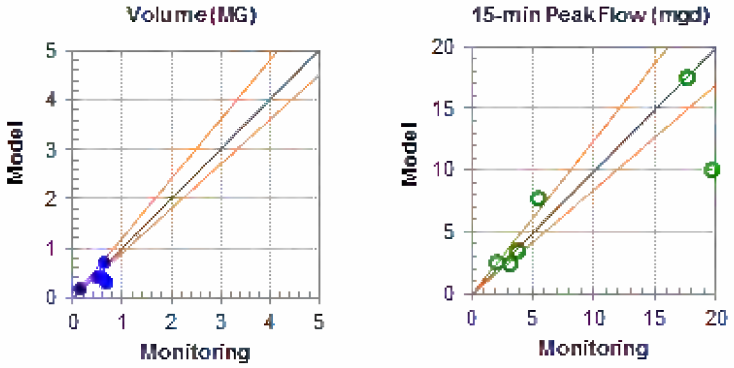
CSO-14 Model Calibration Results (Metered and Modeled Flow)



CSO-14 Model Validation Results (Metered and Modeled Flow)



CSO-14 Overall Model Calibration and Validation Results (Volume and Flow 1:1 Plots)



CSO-14 Model Wet Weather Calibration and Validation Summary								
Event	Peak Flow (MGD)				Volume (MG)			
	Monitored	Model	Criteria	Achieved	Monitored	Model	Criteria	Achieved
E1	17.57	17.55	-15% to +25%	0%	0.63	0.75	-10% to +20%	19%
E2	5.47	7.82	-15% to +25%	43%	0.45	0.43	-10% to +20%	-4%
E3	2.03	2.59	-15% to +25%	27%	0.10	0.21	-10% to +20%	100%
E4	3.16	2.50	-15% to +25%	-21%	0.65	0.33	-10% to +20%	-49%
E5	3.76	3.49	-15% to +25%	-7%	0.57	0.42	-10% to +20%	-25%
E6	19.66	10.03	-15% to +25%	-49%	0.67	0.36	-10% to +20%	-46%

Note: Four of the six wet weather event volumes are calibrated well within or close to the industry criteria. This is the CSO meter from Regulator 14, the calibration of Regulator 14 meters (including Influent meter, effluent meter and CSO meter) are more focused on matching the peak flow and flow volume of the influent and CSO meters. The CSO meter flow volume is challenging to calibrate especially for the small overflow events like E3. Based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

	Monitored	Model	Criteria	Achieved	Monitored	Model	Criteria	Achieved
E1	0.12	0.11	-10% to +10%	-6%	0.20	0.20	-10% to +10%	0%
E2	0.18	0.15	-10% to +10%	-15%	0.29	0.27	-10% to +10%	-7%
E3	0.19	0.15	-10% to +10%	-19%	0.31	0.28	-10% to +10%	-9%
E4	0.20	0.19	-10% to +10%	-6%	0.35	0.35	-10% to +10%	0%
E5	0.11	0.11	-10% to +10%	1%	0.19	0.20	-10% to +10%	9%
E6	0.15	0.13	-10% to +10%	-11%	0.22	0.24	-10% to +10%	9%

IN-17 Model Wet Weather Calibration and Validation Summary								
Event	Peak Flow (MGD)				Volume (MG)			
	Monitored	Model	Criteria	Achieved	Monitored	Model	Criteria	Achieved
E1	5.19	14.26	-15% to +25%	175%	0.53	1.06	-10% to +20%	101%
E2	6.54	5.11	-15% to +25%	-22%	1.15	1.30	-10% to +20%	13%
E3	7.31	4.01	-15% to +25%	-45%	0.95	0.99	-10% to +20%	4%
E4	3.64	6.57	-15% to +25%	81%	2.19	2.05	-10% to +20%	-6%
E5	3.95	5.17	-15% to +25%	31%	0.79	1.10	-10% to +20%	39%
E6	13.38	12.67	-15% to +25%	-5%	0.61	0.72	-10% to +20%	18%

Note: Only two of the six wet weather event volumes are calibrated well within the industry criteria. Flow meter data recorded for some of the events (E1, E4) is not consistent with the recorded rainfall intensity. Based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

E5	0.26	0.24	-10% to +10%	-7%	0.47	0.45	-10% to +10%	-5%
E6	0.23	0.22	-10% to +10%	-7%	0.41	0.41	-10% to +10%	-1%

Side-2 Model Wet Weather Calibration and Validation Summary								
Event	Peak Flow (MGD)				Volume (MG)			
	Monitored	Model	Criteria	Achieved	Monitored	Model	Criteria	Achieved
E1	0.65	1.44	-15% to +25%	120%	0.36	0.38	-10% to +20%	5%
E2	0.68	0.75	-15% to +25%	10%	0.67	0.76	-10% to +20%	15%
E3	0.56	0.54	-15% to +25%	-3%	0.58	0.59	-10% to +20%	2%
E4	1.21	0.67	-15% to +25%	-45%	1.94	1.66	-10% to +20%	-14%
E5	0.76	0.65	-15% to +25%	-14%	0.78	0.71	-10% to +20%	-8%
E6	0.87	0.85	-15% to +25%	-3%	0.42	0.41	-10% to +20%	-4%

Note: Four of the six wet weather events are calibrated well within the industry criteria. Flow meter data recorded for some of the events (E1 and E4) is not consistent with the recorded rainfall intensity. Based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

E4	2.74	2.31	-10% to +10%	-16%	3.78	3.84	-10% to +10%	2%
E5	2.55	2.38	-10% to +10%	-7%	3.77	3.95	-10% to +10%	5%
E6	1.99	2.05	-10% to +10%	3%	3.25	3.44	-10% to +10%	6%

NCPS Model Wet Weather Calibration and Validation Summary								
Event	Peak Flow (MGD)				Volume (MG)			
	Monitored	Model	Criteria	Achieved	Monitored	Model	Criteria	Achieved
E1	7.95	5.65	-15% to +25%	-29%	3.67	3.51	-10% to +20%	-4%
E2	5.71	5.63	-15% to +25%	-1%	6.02	7.83	-10% to +20%	30%
E3	3.95	5.62	-15% to +25%	42%	5.29	5.61	-10% to +20%	6%
E4	7.75	5.61	-15% to +25%	-28%	16.38	14.07	-10% to +20%	-14%
E5	5.51	5.66	-15% to +25%	3%	7.07	6.64	-10% to +20%	-6%
E6	5.51	5.67	-15% to +25%	3%	3.53	4.03	-10% to +20%	14%

Note: Four of the six wet weather events are calibrated well within the industry criteria. The under-predicted peak flow for E1 and E4 is probably due to the pump capacity limit put in the model based on received pump curves. Based on the calibration results of the overall model, the model calibration is adequate for purposes of long term control planning.

Chester, PA 19013

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. DiSantis:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Regional Water Quality Control Authority (DELCORA) Sewer System Hydrologic and Hydraulic Model Report Revised Appendix C dated March 1, 2018. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). EPA accepts and approves the subject report.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

Section 1 Introduction

The Delaware County Regional Water Quality Control Authority (DELCORA) entered into a Consent Decree (CD) with the United States Government in August 2015. The purpose of the Consent Decree is to establish a schedule for implementation of Long Term Control Plan Update (LTCPU) to achieve full compliance with the Clean Water Act and the regulations and Clean Streams Law and regulations. The lodging of this Consent Decree was entered by the court on August 17, 2015, it was signed and filed on November 10, 2015 by the United States District Court for the Eastern District of Pennsylvania.

According to the Consent Decree, DELCORA's Hydrologic and Hydraulic Model (H&H Model) must be updated to meet the requirements in Section V.A.14 of the Consent Decree. A detailed plan to update, calibrate and validate the H&H model has been submitted and approved by the USEPA on March 1, 2016. Additional rainfall and flow monitoring is required to calibrate and validate the H&H model. Requirements of rainfall and flow monitoring are detailed in the Consent Decree Section V.A.14.d and e, which is included in the following:

> "*d.* *Rainfall and flow monitoring shall be carried out in accordance with current good industry practice for a period of at least twelve* ***(12) months****, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization of dry and wet weather flows from the entire Model Area, and the response of each CSO to wet weather flows.*
>
> *e.* *For all rainfall and flow monitoring carried out in support of efforts to update and calibrate the H&H Model, DELCORA shall prepare and submit to Plaintiffs for review and comment in accordance with the requirements of Section VI (Review and Approval of Submittals) quarterly technical memoranda documenting the results and quality of the rainfall and flow monitoring data."*

In summary, rainfall and flow monitoring shall be conducted for at least 12 months, and quarterly technical memoranda shall be submitted to Plaintiffs for review.

To satisfy the above mentioned rainfall and flow monitoring requirements, and in accordance with the submitted DELCORA H&H Model Update and Calibration Plan, DELCORA has installed 5 new rain gauges and 38 new flow meters in its sewer collection system. Starting from March 18, 2016, most of the newly installed rain gauges and flow meters were in service and began generating data.

This report is a summary of the first quarter reporting for Rainfall and Flow Monitoring during March 18, 2016 to June 30, 2016.

Section 2 Rainfall Monitoring

2.1 Rainfall Monitoring Locations

The site locations of the four existing and five newly installed rain gauges are shown in **Figure 1**. These rain gauges provide an effective spatial coverage of the entire WRTP's service area.

The four (4) existing rainfall gauges are in Delaware County that record precipitation in 15-minute increments. The gauges are located at the following DELCORA owned facilities:

- Western Regional Treatment Plant (WRTP, will be used for model calibration)
- Central Delaware County Pump Station (CDPS, will be used for model calibration)
- Muckinipates Pump Station (MPS, will be used for model calibration)
- Darby Creek Pump Station (DCPS, will NOT be used for model calibration)

The five (5) newly installed rain gauges are listed in **Table 1** with detail information of rain gauge location, service starting date, and data recording interval.

Table 1: Newly Installed Rain Gauges

	Rain Gauge ID	Location	Service Start Date	Data Interval
1	RG_Rose Valley	18 N. Longpoint Lane, Media, PA	3/05/16	5-minute
2	RG_Chester-PS	55 East 2nd Street, Chester, PA	3/05/16	5-minute
3	RG_NCPS	1628 Naamans Creek Rd., Marcus Hook, PA	3/05/16	5-minute
4	RG_Springfield	217 Saxer Avenue, Springfield, PA	4/03/16	5-minute
5	RG_UCT	1671 N. Upper Providence Road, Media, PA	4/16/16	5-minute

2.2 Rain Gauge Calibration/Verification Procedure

Rain Gauge calibrations were performed during the rain gauge installation. Additional calibrations will be performed to the manufacturer's specifications on a bi-annual basis or as needed if irregular data is observed. Rain gauges are routinely checked for debris, and cleared after snow/ice storms.

Each "tip" of the rain gauge bucket should correspond with 0.01" of rain. To ensure the modem is reading the tipping bucket pulse accurately, the tech will tip the bucket 10 times in rapid succession. The tech should see that 0.1" of rain is recorded.

2.3 Rainfall Event Summary

Rainfall events were analyzed for each individual rain gauge based on the inter-event time of 12 hours. In total there were 31 rainfall events during reporting period. **Table 2** lists rainfall events with total precipitation greater than 0.1 inch.

Figure 1: Rain Gauge Locations

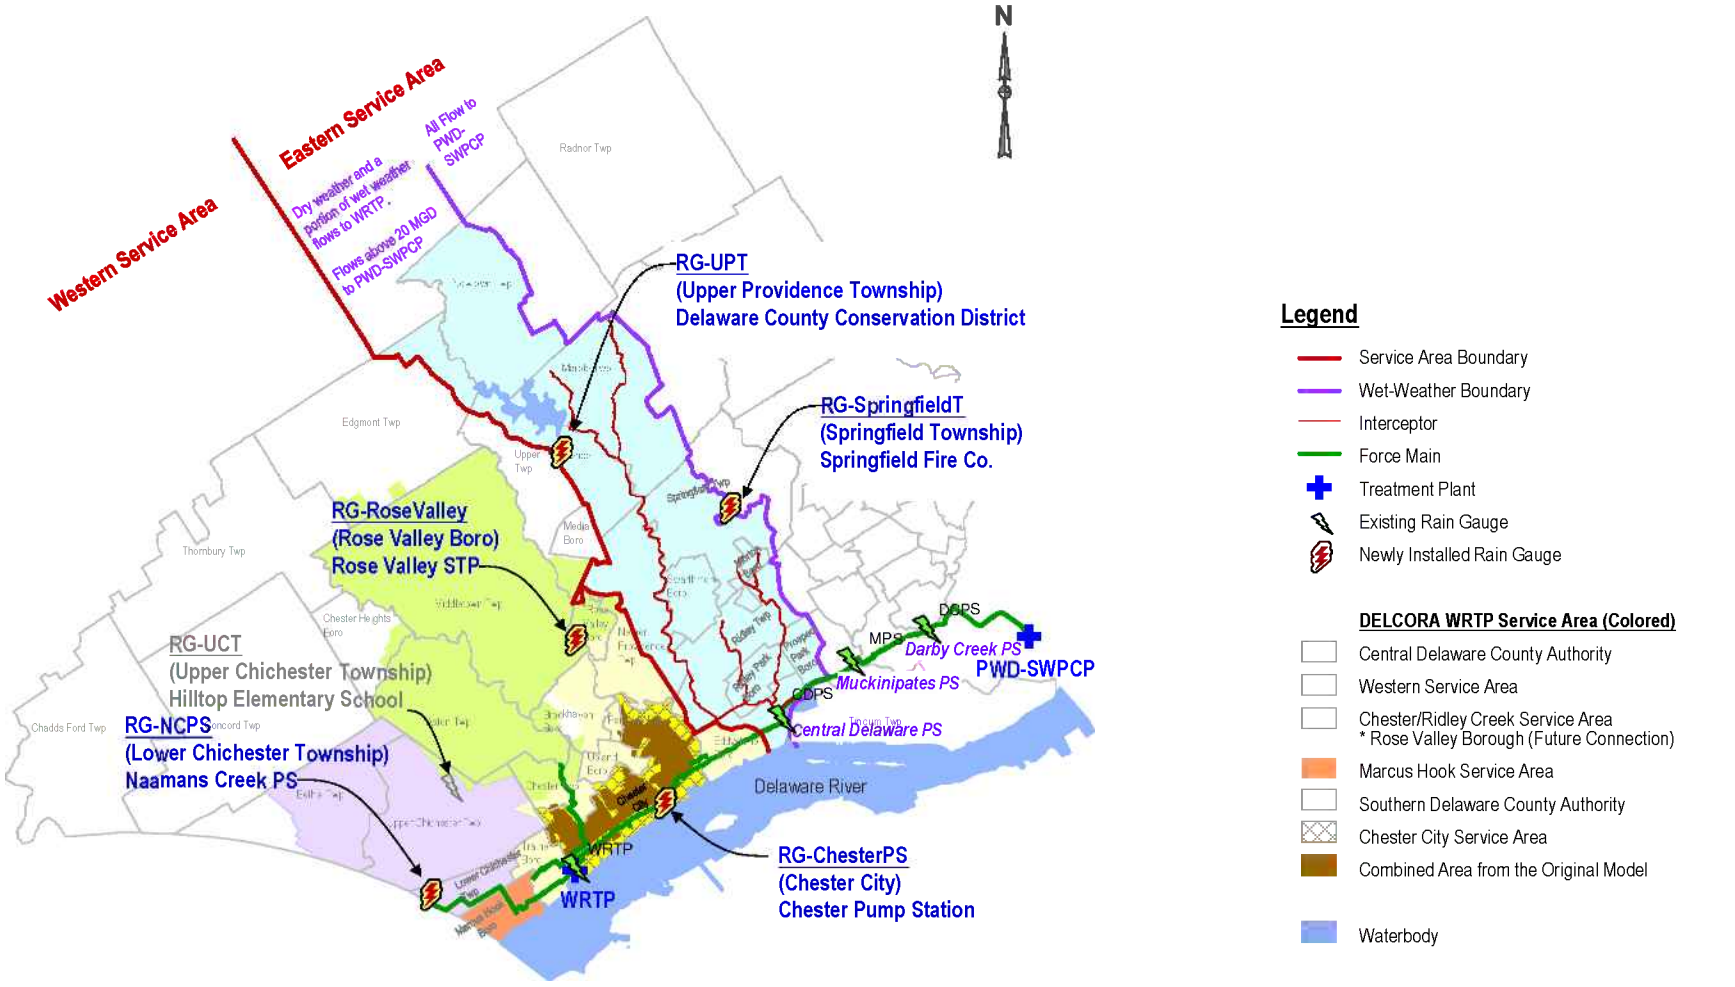

Figure 2 shows rainfall amounts at each rain gauge in each month for April (includes March data), May and June. It is obvious that rainfall in the area has significant spatial and temporal variance. As an example, during this reporting period, the rain gauge at the Chester Pump Station (Chester PS) recorded a total rainfall of 9.1 inches while the gauge at the Naamans Creek Pump Station (NCPS) recorded 13.39 inches. **Figure 3** shows the 1-hour rainfall profile for all of the 5 new rain gauges.

Table 2: Rainfall Event Summary, 3/18/16 - 6/30/16

Note: Meter not in service. See Table 1 above.

Figure 2: Rainfall Event Summary, 3/18/16 – 6/30/16

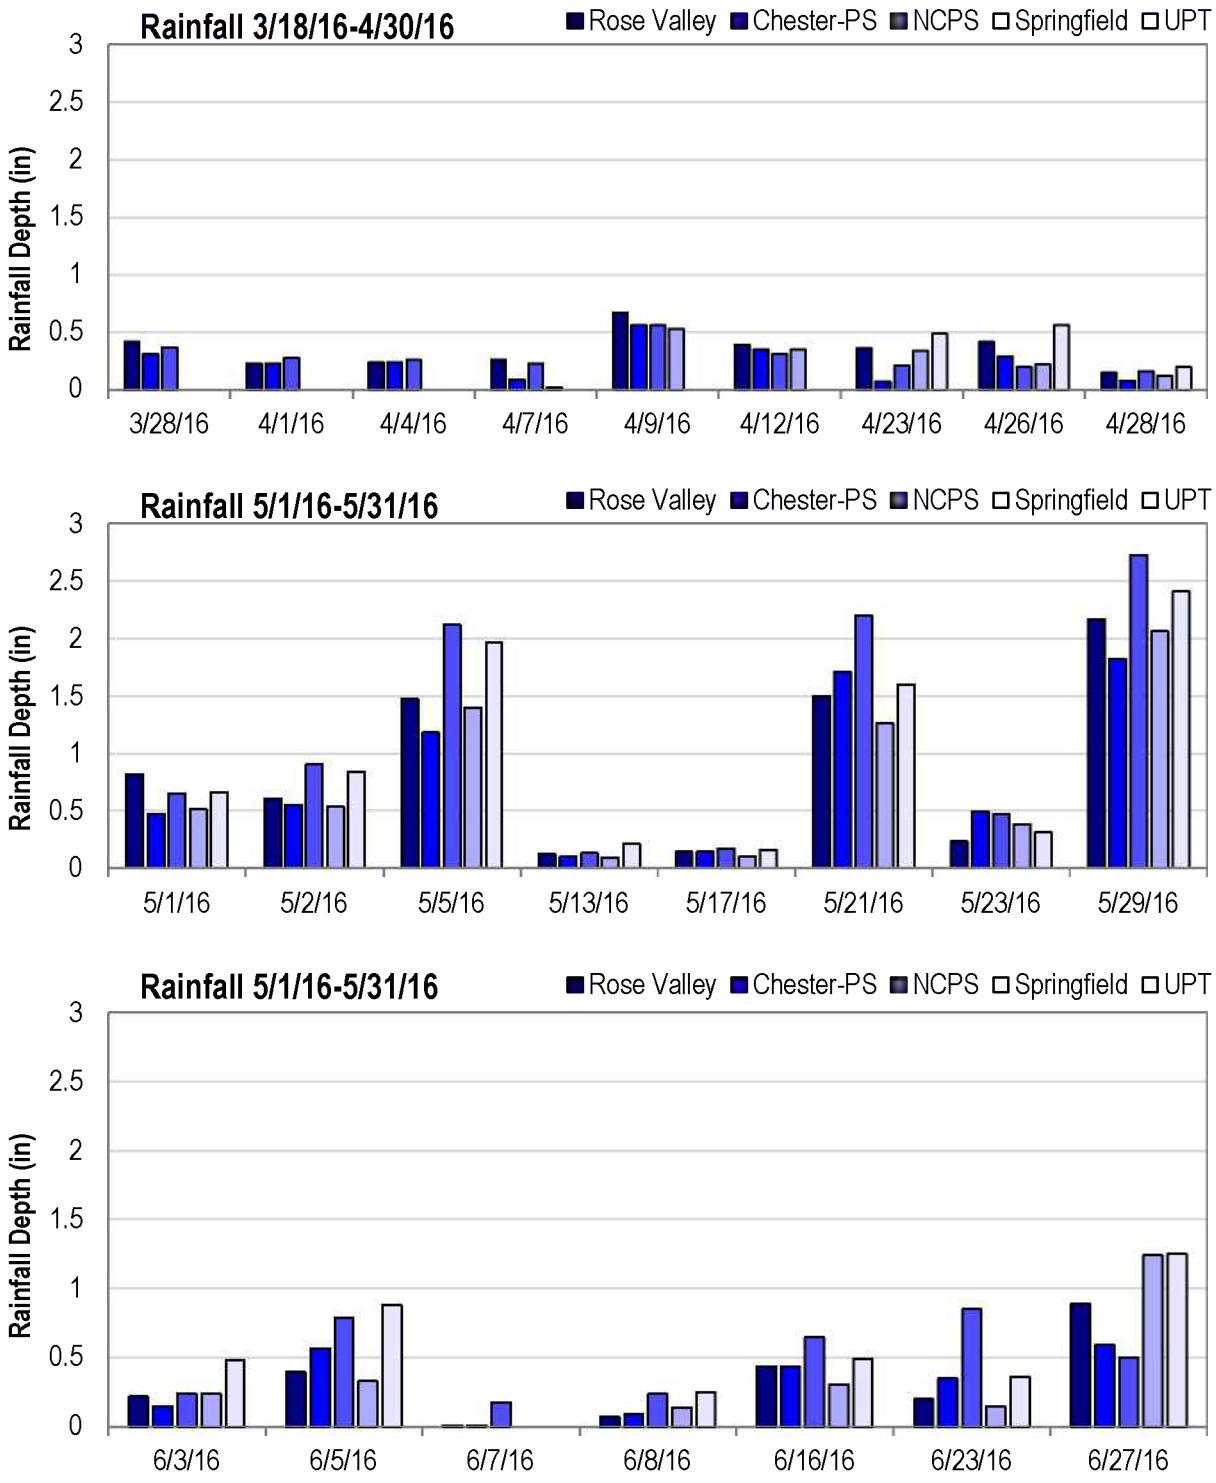

Figure 3: Hourly Rainfall Profile

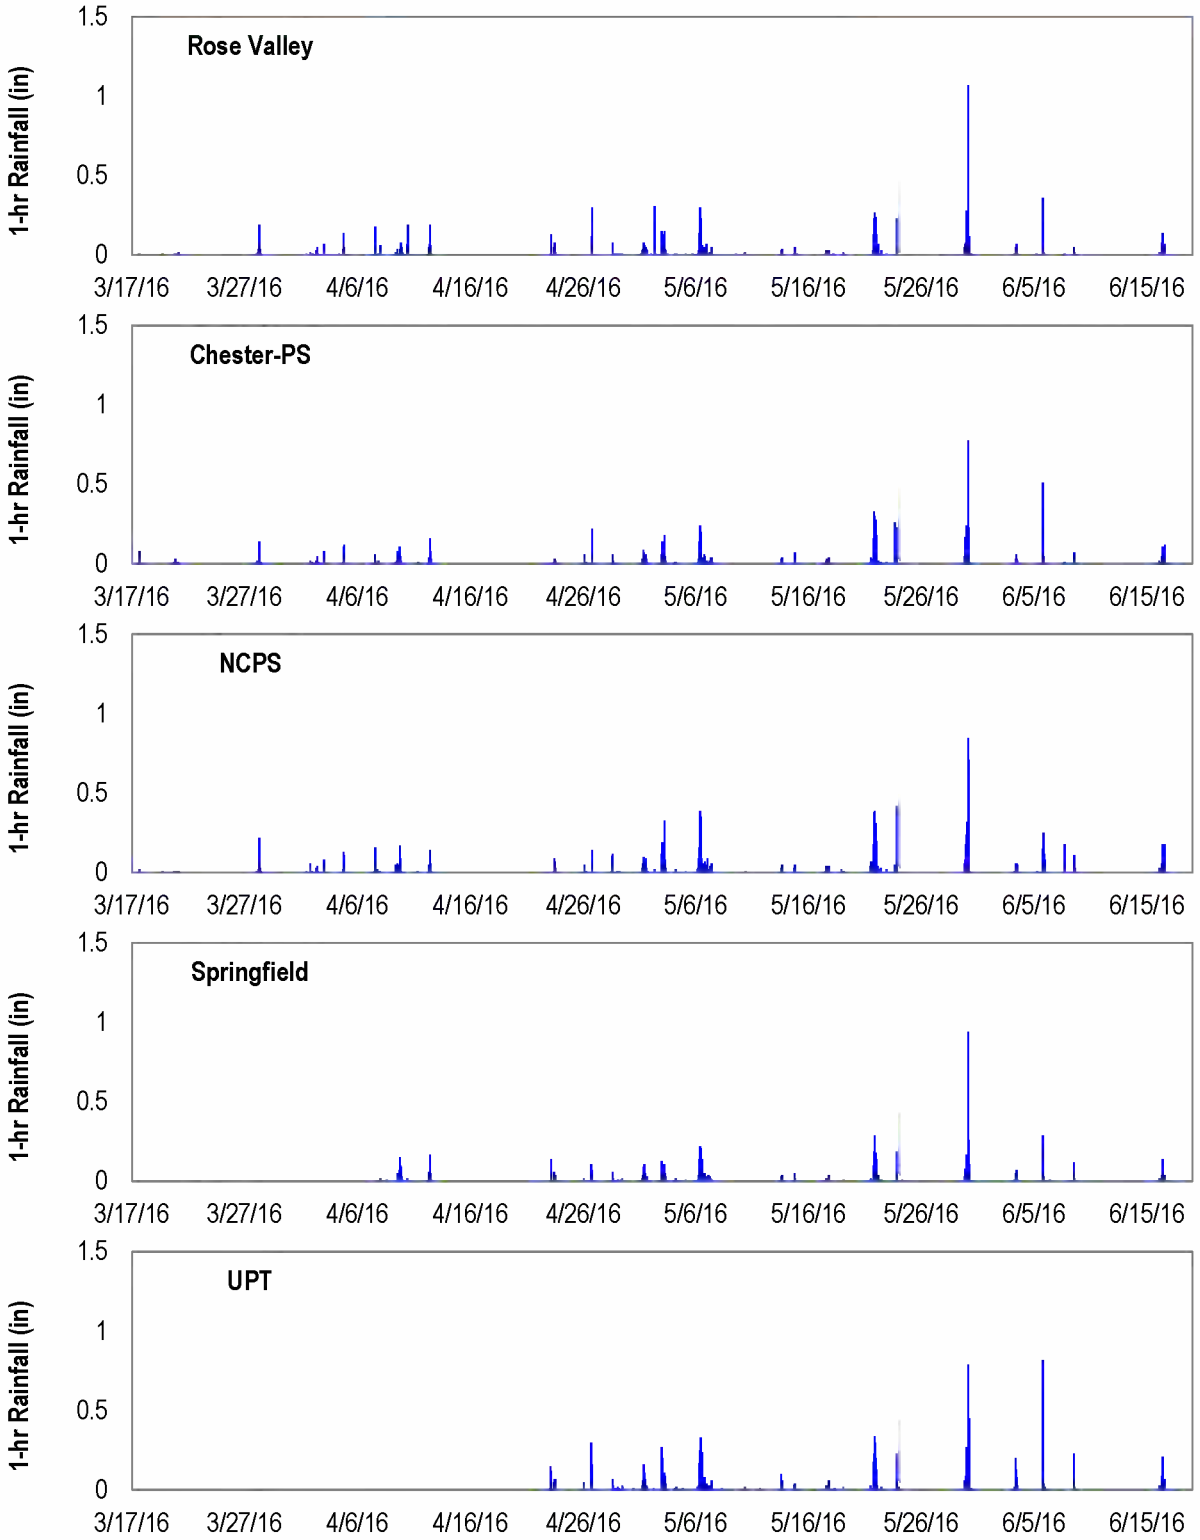
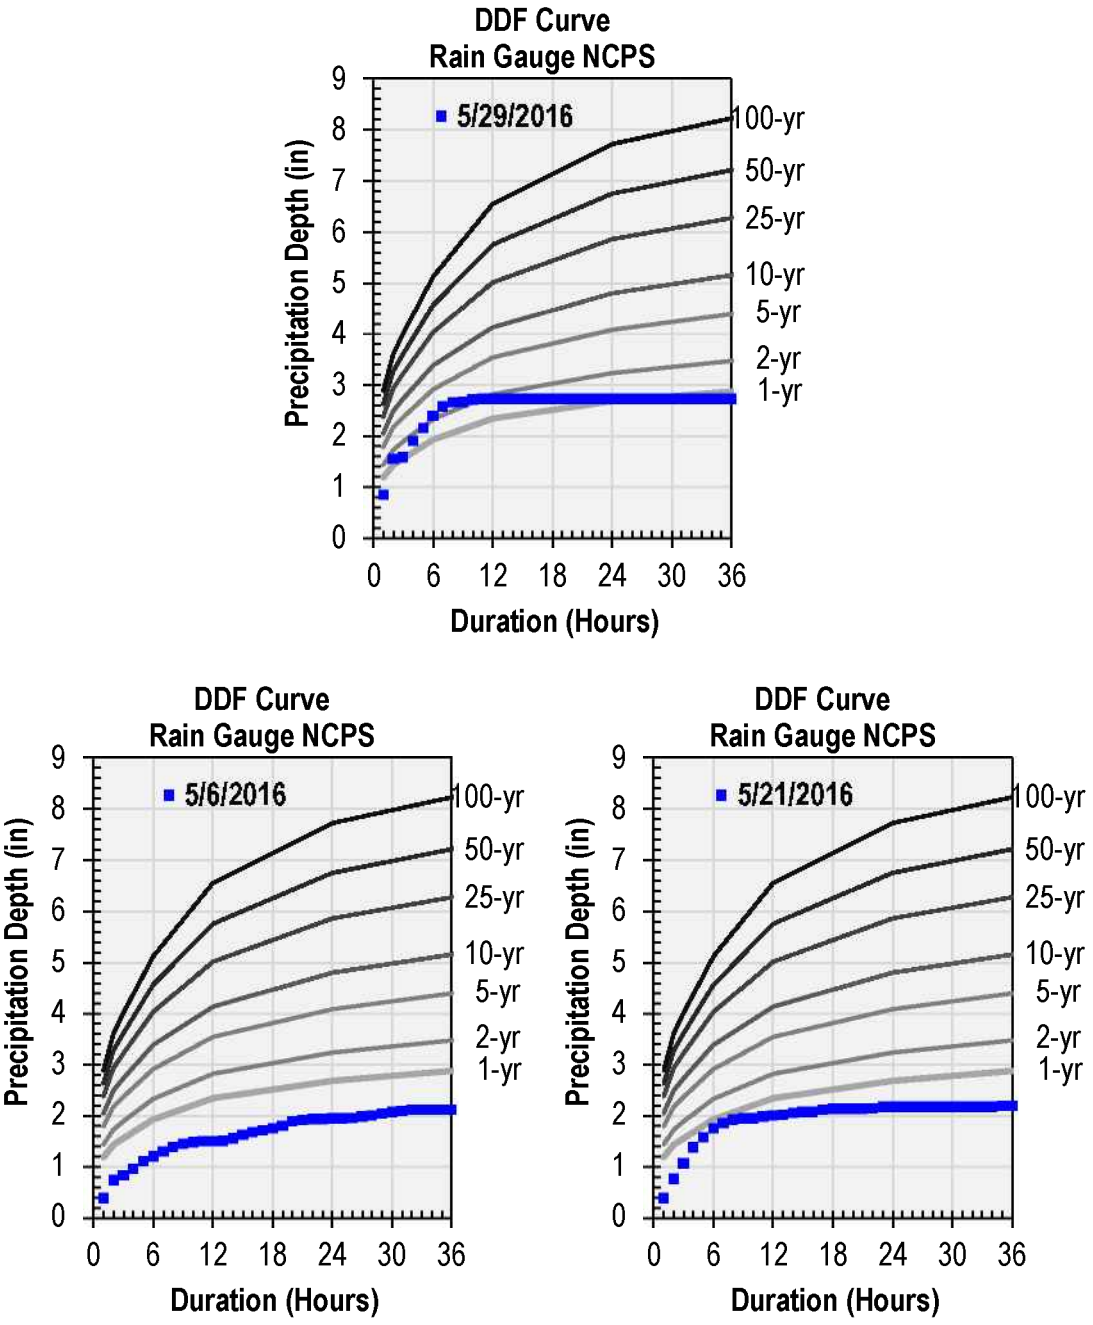


2.3.1 Rainfall Return Frequency

Rain gauge RG_NCPS was selected for return frequency analysis because it recorded the maximum rainfall amount from the five newly installed gauges. For the three storm events greater than 1 inch, the 5/29/16 storm has a return frequency of 2-years, the 5/21/16 storm is close to 1-year, and the 5/6/16 storm is less than 1-year event (**Figure 4**).

Figure 4: Duration-Depth-Frequency (DDF) Plot



Section 3 Flow Meter Monitoring

3.1 Flow Monitoring Program

The site locations of the existing and newly installed flow meters are shown in **Figure 5**. **Figure 6** shows the newly installed flow meters on a larger scale, mostly in the combined area. These new meters were installed to investigate surface runoff from the combined area and CSO discharges, rainfall-derived inflow and infiltration (RDII) from the separated area, and system response to the wet weather conditions. The schematic of the newly installed flow meters is included in **Figure 7**.

The newly installed flow meter locations are categorized into the following four types:

- Category 1: Located on the influent pipe to CSO regulators, this is to measure the influent flow to CSO regulators and for combined area runoff calibration. Sixteen (16) meters were installed for this category.
- Category 2: Located on the effluent pipe and overflow pipe of CSO regulators, this is to measure the CSO overflows and calibrate CSO regulator parameters. Twelve (12) meters were installed for this category. They are on the effluent and overflow pipe of CSOs 02, 03, 05, 08, 14, & 19.
- Category 3: Located on the side-line from the combined areas (flows from the combined area tie into interceptor instead of CSO regulator). This is to measure flows from the combined area and to calibrate combined area runoff parameters. Two (2) meters were installed for this category.
- Category 4: Located upstream of the combined area, this is to measure flows from the upstream separated area for RDII characterization. Three (3) meters were installed for this category.
- Category 5: Located in the main interceptors to measure level and flows in the major interceptors. Five (5) meters were installed for this category.

In total, 38 additional flow meters have been installed. Details of the newly installed flow meters are included in **Table 3**.

3.2 Flow Meters Field Calibration/Verification Procedures

As part of the operation of flow meters, verifications of meter accuracy are performed on a regular basis. Calibrations are performed at a minimum every eight weeks, or more as needed.

The procedure used for performing meter calibrations is outlined below. This procedure only defines the required result. Any specific equipment function issues should be referred to the equipment manual or the manufacturer's technical support department.

Figure 5: Existing and Newly Installed Flow Meter Locations

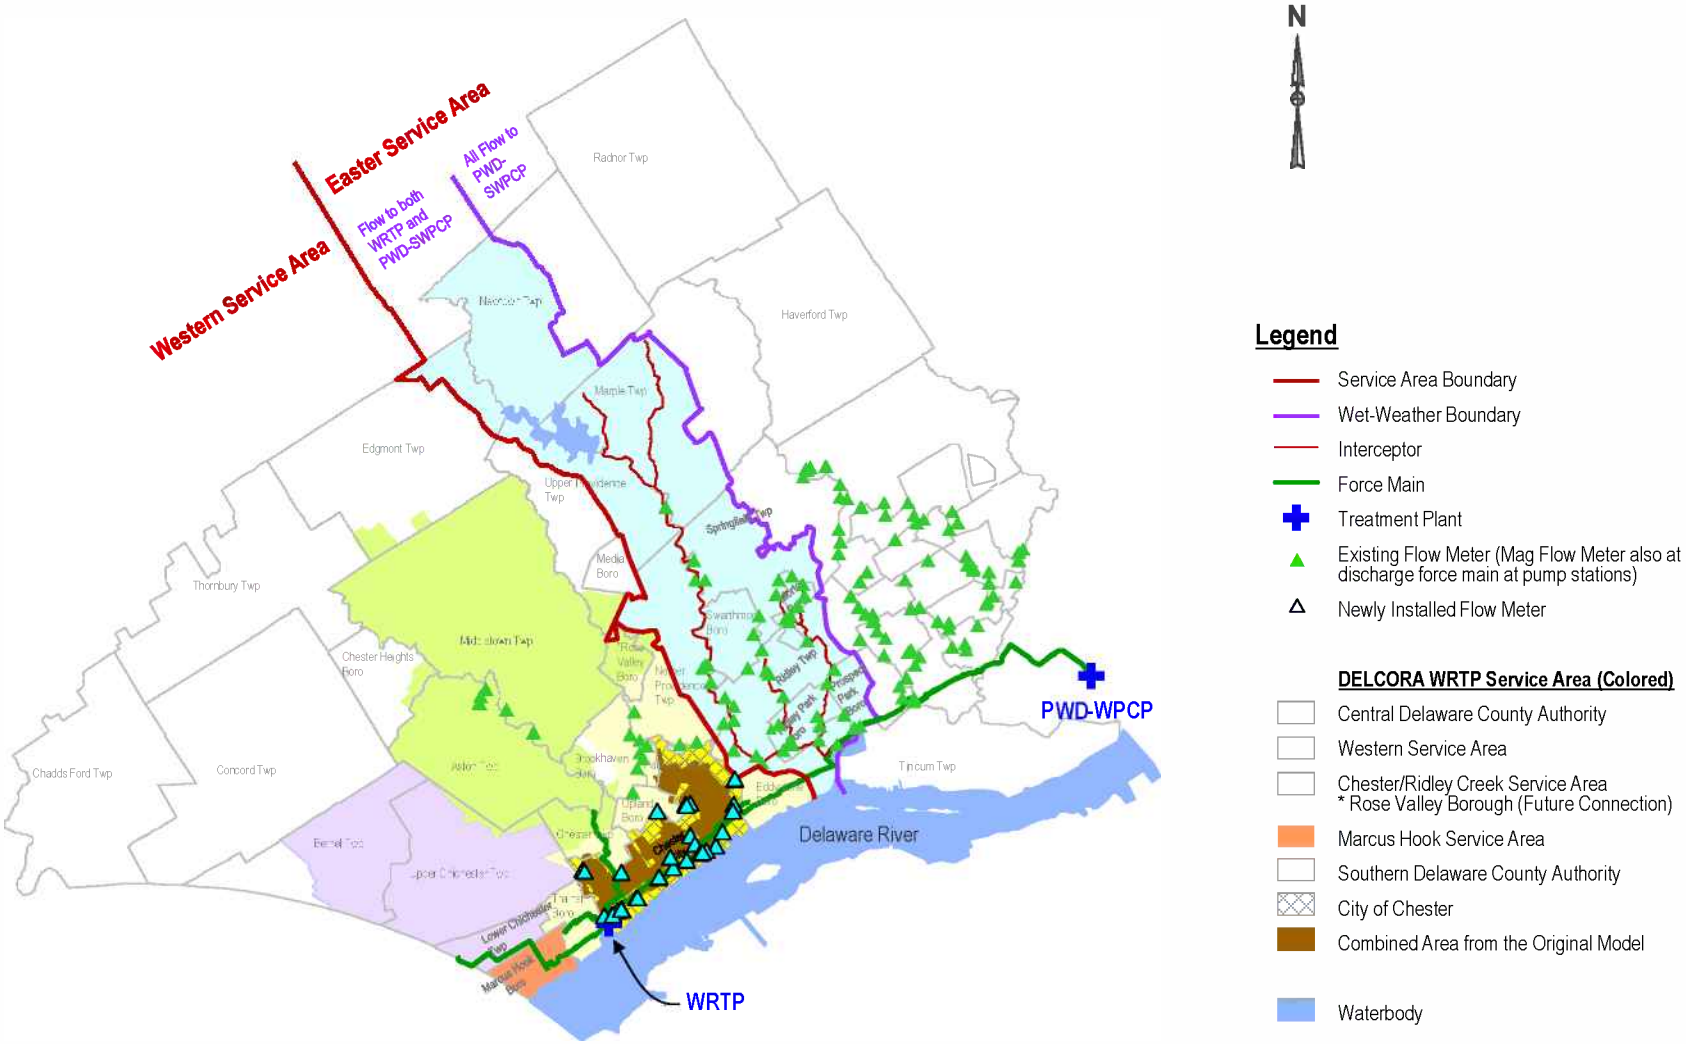

Figure 6: Newly Installed Flow Meter Locations

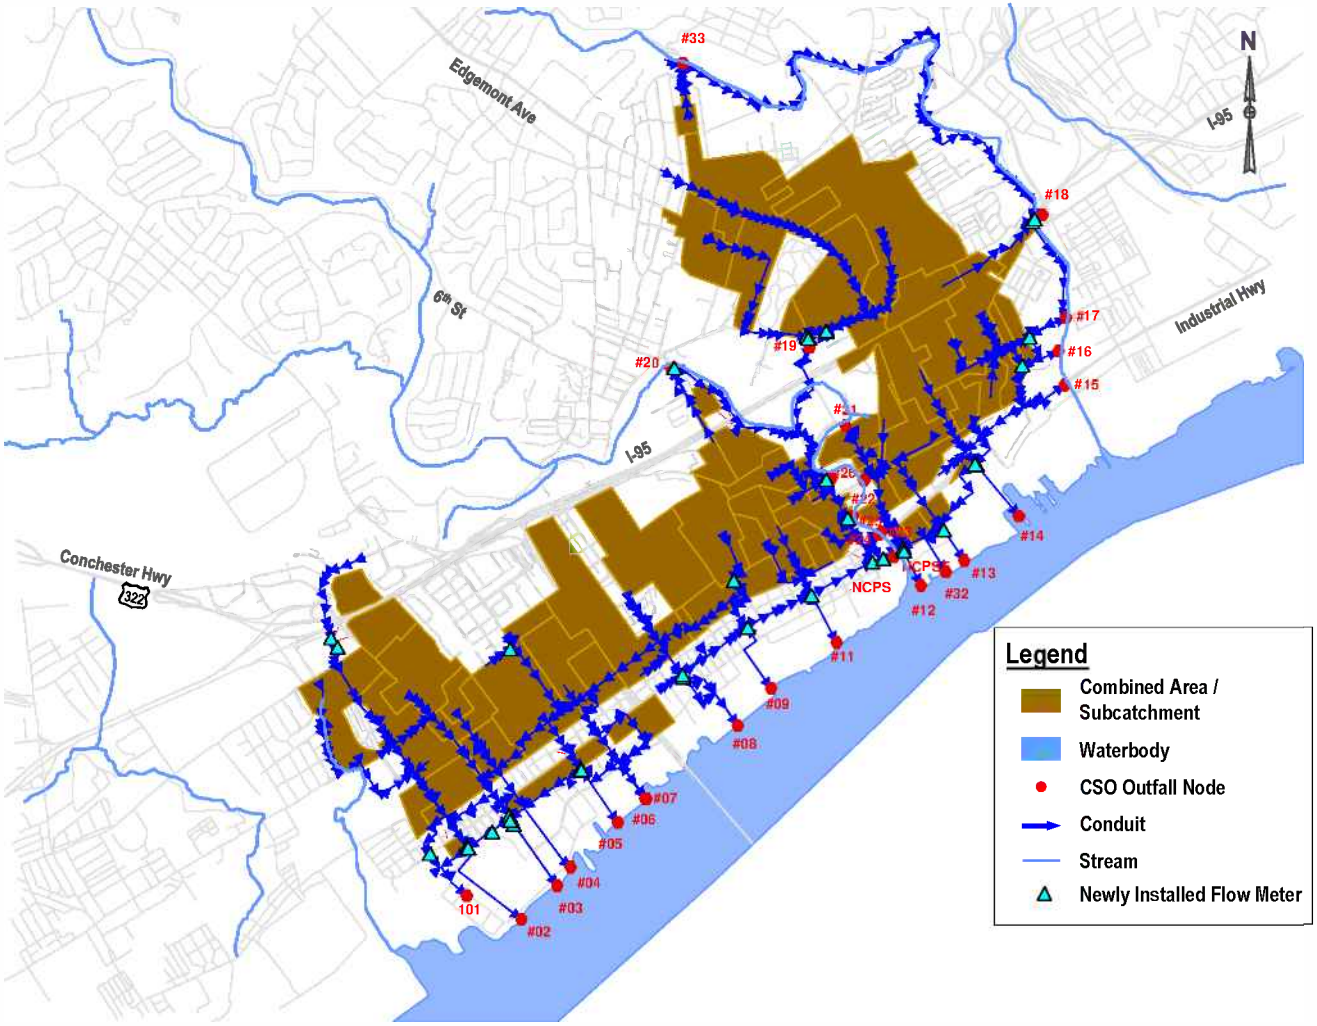

Figure 7: Flow Monitoring Schematic

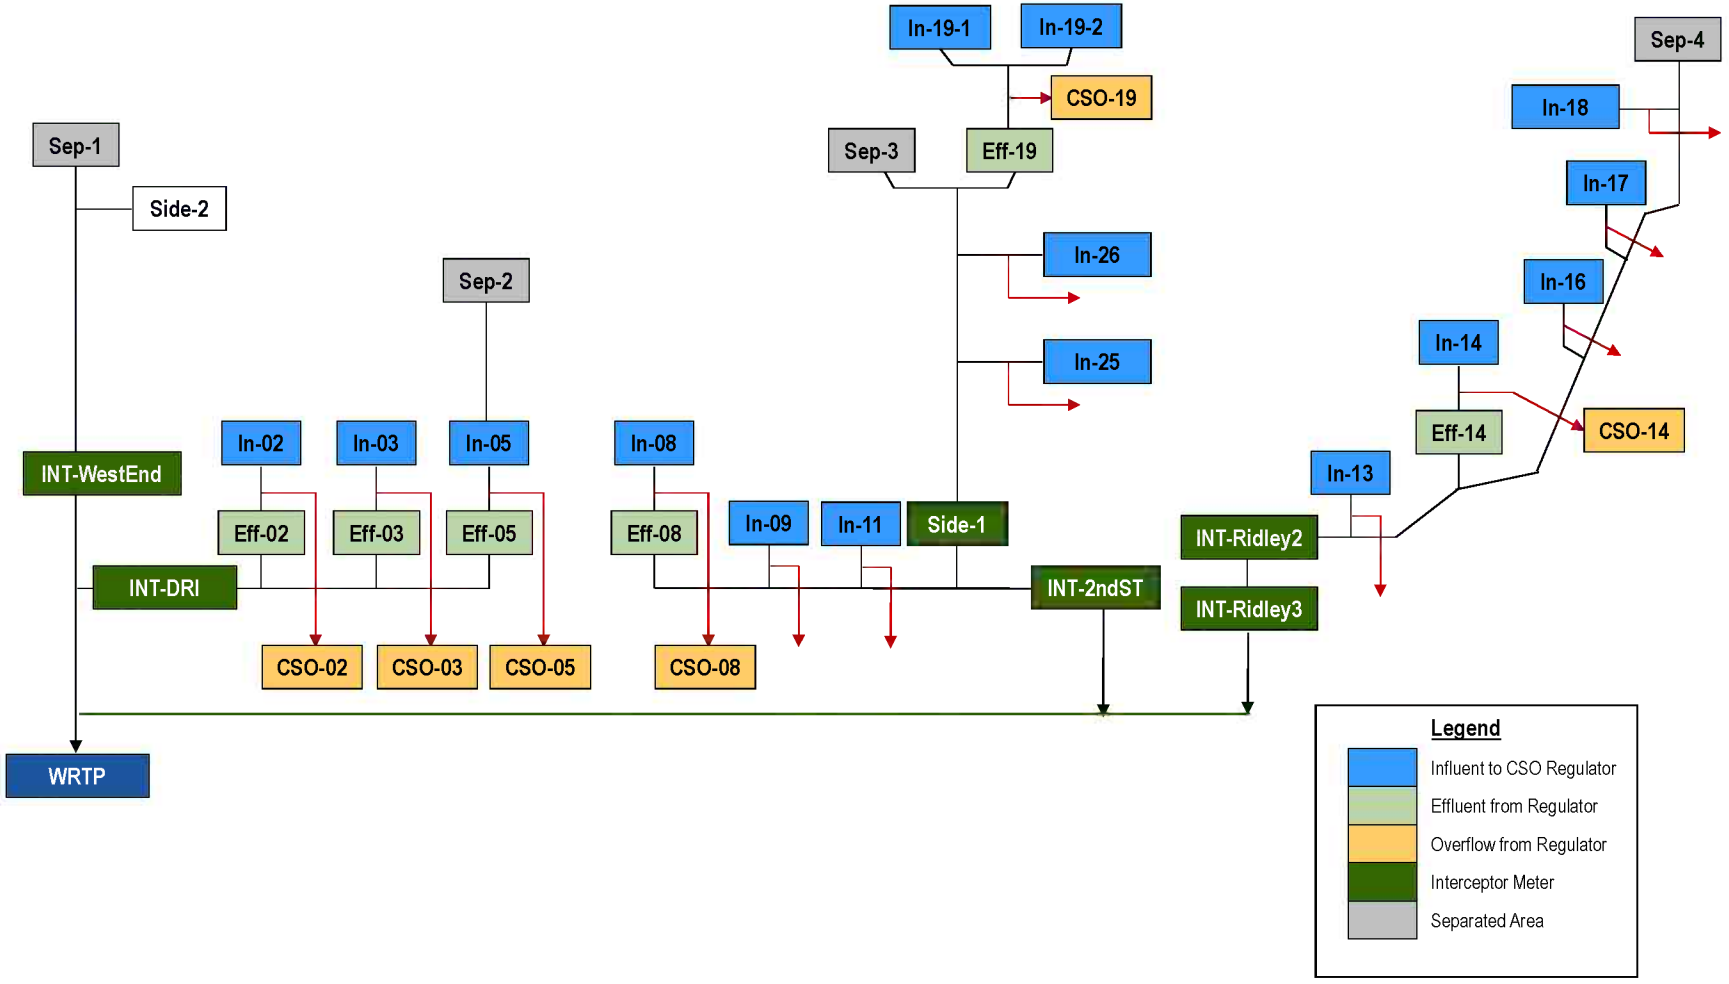

Manually Downloaded Meters
This method is used for any meter that cannot be interrogated remotely by the data analyst. Field technicians use the *Daily Field Download Sheet* for recording the calibration results.

- Record the date.
- Record the field time, which is the local time.
- Record the meter time.
- Record the instantaneous depth reading from the meter.
- Measure the peak velocity.
- Record the instantaneous average or peak, whichever is applicable.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Remote Connection Meters
This method is used for any meter that can be interrogated remotely. The data analyst uses the *Daily Field Download Sheet* for single depth and velocity meters and the *Multi- Sensor Calibration Sheet* for meter types that record multiple depth and/or velocity readings.

- Fill all site visit information fields on form.
- Have the field tech measure the depth of flow and record with time.
- Record the time and instantaneous depth reading from the meter or the depth sensor, whichever is applicable. All available depth sensors should be activated and compared to the field measurement.
- Have the field tech measure the peak the velocity or have them perform a velocity profile if the depth is sufficient then record with time.
- Record the time and instantaneous velocity reading from the meter or the velocity sensor, whichever is applicable. All available velocity sensors should be activated and compared to the field measurement.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Special Cases

- Blind Verifications: A blind verification occurs when a field technician's only role is to measure the depth and velocity of the flow and report the values to the data analyst. In these cases, the crew is "blind" to what the meter is reading. The data analyst will then compare the readings to current/recent data or live readings. Should the blind verification be out of tolerance, the analyst can direct the crew to perform additional blind verifications or perform a conventional verification and/or troubleshoot as necessary.

- Installations/Removals: When installing or removing meters, the above calibration method should be used for three consecutive verifications, performed at 5 minute intervals.
- Third Party Audit: When performing a calibration at a meter that is not maintained by CSL and where CSL is to verify the meter function, the CSL Audit report should be used.

3.3 Flow Monitoring Data Summary

Flow, level and velocity data are received for each flow monitoring site at 5-minute intervals. Metering data is analyzed for dry weather flows (DWF), hourly peak flows, and hourly peaking factors for each monitoring site. A "dry weather" condition was defined as a period with no precipitation that begins three days after the last wet weather event and lasts until the beginning of the next precipitation event.

Table 4 shows dry weather flow (DWF), hourly peak flow, hourly peaking factor and flow condition observations.

The dry weather flows are also shown in the schematic in **Figure 8**. Generally the downstream dry weather flow is greater than the upstream locations for all of the meters. For meters immediately upstream and downstream of CSO regulators, the upstream and downstream dry weather flows should be similar. **Figure 9** shows the influent and effluent from CSO#08 as an example to indicate that the dry weather of the two are similar.

The hourly peaking factor in the combined area is in the range of 11 to 88 and average at 40. The hourly peaking factor for the interceptor is between 3.8 and 6.8 with an average of 4.4. The hourly peaking factor is between 3.6 and 6.4 for the separated area, with an average of 5.0.

A detailed hydrograph and scattergraph for each flow monitoring site is shown in **Figure 10** to **Figure 47**, each includes:

- The flow hydrographs show hourly flow and rainfall profile. Hourly Rainfall data is included for the convenience of reviewing flow response to the wet weather conditions. Hourly flow and rainfall were calculated from the 5-min interval.
- The scattergraphs (based on 5-min data) are essentially a plotting of flow rate versus depth. This plotting helps to understand the flow patterns and conditions on the individual monitored sewer pipes.
- For CSOs 02, 03, 05, 08, 14, & 19, flows including influent, effluent and overflows were plotted in the same plot.

Table 4: Flow Monitoring Summary

Meter ID	Hourly Peak (MGD)DWF	DWF (MGD)	Hourly Peaking Factor	Comments
In-02	8.13	0.30	27.1	Free flow most of the time

Section 1 Introduction

The Delaware County Regional Water Quality Control Authority (DELCORA) entered into a Consent Decree (CD) with the United States Government in August 2015. The purpose of the Consent Decree is to establish a schedule for implementation of Long Term Control Plan Update (LTCPU) to achieve full compliance with the Clean Water Act and the regulations and Clean Streams Law and regulations. The lodging of this Consent Decree was entered by the court on August 17, 2015, it was signed and filed on November 10, 2015 by the United States District Court for the Eastern District of Pennsylvania.

According to the Consent Decree, DELCORA's Hydrologic and Hydraulic Model (H&H Model) must be updated to meet the requirements in Section V.A.14 of the Consent Decree. A detailed plan to update, calibrate and validate the H&H model has been submitted and approved by the USEPA on March 1, 2016. Additional rainfall and flow monitoring is required to calibrate and validate the H&H model. Requirements of rainfall and flow monitoring are detailed in the Consent Decree Section V.A.14.d and e, which is included in the following:

> "*d.* *Rainfall and flow monitoring shall be carried out in accordance with current good industry practice for a period of at least twelve* ***(12) months****, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization of dry and wet weather flows from the entire Model Area, and the response of each CSO to wet weather flows.*
>
> *e.* *For all rainfall and flow monitoring carried out in support of efforts to update and calibrate the H&H Model, DELCORA shall prepare and submit to Plaintiffs for review and comment in accordance with the requirements of Section VI (Review and Approval of Submittals) quarterly technical memoranda documenting the results and quality of the rainfall and flow monitoring data."*

In summary, rainfall and flow monitoring shall be conducted for at least 12 months, and quarterly technical memoranda shall be submitted to Plaintiffs for review.

To satisfy the above mentioned rainfall and flow monitoring requirements, and in accordance with the submitted DELCORA H&H Model Update and Calibration Plan, DELCORA has installed 5 new rain gauges and 39 new flow meters in its sewer collection system. Starting from March 18, 2016, most of the newly installed rain gauges and flow meters were in service and began generating data.

This report is a summary of the Rainfall and Flow Monitoring during July 1, 2016 to September 30, 2016.

Section 2 Rainfall Monitoring

2.1 Rainfall Monitoring Locations

The site locations of the four existing and five newly installed rain gauges are shown in **Figure 1**. These rain gauges provide an effective spatial coverage of the entire WRTP's service area.

The four (4) existing rainfall gauges are in Delaware County that record precipitation in 15-minute increments. The gauges are located at the following DELCORA owned facilities:

- Western Regional Treatment Plant (WRTP, will be used for model calibration)
- Central Delaware County Pump Station (CDPS, will be used for model calibration)
- Muckinipates Pump Station (MPS, will be used for model calibration)
- Darby Creek Pump Station (DCPS, will NOT be used for model calibration)

The five (5) newly installed rain gauges are listed in **Table 1** with detail information of rain gauge location, service starting date, and data recording interval.

Table 1: Newly Installed Rain Gauges

	Rain Gauge ID	Location	Service Start Date	Data Interval
1	RG_Rose Valley	18 N. Longpoint Lane, Media, PA	3/05/16	5-minute
2	RG_Chester-PS	55 East 2nd Street, Chester, PA	3/05/16	5-minute
3	RG_NCPS	1628 Naamans Creek Rd., Marcus Hook, PA	3/05/16	5-minute
4	RG_Springfield	217 Saxer Avenue, Springfield, PA	4/03/16	5-minute
5	RG_UCT	1671 N. Upper Providence Road, Media, PA	4/16/16	5-minute

2.2 Rain Gauge Calibration/Verification Procedure

Rain Gauge calibrations were performed during the rain gauge installation. Additional calibrations will be performed to the manufacturer's specifications on a bi-annual basis or as needed if irregular data is observed. Rain gauges are routinely checked for debris, and cleared after snow/ice storms.

Each "tip" of the rain gauge bucket should correspond with 0.01" of rain. To ensure the modem is reading the tipping bucket pulse accurately, the tech will tip the bucket 10 times in rapid succession. The tech should see that 0.1" of rain is recorded.

2.3 Rainfall Event Summary

Rainfall events were analyzed for each individual rain gauge based on the inter-event time of 12 hours. In total there were 26 rainfall events during reporting period. **Table 2** lists rainfall events with total precipitation greater than 0.1 inch.

Figure 1: Rain Gauge Locations

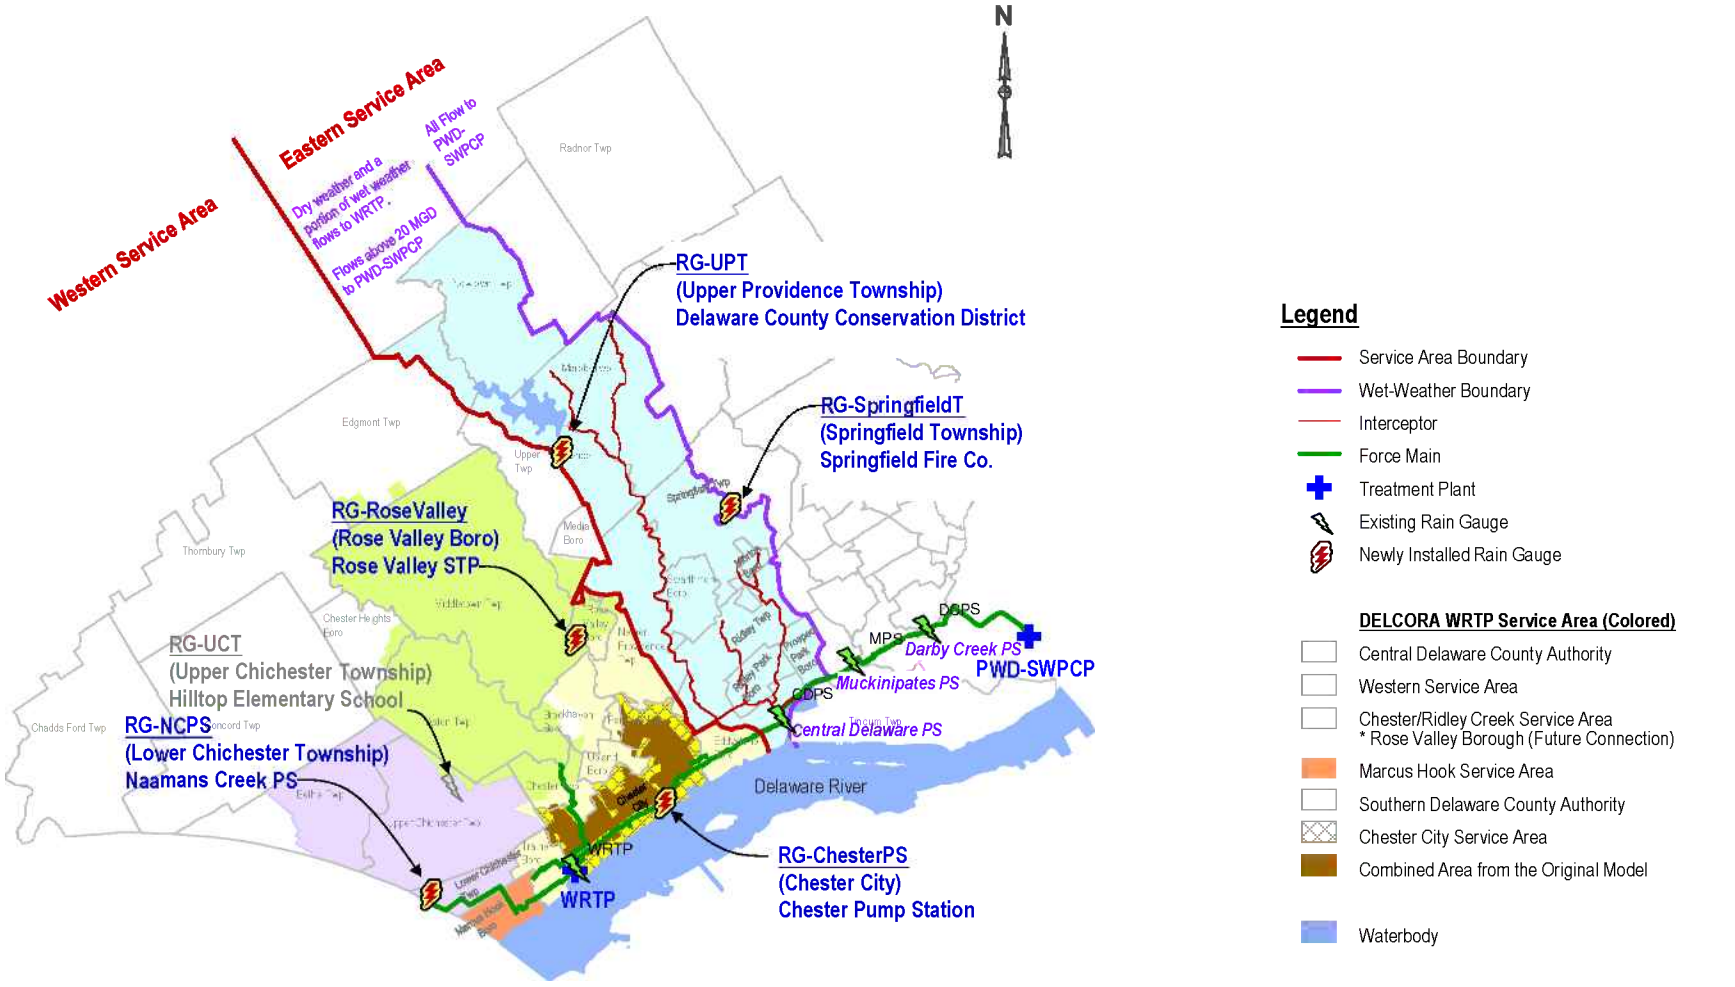

Figure 2 shows rainfall amounts at each rain gauge in each month for July, August and September. It is obvious that rainfall in the area has significant spatial and temporal variance. As an example, during this reporting period, the rain gauge at the Chester Pump Station (Chester PS) recorded a total rainfall of 8.371 inches while the gauge at the Upper Providence Township (UPT) recorded 14.74 inches. **Figure 3** shows the 1-hour rainfall profile for all of the 5 rain gauges.

Table 2: Rainfall Event Summary, 7/1/16 - 9/30/16

	Rain Event Starting Time	Rose Valley	Chester-PS	NCPS	Springfield	UPT
1	7/1/2016 13:40	0.19	0	0	0.12	0.01
2	7/4/2016 14:55	0.44	0.45	0.88	0.46	0.66
3	7/9/2016 16:00	0.25	0.03	0.3	0.1	0.21

Figure 2: Rainfall Event Summary, 7/1/16 - 9/30/16

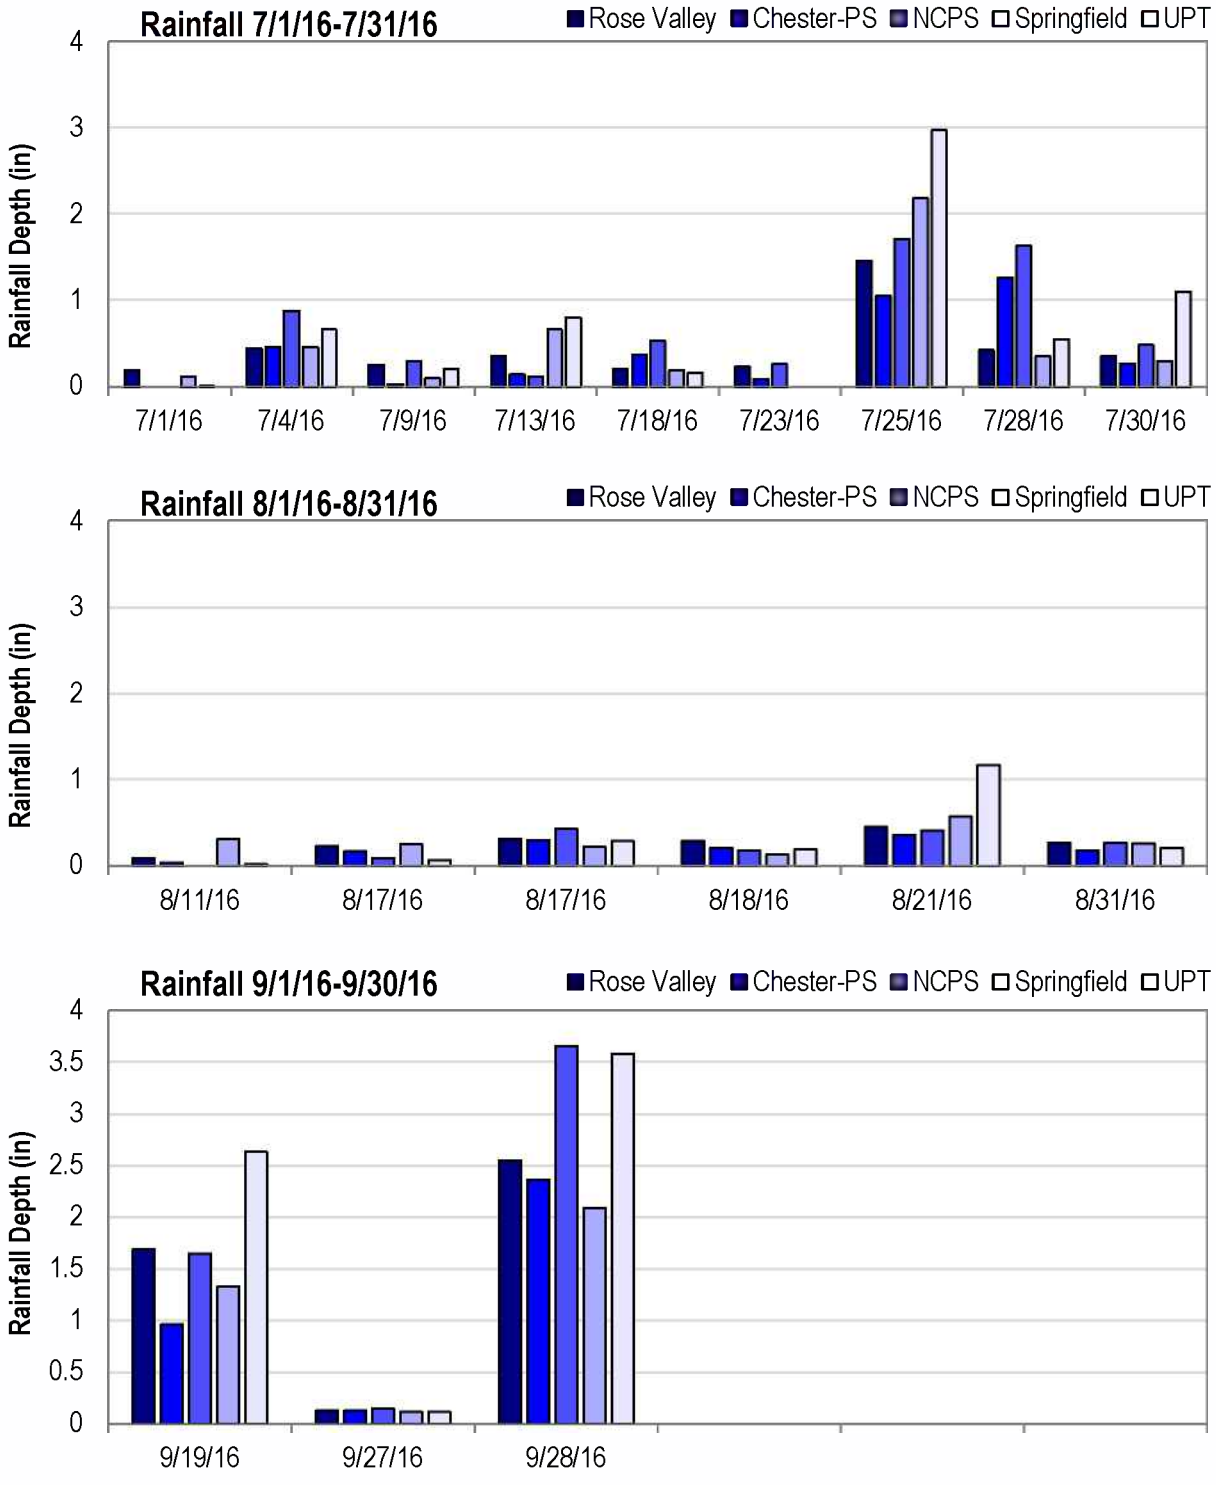

Figure 3: Hourly Rainfall Profile

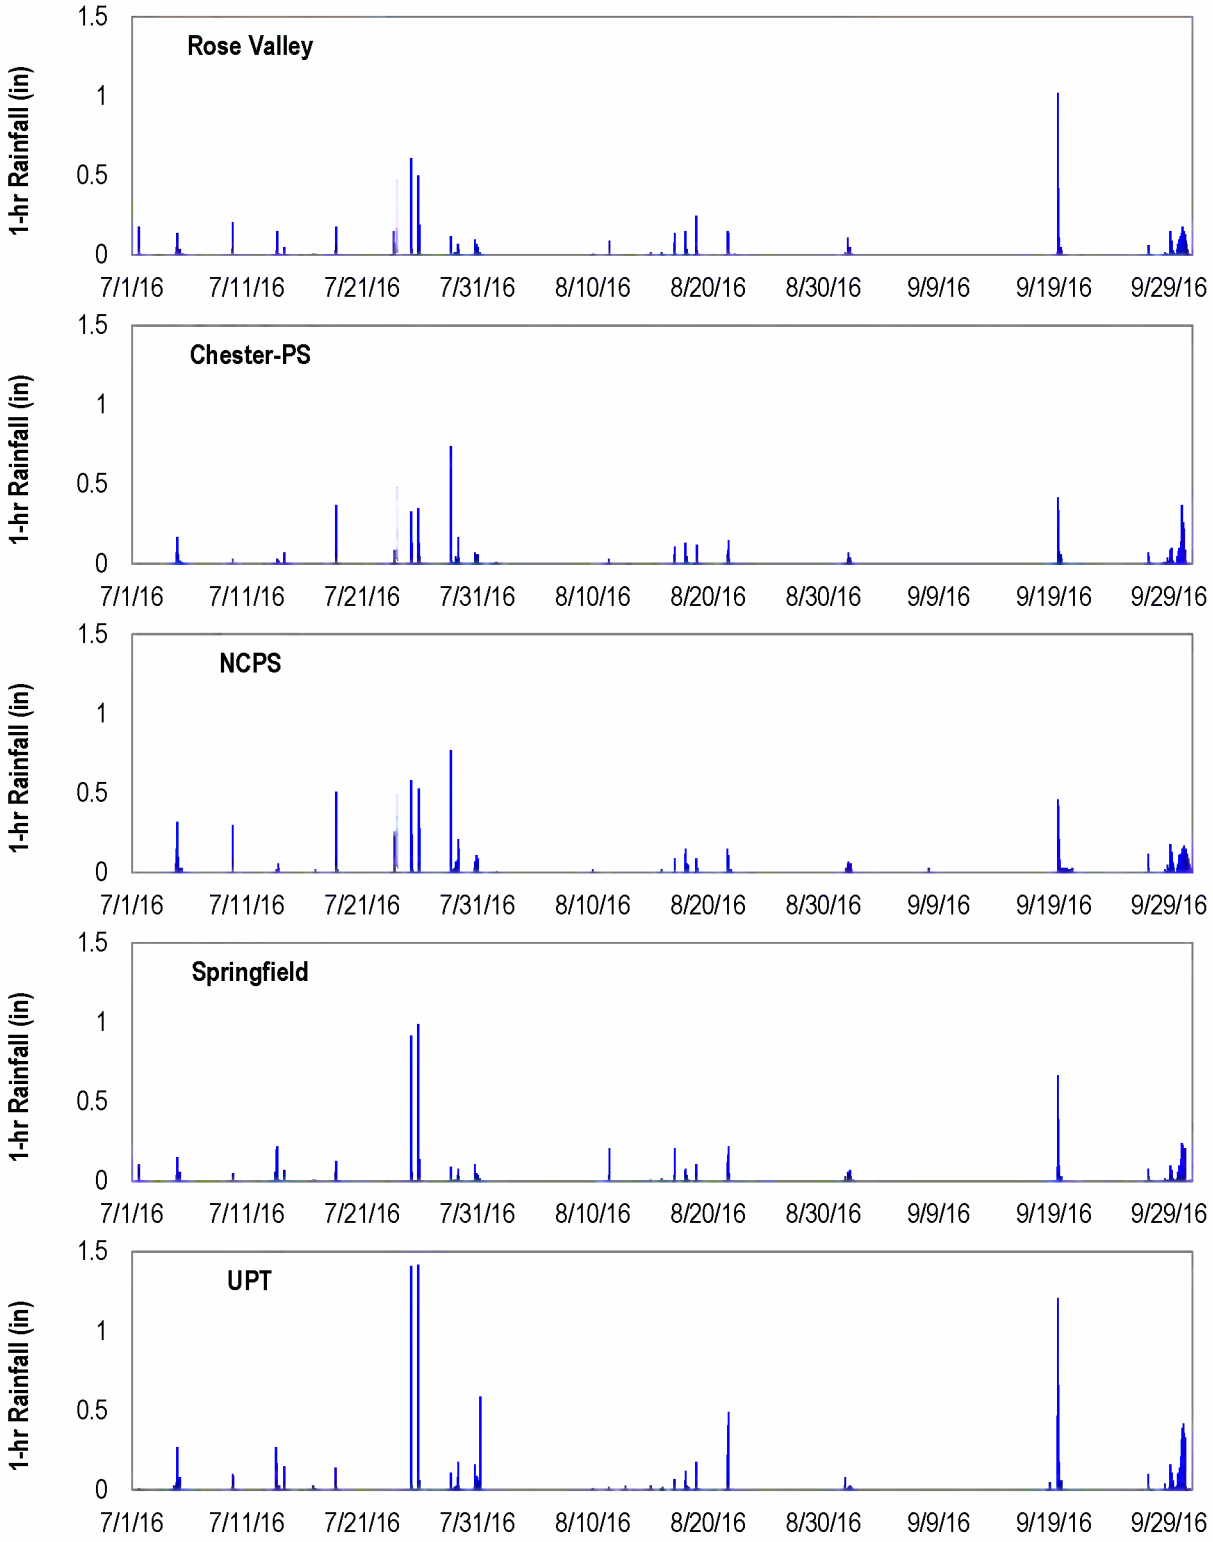

2.3.1 Rainfall Return Frequency

Rainfall return frequency was analyzed for rain gauges RG_NCPS and RG_UPT because they recorded greater rainfall amounts than the others. The frequency analysis was also performed for RG_ChesterPS because it is located in the combined area.

Figure 4 shows Duration-Depth-Frequency (DDF) plot for RG_NCPS. Three storms were recorded with total precipitation volumes greater than 1 inch. The 9/28/16 storm has a return frequency of 2-year, and the other two events (7/28/16 and 9/19/16) are less than 1-year events.

Figure 4: Duration-Depth-Frequency (DDF) Plot, RG_NCPS

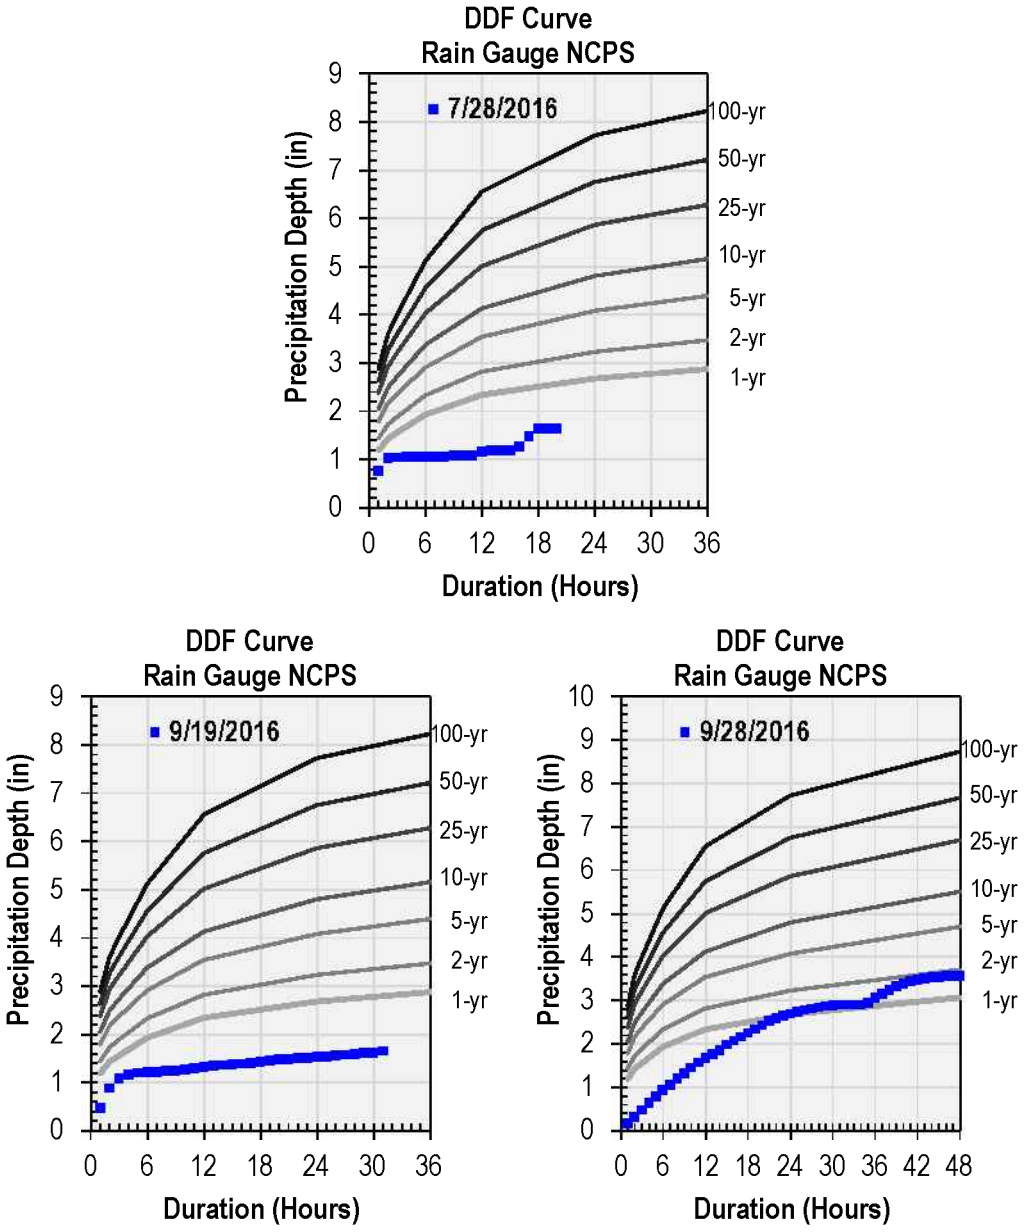

Figure 5 shows Duration-Depth-Frequency (DDF) plot for RG_UPT. Six storms were recorded with a total precipitation volume greater than 1 inch. Both short storms in 7/25/16 storm have return frequencies close to 2-year, the other storm in 9/19/2016 is a 5-year storm, the storm in 9/28/2016 is a 2-year storm, and the other two events (7/30/16 and 8/21/16) are less than 1-year events.

Figure 5: Duration-Depth-Frequency (DDF) Plot, RG_UPT

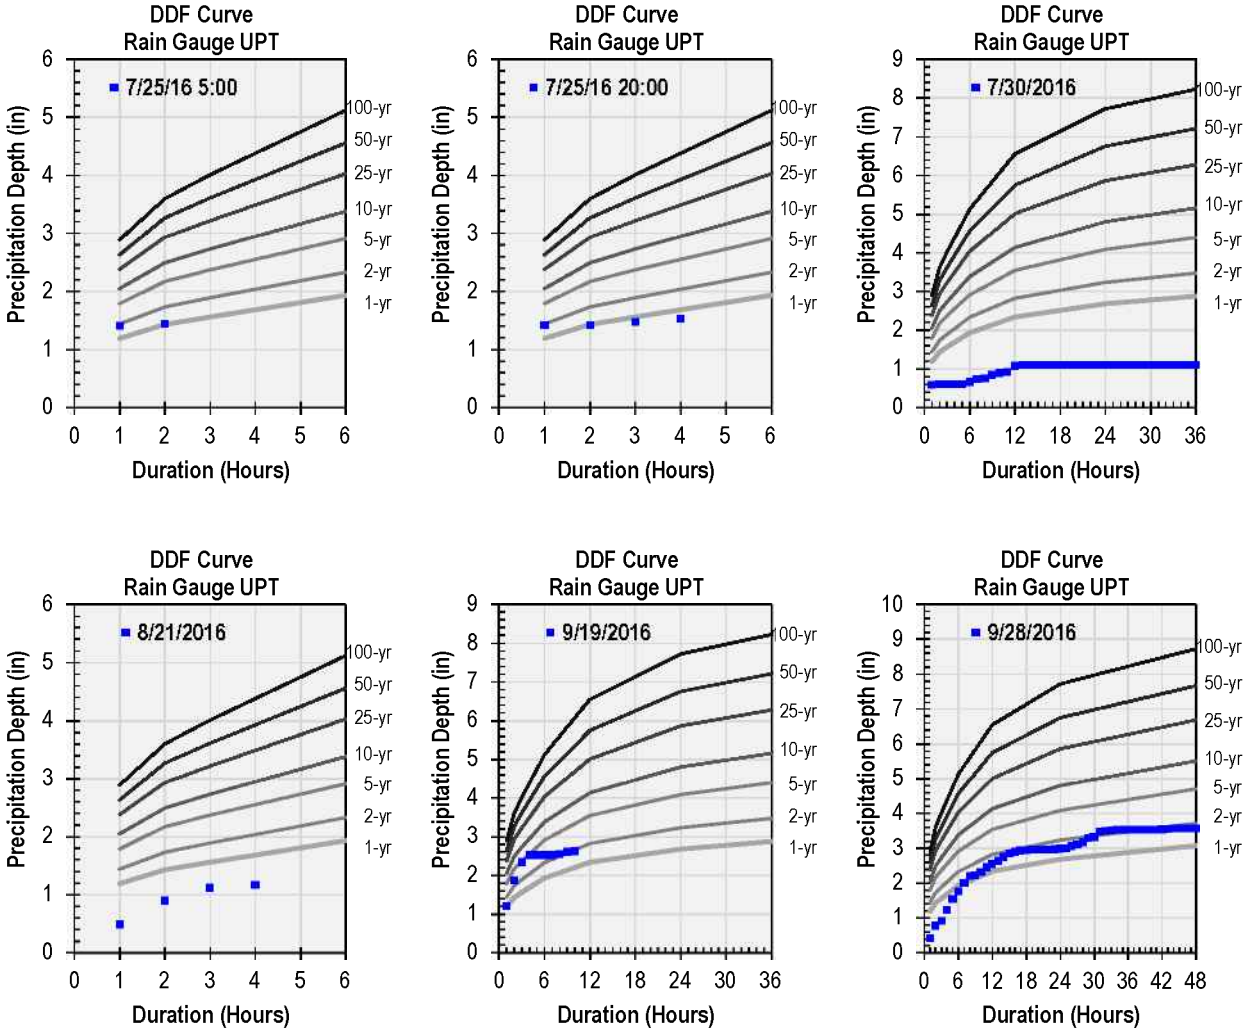

Figure 6 shows Duration-Depth-Frequency (DDF) plot for RG_ChesterPS. Two storms were recorded with a total precipitation volume greater than 1 inch. Both of them (7/28/16 and 9/28/16) are less than 1-year events.

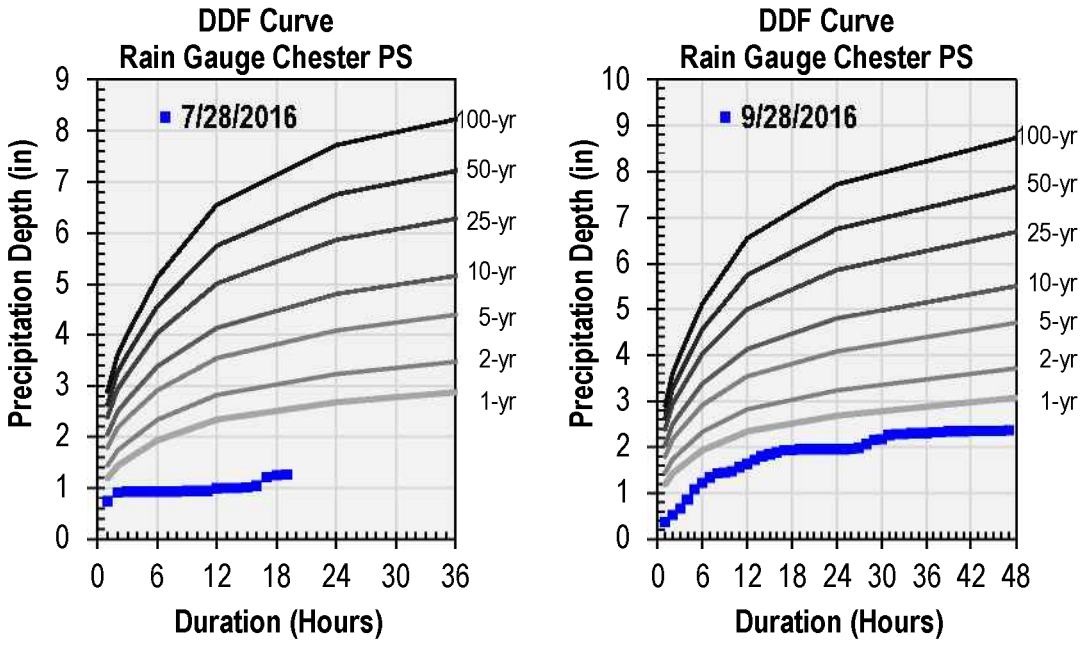
Figure 6: Duration-Depth-Frequency (DDF) Plot, RG_Chester PS



Section 3 Flow Meter Monitoring

3.1 Flow Monitoring Program

The site locations of the existing and newly installed flow meters are shown in **Figure 7**. **Figure 8** shows the newly installed flow meters on a larger scale, mostly in the combined area. These new meters were installed to investigate surface runoff from the combined area and CSO discharges, rainfall-derived inflow and infiltration (RDII) from the separated area, and system response to the wet weather conditions. The schematic of the newly installed flow meters is included in **Figure 9**.

The newly installed flow meter locations are categorized into the following four types:

- Category 1: Located on the influent pipe to CSO regulators, this is to measure the influent flow to CSO regulators and for combined area runoff calibration. Sixteen (16) meters were installed for this category.
- Category 2: Located on the effluent pipe and overflow pipe of CSO regulators, this is to measure the CSO overflows and calibrate CSO regulator parameters. Twelve (12) meters were installed for this category. They are on the effluent and overflow pipe of CSOs 02, 03, 05, 08, 14, & 19.
- Category 3: Located on the side-line from the combined areas (flows from the combined area tie into interceptor instead of CSO regulator). This is to measure flows from the combined area and to calibrate combined area runoff parameters. Two (2) meters were installed for this category.
- Category 4: Located upstream of the combined area, this is to measure flows from the upstream separated area for RDII characterization. Three (3) meters were installed for this category.
- Category 5: Located in the main interceptors to measure level and flows in the major interceptors. Five (5) meters were installed for this category.

One meter was proposed at manhole MH3029 to measure flow from the separated area upstream of the combined area (CSO#018). The site was severely surcharged during field investigation. Meanwhile it was found that at manhole MH3002 (four manholes upstream of MH3029, approximately 800 feet upstream) another CSL flow meter (Ridley Creek MH-28) was already installed for DELCORA. It was determined that instead of installing a new flow meter around the site, the team will use the existing meter Ridley Creek MH-28 for this flow monitoring program.

In total, 39 flow meters are included in this monitoring program. Details of the installed flow meters are included in **Table 3**.

3.2 Flow Meters Field Calibration/Verification Procedures

As part of the operation of flow meters, verifications of meter accuracy are performed on a regular basis. Calibrations are performed at a minimum every eight weeks, or more as needed.

The procedure used for performing meter calibrations is outlined below. This procedure only defines the required result. Any specific equipment function issues should be referred to the equipment manual or the manufacturer's technical support department.

Figure 7: Existing and Newly Installed Flow Meter Locations

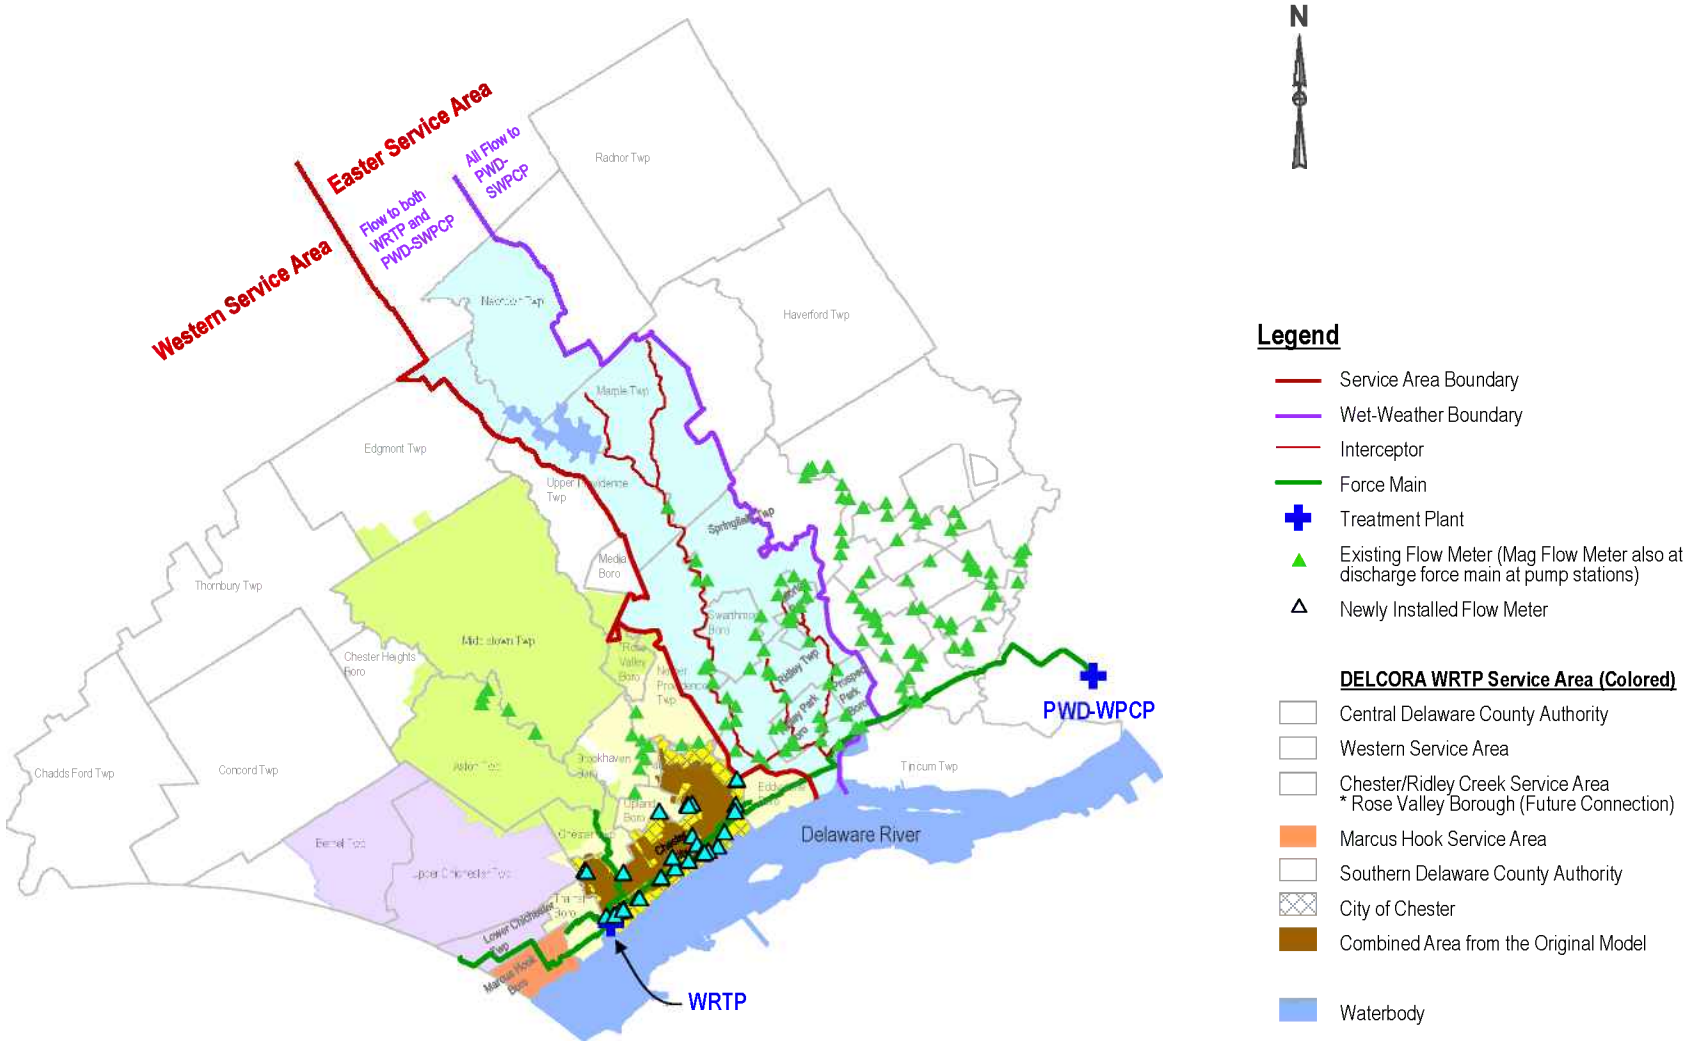

Figure 8: Newly Installed Flow Meter Locations

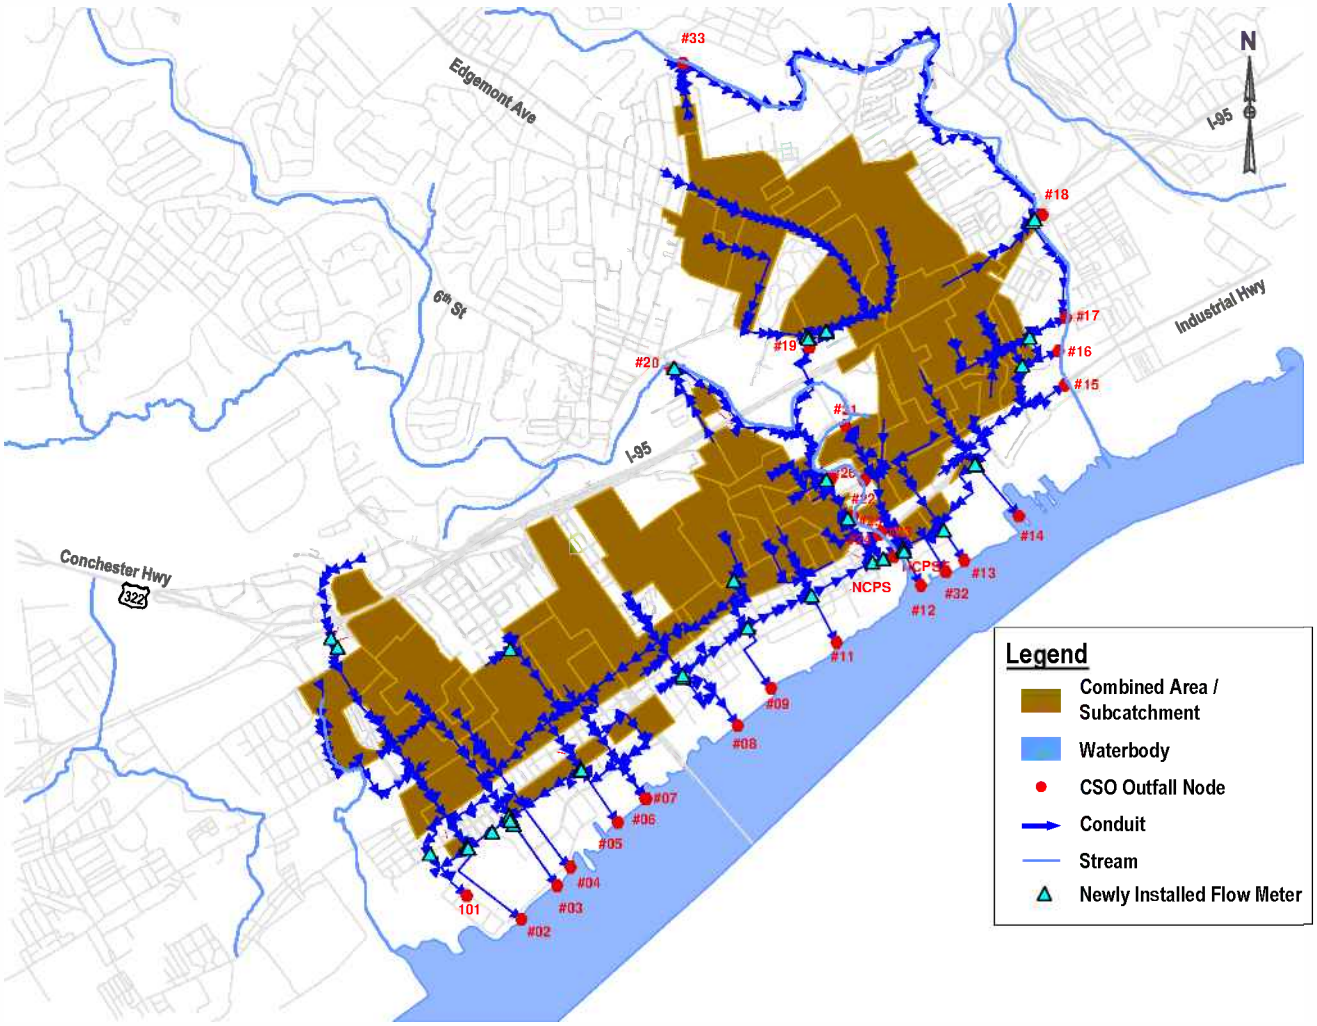

Figure 9: Flow Monitoring Schematic

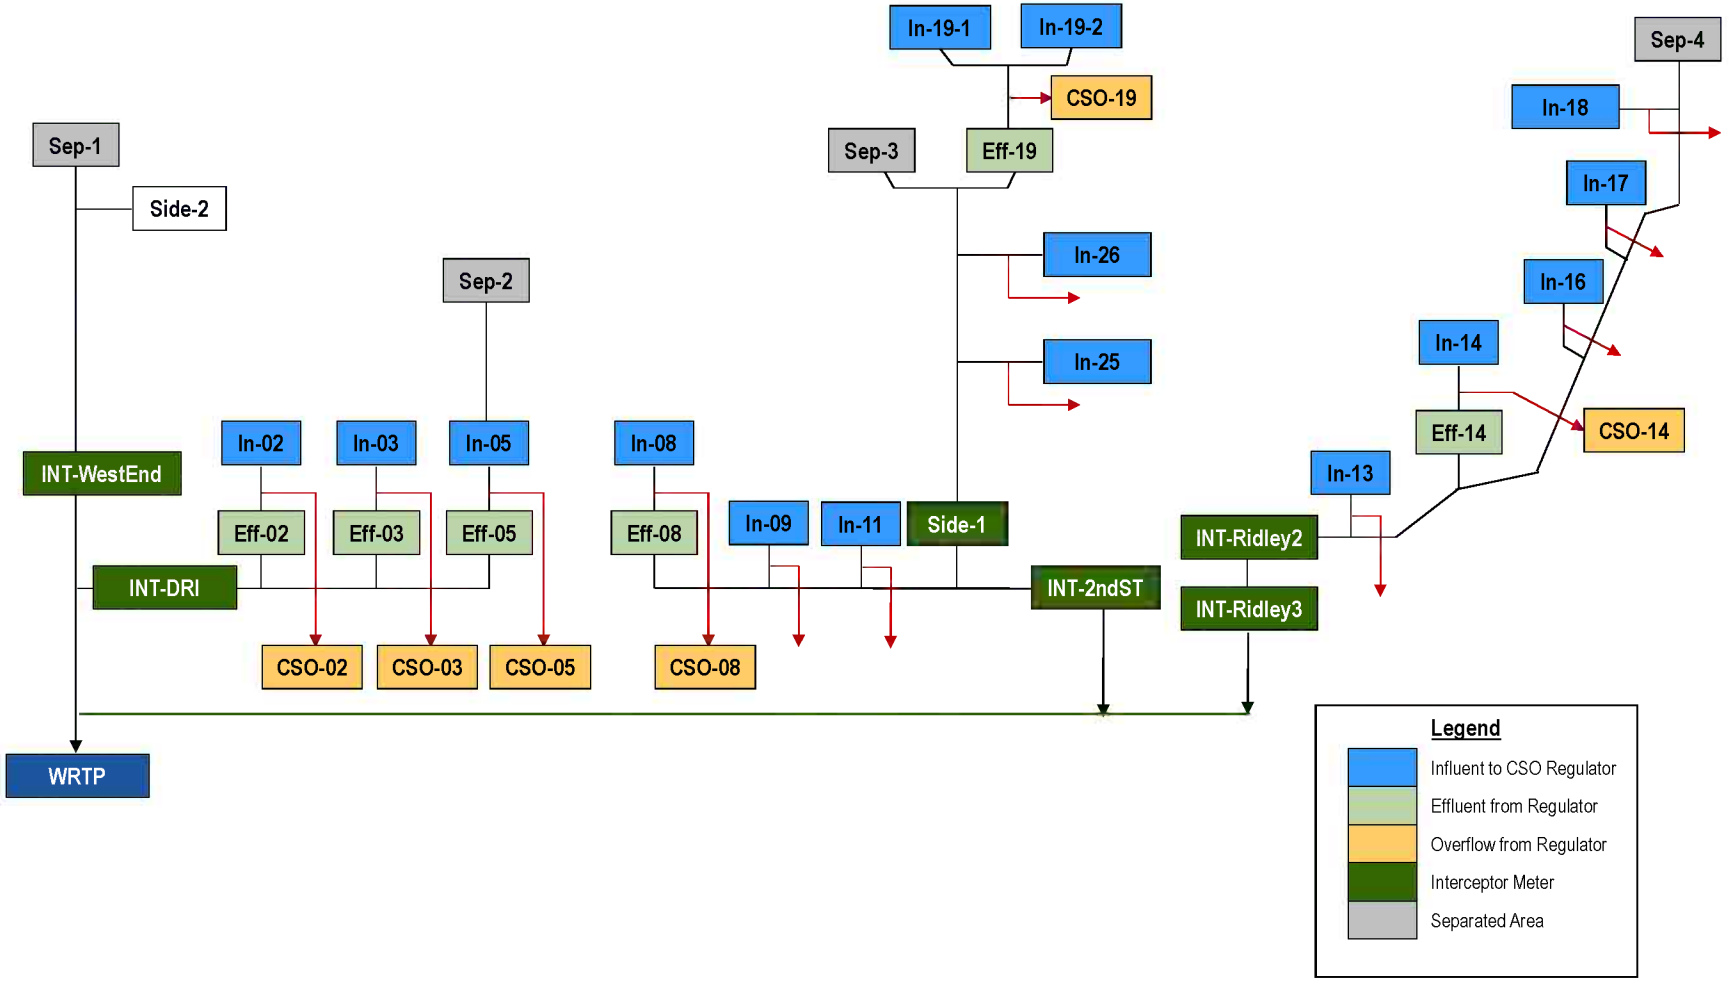

Manually Downloaded Meters
This method is used for any meter that cannot be interrogated remotely by the data analyst. Field technicians use the *Daily Field Download Sheet* for recording the calibration results.

- Record the date.
- Record the field time, which is the local time.
- Record the meter time.
- Record the instantaneous depth reading from the meter.
- Measure the peak velocity.
- Record the instantaneous average or peak, whichever is applicable.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Remote Connection Meters
This method is used for any meter that can be interrogated remotely. The data analyst uses the *Daily Field Download Sheet* for single depth and velocity meters and the *Multi- Sensor Calibration Sheet* for meter types that record multiple depth and/or velocity readings.

- Fill all site visit information fields on form.
- Have the field tech measure the depth of flow and record with time.
- Record the time and instantaneous depth reading from the meter or the depth sensor, whichever is applicable. All available depth sensors should be activated and compared to the field measurement.
- Have the field tech measure the peak the velocity or have them perform a velocity profile if the depth is sufficient then record with time.
- Record the time and instantaneous velocity reading from the meter or the velocity sensor, whichever is applicable. All available velocity sensors should be activated and compared to the field measurement.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Special Cases

- Blind Verifications: A blind verification occurs when a field technician's only role is to measure the depth and velocity of the flow and report the values to the data analyst. In these cases, the crew is "blind" to what the meter is reading. The data analyst will then compare the readings to current/recent data or live readings. Should the blind verification be out of tolerance, the analyst can direct the crew to perform additional blind verifications or perform a conventional verification and/or troubleshoot as necessary.

- Installations/Removals: When installing or removing meters, the above calibration method should be used for three consecutive verifications, performed at 5 minute intervals.
- Third Party Audit: When performing a calibration at a meter that is not maintained by CSL and where CSL is to verify the meter function, the CSL Audit report should be used.

3.3 Flow Monitoring Data Summary

Flow, level and velocity data are received for each flow monitoring site at 5-minute intervals (Sep-4 has 15-min interval data). Metering data is analyzed for dry weather flows (DWF), hourly peak flows, and hourly peaking factors for each monitoring site. A "dry weather" condition was defined as a period with no precipitation that begins three days after the last wet weather event and lasts until the beginning of the next precipitation event.

Table 4 shows dry weather flow (DWF), hourly peak flow, hourly peaking factor and flow condition observations.

The dry weather flows are also shown in the schematic in **Figure 10**. Generally the downstream dry weather flow is greater than the upstream locations for all of the meters. For meters immediately upstream and downstream of CSO regulators, the upstream and downstream dry weather flows should be similar. **Figure 11** shows the influent and effluent from CSO#08 as an example to indicate that the dry weather of the two are similar.

The hourly peaking factor in the combined area is in the range of 9 to 85 and average at 39. The hourly peaking factor for the interceptor is between 2.8 and 8.5 with an average of 4.6. The hourly peaking factor is between 2.9 and 5.5 for the separated area, with an average of 4.1.

A detailed hydrograph and scattergraph for each flow monitoring site is shown in **Figure 12** to **Figure 50**, each includes:

- The flow hydrographs show hourly flow and rainfall profile. Hourly Rainfall data is included for the convenience of reviewing flow response to the wet weather conditions. Hourly flow and rainfall were calculated from the 5-min interval.
- The scattergraphs (based on 5-min data) are essentially a plotting of flow rate versus depth. This plotting helps to understand the flow patterns and conditions on the individual monitored sewer pipes.
- For CSOs 02, 03, 05, 08, 14, & 19, flows including influent, effluent and overflows were plotted in the same plot.

Table 4: Flow Monitoring Summary

Meter ID	Hourly Peak (MGD)DWF	DWF (MGD)	Hourly Peaking Factor	Comments
In-02	6.25	0.29	21.7	Free flow most of the time

Section 1 Introduction

The Delaware County Regional Water Quality Control Authority (DELCORA) entered into a Consent Decree (CD) with the United States Government in August 2015. The purpose of the Consent Decree is to establish a schedule for implementation of Long Term Control Plan Update (LTCPU) to achieve full compliance with the Clean Water Act and the regulations and Clean Streams Law and regulations. The lodging of this Consent Decree was entered by the court on August 17, 2015, it was signed and filed on November 10, 2015 by the United States District Court for the Eastern District of Pennsylvania.

According to the Consent Decree, DELCORA's Hydrologic and Hydraulic Model (H&H Model) must be updated to meet the requirements in Section V.A.14 of the Consent Decree. A detailed plan to update, calibrate and validate the H&H model has been submitted and approved by the USEPA on March 1, 2016. Additional rainfall and flow monitoring is required to calibrate and validate the H&H model. Requirements of rainfall and flow monitoring are detailed in the Consent Decree Section V.A.14.d and e, which is included in the following:

> "*d.* *Rainfall and flow monitoring shall be carried out in accordance with current good industry practice for a period of at least twelve* ***(12) months****, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization of dry and wet weather flows from the entire Model Area, and the response of each CSO to wet weather flows.*
>
> *e.* *For all rainfall and flow monitoring carried out in support of efforts to update and calibrate the H&H Model, DELCORA shall prepare and submit to Plaintiffs for review and comment in accordance with the requirements of Section VI (Review and Approval of Submittals) quarterly technical memoranda documenting the results and quality of the rainfall and flow monitoring data."*

In summary, rainfall and flow monitoring shall be conducted for at least 12 months, and quarterly technical memoranda shall be submitted to Plaintiffs for review.

To satisfy the above mentioned rainfall and flow monitoring requirements, and in accordance with the submitted DELCORA H&H Model Update and Calibration Plan, DELCORA has installed 5 new rain gauges and 39 new flow meters in its sewer collection system. Starting from March 18, 2016, most of the newly installed rain gauges and flow meters were in service and began generating data.

This report is a summary of the Rainfall and Flow Monitoring during October 1, 2016 to December 31, 2016.

Section 2 Rainfall Monitoring

2.1 Rainfall Monitoring Locations

The site locations of the four existing and five newly installed rain gauges are shown in **Figure 1**. These rain gauges provide an effective spatial coverage of the entire WRTP's service area.

The four (4) existing rainfall gauges are in Delaware County that record precipitation in 15-minute increments. The gauges are located at the following DELCORA owned facilities:

- Western Regional Treatment Plant (WRTP, will be used for model calibration)
- Central Delaware County Pump Station (CDPS, will be used for model calibration)
- Muckinipates Pump Station (MPS, will be used for model calibration)
- Darby Creek Pump Station (DCPS, will NOT be used for model calibration)

The five (5) newly installed rain gauges are listed in **Table 1** with detail information of rain gauge location, service starting date, and data recording interval.

Table 1: Newly Installed Rain Gauges

	Rain Gauge ID	Location	Service Start Date	Data Interval
1	RG_Rose Valley	18 N. Longpoint Lane, Media, PA	3/05/16	5-minute
2	RG_Chester-PS	55 East 2nd Street, Chester, PA	3/05/16	5-minute
3	RG_NCPS	1628 Naamans Creek Rd., Marcus Hook, PA	3/05/16	5-minute
4	RG_Springfield	217 Saxer Avenue, Springfield, PA	4/03/16	5-minute
5	RG_UCT	1671 N. Upper Providence Road, Media, PA	4/16/16	5-minute

2.2 Rain Gauge Calibration/Verification Procedure

Rain Gauge calibrations were performed during the rain gauge installation. Additional calibrations will be performed to the manufacturer's specifications on a bi-annual basis or as needed if irregular data is observed. Rain gauges are routinely checked for debris, and cleared after snow/ice storms.

Each "tip" of the rain gauge bucket should correspond with 0.01" of rain. To ensure the modem is reading the tipping bucket pulse accurately, the tech will tip the bucket 10 times in rapid succession. The tech should see that 0.1" of rain is recorded.

2.3 Rainfall Event Summary

Rainfall events were analyzed for each individual rain gauge based on the inter-event time of 12 hours. In total there were 17 rainfall events during reporting period. **Table 2** lists all 13 rainfall events with total precipitation greater than 0.1 inch.

Figure 1: Rain Gauge Locations

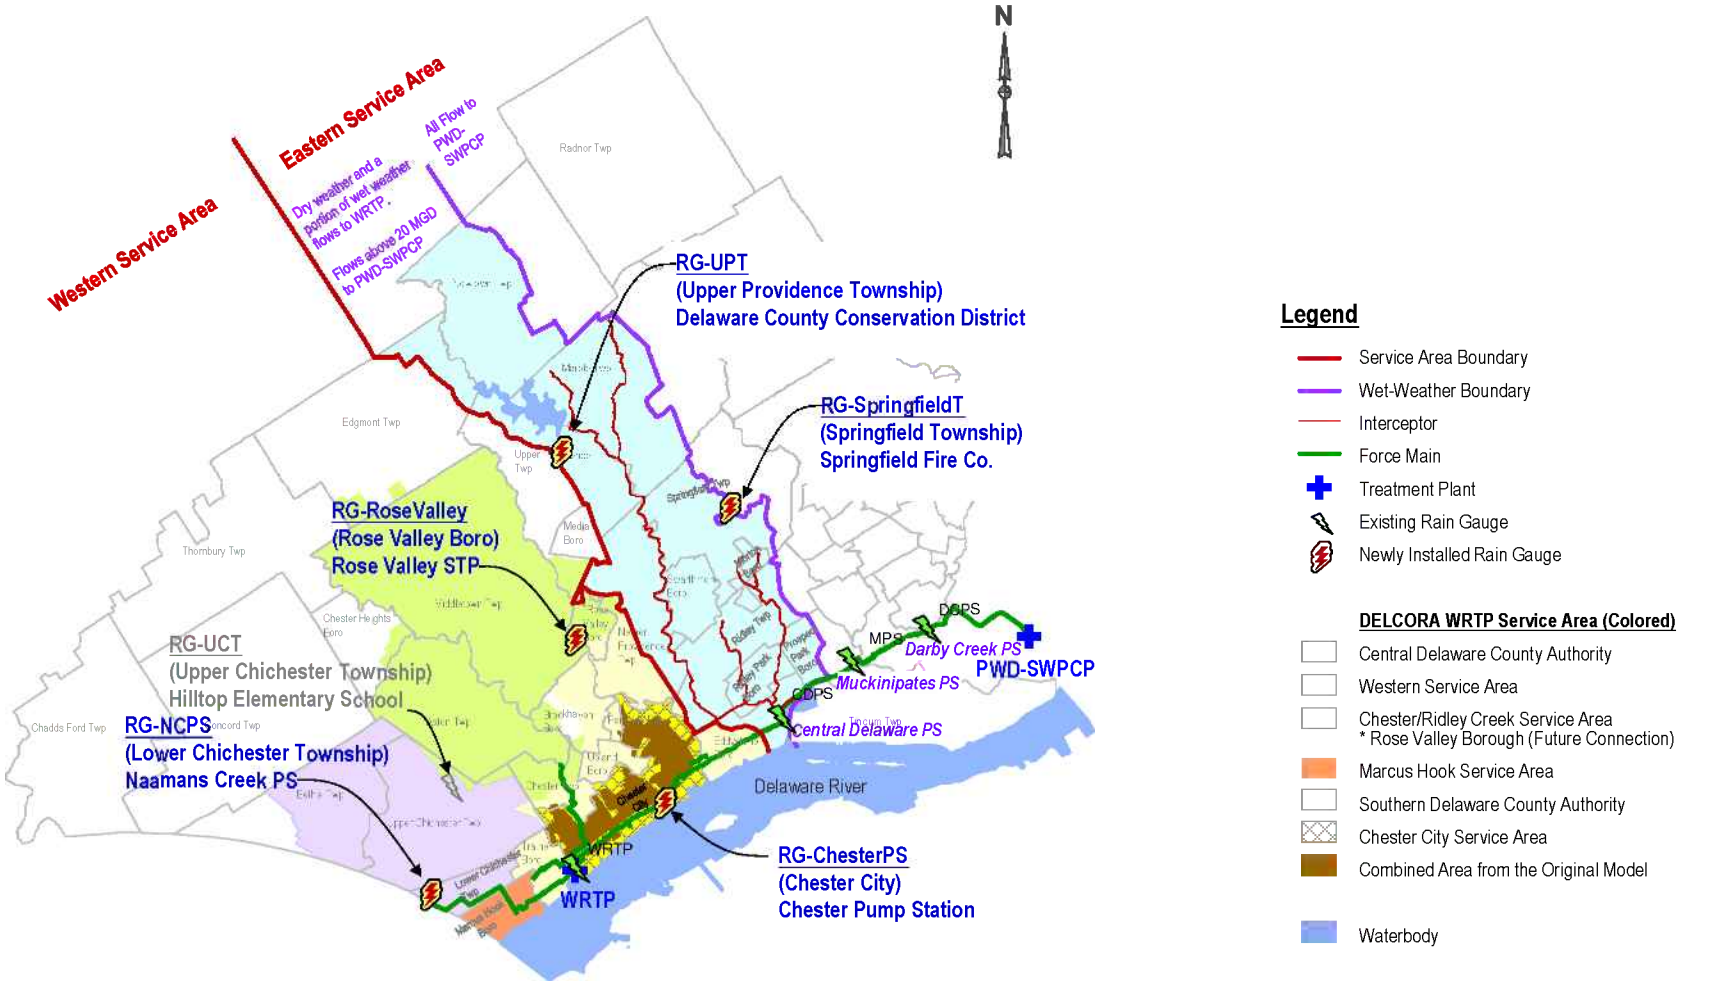

Figure 2 shows rainfall amounts at each rain gauge in each month for October, November and December. It is obvious that rainfall in the area has significant spatial and temporal variance. As an example, during this reporting period, the rain gauge at the Chester Pump Station (Chester PS) recorded a total rainfall of 6.65 inches while the gauge at the Upper Providence Township (UPT) recorded 8.52 inches. **Figure 3** shows the 1-hour rainfall profile for all of the 5 rain gauges.

Table 2: Rainfall Event Summary, 10/1/16 - 12/31/16

	Rain Event Starting Time	Rose Valley	Chester-PS	NCPS	Springfield	UPT
1	10/8/2016 13:25	0.91	1	1.1	0.82	1.05
2	10/21/2016 20:55	0.24	0.2	0.2	0.24	0.36
3	10/27/2016 8:30	0.45	0.54	0.71	0.32	0.43
4	10/30/2016 17:45	0.25	0.23	0.21	0.37	0.65
5	11/9/2016 7:25	0.26	0.23	0.31	0.29	0.33
6	11/19/2016 20:25	0.08	0.03	0.17	0.06	0.14
7	11/29/2016 5:30	1.74	1.84	2.13	2.39	2.37
8	12/5/2016 0:25	0.14	0.12	0.12	0.14	0.14
9	12/6/2016 13:35	0.8	0.69	0.22	0.92	0.99

	Subtotal (10/1/16-12/31/16)	**7.01**	**6.65**	**7.33**	**7.55**	**8.52**

Figure 2: Rainfall Event Summary, 10/1/16 - 12/31/16

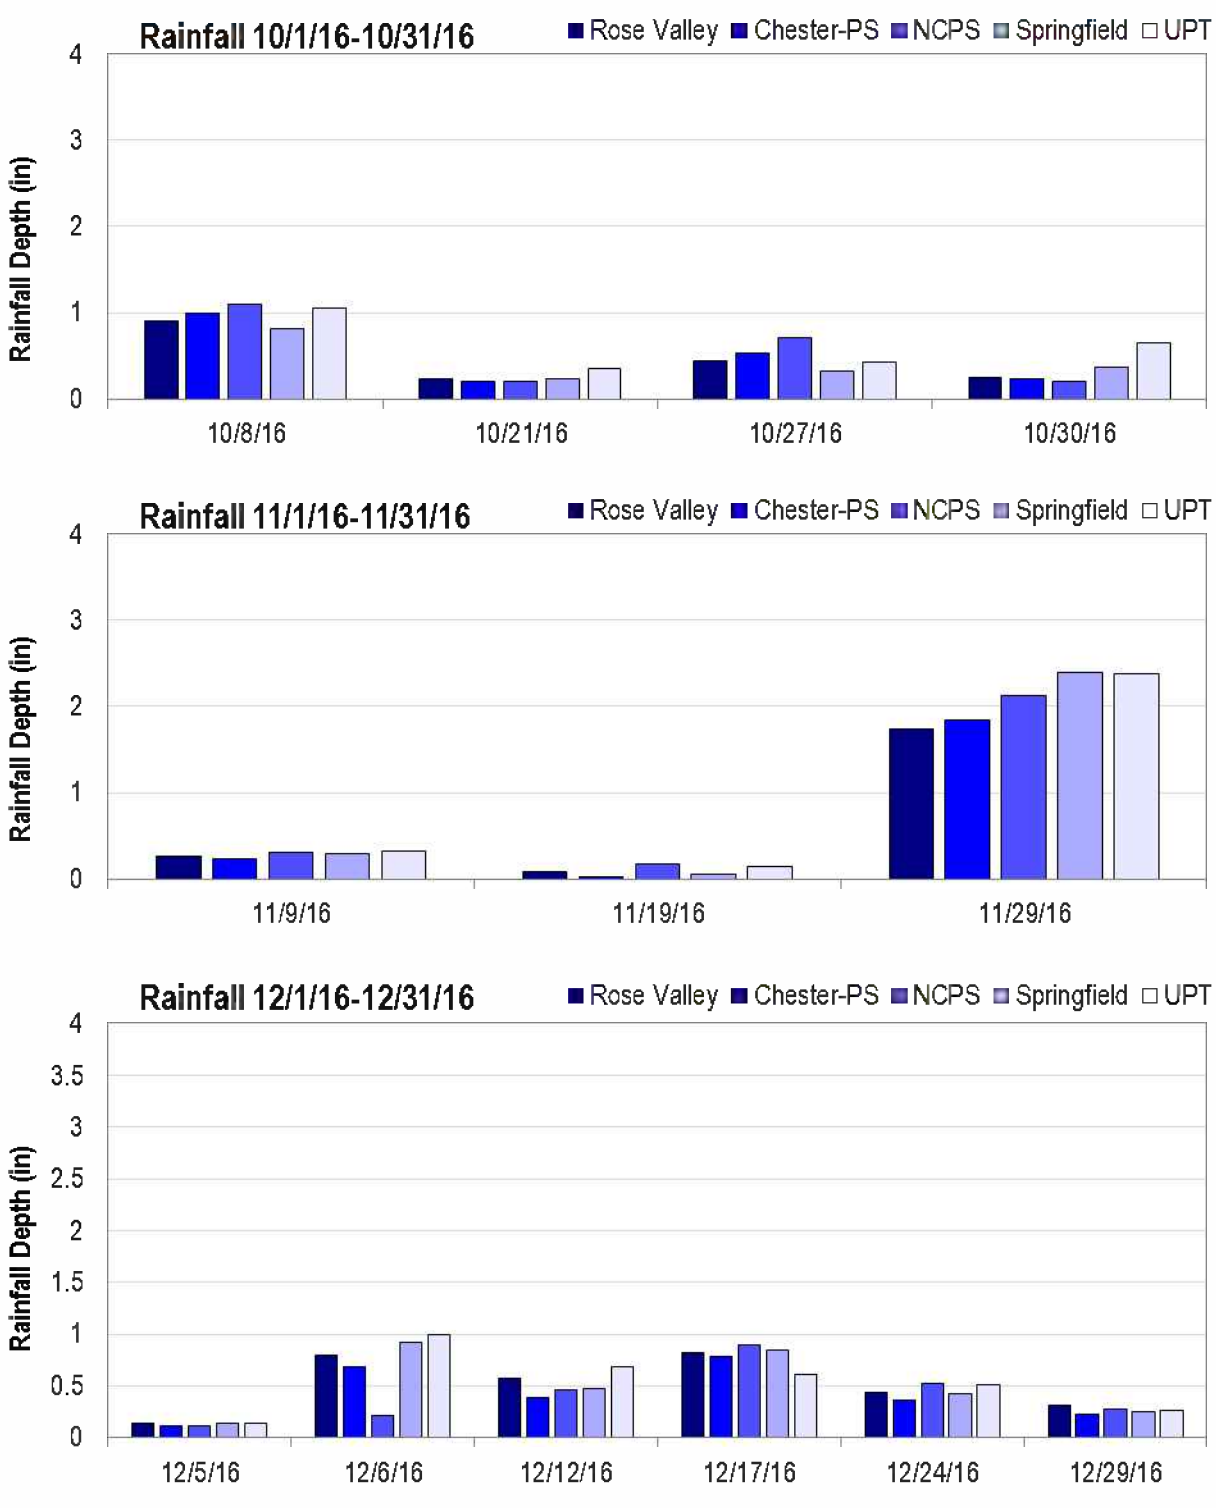

Figure 3: Hourly Rainfall Profile

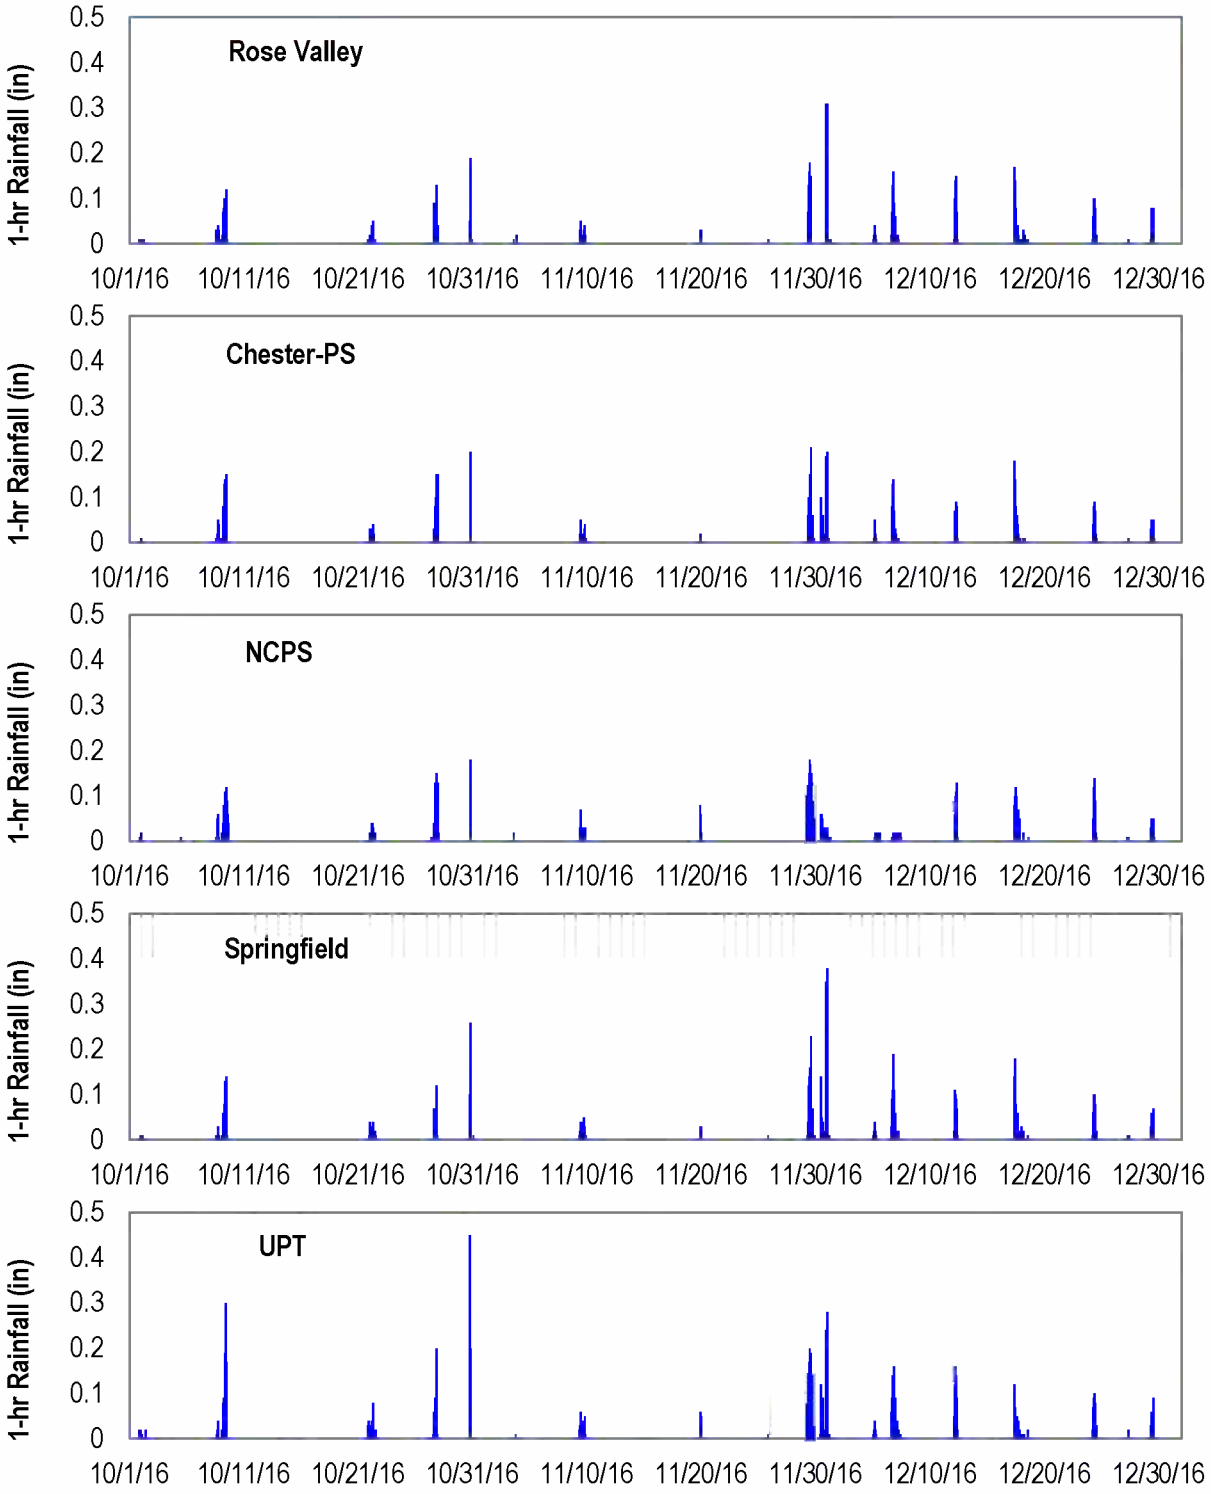

2.3.1 Rainfall Return Frequency

Rainfall return frequency was analyzed for rain gauges RG_NCPS and RG_UPT because they usually record greater rainfall amounts than the others. The frequency analysis was also performed for RG_ChesterPS because it is located in the combined area.

Figure 4 shows Duration-Depth-Frequency (DDF) plot for RG_NCPS. Two storms were recorded with total precipitation volumes greater than 1 inch. Both events (10/8/17 and 11/29/17) are less than 1-year events.

Figure 4: Duration-Depth-Frequency (DDF) Plot, RG_NCPS

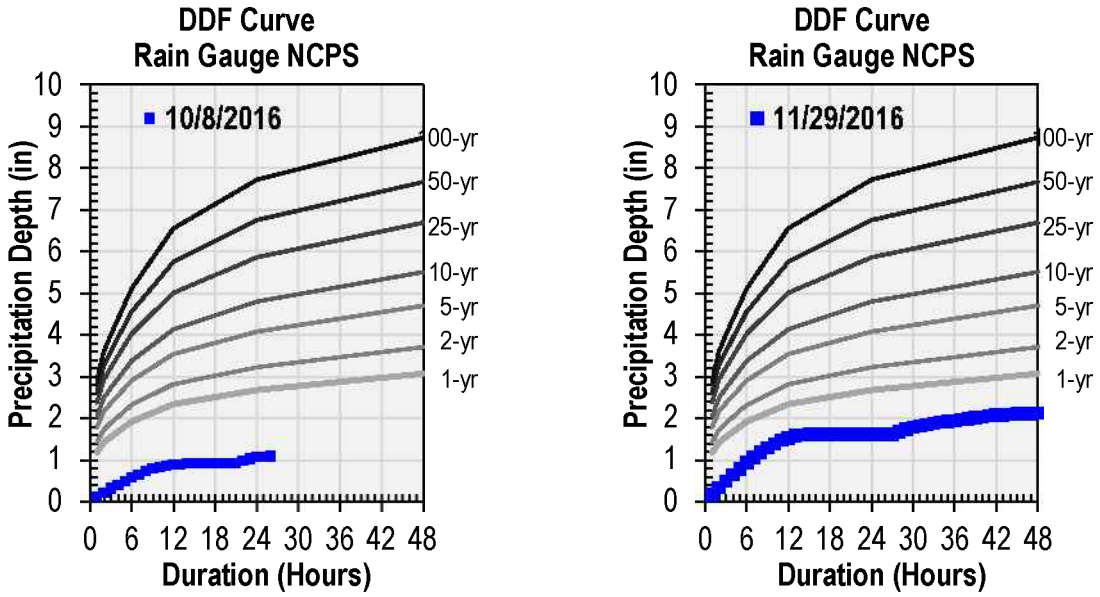

Figure 5 shows Duration-Depth-Frequency (DDF) plot for RG_UPT. Two storms were recorded with total precipitation volumes greater than 1 inch. Both events (10/8/17 and 11/29/17) are less than 1-year events.

Figure 5: Duration-Depth-Frequency (DDF) Plot, RG_UPT

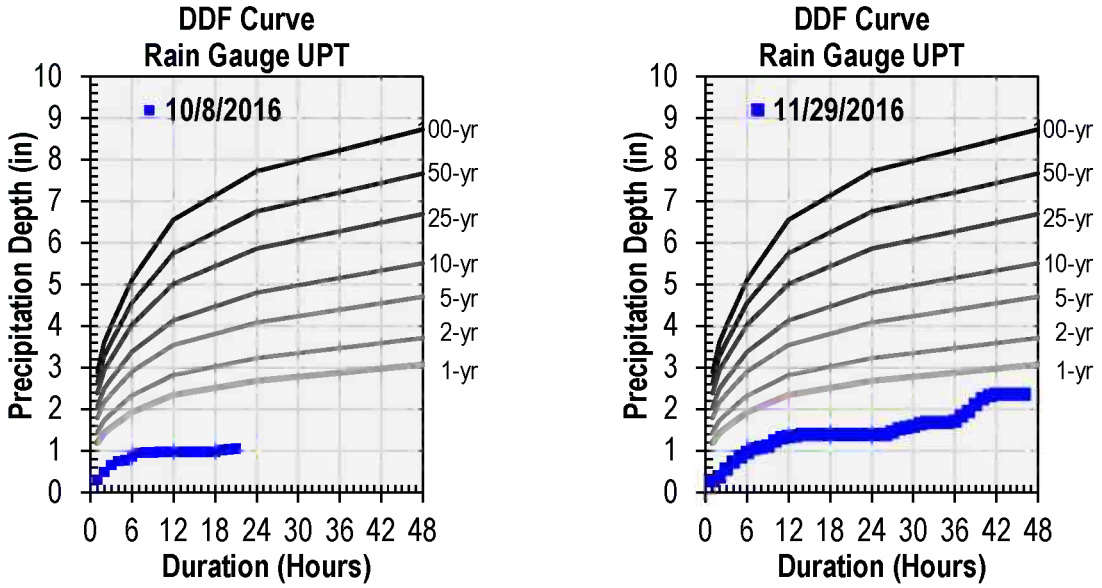

Figure 6 shows Duration-Depth-Frequency (DDF) plot for RG_ChesterPS. Only one storm (11/29/17) was recorded with a total precipitation volume greater than 1 inch. It is less than a 1-year event.

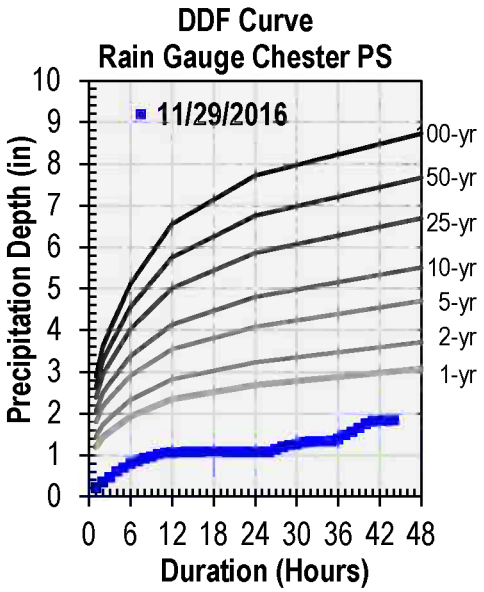
Figure 6: Duration-Depth-Frequency (DDF) Plot, RG_Chester PS



Section 3 Flow Meter Monitoring

3.1 Flow Monitoring Program

The site locations of the existing and newly installed flow meters are shown in **Figure 7**. **Figure 8** shows the newly installed flow meters on a larger scale, mostly in the combined area. These new meters were installed to investigate surface runoff from the combined area and CSO discharges, rainfall-derived inflow and infiltration (RDII) from the separated area, and system response to the wet weather conditions. The schematic of the newly installed flow meters is included in **Figure 9**.

The newly installed flow meter locations are categorized into the following four types:

- Category 1: Located on the influent pipe to CSO regulators, this is to measure the influent flow to CSO regulators and for combined area runoff calibration. Sixteen (16) meters were installed for this category.
- Category 2: Located on the effluent pipe and overflow pipe of CSO regulators, this is to measure the CSO overflows and calibrate CSO regulator parameters. Twelve (12) meters were installed for this category. They are on the effluent and overflow pipe of CSOs 02, 03, 05, 08, 14, & 19.
- Category 3: Located on the side-line from the combined areas (flows from the combined area tie into interceptor instead of CSO regulator). This is to measure flows from the combined area and to calibrate combined area runoff parameters. Two (2) meters were installed for this category.
- Category 4: Located upstream of the combined area, this is to measure flows from the upstream separated area for RDII characterization. Three (3) meters were installed for this category.
- Category 5: Located in the main interceptors to measure level and flows in the major interceptors. Five (5) meters were installed for this category.

One meter was proposed at manhole MH3029 to measure flow from the separated area upstream of the combined area (CSO#018). The site was severely surcharged during field investigation. Meanwhile it was found that at manhole MH3002 (four manholes upstream of MH3029, approximately 800 feet upstream) another CSL flow meter (Ridley Creek MH-28) was already installed for DELCORA. It was determined that instead of installing a new flow meter around the site, the team will use the existing meter Ridley Creek MH-28 for this flow monitoring program.

In total, 39 flow meters are included in this monitoring program. Details of the installed flow meters are included in **Table 3**.

3.2 Flow Meters Field Calibration/Verification Procedures

As part of the operation of flow meters, verifications of meter accuracy are performed on a regular basis. Calibrations are performed at a minimum every eight weeks, or more as needed.

The procedure used for performing meter calibrations is outlined below. This procedure only defines the required result. Any specific equipment function issues should be referred to the equipment manual or the manufacturer's technical support department.

Figure 7: Existing and Newly Installed Flow Meter Locations

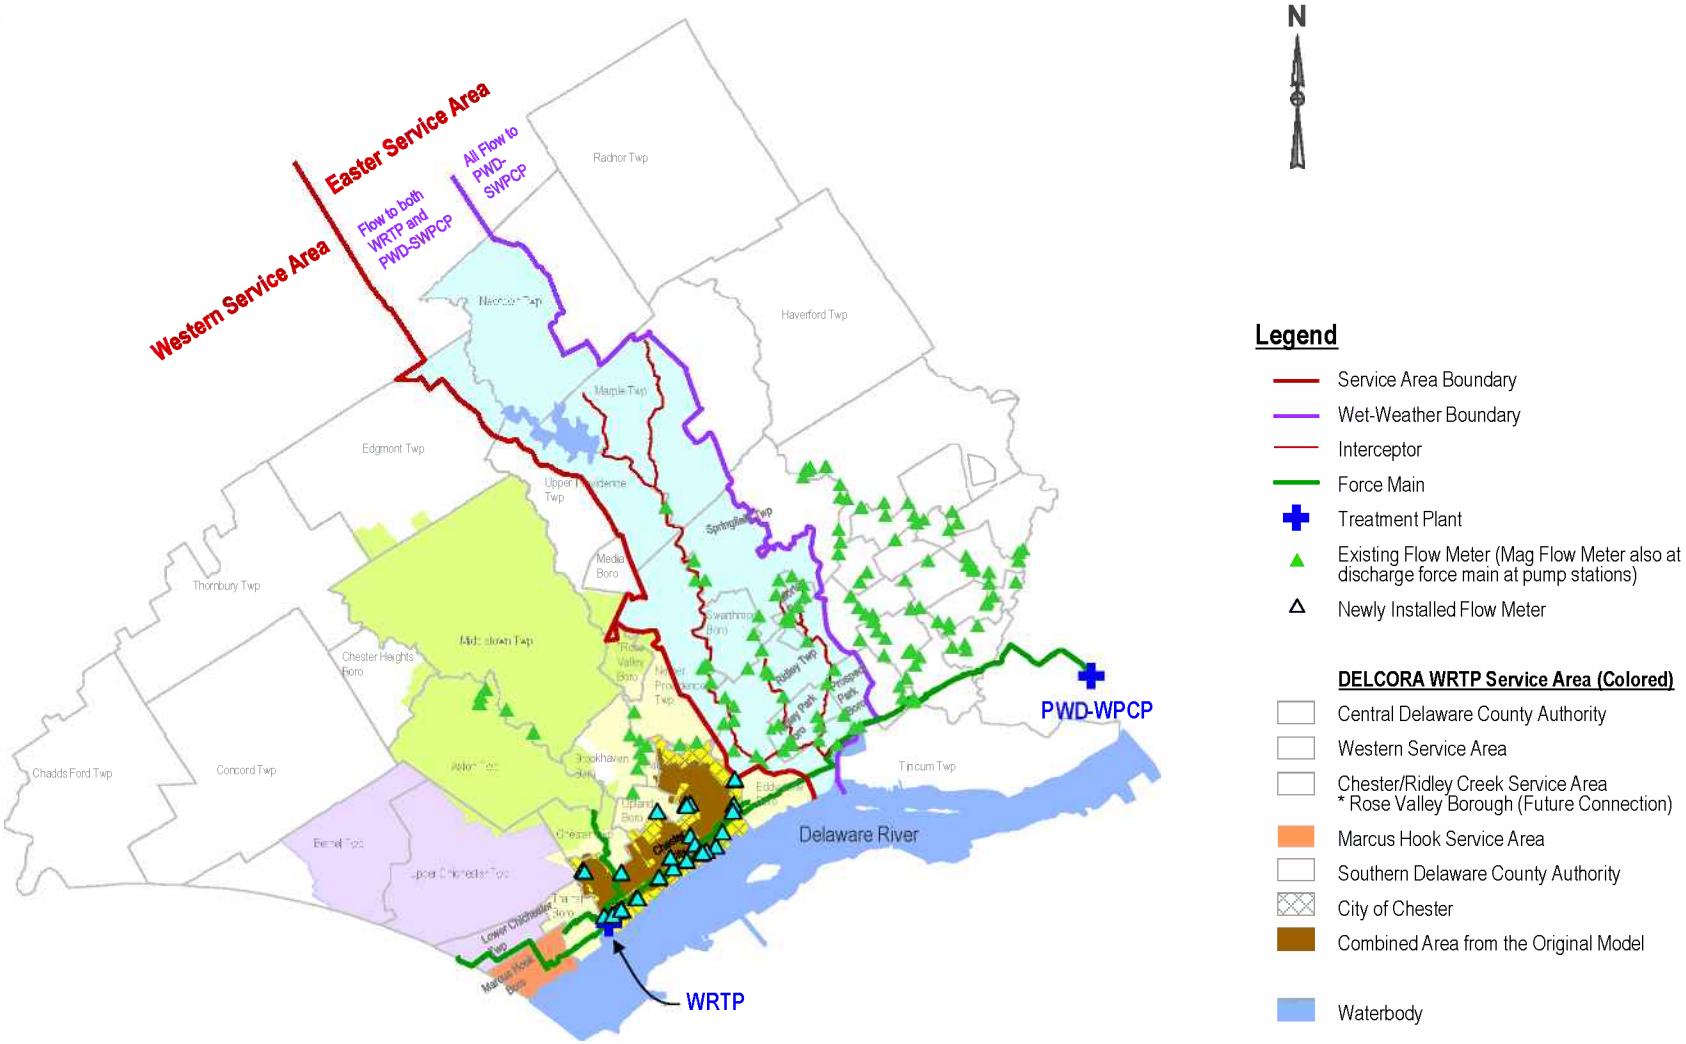

Figure 8: Newly Installed Flow Meter Locations

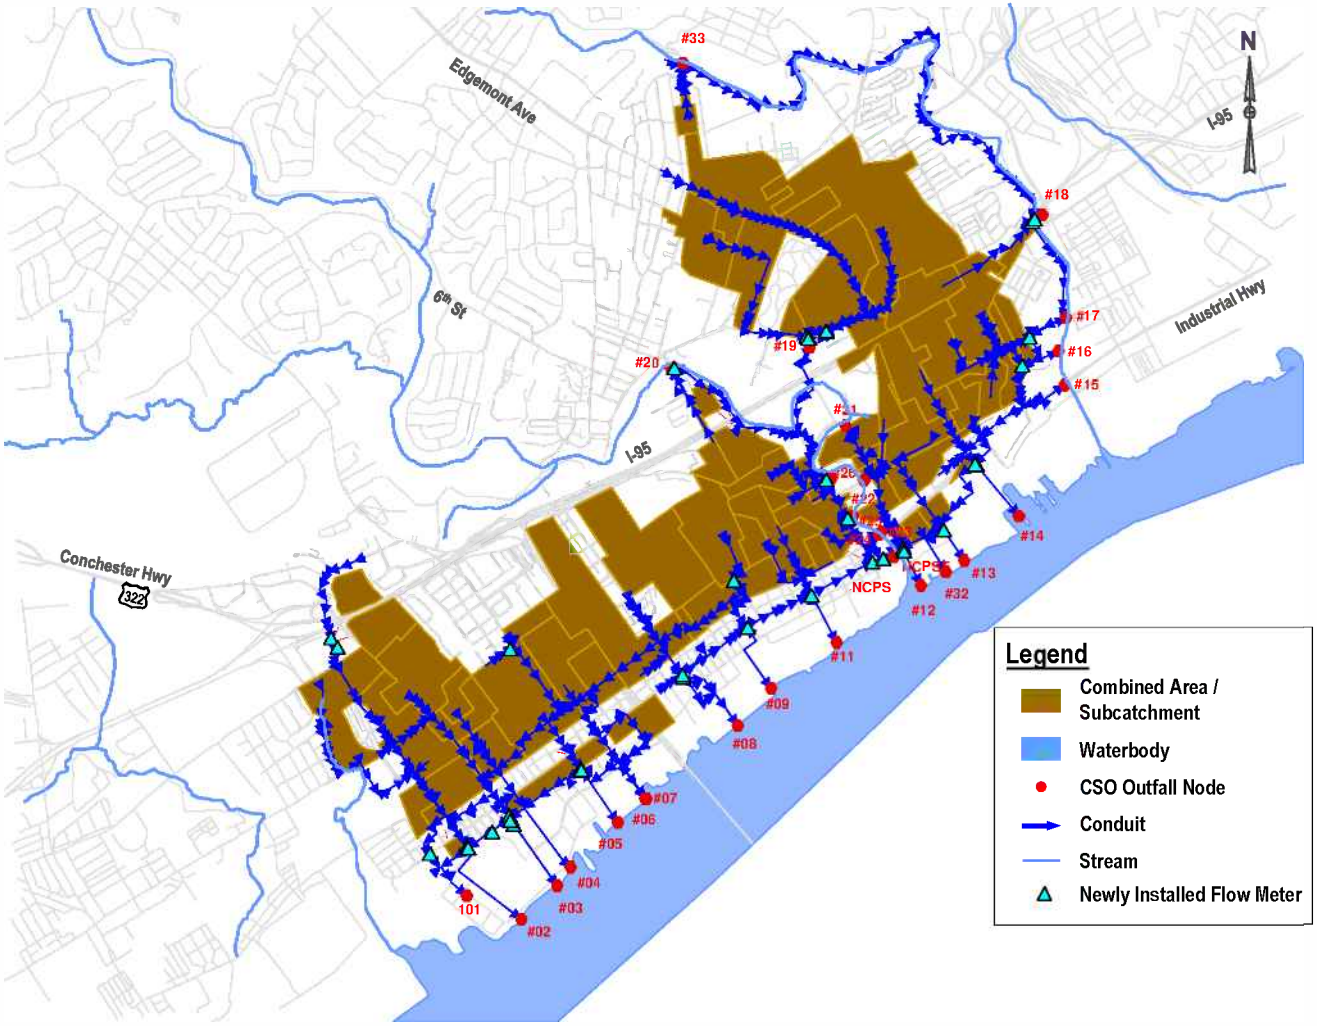

Figure 9: Flow Monitoring Schematic

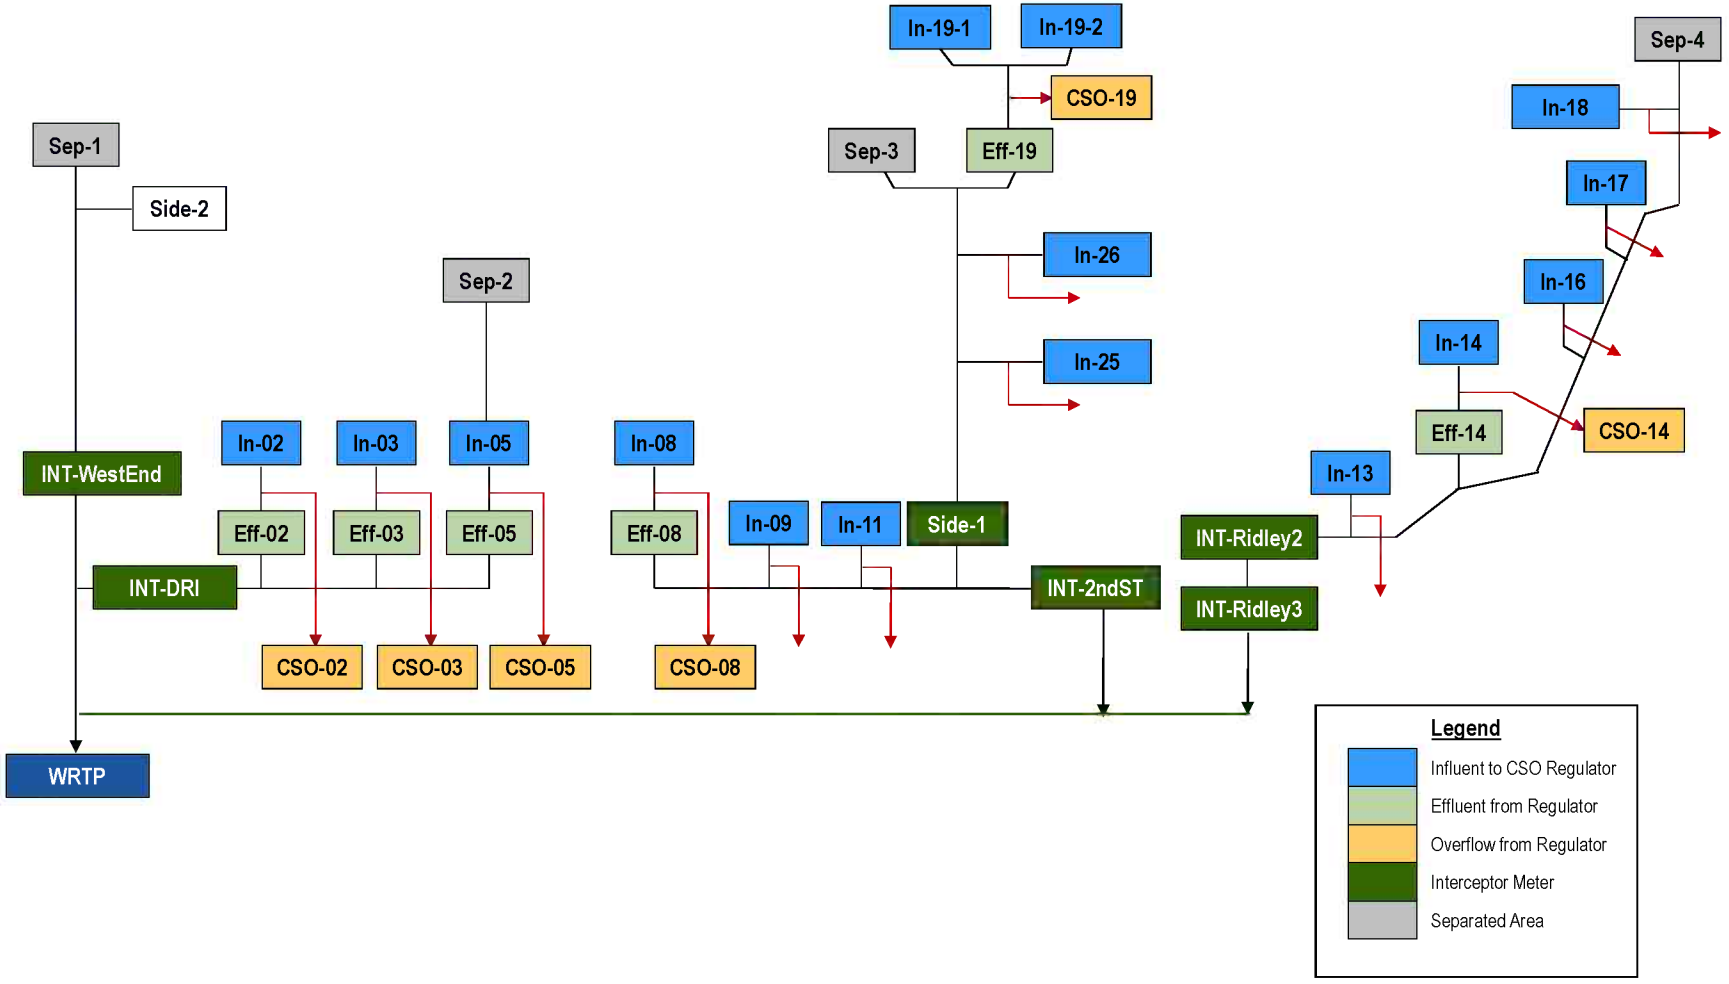

Manually Downloaded Meters
This method is used for any meter that cannot be interrogated remotely by the data analyst. Field technicians use the *Daily Field Download Sheet* for recording the calibration results.

- Record the date.
- Record the field time, which is the local time.
- Record the meter time.
- Record the instantaneous depth reading from the meter.
- Measure the peak velocity.
- Record the instantaneous average or peak, whichever is applicable.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Remote Connection Meters
This method is used for any meter that can be interrogated remotely. The data analyst uses the *Daily Field Download Sheet* for single depth and velocity meters and the *Multi- Sensor Calibration Sheet* for meter types that record multiple depth and/or velocity readings.

- Fill all site visit information fields on form.
- Have the field tech measure the depth of flow and record with time.
- Record the time and instantaneous depth reading from the meter or the depth sensor, whichever is applicable. All available depth sensors should be activated and compared to the field measurement.
- Have the field tech measure the peak the velocity or have them perform a velocity profile if the depth is sufficient then record with time.
- Record the time and instantaneous velocity reading from the meter or the velocity sensor, whichever is applicable. All available velocity sensors should be activated and compared to the field measurement.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Special Cases

- Blind Verifications: A blind verification occurs when a field technician's only role is to measure the depth and velocity of the flow and report the values to the data analyst. In these cases, the crew is "blind" to what the meter is reading. The data analyst will then compare the readings to current/recent data or live readings. Should the blind verification be out of tolerance, the analyst can direct the crew to perform additional blind verifications or perform a conventional verification and/or troubleshoot as necessary.

- Installations/Removals: When installing or removing meters, the above calibration method should be used for three consecutive verifications, performed at 5 minute intervals.
- Third Party Audit: When performing a calibration at a meter that is not maintained by CSL and where CSL is to verify the meter function, the CSL Audit report should be used.

3.3 Flow Monitoring Data Summary

Flow, level and velocity data are received for each flow monitoring site at 5-minute intervals (Sep-4 has 15-min interval data). Metering data is analyzed for dry weather flows (DWF), hourly peak flows, and hourly peaking factors for each monitoring site. A "dry weather" condition was defined as a period with no precipitation that begins three days after the last wet weather event and lasts until the beginning of the next precipitation event.

Table 4 shows dry weather flow (DWF), hourly peak flow, hourly peaking factor and flow condition observations.

The dry weather flows are also shown in the schematic in **Figure 10**. Generally the downstream dry weather flow is greater than the upstream locations for all of the meters. For meters immediately upstream and downstream of CSO regulators, the upstream and downstream dry weather flows should be similar. **Figure 11** shows the influent and effluent from CSO#08 as an example to indicate that the dry weather of the two are similar.

The hourly peaking factor in the combined area is in the range of 7 to 99 and average at 27. The hourly peaking factor for the interceptor is between 2.8 and 5.2 with an average of 3.9. The hourly peaking factor is between 2.7 and 3.6 for the separated area, with an average of 3.1.

A detailed hydrograph and scattergraph for each flow monitoring site is shown in **Figure 12** to **Figure 50**, each includes:

- The flow hydrographs show hourly flow and rainfall profile. Hourly Rainfall data is included for the convenience of reviewing flow response to the wet weather conditions. Hourly flow and rainfall were calculated from the 5-min interval.
- The scattergraphs (based on 5-min data, excepting 15-min data for Sep-4) are essentially a plotting of flow rate versus depth. This plotting helps to understand the flow patterns and conditions on the individual monitored sewer pipes.
- For CSOs 02, 03, 05, 08, 14, & 19, flows including influent, effluent and overflows were plotted in the same plot.

Table 4: Flow Monitoring Summary

Meter ID	Hourly Peak (MGD)DWF	DWF (MGD)	Hourly Peaking Factor	Comments
In-02	6.25	0.29	21.7	Free flow most of the time
Eff-02	1.19	0.26	4.5	Surcharged under common conditions

Section 1 Introduction

The Delaware County Regional Water Quality Control Authority (DELCORA) entered into a Consent Decree (CD) with the United States Government in August 2015. The purpose of the Consent Decree is to establish a schedule for implementation of Long Term Control Plan Update (LTCPU) to achieve full compliance with the Clean Water Act and the regulations and Clean Streams Law and regulations. The lodging of this Consent Decree was entered by the court on August 17, 2015, it was signed and filed on November 10, 2015 by the United States District Court for the Eastern District of Pennsylvania.

According to the Consent Decree, DELCORA's Hydrologic and Hydraulic Model (H&H Model) must be updated to meet the requirements in Section V.A.14 of the Consent Decree. A detailed plan to update, calibrate and validate the H&H model has been submitted and approved by the USEPA on March 1, 2016. Additional rainfall and flow monitoring is required to calibrate and validate the H&H model. Requirements of rainfall and flow monitoring are detailed in the Consent Decree Section V.A.14.d and e, which is included in the following:

> "*d.* *Rainfall and flow monitoring shall be carried out in accordance with current good industry practice for a period of at least twelve* ***(12) months****, in accordance with the schedule included in the approved plan. Rainfall data shall be obtained at a minimum effective density of 1 gauge/virtual radar-based gauge per square kilometer, for the entire Model Area. Flow monitoring shall be carried out using sufficient monitors to allow the accurate characterization of dry and wet weather flows from the entire Model Area, and the response of each CSO to wet weather flows.*
>
> *e.* *For all rainfall and flow monitoring carried out in support of efforts to update and calibrate the H&H Model, DELCORA shall prepare and submit to Plaintiffs for review and comment in accordance with the requirements of Section VI (Review and Approval of Submittals) quarterly technical memoranda documenting the results and quality of the rainfall and flow monitoring data."*

In summary, rainfall and flow monitoring shall be conducted for at least 12 months, and quarterly technical memoranda shall be submitted to Plaintiffs for review.

To satisfy the above mentioned rainfall and flow monitoring requirements, and in accordance with the submitted DELCORA H&H Model Update and Calibration Plan, DELCORA has installed 5 new rain gauges and 39 new flow meters in its sewer collection system. Starting from March 18, 2016, most of the newly installed rain gauges and flow meters were in service and began generating data.

This report is a summary of the Rainfall and Flow Monitoring during January 1, 2017 to April 1, 2017.

Section 2 Rainfall Monitoring

2.1 Rainfall Monitoring Locations

The site locations of the four existing and five newly installed rain gauges are shown in **Figure 1**. These rain gauges provide an effective spatial coverage of the entire WRTP's service area.

The four (4) existing rainfall gauges are in Delaware County that record precipitation in 15-minute increments. The gauges are located at the following DELCORA owned facilities:

- Western Regional Treatment Plant (WRTP, will be used for model calibration)
- Central Delaware County Pump Station (CDPS, will be used for model calibration)
- Muckinipates Pump Station (MPS, will be used for model calibration)
- Darby Creek Pump Station (DCPS, will NOT be used for model calibration)

The five (5) newly installed rain gauges are listed in **Table 1** with detail information of rain gauge location, service starting date, and data recording interval.

Table 1: Newly Installed Rain Gauges

	Rain Gauge ID	Location	Service Start Date	Data Interval
1	RG_Rose Valley	18 N. Longpoint Lane, Media, PA	3/05/16	5-minute
2	RG_Chester-PS	55 East 2nd Street, Chester, PA	3/05/16	5-minute
3	RG_NCPS	1628 Naamans Creek Rd., Marcus Hook, PA	3/05/16	5-minute
4	RG_Springfield	217 Saxer Avenue, Springfield, PA	4/03/16	5-minute
5	RG_UCT	1671 N. Upper Providence Road, Media, PA	4/16/16	5-minute

2.2 Rain Gauge Calibration/Verification Procedure

Rain Gauge calibrations were performed during the rain gauge installation. Additional calibrations will be performed to the manufacturer's specifications on a bi-annual basis or as needed if irregular data is observed. Rain gauges are routinely checked for debris, and cleared after snow/ice storms.

Each "tip" of the rain gauge bucket should correspond with 0.01" of rain. To ensure the modem is reading the tipping bucket pulse accurately, the tech will tip the bucket 10 times in rapid succession. The tech should see that 0.1" of rain is recorded.

2.3 Rainfall Event Summary

Rainfall events were analyzed for each individual rain gauge based on the inter-event time of 12 hours. In total there were 33 rainfall events during reporting period. **Table 2** lists all 18 rainfall events with total precipitation greater than 0.1 inch.

Figure 1: Rain Gauge Locations

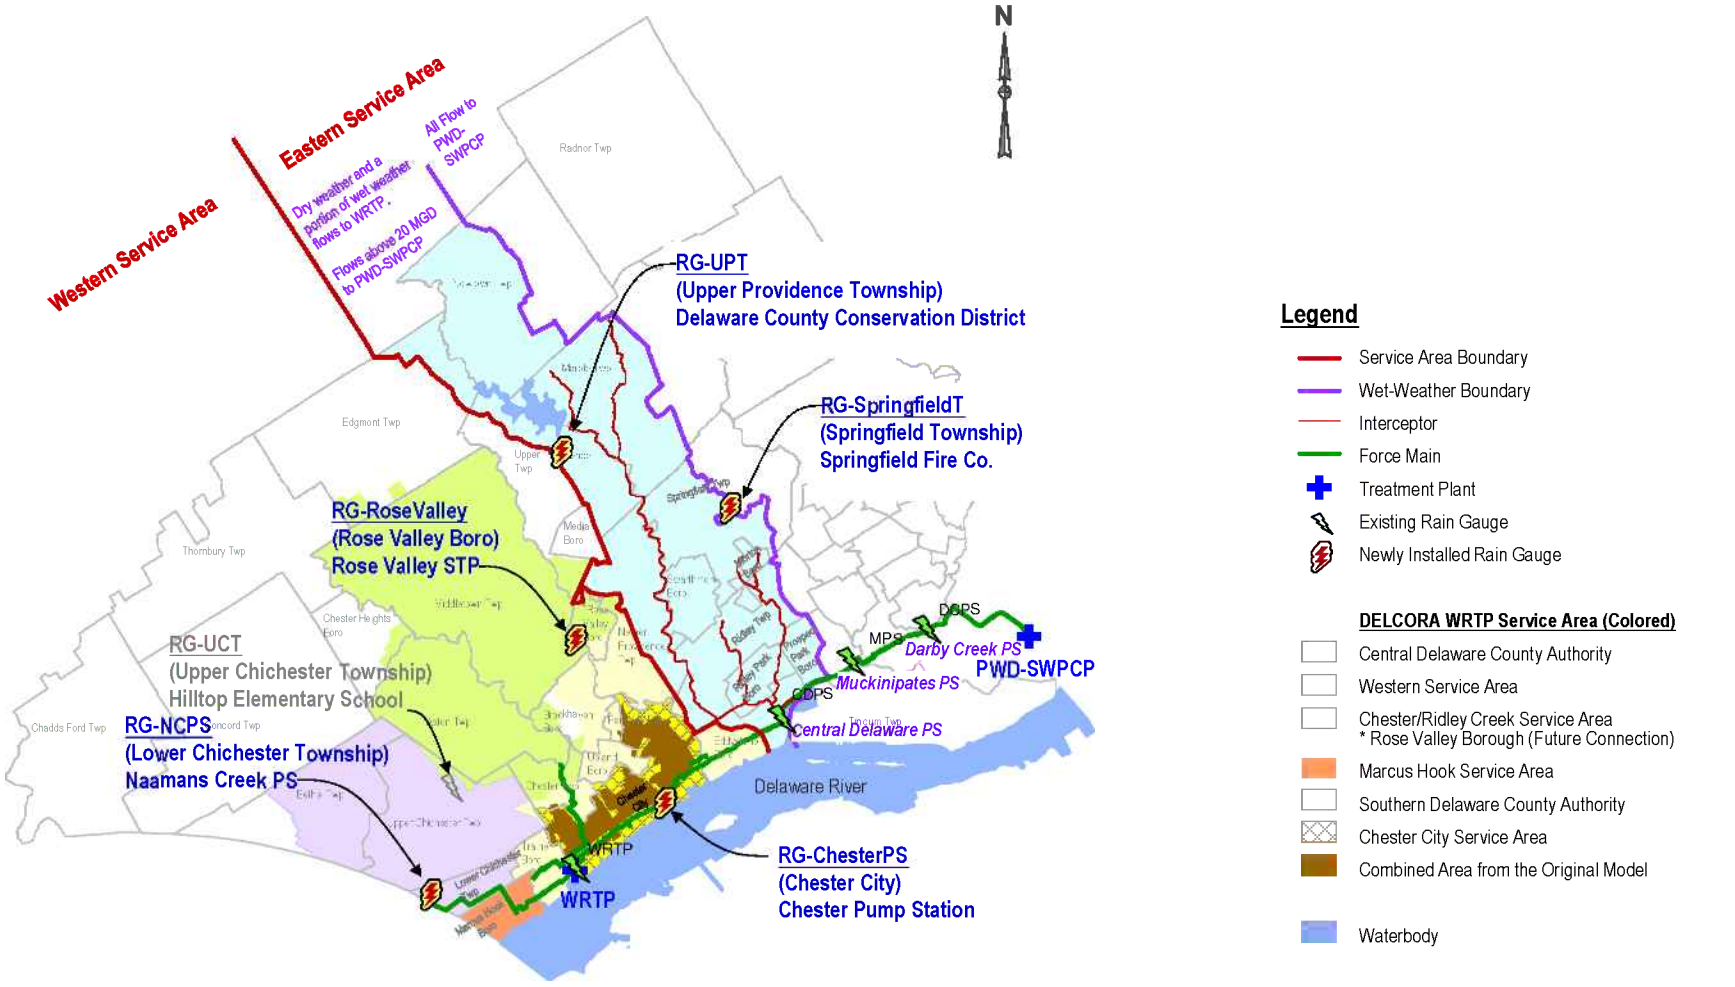

Figure 2 shows rainfall amounts at each rain gauge in each month for January, February and March. It is obvious that rainfall in the area has significant spatial and temporal variance. As an example, during this reporting period, the rain gauge at the Chester Pump Station (Chester PS) recorded a total rainfall of 7.63 inches while the gauge at the Upper Providence Township (UPT) recorded 9.23 inches. **Figure 3** shows the 1-hour rainfall profile for all of the 5 rain gauges.

Table 2: Rainfall Event Summary, 1/1/17 - 4/1/17

	Rain Event Starting Time	Rose Valley	Chester-PS	NCPS	Springfield	UPT
1	1/2/2017 4:25	0.9	0.78	0.95	0.84	0.93
2	1/10/2017 12:20	0.4	0.25	0.42	0.23	0.39
3	1/11/2017 20:05	0.21	0.22	0.33	0.18	0.28
4	1/17/2017 10:15	0.51	0.29	0.41	0.66	0.57
5	1/20/2017 11:35	0.28	0.19	0.26	0.19	0.11
6	1/21/2017 23:15	0.89	0.82	0.95	1.02	1.01
7	2/7/2017 9:45	0.06	0.03	0.07	0.1	0.08
8	2/9/2017 1:35	0.5	0.53	0.65	0.37	0.45
9	2/11/2017 10:30	0.06	0	0	0.12	0.31
10	2/12/2017 9:50	0.23	0.21	0.27	0.31	0.4
11	2/25/2017 16:30	0.6	0.59	0.25	0.69	0.66
12	2/28/2017 11:55	0.4	0.19	0.25	0.22	0.33
13	3/10/2017 7:00	0.37	0.31	0.38	0.36	0.29
14	3/14/2017 4:30	0.35	0.67	0.67	0.1	0.01
15	3/16/2017 9:20	0.24	0.17	0.54	0.41	0.34
16	3/26/2017 22:00	0.16	0.14	0.16	0.15	0.28

18	3/30/2017 20:50	2.18	1.83	2.51	1.83	2.27
	Subtotal (1/1/17-4/1/17)	8.79	7.63	9.56	8.44	9.23

Figure 2: Rainfall Event Summary, 1/1/17 - 4/1/17

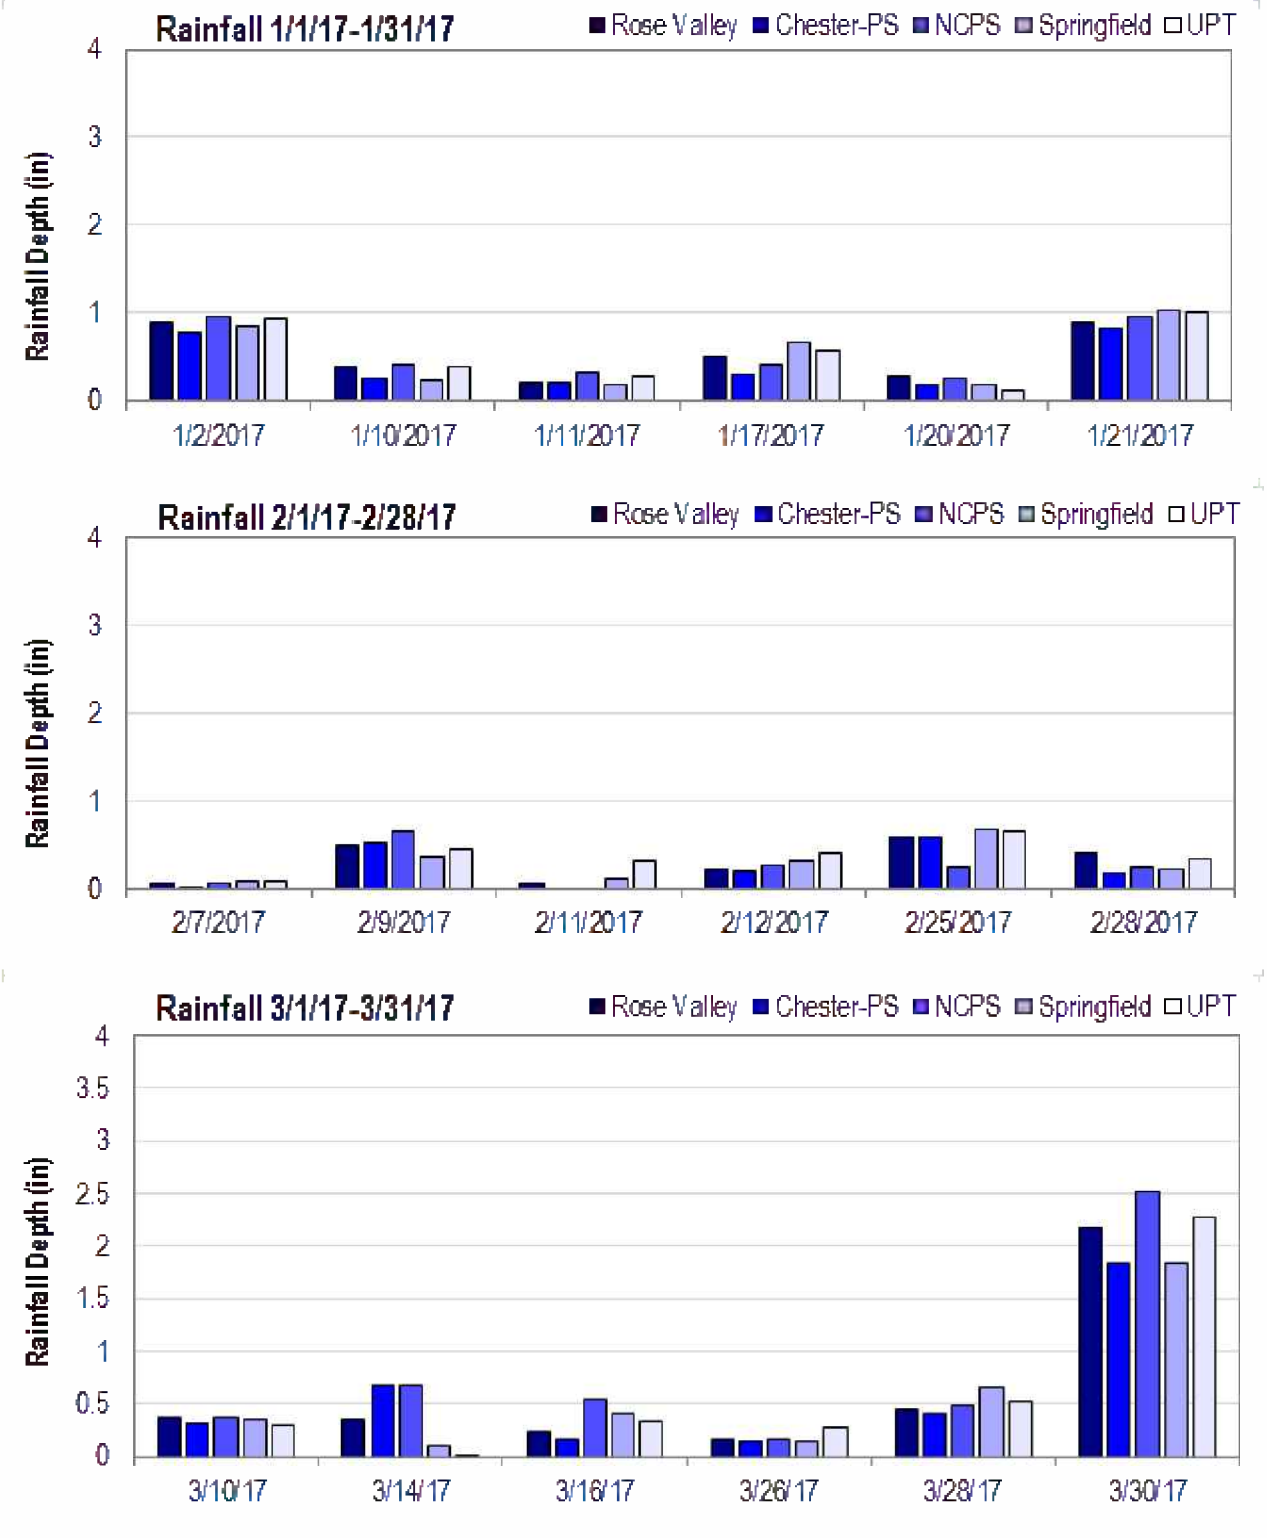

Figure 3: Hourly Rainfall Profile

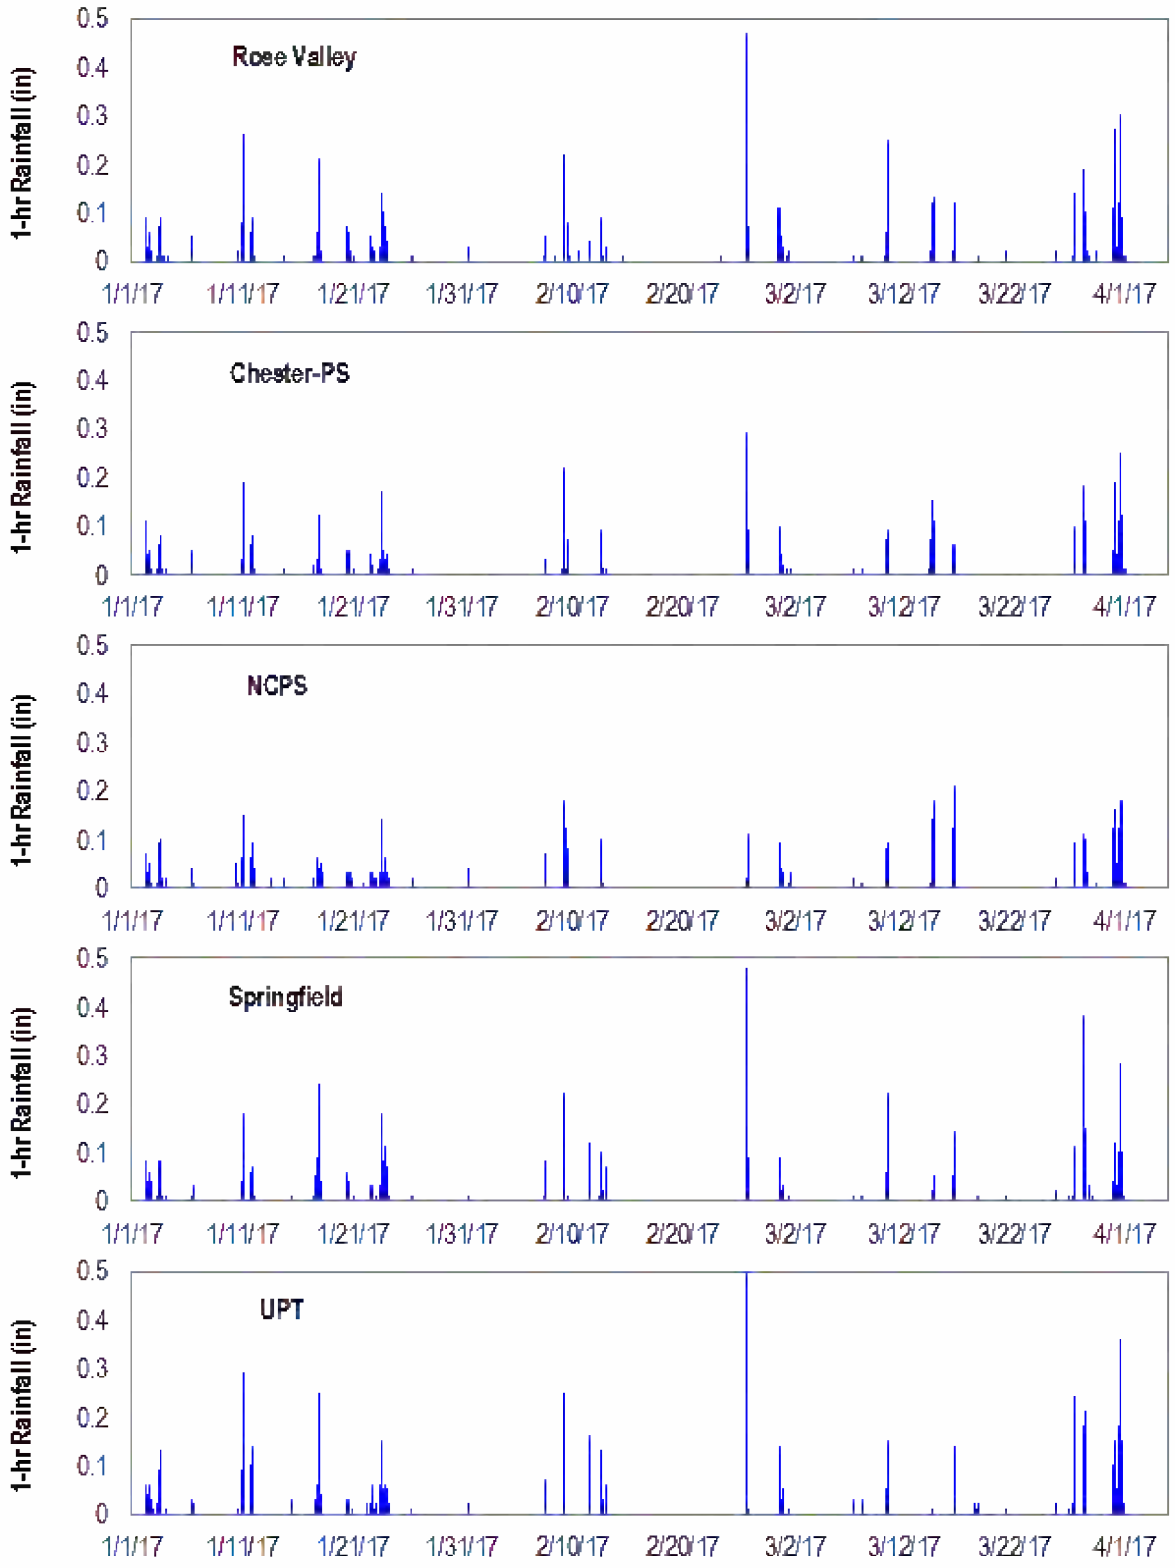

2.3.1 Rainfall Return Frequency

Rainfall return frequency was analyzed for rain gauges RG_NCPS and RG_UPT because they usually record greater rainfall amounts than the others. The frequency analysis was also performed for RG_ChesterPS because it is located in the combined area.

Figure 4 shows Duration-Depth-Frequency (DDF) plot for RG_NCPS. One storm was recorded with total precipitation volumes greater than 1 inch. The event (3/30/17) is less than a 1-year event.

Figure 4: Duration-Depth-Frequency (DDF) Plot, RG_NCPS

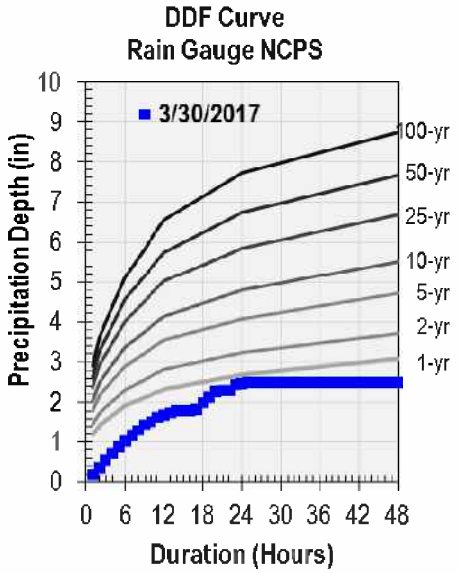

Figure 5 shows two Duration-Depth-Frequency (DDF) plots for RG_UPT. Two storms were recorded with total precipitation volumes greater than 1 inch. Both events (1/22/17 and 3/31/17) are less than 1-year events.

Figure 5: Duration-Depth-Frequency (DDF) Plot, RG_UPT

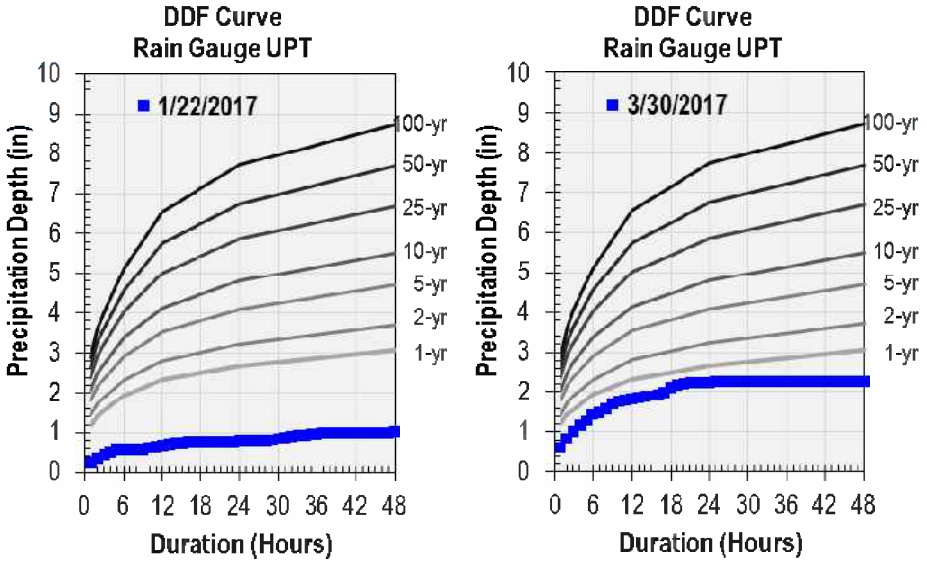

Figure 6 shows Duration-Depth-Frequency (DDF) plot for RG_ChesterPS. Only one storm (11/29/17) was recorded with a total precipitation volume greater than 1 inch. It is less than a 1-year event.

Figure 6: Duration-Depth-Frequency (DDF) Plot, RG_Chester PS

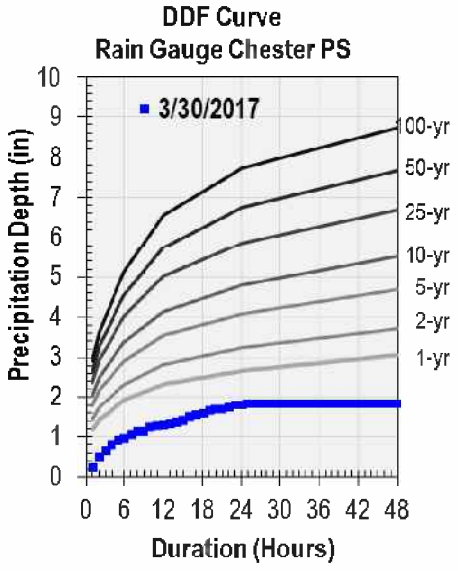

Figure 7 shows two Duration-Depth-Frequency (DDF) plots for RG_Springfield. Two storms (1/22/17 and 3/30/17) were recorded with a total precipitation volume greater than 1 inch. They are both less than a 1-year event.

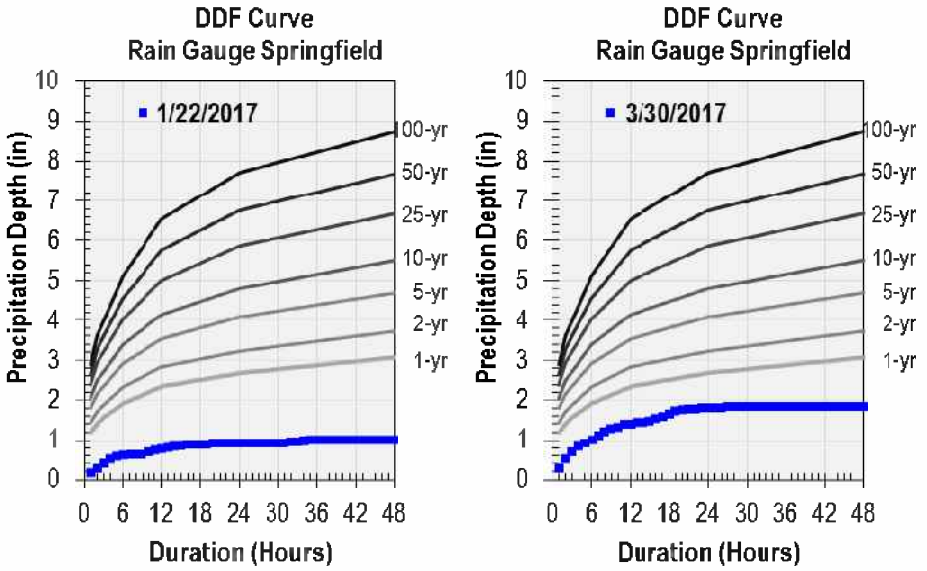
Figure 7: Duration-Depth-Frequency (DDF) Plot, RG_Springfield



Section 3 Flow Meter Monitoring

3.1 Flow Monitoring Program

The site locations of the existing and newly installed flow meters are shown in **Figure 8**. **Figure 9** shows the newly installed flow meters on a larger scale, mostly in the combined area. These new meters were installed to investigate surface runoff from the combined area and CSO discharges, rainfall-derived inflow and infiltration (RDII) from the separated area, and system response to the wet weather conditions. The schematic of the newly installed flow meters is included in **Figure 10**.

The newly installed flow meter locations are categorized into the following four types:

- Category 1: Located on the influent pipe to CSO regulators, this is to measure the influent flow to CSO regulators and for combined area runoff calibration. Sixteen (16) meters were installed for this category.
- Category 2: Located on the effluent pipe and overflow pipe of CSO regulators, this is to measure the CSO overflows and calibrate CSO regulator parameters. Twelve (12) meters were installed for this category. They are on the effluent and overflow pipe of CSOs 02, 03, 05, 08, 14, & 19.
- Category 3: Located on the side-line from the combined areas (flows from the combined area tie into interceptor instead of CSO regulator). This is to measure flows from the combined area and to calibrate combined area runoff parameters. Two (2) meters were installed for this category.
- Category 4: Located upstream of the combined area, this is to measure flows from the upstream separated area for RDII characterization. Three (3) meters were installed for this category.
- Category 5: Located in the main interceptors to measure level and flows in the major interceptors. Five (5) meters were installed for this category.

One meter was proposed at manhole MH3029 to measure flow from the separated area upstream of the combined area (CSO#018). The site was severely surcharged during field investigation. Meanwhile it was found that at manhole MH3002 (four manholes upstream of MH3029, approximately 800 feet upstream) another CSL flow meter (Ridley Creek MH-28) was already installed for DELCORA. It was determined that instead of installing a new flow meter around the site, the team will use the existing meter Ridley Creek MH-28 for this flow monitoring program.

In total, 39 flow meters are included in this monitoring program. Details of the installed flow meters are included in **Table 3**.

3.2 Flow Meters Field Calibration/Verification Procedures

As part of the operation of flow meters, verifications of meter accuracy are performed on a regular basis. Calibrations are performed at a minimum every eight weeks, or more as needed.

The procedure used for performing meter calibrations is outlined below. This procedure only defines the required result. Any specific equipment function issues should be referred to the equipment manual or the manufacturer's technical support department.

Table 3: Details of the Newly Installed Flow Meters

Figure 8: Existing and Newly Installed Flow Meter Locations

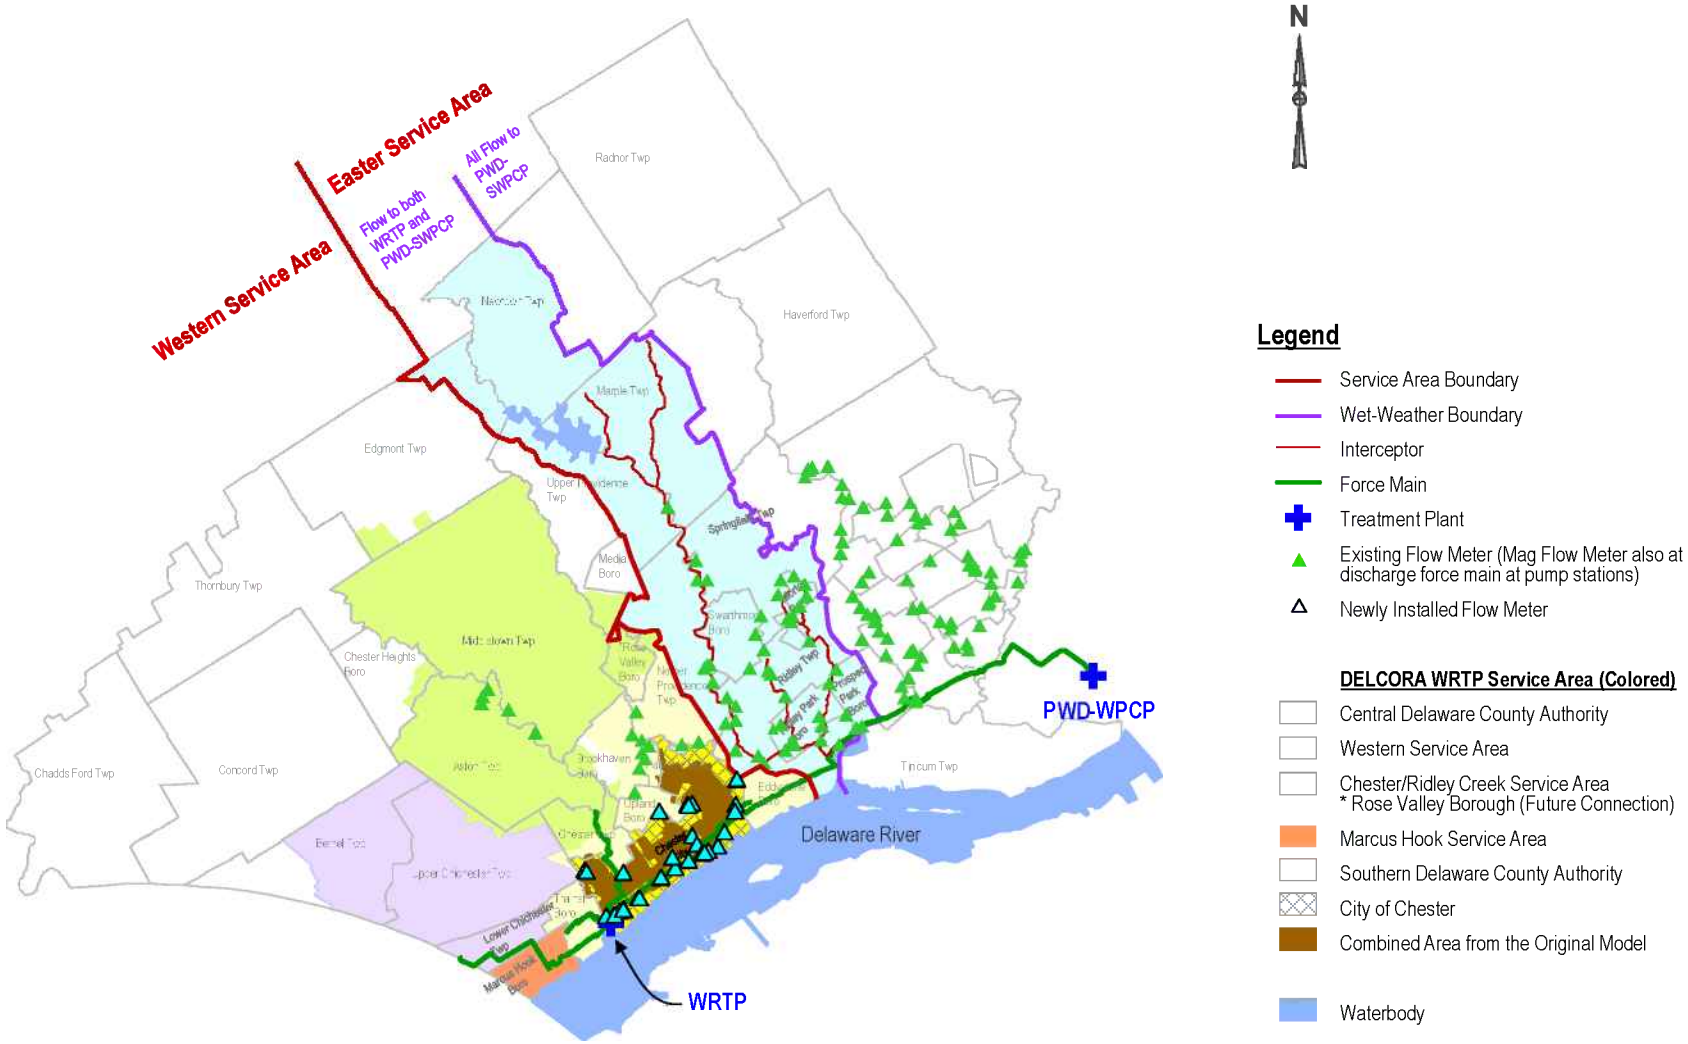

Figure 9: Newly Installed Flow Meter Locations

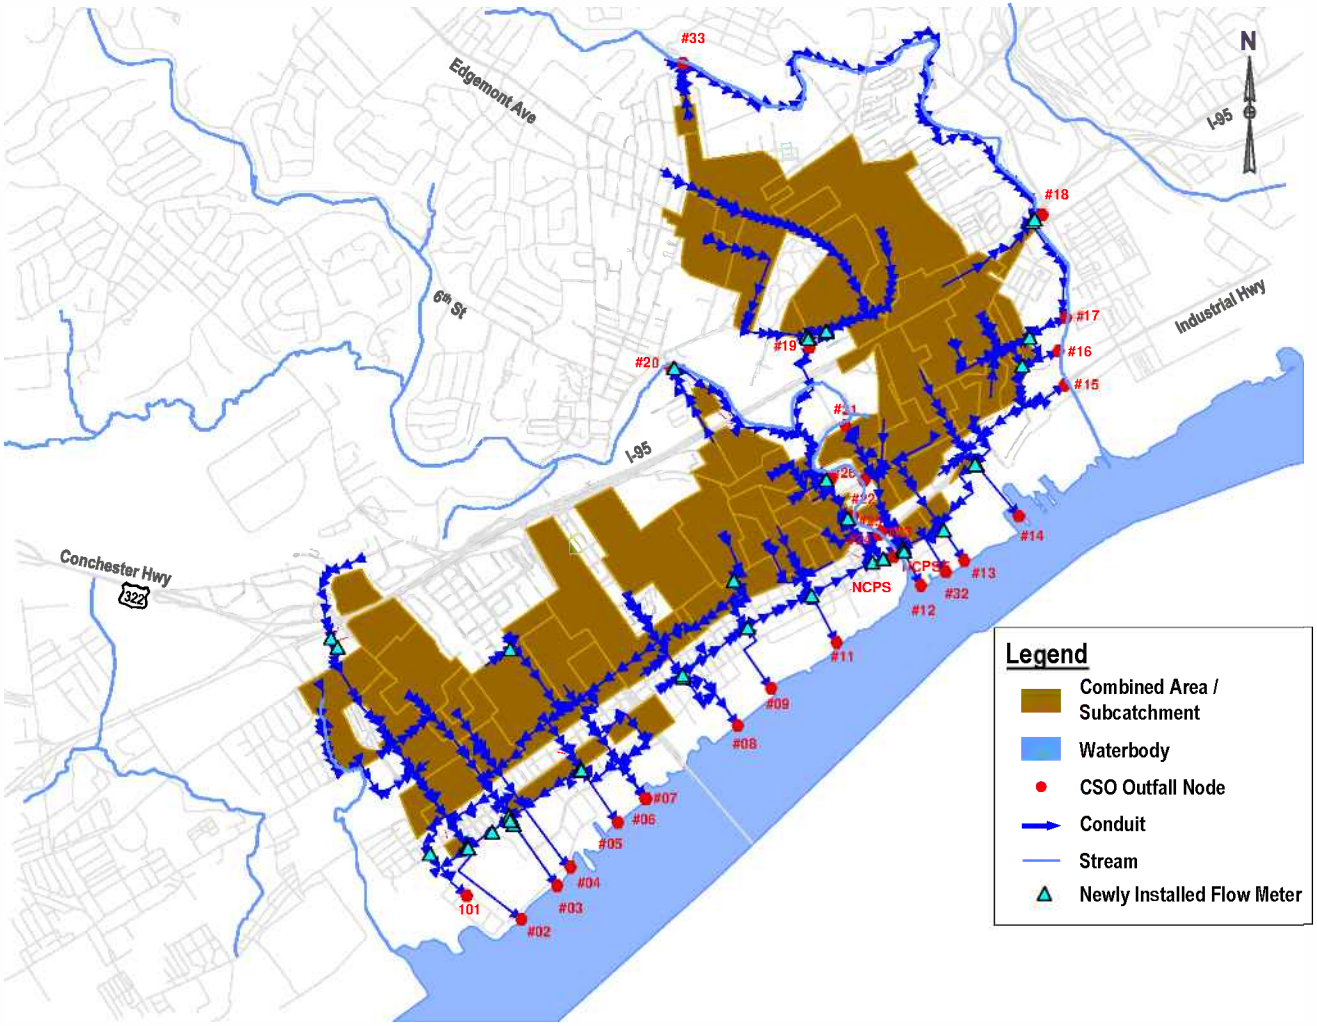

Figure 10: Flow Monitoring Schematic

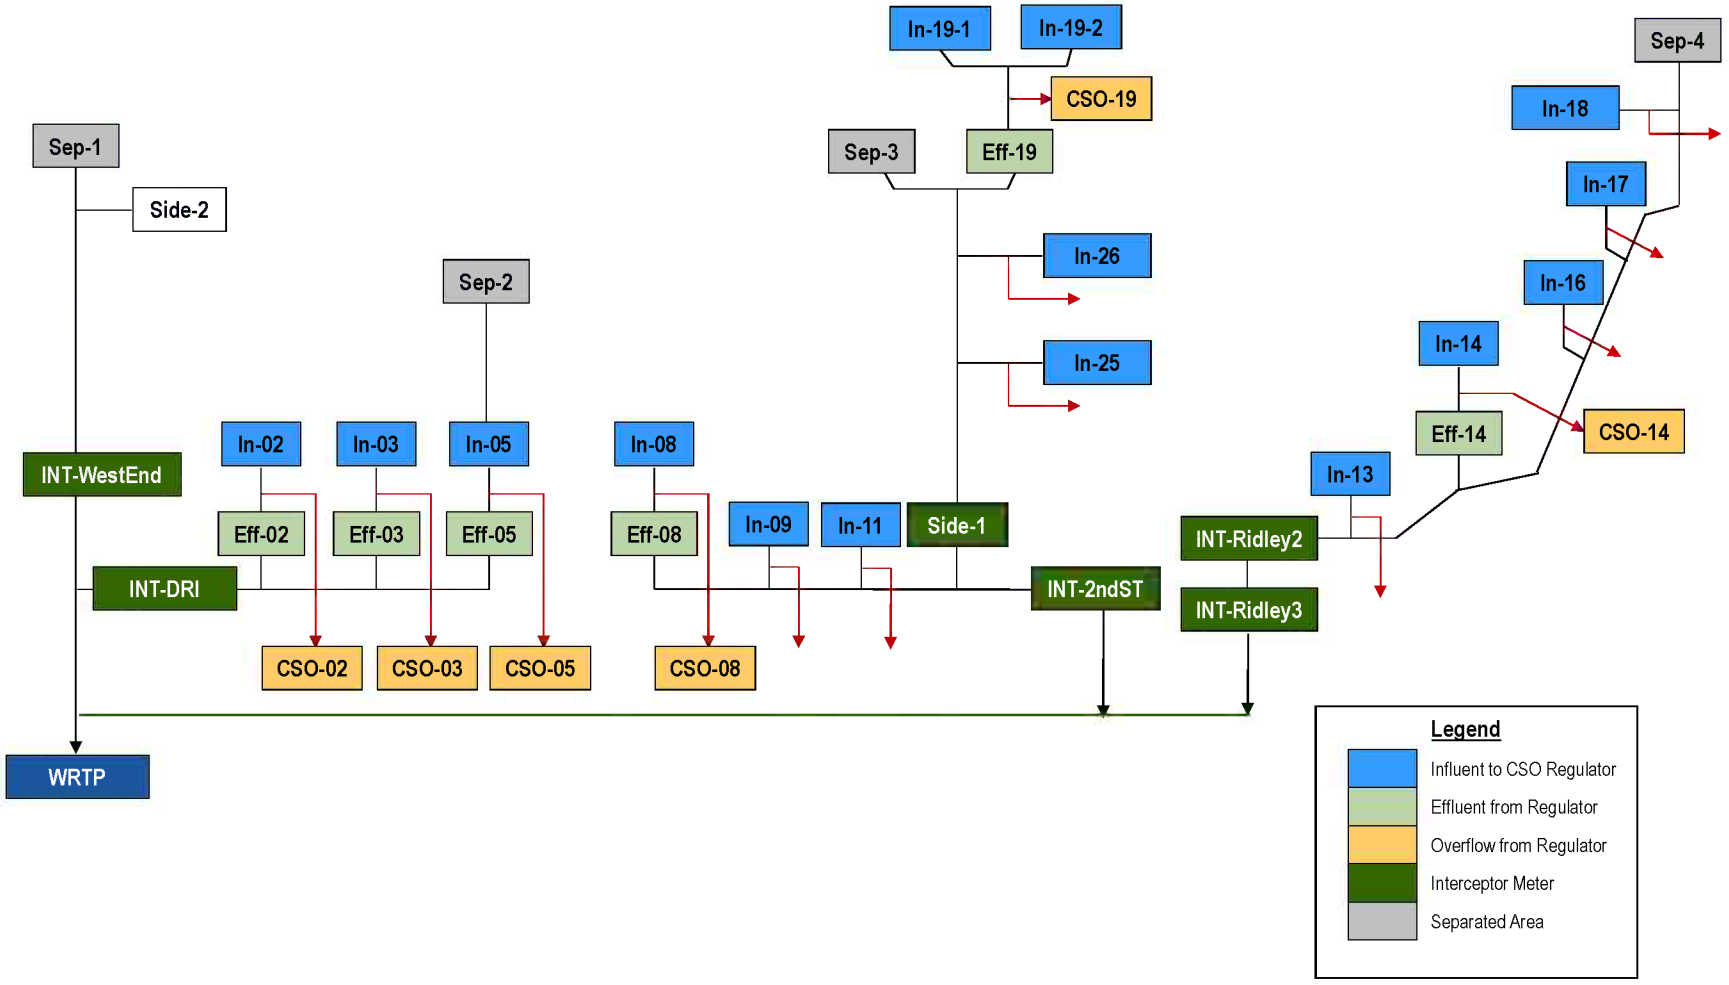

Manually Downloaded Meters
This method is used for any meter that cannot be interrogated remotely by the data analyst. Field technicians use the *Daily Field Download Sheet* for recording the calibration results.

- Record the date.
- Record the field time, which is the local time.
- Record the meter time.
- Record the instantaneous depth reading from the meter.
- Measure the peak velocity.
- Record the instantaneous average or peak, whichever is applicable.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Remote Connection Meters
This method is used for any meter that can be interrogated remotely. The data analyst uses the *Daily Field Download Sheet* for single depth and velocity meters and the *Multi- Sensor Calibration Sheet* for meter types that record multiple depth and/or velocity readings.

- Fill all site visit information fields on form.
- Have the field tech measure the depth of flow and record with time.
- Record the time and instantaneous depth reading from the meter or the depth sensor, whichever is applicable. All available depth sensors should be activated and compared to the field measurement.
- Have the field tech measure the peak the velocity or have them perform a velocity profile if the depth is sufficient then record with time.
- Record the time and instantaneous velocity reading from the meter or the velocity sensor, whichever is applicable. All available velocity sensors should be activated and compared to the field measurement.
- Note any service performed at the site, included sensor scrubbing.

The resulting meter readings should be within 0.25" for depth and within 10% for peak-to-peak or average-to-average for velocity. Should readings be outside these guidelines, troubleshooting is conducted per the manufacturer guidelines. If this does not resolve the discrepancy, the data manager is notified.

Special Cases

- Blind Verifications: A blind verification occurs when a field technician's only role is to measure the depth and velocity of the flow and report the values to the data analyst. In these cases, the crew is "blind" to what the meter is reading. The data analyst will then compare the readings to current/recent data or live readings. Should the blind verification be out of tolerance, the analyst can direct the crew to perform additional blind verifications or perform a conventional verification and/or troubleshoot as necessary.

- Installations/Removals: When installing or removing meters, the above calibration method should be used for three consecutive verifications, performed at 5 minute intervals.
- Third Party Audit: When performing a calibration at a meter that is not maintained by CSL and where CSL is to verify the meter function, the CSL Audit report should be used.

3.3 Flow Monitoring Data Summary

Flow, level and velocity data are received for each flow monitoring site at 5-minute intervals (Sep-4 has 15-min interval data). Metering data is analyzed for dry weather flows (DWF), hourly peak flows, and hourly peaking factors for each monitoring site. A "dry weather" condition was defined as a period with no precipitation that begins three days after the last wet weather event and lasts until the beginning of the next precipitation event.

Table 4 shows dry weather flow (DWF), hourly peak flow, hourly peaking factor and flow condition observations.

The dry weather flows are also shown in the schematic in **Figure 11**. Generally the downstream dry weather flow is greater than the upstream locations for all of the meters. For meters immediately upstream and downstream of CSO regulators, the upstream and downstream dry weather flows should be similar. **Figure 12** shows the influent and effluent from CSO#08 as an example to indicate that the dry weather of the two are similar.

The hourly peaking factor in the combined area is in the range of 7 to 99 and average at 27. The hourly peaking factor for the interceptor is between 2.8 and 5.2 with an average of 3.9. The hourly peaking factor is between 2.7 and 3.6 for the separated area, with an average of 3.1.

A detailed hydrograph and scattergraph for each flow monitoring site is shown in **Figure 13** to **Figure 51**, each includes:

- The flow hydrographs show hourly flow and rainfall profile. Hourly Rainfall data is included for the convenience of reviewing flow response to the wet weather conditions. Hourly flow and rainfall were calculated from the 5-min interval.
- The scattergraphs (based on 5-min data, excepting 15-min data for Sep-4) are essentially a plotting of flow rate versus depth. This plotting helps to understand the flow patterns and conditions on the individual monitored sewer pipes.
- For CSOs 02, 03, 05, 08, 14, & 19, flows including influent, effluent and overflows were plotted in the same plot.

Table 4: Flow Monitoring Summary

Meter ID	Hourly Peak (MGD)DWF	DWF (MGD)	Hourly Peaking Factor	Comments
In-02	6.66	0.28	23.66	Free flow most of the time
Eff-02	0.68	0.28	2.43	Surcharged under common conditions

Section 1 Introduction

1.1 Background of DELCORA's Facilities

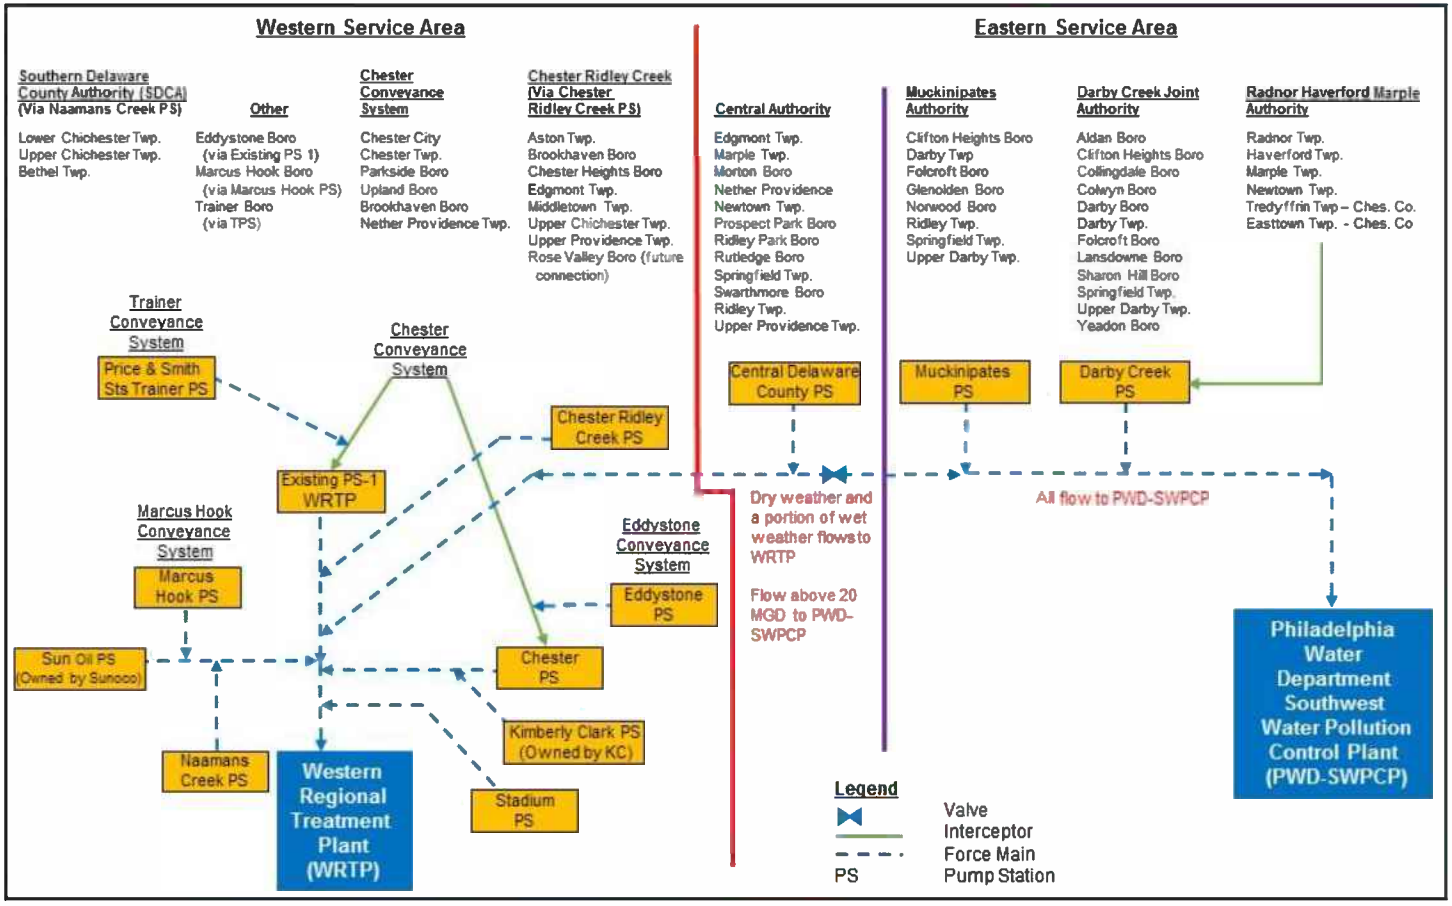
Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1. The total service area served by DELCORA, as shown on Figure 1-2, is approximately 82,977 acres which illustrates that DELCORA serves a significant and widespread portion of Delaware County.

The combined sewer area simulated in DELCORA's existing Hydrologic and Hydraulic model is located within the City of Chester and consists of a drainage area of approximately 1,510 acres. It comprises approximately half of Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows. The location of Chester City's service area is illustrated on Figure 1-2.

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western service area discharges to DELCORA's Western Regional Treatment Plant (WRTP). The Eastern service area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWDSWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are directed to the PWDSWPCP. As such, dry weather flows and a portion of the wet weather flows (total flow less than 20 MGD) from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

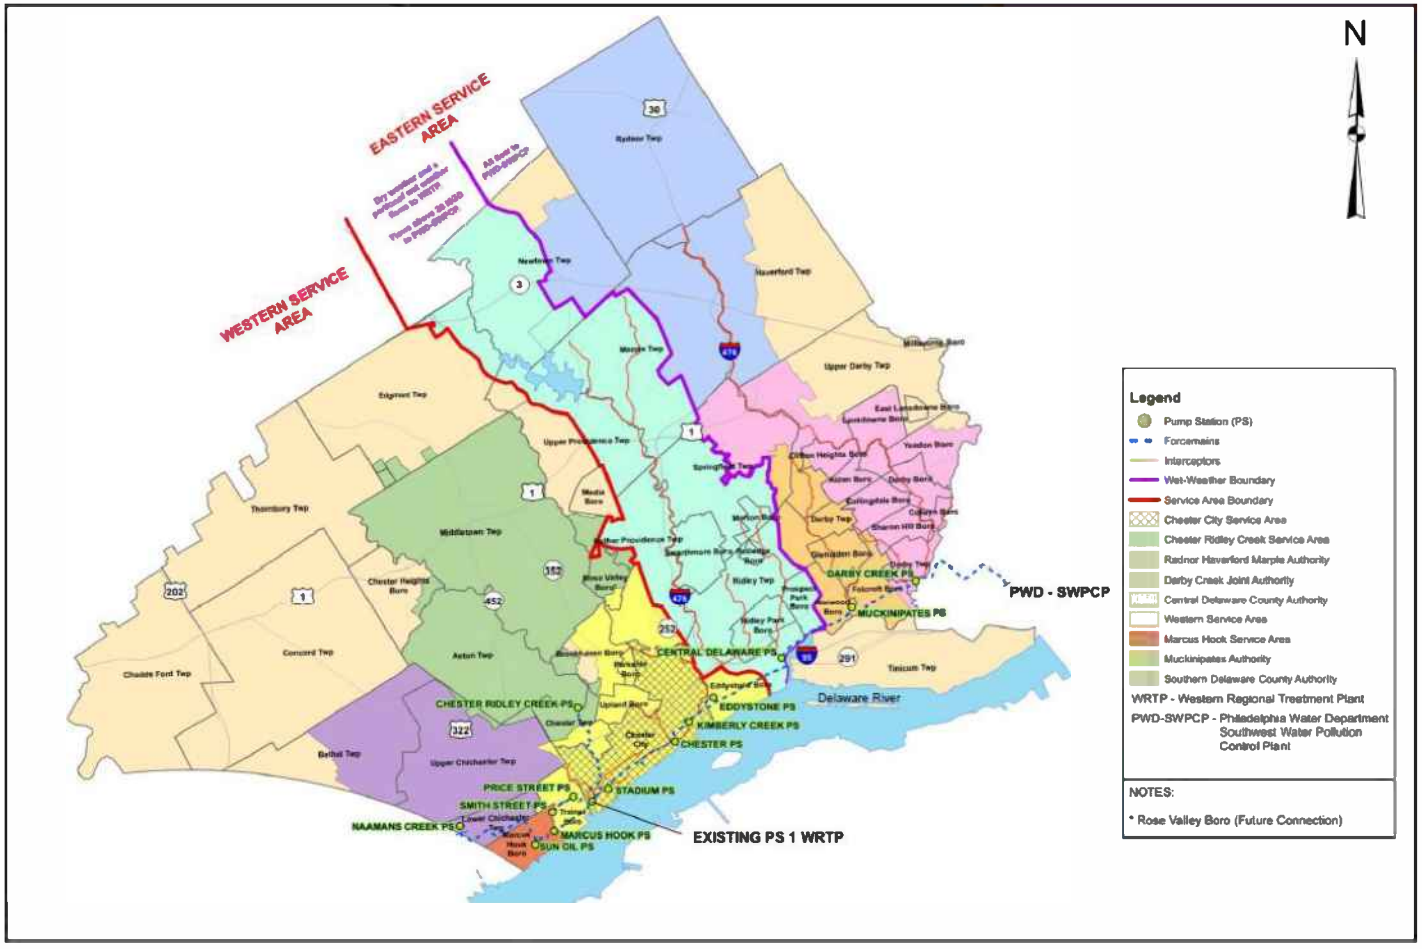
There are a total of 26 combined sewer overflow outfalls listed with 25 discharge points (Outfall #009 and #010 both discharge at Outfall #009) in DELCORA's existing National Pollutant Discharge Elimination System (NPDES) Permit. Under its NPDES Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow outfalls (#002-#026, #032, #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

Figure 1-1: DELCORA's Conveyance System



CSO Long-Term Control Plan Delaware County Regional Water Quality Control Authority	GREELEY AND HANSEN WESTON SOLUTIONS	Figure 1-1 DELCORA'S CONVEYANCE SYSTEM

Figure 1-2: DELCORA's Service Area



Part C – Other Requirements, Section V – Combined Sewer Overflows of the NPDES Permit details DELCORA's responsibilities with respect to the CSO system including reporting, continued implementation of and continued compliance with the Nine Minimum Controls (NMC), and implementation of the existing Long-Term Control Plan (LTCP) dated April 1999 and the July 2008 addendum to the LTCP until the updated LTCP is approved.

1.2 Consent Decree

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated LTCP to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. Consent Decree Paragraph V.A.15 (Water Quality Model Plan) requires that within ninety (90) days after EPA reviews and approves the Alternatives Evaluation Approach, DELCORA shall submit to EPA and PADEP a Water Quality Model Plan for review and approval. Details of the Consent Decree requirements for Water Quality Modeling and Monitoring Plan are respectively found in Section 2.1 and 3.1.1.

1.3 CSO and Receiving Water System Description

The combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's serviced area. The combined wastewater/stormwater system in the City of Chester is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, and CSO regulators and CSO outfalls. The City owns, operates and maintains the inlets, stormwater-only sewers that connect to the combined sewer system and any stormwater-only outfalls. The City is also responsible for the maintenance and cleaning of the streets, planning, zoning, and development controls. The Chester CSO system contains 26 permitted outfalls and they discharge to three receiving water bodies: the Delaware River, Chester Creek, and Ridley Creek. However, there are only 25 CSO discharge locations, as CSO #010 discharges to the Delaware River through CSO #009. Figure 1-3 depicts the locations of CSO regulators and outfalls that are DELCORA's responsibility. Figure 1-3 also provides a sewer system characterization and illustrate the breakdown of each outfall and how each drainage area has combined sewers and separate sewers. Figure 1-4 is a schematic of the Chester CSO system and shows the outfalls and the interceptors that are connected to each CSO.

1.4 Work Plan Purpose and Objectives

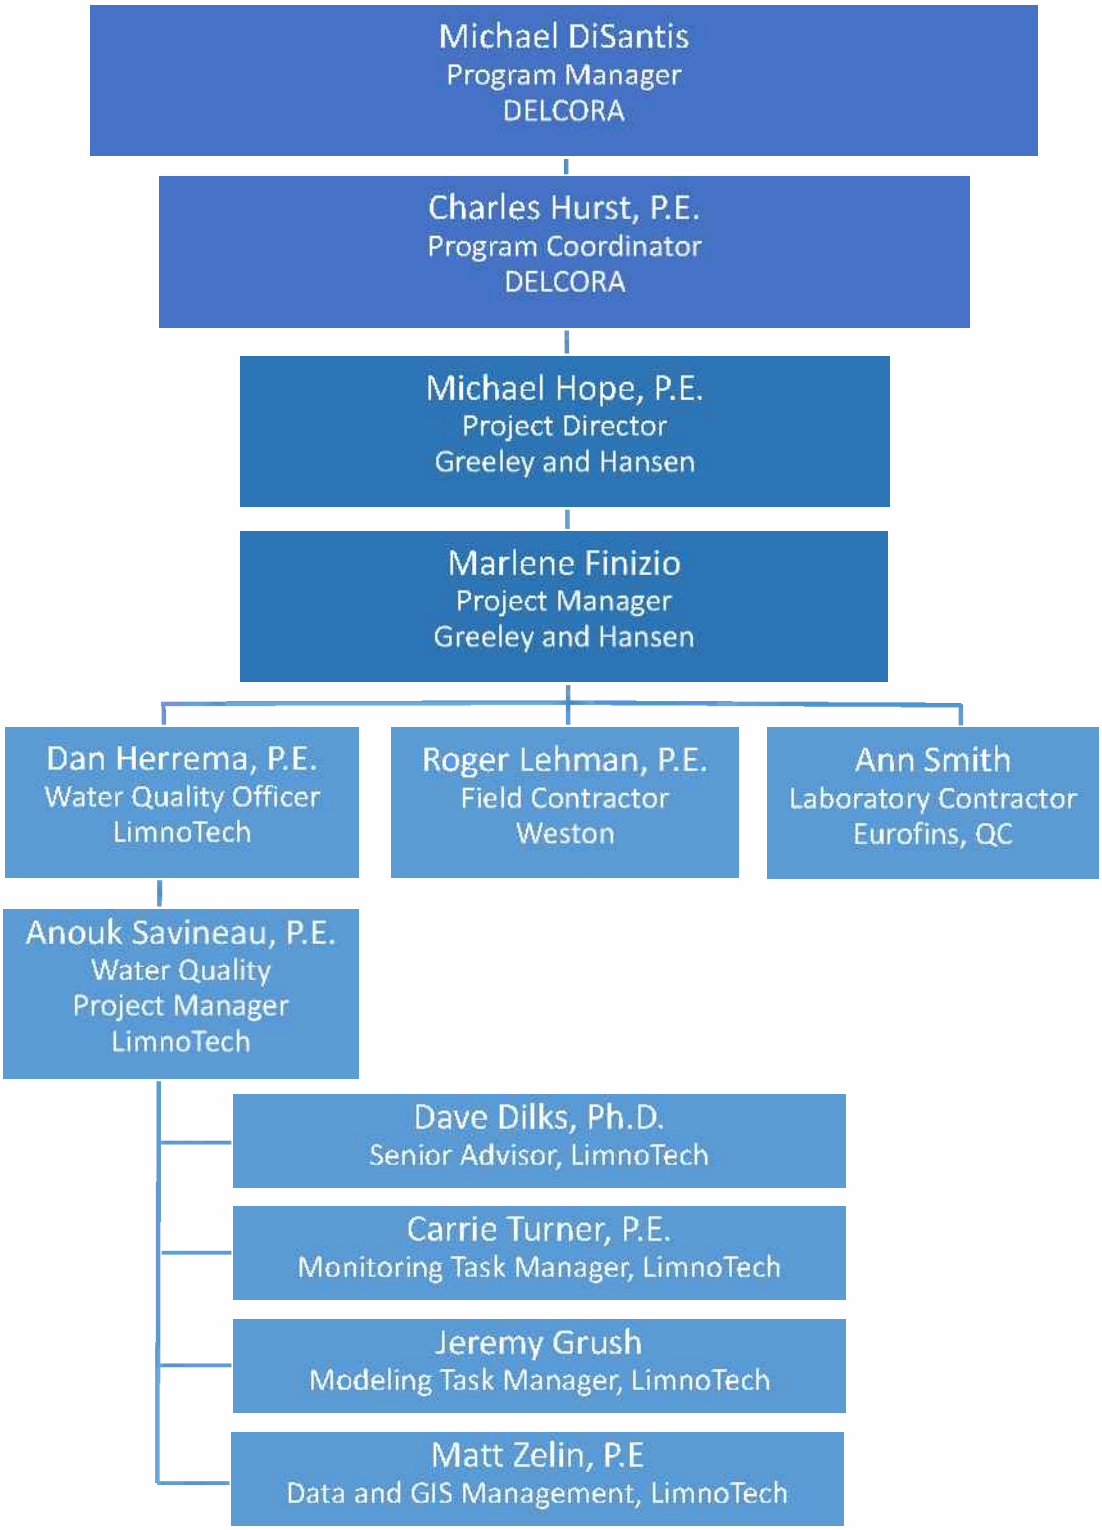
The purpose and objective of the Water Quality Monitoring and Modeling Work Plan is to provide a blueprint for the water quality modeling and monitoring work that will be consistent with EPA requirements as listed in DELCORA's Consent Decree.

1.5 Project Team Organization

The proposed project team organization, including key project personnel and their corresponding responsibilities, are shown in Figure 1-5.

.

Figure 1-5: Project Team Organization



Section 2 Water Quality Model Plan

2.1 Regulatory Requirements

2.1.1 Consent Decree Requirements

The Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania on August 17, 2015, and was approved by the Federal District Court on November 10, 2015. The Consent Decree requires DELCORA to complete and submit a revised and updated LTCP to the USEPA and the PADEP for review and approval. Consent Decree Paragraph V.A.15 (Water Quality Model Plan) requires that within ninety (90) days after EPA reviews and approves the Alternatives Evaluation Approach, DELCORA shall submit to EPA and PADEP a Water Quality Model Plan for review and approval. For each water body[1] in which the Demonstration Approach is to be used, the Water Quality Model Plan shall address:

i. Background, Scope and Purpose, Description of System;

ii. Water quality modeling software to be employed;

iii. Model configuration and development, including reaches to be modeled, and segmentation and boundary conditions;

iv. Calibration and validation (dry weather and wet weather, including events and data to be employed, detailed information regarding all additional data collection activities (if needed), quantitative and qualitative calibration criteria, and utilization of H&H Model outputs;

v. Use of the Water Quality Model to evaluate Typical Year instream conditions for each identified pollutant of concern;

vi. Schedule for model development and implementation, including integration into LTCP development consistent with other dates required pursuant to the Consent Decree.

The Consent Decree further specifies that within sixty (60) days after the approved Water Quality Model Plan is fully implemented according to the schedule included therein, DELCORA shall submit to EPA and PADEP a Water Quality Model Report for review and approval pursuant to Section VI (Review and Approval of Submittals) which shall specifically address each item set forth in Paragraph 15(a)(i)-(vi).

[1] Water bodies include the Delaware River, Chester Creek and Ridley Creek.

2.2 Model Selection/Software

This section describes the objectives and criteria used to select the appropriate modeling approach and model software.

2.2.1 Objectives

The objective of the water quality modeling is to assess the impacts of the DELCORA combined sewer system overflows on the bacteria concentrations in the receiving waters, both under existing conditions and future LTCP alternatives conditions, and assess these impacts against applicable water quality standards. In order to achieve these objectives, a linked CSO, watershed, and receiving water model will be created. The CSO model, also called the "H&H" model, is currently being developed for the Long Term Control Plan, with calibration and validation to be completed in April 2017. The H&H model is designed to simulate CSO discharges from the DELCORA service area within the City of Chester. The watershed model is a new model that will be created to model the non-CSO areas that are within the DELCORA service area and the extent of the receiving water model. The receiving water quality model is also a new model that will be developed to simulate the bacteria concentrations in the receiving waters, including the Delaware River, Chester Creek and Ridley Creek. The receiving water quality model will account for bacteria load contributions from various sources such as upstream, CSO, and stormwater loads, as well as processes that account for bacteria transport and decay.

There are several objectives to consider when selecting appropriate modeling software for the watershed and receiving water model, including:

- Technical objectives: Can the model software adequately represent the physical, chemical, and temporal characteristics of the project site? Can it address the complexities of the project site without being overly complex or overly simplistic?
- Regulatory objectives: Can the model software produce results that can be used to evaluate water quality against applicable water quality standards? Does it have a proven track record with similar regulatory projects? Will it help fulfill regulatory requirements as described in the Consent Decree?
- User objectives: Does the end user have the necessary hardware and expertise to properly apply the model software to its fullest potential? Are there financial constraints to be considered with the model?

These objectives and how they were applied to select the watershed and receiving water models are further described in sections 2.2.3 and 2.2.4 respectively. The selection of the CSO H&H model was previously described in the H&H Model Update and Calibration Plan (DELCORA, 2015).

2.2.2 Review of Existing Studies

There have been numerous water quality modeling studies performed on the Delaware River and its associated tributaries. Some of these studies were used to inform the DELCORA work plan, and may be used in the future to further inform or develop the water quality modeling and monitoring efforts. A brief overview of these studies is provided below.

- The Philadelphia Water Department's "Tidal Waters Water Quality Model for Bacteria and Dissolved Oxygen Model" was completed in June 2015 (PWD, 2015) using EFDC as the model framework. The model was developed in response to requirements in the 2011 Consent Order and Agreement between the Pennsylvania Department of Environmental Protection (PDEP) and the Philadelphia Water Department (PWD). The objectives of the model were to represent bacteria and DO in the tidal receiving waters. The model's extent is from the head of tide at Trenton, New Jersey to near Delaware City, Delaware. Also included were 28 tributaries to the Delaware River including eight miles of the tidal portion of the Schuylkill River.
- The Delaware River Basin Commission's "DYNHYD5 Hydrodynamic Model (Version 2.0) and Chloride Water Quality Model for the Delaware Estuary" was completed in December 2003 (DRBC, 2003). The model was used for the development of the Stage 1 TMDLs for polychlorinated biphenyls (PCBs) for the Delaware River Estuary. The model's extent is from Trenton, NJ to the Mouth of the Delaware River. PCBs and chloride were the only water quality parameters modeled. Note that DRBC is currently evaluating the nutrient criteria strategy for the Delaware River and has an initiative to create a new eutrophication model to address dissolved oxygen issues in the river (DRBC, 2012). The new model would include an improved hydrodynamic model of the tidal Delaware River and a dissolved oxygen and nutrient water quality model.
- The University of Delaware's Center for Applied Coastal Research developed a "Hydrodynamic Model of Delaware Bay and the Adjacent Coastal Region" (UD 2011) using the Regional Ocean Modeling System (ROMS) framework. The latest model update was performed in 2011, with other similar studies performed since the 1990s. The purpose of this model is further characterize the hydrodynamics of the Delaware Bay and surrounding area. Salinity is the only water quality parameter modeled. The models domain extends into the offshore into the Atlantic Ocean and into the Delaware Bay.
- Hydraulic models have also been created for the purpose of FEMA's National Flood Insurance Program to analyze risk of flooding. These models were developed for FEMA by federal contractors. For Chester and Ridley Creek, the most recent modeling effort is likely from the 1970's. These models were only used to assess flood risk so no water quality parameters are modeled. The model extent for these two creeks extends from their confluence with Delaware River upstream into Delaware County.

Limited topographic and bathymetric surveys were performed for these models which will be useful in characterizing the bathymetry of Chester and Ridley Creek.

2.2.3 Watershed Model Selection

Many watershed model software packages are available and these models vary in their recognition by USEPA and their applicability to the Delaware River and its tributaries. The proposed watershed model framework for this project is EPA Storm Water Management Model (SWMM), which is supported by the USEPA and has been successfully applied by the project team at similar sites and for related purposes, including in East Rutherford, NJ, Washington, DC, and Richmond, VA. SWMM is a dynamic rainfall-runoff simulation model used for single event or continuous simulation of runoff quantity and quality from primarily urban areas (USEPA, 2015). A review of the Chester Creek and Ridley Creek watersheds using the USGS StreamStats[2] tool show that these two watersheds are 42% and 37% urban respectively. Additionally, the current H&H model for the DELCORA service area is also built using the SWMM software, so choosing SWMM for the watershed model provides consistency in the suite of models used by DELCORA.

A variety of enhanced SWMM platforms are available that integrate the EPA SWMM software with user friendly interfaces and GIS capabilities. For this project, PCSWMM, developed by CHI, will be used. Once the watershed model is built, the model files can be provided as PCSWMM or EPA SWMM files.

2.2.3.1 Attributes

The main attributes of the proposed watershed model are that it will be able to predict dry and wet weather flows and associated bacteria loads. The watershed model will provide necessary spatial resolution to account for different subcatchment physical characteristics such as slope, imperviousness, length and width, and soils. Additional, it will be able to predict variations in timing, peak flows, and flow volumes.

The inputs and outputs of the SWMM model are described in more detail in the following section.

2.2.3.2 Inputs and Outputs

Model inputs are site-specific estimates of environmental conditions or assumptions that influence modeled water quantity and quality. Model outputs are results of model calculations that describe conditions related to water quantity and quality. Table 2-1 describes the SWMM watershed model inputs and outputs that will be used for this project.

[2] http://water.usgs.gov/osw/streamstats/

Table 2-1: Watershed Model Inputs and Outputs

Process	Inputs	Outputs
Runoff Calculations	Area, width, imperviousness, slope, roughness, depression storage, soil infiltration, meteorology (precipitation, temperature)	Catchment runoff volume and flow rate, hydrograph of flow vs. time.
Water Quality Calculations	Event Mean Concentration for stormwater and CSO outfalls	Bacteria concentrations in dry and wet weather flows, pollutographs of pollutant concentration vs. time
Routing Calculations	Pipe and/or channel geometry, slope, roughness.	Dry and wet weather flow volumes and rates, hydrographs of flow vs. time

The runoff component of SWMM operates on a collection of subcatchment areas that receive precipitation and generate runoff and pollutant loads according to their landuse, landcover, and soil characteristics (USEPA, 2014). Additional information on the main model inputs that will have to be defined for the runoff component of SWMM are shown in Table 2-2.

Table 2-2: SWMM Runoff Model Inputs

Inputs	Source of Information
Area	Delineated in GIS using topography and sewer network data
Width	Calculated in GIS based on the watershed delineation
Slope	Calculated in GIS using topography
Imperviousness	Calculated in GIS using NLCD data or estimated from landuse data
Roughness	Based on published values for impervious and pervious area
Depression Storage	Based on published values for different land covers
Soil Infiltration	Based on soil data and characteristics published by USGS (SSURGO). The Horton method is the preferred method to account for infiltration losses for this project.
Meteorology	Precipitation, temperature, evaporation data obtained from nearby weather stations

To calculate the bacteria loads associated with the watershed flows, bacteria event mean concentrations (EMCs) will be assigned to the flows. An EMC represents the average pollutant (bacteria) concentration present in runoff. The appropriate EMCs will be obtained through the sampling efforts as described in Section 3.

For the purpose of this project, the predicted runoff from the watershed model will be directly connected to the receiving water quality model. In other words, routing through the pipe/channel system will not be simulated unless the calibration of the receiving water model demonstrates a need for additional resolution in flow timing is needed. If explicit routing is needed, pipe and/or channel attributes such as slope, roughness, or cross-sectional geometry will be obtained from DELCORA or field studies. Routing would further be accomplished by applying the kinematic or dynamic wave routing method.

2.2.4 Receiving Water Quality Model Selection

Many water quality model frameworks are available and these models vary in their recognition by USEPA, adaptability for project-specifics needs, and their applicability to the Delaware River and its tributaries. The proposed water quality model framework for this project is EFDC (Environmental Fluid Dynamics Code), which is supported by the USEPA and has been successfully applied by the project team at similar sites and for related purposes. It may be beneficial to couple EFDC with another model to reduce simulation run times. EFDC could be used to compute hydrodynamics and those results could be linked to the RCA (Row-column AESOP) water quality model for water quality calculations. This potential approach would reduce model run times by allowing for a longer time step and for a smaller water quality model extent. RCA, like EFDC, is a highly regarded water quality model that has been applied at numerous sites.

EFDC is a state-of-the-art finite difference model that can be used to simulate hydrodynamic and water quality behavior in one, two, or three dimensions in riverine, lacustrine, and estuarine environments (TetraTech 2007a, 2007b). The model was developed by John Hamrick at the Virginia Institute of Marine Science in the 1980s and 1990s, and it is currently maintained under support from the USEPA. The model has been applied to hundreds of water bodies, including Chesapeake Bay and the Delaware River. Recently, LimnoTech has successfully applied EFDC to a number of estuarine sites including Newark Bay, East Rutherford, NJ, and San Diego Bay. The EFDC model is both public domain and open source, meaning that the model can be used free of charge, and the original source code can be modified to tailor the model to the specific needs of a particular application. As a result, EFDC provides a powerful and highly flexible framework for simulating hydrodynamic behavior and water quality dynamics for the Delaware River and Chester Creek and Ridley Creek.

The RCA model is a part of a family of generalized water quality models developed by HydroQual, Inc. and known as AESOP (Advanced Ecological Systems Operating Program) (HydroQual, 2004). The RCA model framework is capable of simulating water quality dynamics on a fine-scale, multi-dimensional computational grid based on linkage to an external hydrodynamic model application. RCA is specifically designed to interface with the EFDC model via a series of binary files generated by the latter model. The general transport fields predicted by EFDC (or another hydrodynamic model) are used by RCA to advect and disperse water quality constituents throughout the water column.

2.2.4.1 Attributes

To compute the movement (transport) and concentrations of pollutants, a water quality model must represent the primary physical and kinetic processes that influence transport and pollutant concentrations. It is anticipated that the following processes will be necessary to represent in this model application:

- Loading of local bacterial pathogens from the watershed, MS4s, CSOs, treatment plant(s), and other known sources to Chester Creek, Ridley Creek, and the Delaware River;
- Transport of pathogens from the riverine portions of creeks to the Delaware River estuary;
- Transport of pathogens via tidal currents and mixing within the Delaware River estuary; and,
- Net losses of pathogens during transport.

These attributes are described in more detail in the following section.

2.2.4.2 Inputs and Outputs

Model inputs are site-specific estimates of environmental conditions or assumptions that influence modeled water quality. Model outputs are results of model calculations that describe conditions related to water quality. Table 2-3 below describes model inputs and outputs relating to the primary physical and kinetic processes described in the previous section.

Table 2-3: EFDC Model Inputs and Outputs

Water Quality Model Process	Related Inputs	Related Outputs
Bacterial pathogen loadings	Pollutant concentrations for: • Delaware River boundaries • Chester Creek upstream watershed • Ridley Creek upstream watershed • CSOs • MS4 areas • WWTPs	• Pollution in-stream concentrations
Transport of pathogens within the riverine portions of creeks	Flow rates for: • Creeks • CSOs • MS4 areas • WWTPs Stream bathymetry	• Water depths and velocities in the creeks
Transport of pathogens via tidal currents and mixing within the Delaware River estuary	• Delaware River and major tributary flow rates, • Tidal water levels, and • Delaware River bathymetry	• Water depths and velocities in the Delaware River
Net losses of pathogens during transport	• First order bacteria decay rate • Water temperatures • Parameters influencing dependence of decay on water temperature	• Pollutant in-stream concentrations

2.2.5 Data Sources

Table 2-4 below describes data sources that are expected to help inform model inputs relating to the primary physical and kinetic processes described above.

Table 2-4: Data Sources Supporting Model Inputs

Water Quality Model Process	Related Inputs	Data Sources
Bacterial pathogen loadings	Pollutant concentrations for: • Creeks • CSOs • MS4 areas • WWTPs	• Bacterial pathogen concentration data (existing data and data proposed in Section 3 of this work plan to be collected) • WWTP DMR (discharge monitoring report data) • Literature-based event mean concentration data
Transport of pathogens within the riverine portions of local creeks	Flow rates for: • Creeks • CSOs • MS4 areas • WWTPs Stream bathymetry	• USGS flow data • Collection system model overflow rates • Watershed model flow rates • Bathymetric data
Transport of pathogens via tidal currents and mixing within the Delaware River estuary	• Delaware River and major tributary flow rates • Tidal water levels • Delaware River bathymetry	• USGS flow data • NOAA water level data • NOAA Delaware River bathymetric data
Net losses of pathogens during transport	• First order bacteria decay rate • Water temperatures • Parameters influencing dependence of decay on water temperature	• USGS and/or NOAA water temperature data • Bacterial pathogen concentration data (existing data and data proposed in Section 3 of this work plan to be collected)

2.3 Model Development and Configuration

2.3.1 Watershed Model

The watershed model will be developed and configured in order to calculate the runoff and bacteria loads generated by the Ridley Creek and Chester Creek watersheds, as well as by the separate stormwater areas within the DELCORA service area.

2.3.1.1 Extent

The flows and bacteria loads from the upstream portion of the Ridley Creek and Chester Creek watershed area will be represented through the use of boundary conditions. These boundary

conditions will be determined through an analysis of USGS flow gage data and bacteria monitoring data. The portions of the Ridley Creek and Chester Creek watersheds that are within the DELCORA service area (and a small area upstream of the DELCORA service area) will be explicitly modeled using SWMM. Figure 2-1 below shows the extent of the proposed watershed model.

2.3.1.2 Segmentation

As described in the section above, the Ridley Creek and Chester Creek watersheds will be divided into upstream and downstream areas. The upstream area will be represented through the use of boundary conditions that describe the flow and load that are generated from the upstream area under different meteorological conditions. The downstream area will be divided into relatively small and homogenous catchments.

Figure 2-1: Proposed Extent of the Watershed Model

2.3.2 Receiving Water Quality Model

A few considerations guide the design of a receiving water quality model. First, models are designed to cover the locations of interest with respect to site-specific management questions. Second, the spatial extent of a model should be chosen to allow for accurate calculations of transport. This requires that the model's edges (boundaries) occur at locations where environmental conditions (e.g. flow rates) are well known and readily defined. For instance, it is often beneficial to locate a model boundary at the head of tide where tidal flows are zero, or at a monitoring location where tidal water levels are known. Third, an appropriate spatial resolution should be determined to balance the level of detail in the model against the run times of simulations. Finally, the model boundaries should be sufficiently distant from the source such that the pollutant mass assumptions from these boundaries would not significantly affect conditions simulated in the area of interest. The proposed model extent and spatial resolution are described in the following sections.

2.3.2.1 Extent and Reaches

On the Delaware River, we propose that the receiving water model extends from NOAA station 8551762 (Delaware City, DE) to the head of tide at Trenton near USGS station 01463500 (Delaware River at Trenton, NJ). Environmental conditions at these locations are well defined by data and the locations are sufficiently far from Delaware County that model results are not expected to be strongly influenced by water quality assumptions at the boundaries.

We propose that the receiving water model extends through the tidally influenced portion of the creeks and through all reaches adjacent to the DELCORA combined sewer system. This is because the receiving water model is better suited for representing tidal conditions at the mouth of the creeks than the watershed model, and representing CSOs exclusively in the receiving water model simplifies the modeling process. Tidal transport will likely influence the duration of time that pathogen sources influence the lower reaches of each creek. In some cases, it may be beneficial to extend the model farther in to the creeks (i.e. upstream of the tidally influenced reaches) to a sampling or monitoring location.

2.3.2.2 Segmentation

The segmentation of a model defines the degree of spatial detail in the model results and also determines how much time is required for a simulation to run. Determining an appropriate degree of spatial detail is related to both the detail necessary to address management questions and the degree of detail necessary to accurately model the processes of an environmental system. Occasionally, model segmentation must be iteratively refined during the model development process to reach a suitable degree of detail.

We propose that the receiving water quality model have roughly the following characteristics:

- Five to ten cells spanning the Delaware River cross section;
- One cell spanning the cross section of each creek;
- 2,000 to 4,000 total grid cells within the model extent;
- Typical Delaware River cell dimensions of roughly 150-300 feet (width) by 1,000 to 2,000 feet (length). Typical creek cell lengths of 200 to 400 feet; and,
- Five cells spanning the water depth.

The Delaware River is relatively deep (30-40 feet deep) near the location of maximum DELCORA impact, so a three-dimensional model is recommended for computing near-surface pathogen concentrations, which are occasionally elevated relative to those at greater depths due to discharge of CSOs near the water surface. A depth-averaged (two-dimensional) model would instantaneously mix pollutant concentrations over the water depth and understate near-surface concentrations.

2.3.2.3 Linkage with CSO (H&H) Model

The CSO H&H model will be linked to the receiving water quality model. The H&H model will be run for the calibration period as well as for each CSO alternative of interest, and CSO outfall results will be inserted into the EFDC model at the appropriate grid location in EFDC.

2.3.3 Linkage with Watershed Model

The watershed model will be linked to the receiving water quality model. The watershed model will be run for the appropriate meteorological period and results will be inserted into the EFDC model at the appropriate grid locations in EFDC.

2.3.4 Water Quality Parameters

The water quality parameters that will be evaluated in the water quality model are fecal coliform bacteria, *Enterococcus* bacteria, and *Escherichia coliform* (*E. coli*). These parameters are discussed in detail in the Identification of Sensitive Areas and Pollutants of Concern Report (DELCORA, 2016).

2.3.5 Boundary Conditions

Boundary conditions define environmental conditions at the edges of the model spatial domain and influence model calculations within the model domain. Boundary conditions will be used in both the watershed model and receiving water quality model.

Two types of boundary conditions are required in the watershed model: flow boundary conditions and water quality boundary conditions. As explained in Section 2.3.1, the flows

and loads from the upstream portion of the Ridley Creek and Chester Creek watersheds will be represented through the use of boundary conditions. These boundary conditions will be determined through the analysis of USGS flow gage data and bacteria monitoring data. The flow and bacteria boundary conditions will vary according to meteorological and seasonal conditions.

Two types of boundary conditions are also required in the receiving water quality model: hydrodynamic boundary conditions and water quality boundary conditions. Hydrodynamic boundary conditions will include a water level boundary condition, which will define how water levels vary with the tides and other atmospheric conditions, and inflow boundary conditions, which will define flow rates into the model from freshwater sources such as from the Delaware River above Trenton, major tributaries, creeks of interest, MS4s, CSOs, and treatment plants. Water quality boundary conditions define the pollutant concentrations associated with all inflows to the model. Water quality boundary conditions will be defined based on the available sampling data for all pollutant sources of interest.

2.4 Model Calibration and Validation

Model calibration is described in USEPA guidance (USEPA, 1994) as the "process of adjusting model parameters within physically defensible ranges until the resulting predictions give the best possible fit to the observed data." Calibration will occur for the runoff and water quality components of the watershed model, as well for the hydrodynamic and water quality components of the receiving water quality model. Calibration will occur through the use of available monitoring data.

2.4.1 Calibration Objectives

The objectives for the hydrodynamic model calibration are to determine a set of model inputs (primarily bed roughness and turbulent mixing parameters) that produce model results consistent with the observed data. During the hydrodynamic model calibration, comparisons between modeled and observed water surface elevations and velocities will be made. The comparisons will allow for any adjustments to be made.

The objectives for the water quality model calibration are to interpret the water quality data to improve initial estimates of pollutant loads and potentially constrain assumptions related to bacterial decay. For instance, model tests would be run with different assumptions about pollutant concentrations in combined sewer overflows. Those tests would be evaluated for consistency with the receiving water sampling data to determine a range of pollutant concentration assumptions that are supportable. Likewise, model tests would be run with different assumptions about bacterial decay, and those tests would be evaluated to refine inputs related to decay.

2.4.2 Data for Calibration/Validation

Data available for the hydrodynamic model calibration include NOAA water level and velocity data, and USGS water level and flow data. Primary hydrodynamic model calibration stations include the following NOAA stations:

- Water level gages: #8540433 (Philadelphia, PA), #8546252 (Bridesburg, PA), #8539094 (Burlington, NJ), and #8548989 (Newbold, PA).
- Current velocity meter: Station dB0301 (Philadelphia, PA).

Model results will be compared to hourly water level and current velocity data at these locations.

Data available for the water quality calibration are pathogen grab sample data. Section 3 of this work plan summarizes the currently available water quality data by sample location. We propose to supplement these data with an additional sampling program described in Section 3 of this work plan.

2.4.3 Calibration Criteria

Hydraulic calibration will primarily focus on reproducing observed water levels and current velocities in the Delaware River. This approach provides a robust calibration by focusing on the hydraulic attributes that are the primary dependent variables of the hydrodynamic model. Calibration goodness will be determined by qualitative visual comparison of model and data time series, one-to-one plots, and cumulative frequency distributions (CFDs). Calibration will involve adjustment of the roughness height to values that best replicate water level and velocities at NOAA stations.

Bacteria models are often evaluated qualitatively with multiple tools such as time series plots, CFDs, and 1:1 plots. Because bacteria concentrations vary over many orders of magnitude and sources can be numerous, distributed, and highly variable with time, bacteria model results are not often held to quantitative calibration criteria. Instead, a rule of thumb is that modeled bacteria concentrations should mostly be consistent with observed bacteria concentrations within an order of magnitude. Agreement of model and data within a factor of two indicates a high degree of model performance.

2.4.4 Model Sensitivity

Model sensitivity tests complement and illustrate the model calibration. Model sensitivity tests are model simulations in which uncertain inputs are varied to assess their significance in determining, for instance, pollutant concentrations. These tests are useful for evaluating whether the model calibration is optimized within the limits of the available data, and for identifying uncertainty in significant model inputs. For instance, model sensitivity tests varying the assumed CSO pollutant concentrations would illustrate how a range of assumptions are more or less consistent with stream sampling data.

Model sensitivity tests will be conducted for the following inputs:

- Major pollutant loads (including at least CSO, MS4, and local watershed loads).
- Parameters influencing bacteria decay rates.

Results of model sensitivity tests will be summarized using plots such as CFDs, box plots, or time series plots.

2.5 Model Typical Year Application

An evaluation of the typical hydrologic period was conducted for DELCORA and is detailed in the report entitled "Typical Hydrologic Period Report" (DELCORA, 2016). The typical year that will be applied to evaluate CSO scenarios will also be used for the receiving water quality model. The recommended period for typical year application is 1994-1996.

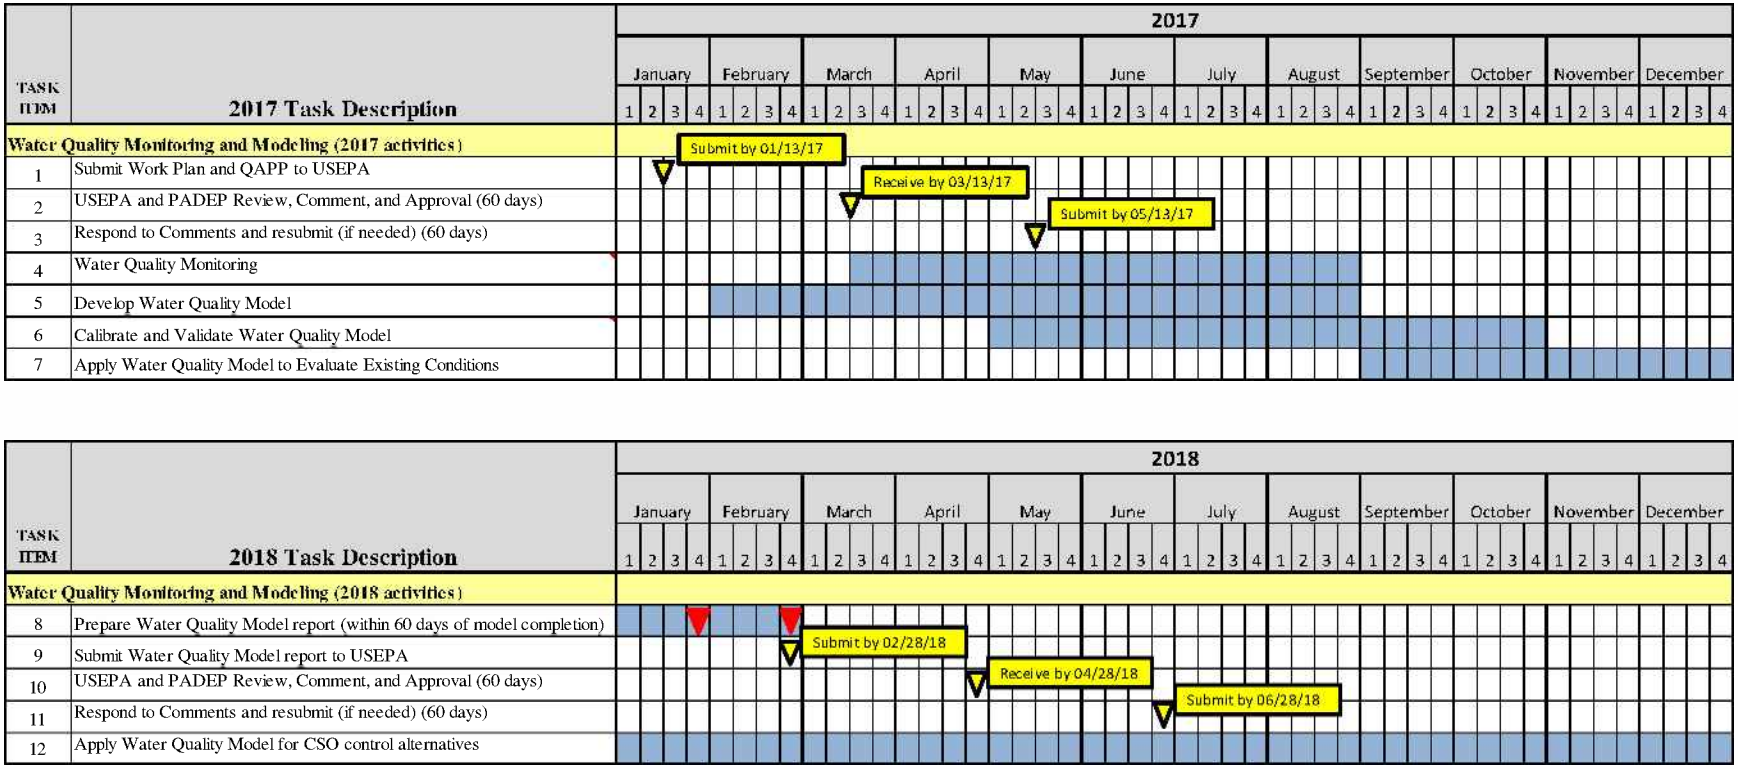
2.6 Model Development Schedule

The schedule for model development and application is shown in Figure 2-2 below. All tasks related to the water quality modeling development and application are included in the schedule. The schedule is integrated into the LTCP development consistent with other dates required to the Consent Decree.

2.7 Model Documentation

A report will be provided that summarizes the development, calibration, application, and results of the receiving water model. In accordance with the Consent Decree, this report will be submitted to EPA and PADEP within sixty (60) days after the approved Water Quality Model Plan is fully implemented according to the schedule included herein.

Figure 2-2: Schedule for Model Development and Application



Section 3 Monitoring Work Plan

3.1 Regulatory Requirements

3.1.1 Consent Decree Requirements

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated LTCP to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. Consent Decree Paragraph V.A.10.e and V.A.10.f require that the development of the LTCP include

V.A.10.e. Develop and implementation of a Water Quality Model

V.A.10.f Characterization of the service area and the Receiving Waters as required by CSO Control Policy Paragraph II.C.1 and associated guidance.

Consent Decree Paragraph V.A.15 (Water Quality Model Plan) requires that within 90 days after review and approval of the Alternatives Evaluation Approach, DELCORA shall submit a report to the USEPA and PADEP that describes the use of the Water Quality Model to support the Demonstration Approach consistent with Section II.C.4 of the CSO Control Policy and the Paragraph V.13 of the Consent Decree (Alternatives Evaluation). Section V.A.15.a of the Consent Decree specifically states:

For each water body in which the Demonstration Approach is to be used, the Water Quality Model Plan shall address:

(i) Background, Scope and Purpose, Description of the System;

(ii) Water quality modeling software to be employed;

(iii) Model configuration and development, including reaches to be modeled, and segmentation and boundary conditions;

(iv) Calibration and validation (dry and wet weather), including events and data to be employed, detailed information regarding all additional data collection activities (if needed), quantitative and qualitative calibration criteria, and utilization of H&H Model outputs;

(v) Use of the Water Quality Model to evaluate Typical Year in-stream conditions for each identified pollutant of concern;

(vi) Schedule for model development and implementation, including integration into LTCP development consistent with other dates required pursuant to this Consent Decree.

3.3 Existing Water Quality Monitoring Overview

The Water Quality Monitoring Program (WQMP) is designed to collect data that will be used to assess water quality concerns identified in the Delaware River watershed and its tributaries, Chester Creek and Ridley Creek, in the vicinity of Chester, PA. Pollutants of concern (POCs) were identified in the Identification of Sensitive Areas and Pollutants of Concern Report (Greeley and Hansen, 2016). These POCs are fecal coliform, *E. coli*, and *Enterococcus* and are the primary focus of the WQMP. In completing the initial step of characterizing the watershed, historical data was compiled, reviewed and assessed to determine the need to augment existing data to address the watershed issues identified. This review indicated that one of the POCs, *E. coli*, has not been sampled in all the receiving waters and the data that have been collected for the remaining POCs are of insufficient frequency and spatial density to be useful in the modeling process.

3.3.1 Historic Sampling

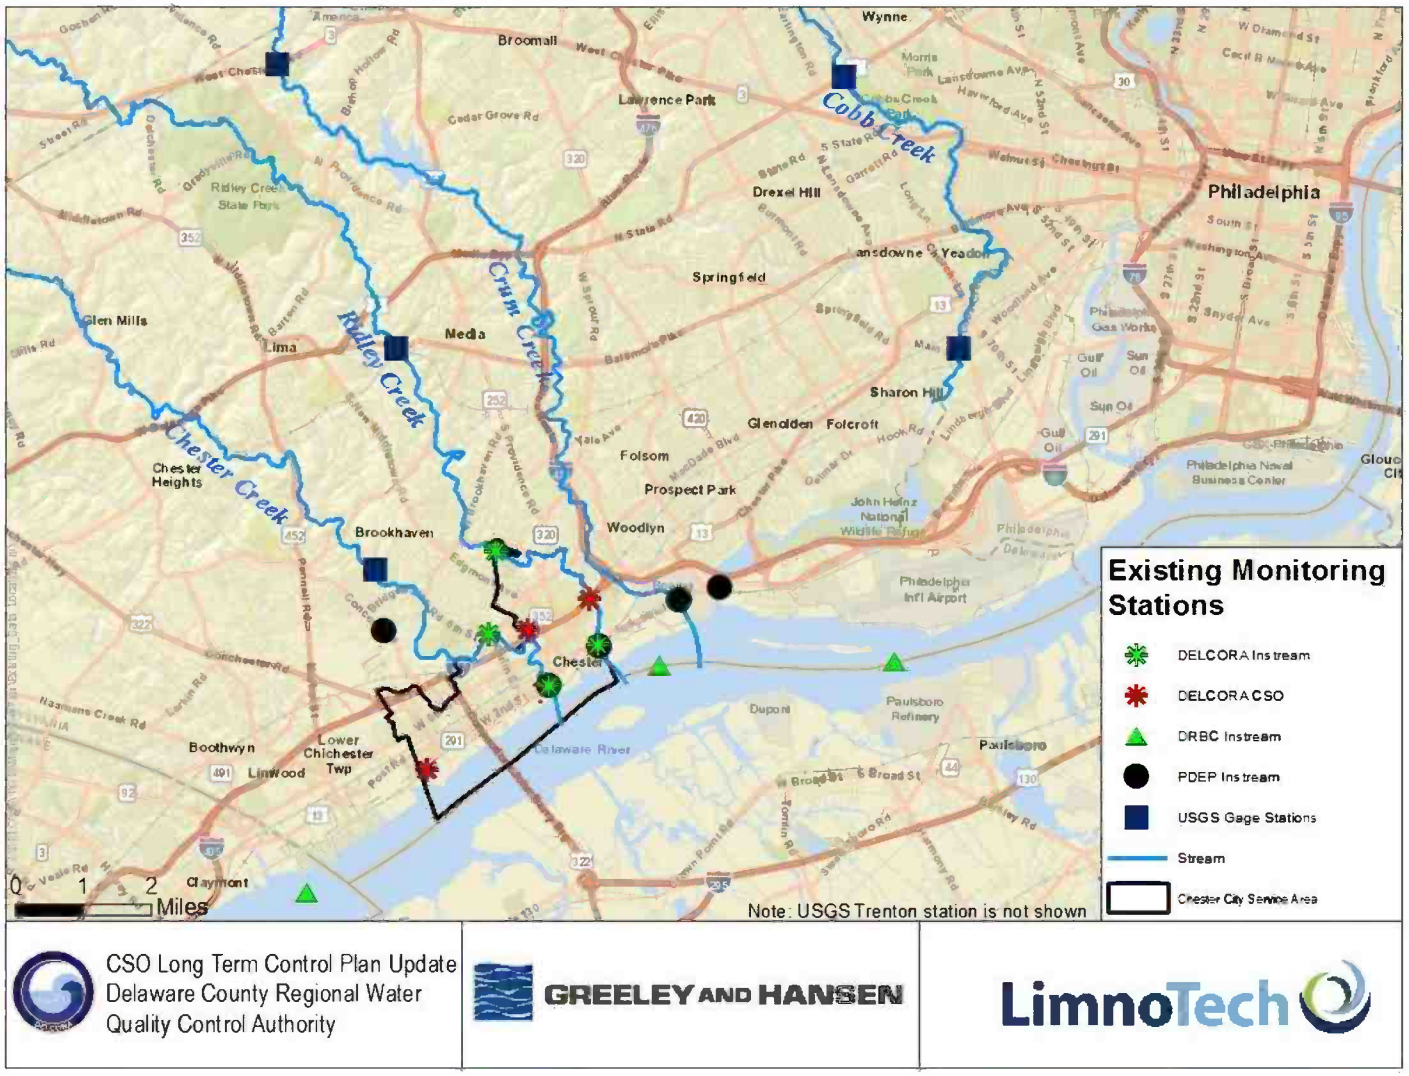
The Water Quality Model requires robust flow and water quality datasets to build confidence in its use as a tool for CSO planning. Data are needed in the modeled receiving waters for use in model calibration and validation as well as for the predominant wet weather sources, such as DELCORA's CSOs and the City of Chester's MS4 runoff to estimate pollutant loadings to the model. The existing water quality data were reviewed for their adequacy in meeting the data needs of the water quality model for the POCs (fecal coliform, *E. coli*, and *Enterococcus*). The review indicated that Chester Creek and Ridley Creek have limited POC data. Although the Delaware River has more extensive POC data, it lacks the temporal frequency needed to characterize wet weather impacts from DELCORA's CSOs. It would be difficult to constrain the Water Quality Model's representation of DELCORA's sources on the receiving waters without additional monitoring data designed specifically for calibrating and validating a robust water quality model. Existing flow data were also reviewed for adequacy; reports of mean daily stream discharge are available from several stream gages along the Delaware River and in tributaries near the DELCORA service area, ranging from as early as 1912 to the present. The existing flow and water quality data are described in this section.

Flow data for the Delaware River and tributaries in the DELCORA service area were obtained from the USGS National Water Information System. Reports of mean daily stream discharge were available from five stream gages in DELCORA service area measuring daily mean discharge: Crum Creek near Newtown Square, PA (1980-2016); Chester Creek near Chester, PA (1931-2016); Ridley Creek near Media, PA (1986-2016); Cobbs Creek at U.S. Highway No. 1 at Philadelphia, PA (1964-2016); and Cobbs Creek at Mt. Moriah Cemetery, Philadelphia, PA (2005-2016). Though not in service area, mean daily discharge data were also obtained from the gage at the Delaware River at Trenton, NJ (1912-2016) because it is expected that these data will be used to inform the upstream boundary for the hydraulic portion of the water quality model. The USGS Pennsylvania Water Science Center has conducted water quality sampling at various points in the state. However, none of their sampling locations are near to the DELCORA service area or local waterways.

Monthly effluent data from DELCORA's WWTP are available from the Pennsylvania Department of Environmental Protection's (PADEP) eDMR website (*www.dep.pa.gov/edmr*). Reported data include monthly geometric mean and instantaneous maximum values for fecal coliform from 2009 through 2016. PADEP also monitors water quality of tidal streams that empty into the Delaware River, through the Pennsylvania Water Quality Tributary Project funded by the Delaware River Basin Commission (DRBC). This program monitored for fecal coliform levels in Chester Creek, Ridley Creek, Darby Creek, Crum Creek, and others twice annually from 2007-2010. PADEP also operates the PA Surface Water Quality Monitoring Network, through which Baldwin Run (a tributary to Chester Creek) was sampled monthly for fecal coliform from 1998-1999.

The Delaware River Basin Commission operates its Boat Run program to monitor ambient, sampling for *E. coli*, *Enterococcus*, and fecal coliform at various sites along the Delaware River (Figure 3-1). Samples were collected from each station between one and three times each month from March through November every year since 1999. Through this program, data are available at three sites near DELCORA: Eddystone (2005-2016), Paulsboro (1999-2016), and Marcus Hook (1999-2016).

Figure 3-1: Historical Flow and Water Quality Sampling Locations Near DELCORA Service Area.



Since 2009, DELCORA has also done their own sampling at CSO outfall sites and in receiving waters. In 2010, a survey was conducted to measure fecal coliform levels in Ridley and Chester Creeks during wet and dry weather. There were two sample sites in each creek, and over the course of the study, six surveys were conducted. Four surveys occurred during dry weather, one during a wet event, and one during a wet event after a storm. During each survey, one sample was collected at each site. In 2009, DELCORA began sampling in the CSO system as required by their NPDES permit. Four outfalls and pump stations were sampled once annually for fecal coliform from 2009-2011, and three outfalls were sampled once annually for fecal coliform from 2012-2014. In 2015, four outfalls and pump stations were sampled for fecal coliform and *Enterococcus*, on three separate occasions. *E. coli* was not measured in any of these surveys.

The extent of existing water quality data and its adequacy to support the Water Quality Model development and calibration can be summarized as follows:

- Some CSO water quality data has been collected but mostly for fecal coliform. There are no CSO data for *E. coli*. Another limitation in the CSO data is that the CSO samples did not coincide with in-stream sampling, making it difficult to directly link CSO loads to in-stream impacts.
- No water quality sampling for the POCs has been done of the stormwater runoff in the separated areas of the DELCORA service area.
- Delaware River has the most data of the receiving waters and it has data for all three POCs. However, the data were collected at regular intervals, independent of weather condition, and typically only one sample per location per survey was collected. These periodic sampling events do not provide enough data to characterize DELCORA loads on the river.
- The tributaries (Chester Creek and Ridley Creek) have been sampled sporadically and rarely within the tidal zone adjacent to DELCORA's service area. Wet weather data collected by DELCORA, consisting of only one sample per event, are not sufficient to characterize the magnitude and duration of the POCs' pollutographs over a storm event. Data are most robust for fecal coliform. There is less data for *Enterococcus* and none for *E. coli*. In addition, no sampling has been conducted in these tributaries since 2010.

The monitoring program presented in this work plan and QAPP builds on the sampling that has already been done while addressing the limitations identified in the existing data. This work plan includes a comprehensive monitoring assessment of all of the POCs to characterize loads and in-stream conditions. These data will be used to inform the Water Quality Model development, calibration and validation.

3.3.2 Ongoing Sampling

There is no routine on-going monitoring for the pollutants of concern in the tributary waterways adjacent to the DELCORA service area. The Delaware River Basin Commission samples the Delaware River near Chester approximately once a month between April and October. The analysis of these samples includes fecal coliform, *E. coli*, and *Enterococcus*, which are the pollutants of concern (POCs).

3.4 Sampling and Analysis Plan Overview

The WQMP is designed to collect data that will be used to develop and calibrate watershed and receiving water quality models which will be used to assess water quality concerns for the POCs identified in the Identification of Sensitive Areas and Pollutants of Concern Report (Greeley and Hansen, 2016). These POCs are fecal coliform, *E. coli*, and *Enterococcus*. Additional *in situ* parameters, such as salinity, temperature, and conductivity will also be collected to inform the development of the Water Quality Model.

Water quality monitoring will be undertaken at up to thirteen (13) in-stream locations (seven of which are Delaware River sampling locations), four (4) CSO locations in the DELCORA combined sewer system area, and two (2) stormwater locations in the City of Chester municipal separate storm sewer system, as shown in Figure 3-2. Water quality monitoring and sampling will be conducted as follows:

- Eleven (11) in-stream locations in the vicinity of the DELCORA CSO area will be sampled for water quality for (3) dry weather events; one of which will be targeted for collection during a tributary low-flow period (less than 25th percentile flow). The mid-stream and far-shore Delaware River locations will not be sampled during the dry weather surveys because it is expected that water quality in the river will be relatively uniform laterally due to the lack of active sources during dry weather. These dry weather events would preferably be distributed across the sampling season, which is assumed to be March through June of 2017. Grab samples and *in situ* measurements will be collected at each location during each event.
- All thirteen (13) in-stream locations will be sampled for water quality using grab samples and *in situ* monitoring for three (3) discrete wet weather events, according to the surface water quality monitoring program protocols described in this Monitoring Work Plan.
- Up to four (4) CSO and two (2) stormwater outfall locations will be sampled for water quality for the same three (3) discrete wet weather events according to the outfall monitoring program protocols described in this Monitoring Work Plan. Samples for all outfalls will be collected as grab samples.
- Field Standard Operating Procedures (SOPs) and the Sampling Analysis Plan (SAP) referenced in the following sections of the Water Quality Monitoring Work Plan are

provided in Appendix C of the Water Quality Modeling and Monitoring Quality Assurance Project Plan (QAPP).

The sampling events are planned to be distributed across the sampling season, which is assumed to be March through June 2017. Additionally, bathymetry surveys in the lower portion of the tributaries may be required to inform the development of the Water Quality Model, pending delivery of HEC models with transect information for these portions of the receiving waters.

3.4.1 Sampling Locations

Monitoring locations have been selected to characterize the watershed at a sub-watershed level, recognizing various political and hydrologic features, land uses and potential pollutant sources. Site selection and analytical parameters are designed to characterize stormwater outfalls, CSOs, tributaries upstream and within the Chester CSO discharge area, and the main stem of the Delaware River in the project area. The sampling locations are shown in Figure 3-2 and listed in Table 3-1, Table 3-2, and Table 3-3.

The tables include summaries of the rationales for each sampling location selected. The Chester Creek and Ridley Creek locations were selected to distinguish, to the extent possible, between upstream, stormwater and Chester CSO pollutant loads. The Delaware River sampling locations will provide a characterization of water quality entering the Chester CSO area from either tidal direction as well as water quality within the CSO discharge area. During wet weather, three samples will be collected across the transect corresponding to the DR-04 sampling location during each sampling round, when sampling across the river is feasible, to characterize lateral variability in the Delaware River during storm events. Delaware River conditions may be too hazardous for safe collection of one or more samples and/or sampling rounds (e.g. during periods of heavy barge traffic, small craft advisories, lightning, etc.). When these conditions occur, sampling will not be conducted in the river for safety reasons.

The CSO sampling locations were selected based on their outfall discharge location, relatively high frequency of overflow, their overflow volume, and their accessibility. The stormwater sampling locations were selected to characterize the water quality associated with the predominant land uses (residential and commercial/industrial) in the study area. Each stormwater sampling location is in an area that is representative of the land use elsewhere in the City's stormwater area.

Note that it may be necessary to adjust the one or more sampling locations in response to hazards, construction or other factors that affect the safety of field sampling personnel. The CSO and stormwater sampling locations will be finalized prior to the initiation of the sampling program based on accessibility of sampling, safety of sampling personnel, equipment risk, and available resources.

Notes:
[1] GPS Coordinates, WGS 1984

3.4.2 Analytical Parameters

All of the in-stream dry and wet weather samples will be analyzed for the parameters shown in Table 3-4. The outfall samples will be analyzed for only *E. coli*, *Enterococcus* and fecal coliform.

Table 3-4: Analytical and Field Parameters

Parameter	Description	Sampling Program	Type of Measurement
E. coli	Escherichia coli	Dry, Wet	Grab
Enterococcus	Enterococcus sp.	Dry, Wet	Grab
Fecal coliform	Fecal coliform	Dry, Wet	Grab
wTemp	Water temperature	Dry, Wet, Receiving Water Only	In-situ
Cond	Conductivity	Dry, Wet, Receiving Water Only	In-situ
Salinity	Salinity	Dry, Wet, Receiving Water Only	In-situ

3.4.3 Sampling Schedule

3.4.3.1 Dry Weather Sampling

Collection of water quality samples will be performed for three (3) dry weather events; with one dry weather sampling event planned to be collected during a low-flow period (less than 25th percentile flow) in Chester Creek and Ridley Creek (if possible). Two rounds of sampling will be conducted for each dry weather survey: one round to be completed during ebb (outgoing) tide and the second round to be completed during flood (incoming) tide.

Dry weather event samples will be taken at up to eleven (11) locations:

- **Three (3) locations on Chester Creek** that will characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations will also reflect these tidal influences on water quality.
- **Three (3) locations on Ridley Creek** that will characterize water quality upstream of DELCORA's service area as well as in the portion of the creek adjacent to DELCORA's CSO discharges and the area adjacent to the City of Chester outside the combined sewer service area. Additionally, because DELCORA's CSO discharges are within the tidal extent of the Delaware Bay, the downstream sampling locations will also reflect these tidal influences on water quality.
- **Five (5) locations on the Delaware River** that will characterize water quality in the vicinity of DELCORA's CSO discharges. Sampling locations have been selected to

separate to the extent possible the effect of DELCORA's CSOs on water quality from other sources contributing pollutants to the waterways. Sampling will be conducted near the shoreline adjacent to the City of Chester.

The locations of these stations are shown in Figure 3-2. Details for these stations are provided in Table 3-1, Table 3-2, and Table 3-3. The set of parameters for which the samples will be analyzed is provided in Table 3-4. In-situ measurements of physical parameters, such as salinity, temperature, and conductivity will be collected at each sampling location with a sonde. In the Delaware River, *in situ* measurements will be made at three depths at each sampling location during each round of sampling.

3.4.3.2 Wet Weather Sampling

Collection of water quality samples will be performed for three (3) wet weather events. The purpose of the wet weather sampling is to characterize the impact of CSO discharges and non-CSO source runoff on in-stream water quality. The wet weather events will span a range of precipitation, flow and seasonal conditions.

Wet weather event samples will be taken at all 13 in-stream locations as well as at up to six source locations in the intervals described below:

- **Six (6) In-Stream Tributary Sampling Locations:** Three (3) locations will be on Chester Creek and three (3) locations on Ridley Creek. The locations will be the same locations used for the dry weather surveys. Tributary locations will be sampled up to five times per event at the following approximate intervals: Hour 0.5-2.5, Hour 4.5-6.5, Hour 8.5-10.5, Hour 14.5-16.5, and Hour 22-24. Sampling intervals will be defined by the start of rainfall rather than CSO or SSO activation. A total of 30 samples will be collected during each wet weather sampling event from in-stream locations. One field blank and one field duplicate will be collected during each event to be used as field quality control (QC).
- **Up to Seven (7) In-Stream Delaware River Locations:** Up to seven locations will be on the Delaware River and will be sampled up to ten times per event at the following approximate intervals: Hour 0, Hour 2, Hour 4, Hour 6, Hour 9, Hour 12, Hour 15, Hour 18, Hour 21, and Hour 24. Sampling intervals will be defined by the start of rainfall rather than CSO or SSO activation. The frequency of sampling is intended to capture in-stream impacts in the vicinity of DELCORA's service area from both DELCORA's CSOs as well as upstream sources. Two additional locations on the Delaware River, one at mid-stream and one near the far shore, have been added to characterize lateral variability in water quality during storm event conditions, when sampling across the river is feasible. The sampling regimen is also designed to allow a semi-quantitative mass balance to be computed over a complete tidal cycle. A total of 70 samples may be collected during each wet weather sampling event. If river conditions are unsafe for sampling (e.g. small craft advisories, heavy barge traffic, etc.), sampling may be suspended for one or more locations and/or sampling rounds. One field blank and one field duplicate will be collected during each event to be used as field QC.

- **Up to Six (6) Outfall Locations:** Sampling will be conducted at up to two (2) stormwater outfalls and up to four (4) combined sewer overflow outfalls. It is assumed that each of the outfall locations will have up to eight sets of samples collected for each event at the following intervals: 1st flush, 30 minutes, and 60 minutes, 2 hours, 4 hours, 8 hours, 12 hours, 24 hours. If a location is not flowing, no sample will be collected. As many as 48 samples may be collected during each wet weather sampling event, depending on the number of monitored outfalls and if all monitored outfalls discharge for 24 hours. However, the actual number of samples is likely to be less than the amount indicated since it is unlikely that all of the monitored outfalls will discharge for the full 24 hour monitoring period. One field blank and one field duplicate will be collected during each event to be used as field QC.

The locations of these stations are shown in Figure 3-2. Details for these stations are provided in Table 3-1, Table 3-2, and Table 3-3. The set of parameters for which the samples will be analyzed are summarized in Table 3-4. *In-situ* measurements will not be collected at the outfall locations.

Sampling crews will conduct all wet weather event sampling using the protocols described in the Quality Assurance Project Plan. Samples will be delivered to the laboratory where the samples will be analyzed for the laboratory parameters identified in Table 3-4.

Determination to mobilize for a Wet Weather Event will be a collaborative effort between Greeley and Hansen, LimnoTech, the Weston Solutions, and Eurofins QC. The intent is to identify a 4 to 6 hour window in which a wet weather event may commence 24 hours in advance to assist in mobilization of the sampling crews.

3.4.3.3 Bathymetric Sampling

The project team has requested HEC models of the receiving waters from the U.S. Army Corps of Engineers. However, in the absence of these models, additional bathymetry data is needed for the tributaries to inform the development of the water quality model. If required, bathymetry surveys will be conducted in approximately the lower three miles of both Chester Creek and Ridley Creek, corresponding to the approximate extent of the water quality model domain. Because these reaches are in the tidal zone, they are unlikely to be wadeable so each transect will be characterized using a boat and a combination of sonar and ADCP profiler equipment. Transects will be spaced approximately every 0.25 miles or at significant morphometric features (e.g. dams, islands, etc.).

3.4.4 Sample Event Initiation Protocol

This section describes the protocols that will be used to initiate the dry and wet weather sampling events.

3.4.4.1 Dry Weather Sampling Protocol

Collection of dry weather water quality samples will be performed for three (3) events; one of which occurred during a low-flow period (less than 25th percentile flow). These events will be distributed across the sampling season, March through June of 2017. The criteria used to define a dry weather event are the following:

- No precipitation within the upstream watershed at least 48 hours before the event;
- No precipitation forecasted for a minimum of three days; and,
- For the low-flow survey, conditions when the in-stream flow at the USGS gage in Chester Creek (01477000) is less than the 25th percentile flow at this location will be targeted for sampling.

Decisions to initiate a dry weather event are given below:

1. Authorization for dry weather events will be determined by Greeley and Hansen, LimnoTech, the field sampling and laboratory contractor personnel as described in Section 3.4.1. LimnoTech will monitor predicted rainfall conditions to identify potential sampling event dates.
2. When the criteria described in the previous section are met (e.g. no rainfall the previous 48 hours), the Chester Creek and Ridley Creek flows are at a desirable level, and no rain is in the near forecast, the team members will be notified of an upcoming dry weather sampling event. The sampling teams will begin mobilizing equipment, bottles and personnel so that they can get into the field before conditions change.
3. The Field Manager will notify the laboratory contact that the sampling teams are planning on conducting a dry weather sampling event.
4. The Field Manager will notify LimnoTech if weather conditions change during the event.
5. Once the decision to conduct sampling has been determined, the Field Manager will confirm with the laboratory that sampling has begun.

3.4.4.2 Wet Weather Sampling Protocol

Three (3) wet weather events will be monitored over the study period. The wet weather events will span a range of precipitation, flow, and seasonal conditions. The goal is to sample storms of at least 0.5 inches of precipitation. The criteria used to define a wet weather event include:

- No precipitation within the upstream watershed 48 hours before the event;

- Forecasts for a 60% (or greater) chance of rain over the entire DELCORA project area; and,
- Approximately 0.50 inches of rainfall forecasted over a six-hour period.

Decisions to initiate and continue sampling for wet weather events are given below:

1. Authorization for wet weather events will be determined by Greeley and Hansen, LimnoTech, the field and laboratory contractor personnel as described in Section 3.4.2. LimnoTech will monitor predicted rainfall conditions to identify potential sampling event dates.
2. Sampling will begin approximately in March and conducted until approximately the end of June. If the water temperature is below 10°C when samples are collected, it is noted that the sample results are not reflective of conditions to assess the potential risk to human health.
3. When precipitation is forecasted meeting the criteria for a wet weather sampling event, the wet weather sampling teams will be put on alert. This alert will be considered "Go" status, unless otherwise notified. The sampling teams will begin mobilizing equipment, bottles and personnel so that they can get into the field as soon as possible after the precipitation begins.
4. The Water Quality Project Manager will notify the laboratory contact that the sampling teams are on alert.
5. The Field Manager's sampling teams will mobilize approximately 2-3 hours before the precipitation is forecasted to begin. Forecast tools include the National Weather Service website (forecast.weather.gov), Weather Underground website (www.wunderground.com), the Weather Channel website (www.twc.com), the Aviation forecast model (http://weather.rap.ucar.edu/model/index.php?model=gfs), local TV weather forecasts, and DELCORA's rain gage network data.
6. Sampling at the outfalls will begin during the first flush when water begins flowing out of the discharges. The field crews will be at the outfall locations waiting to collect the first flush water as soon as it happens.
7. The in-stream locations will be initiated at 0.5 hour after the start of rainfall for the first round of sampling. Subsequent in-stream sampling will be conducted at the intervals described in Section 3.4.3.2. The Field Manager will confirm with the laboratory Technical Director that sampling has begun.
8. Greeley and Hansen, LimnoTech and the Field Manager will continue to monitor the precipitation as the rain event progresses. If the storm conditions are significantly smaller than forecasted (either in rainfall depth or geographical extent), the sampling event will be aborted as soon as can be reasonably determined by Greeley and Hansen, LimnoTech and/or the Field Manager Local rain gages within the study area will be monitored for the event precipitation totals.

9. Samples collected during an aborted wet weather event will be discarded when directed by LimnoTech, after consultation with Greeley and Hansen. The laboratory will be notified as soon as possible by LimnoTech to stop the analysis on any samples they may have already received.

In-stream wet weather sampling will be conducted by 3 crews of two-person teams. Each crew will be responsible for sampling one of the receiving waters. For the outfall locations, a one or two person team will be deployed to each outfall to collect the samples in each round as individual grab samples. Due to the timing of sampling rounds, additional crews will be needed to relieve the sampling teams collecting the first few rounds of samples.

3.5 Field Sampling Methods and Procedures

This section provides a description of the field sampling collection methods, sampling equipment, and decontamination procedures that will be used during the monitoring program. The field sampling methods and procedures will be in accordance with the SOPs provided in Appendix C of the Water Quality Modeling and Monitoring QAPP.

3.5.1 Receiving Water and Source Sample Collection Methods

The physical, microbiological and chemical data that will be collected from the waterbodies are obtained either through direct (*in situ*) measurements or through analysis of a water sample. The microbiological and chemical data collected from the outfall discharges will be obtained through laboratory analysis of the water samples. The general collection procedures for receiving water and outfall sampling are as follows:

1. Clean all sampling equipment prior to sample collection according to the procedures in the SOP for Equipment Cleaning.
2. Don appropriate personal protective equipment (as required by the Field Safety Instructions).
3. Collect samples by dipping a container on a pole, into the water. The water is then poured into a bucket (until enough sample volume has been collected) and then poured from the bucket into the clean sample containers.
4. Care should be taken to avoid capturing bottom sediment or surface foam/scum during sample collection.
5. If field preservation is required, the appropriate preservative will be placed into the sample container prior to sample collection.
6. If field filtering is required, an appropriate sample aliquot will be filtered into the sample container.
7. Label all sample containers with the date, time, site location, sampling personnel, and other requested information.

8. Record sample collection information on the field logs and then store the samples in a cooler with ice as described in the SOP for the Shipping and Handling of Samples.
9. Handle, pack, and ship samples according to the procedures in the SOP for the Shipping and Handling of Samples, including the completion of a Chain-of-Custody (COC) form for each cooler shipped to the laboratory for analyses.

3.5.2 In situ Measurements (Receiving Water Only)

Instantaneous water quality measurements (such as salinity, temperature, and conductivity) using field instruments will be collected at the receiving water locations as specified in the following sections of this Water Quality Monitoring Work Plan. These measurements, along with calibration and maintenance, will be conducted following the SOPs for Water Quality Field Measurements in Appendix C of the Water Quality Modeling and Monitoring QAPP.

Field instruments will be calibrated before initiating monitoring activities for each event and a post-monitoring calibration check will be conducted at the end of the event. All calibration and maintenance activities will be documented on the Instrument Calibration Sheet (see Appendix C of the Water Quality Modeling and Monitoring QAPP). The field instrument calibration must be conducted in accordance with the SOP.

Salinity, temperature, and conductivity will be measured at all in-stream sampling locations using a YSI 6920 or similar instrument during both wet and dry sampling events, prior to sample collection. Measurements will be made mid-channel at mid-depth in the tributaries, whenever possible. In the Delaware River, measurements will be made at the surface, mid-depth and near the bottom, whenever possible. Measurements will be documented in the field logs. Documentation will include: date/time, location, type of measurement, personnel, equipment identification, and general site observations (e.g. weather, stream conditions).

3.5.3 Sampling Equipment

The sampling equipment required for the DELCORA monitoring program is included in Table 3-5.

Table 3-5: Sampling Equipment List

Sampling Activity	Required Equipment	
General Equipment (Required for all sampling activities)	Field log book with weather-proof paper and pen ("Rite-in-the-Rain") or field data sheets Pens and pencils Maps Sample bottles Sample bottle labels Chain-of-custody in zip lock bag Coolers with ice Stainless steel sample bucket and rope	Sample pole Sampling gloves Hand spray bottles with Liquinox solution Scrub brush Distilled water (10 gallons) Hip or chest waders Sun screen PPE as specified in FSI Monitoring Work Plan/QAPP Phone Emergency Contact List Field Safety Instruction
Wet Weather In-Stream Sampling	General Equipment Rain Gear Headlamps for night sampling & extra batteries Hydrolab/YSI multi-parameter sonde and instrument Instrument (sonde) calibration sheet Calibration materials and solutions Sonde instrument manual Sonde service kit Extra batteries for instruments (sondes) Laptop with appropriate power cable, data download cables, and software	
Wet Weather Outfall Sampling	General Equipment Rain Gear Headlamps for night sampling & extra batteries	
Dry Weather Sampling	General Equipment Hydrolab/YSI multi-parameter sonde and instrument Instrument (sonde) calibration sheet Calibration materials and solutions Sonde instrument manual Sonde service kit Extra batteries for instruments (sondes) Laptop with appropriate power cable, data and download cables, and software	

Table 3-6 presents a summary of the number of bottles and coolers needed for each day of each dry weather event. Table 3-7 presents a summary of the number of bottles and coolers needed for each crew for each wet weather sampling circuit. Three (3) bottles at each location are needed to collect the volume of sample required for the laboratory analyses (see footnote in Table 3-6 and Table 3-7). The laboratory will supply the bottles for each location and sample round to the Field Manager in advance of the event.

Table 3-6: Cooler and Bottle Requirements for Each Dry Weather Event

Sample Type	# of Two Person Teams	# of Locations	Locations per Team	Sampling Rounds	Number of Field QC Samples[1]	Number of Bottle Sets per Crew[2]	Number of Coolers per Crew
Chester Creek Tributary	1	3	3	2	1 FB 1 FDUP	8	2
Ridley Creek Tributary	1	3	3	2	1 FDUP	7	2
Delaware River	1	5	5	2	1 FB 1 FDUP	12	2

Notes:
[1] FB = field blank; FDUP = field duplicate
[2] The Bottle Set at each sampling location requires 3 125 ml plastic sterile bottles (bacteria)

Table 3-7: Cooler and Bottle Requirements for Each Wet Weather Event

Sample Type	# of Two Person Teams	# of Locations	Locations per Team	Sampling Rounds	Number of Field QC Samples[1]	Number of Bottle Sets per Crew[2]	Number of Coolers per Crew[3]
Chester Creek Tributary In-Stream	1	3	3	5	1 FB[4] 1 FDUP	17	3
Ridley Creek Tributary In-Stream	1	3	3	5	1 FB[4] 1 FDUP	17	3
Delaware River In-stream	1	7	7	10	1 FB[5] 2 FDUP	73	3
Outfall-Manual	6	6	1	8	1 FB 1 FDUP	8 (10 for crew doing field QC)	3

Notes:
[1] FB = field blank; FDUP = field duplicate.
[2] The Bottle Set at each sampling location requires 3 125 ml plastic sterile bottles (bacteria)
[3] The number of coolers is based on the frequency of sample delivery to the lab to maintain the 8-hour hold time for bacteria samples.
[4] It is assumed that each crew will also collect 1 field duplicate and prepare 1 field blank during one of the first three rounds of sampling (HR 0.5, HR 4.5, HR 8.5).
[5] It is assumed that the crew will collect 1 field duplicate in the first three rounds of sampling (HR 0, HR 2, HR 4), and will prepare 1 field blank and collect 1 field duplicate again in the remaining seven rounds of sampling (HR 6, HR 9, HR 12, HR 15, HR 18, HR 21, HR 24).

3.5.4 Equipment Decontamination

If sampling equipment, such as buckets, etc., are to be reused at more than one location in the field, they must be cleaned prior to collecting the next sample. Prior to leaving a site, the equipment must be rinsed at least three (3) times with distilled water. A brush may be used to remove deposits of material or sediment if necessary. At the next sampling site, the equipment must be rinsed at least three (3) times at each location with creek water prior to sampling.

Standard cleaning procedures for equipment decontamination are provided in SOP (included as Appendix C in the Water Quality Modeling and Monitoring QAPP).

3.6 Sample Handling, Storage and Shipment

Sample handling will be performed so as to collect, store, submit to the laboratory, and analyze representative samples using methods as specified in this section. Sample containers, volumes, preservatives and holding times are summarized in Table 3-8. Sample bottles (including those requiring preservative) will be provided by the laboratory in advance of each event. The laboratory will notify the Field Manager when sample bottles are ready for pickup. Sample bottles will be stored by the Field Manager until use.

3.6.1 Sample Handling

Sample packaging and shipping procedures are designed to ensure that the samples and the chain-of-custody forms will arrive at the laboratory intact and together.

1. All samples collected will be labeled in a clear and precise way for proper identification in the field and for tracking in the laboratory. The laboratory will pre-label each bottle with all information except for the date and time of sample collection using the method described below. The person collecting the sample will complete the label with date and time. No bottle sets will be distributed without the pre-labeling unless specifically agreed upon among Greeley and Hansen, LimnoTech, the field sampling and laboratory contractors prior to the sampling event.

   Use indelible waterproof marking pen and include:

   - *Sample identification code (ID)*– will include*:*
     - Site designation number - sampling round number, as follows:

—	—	-	—	—	—	-	—	-	—
1	2		3	4	5		6		7

Where,

Characters 1-5: Sample Site ID (column 1 in Table Table 3-1, Table 3-2 and Table 3-3)

Character 6: Sampling round number

Character 7: B - Blank sample qualifier (if required)

- Duplicate samples will be labeled with a sample ID of:

"DUP ___ ___ ___- ___ ___".
1 2 3 4 5

Where

Characters 1-3: Duplicate ID number (numbers will be assigned to each sampling crew)

Characters 4-6: Designation of RW for receiving water sample duplicate or OF for outfall sample duplicate

A blank line will be placed in the location, date and time boxes of the sample label so the laboratory does not know where the sample was collected. The duplicate number in the duplicate sample ID will be assigned in the field and recorded in the field log book.

- Blank samples will be given a normal sample ID, with a B qualifier at the end of the ID.

- *Sample type (water);*
- *Analysis required;*
- *Date sampled;*
- *Time sampled;*
- *Name or initials of person who collected the sample;*
- *Mode of collection (composite or grab);*
- *Preservation added, if applicable.*

2. Check the caps on the sample containers so that they are tightly sealed.
3. Cover the label with clear packing tape to secure the label onto the container and prevent the label from being illegible if wet.
4. Store samples in coolers with ice to maintain the samples at ≤6 degrees Celsius until they are received in the laboratory.
5. Complete the information needed on the field log book and the chain-of-custody, primarily sample date and time and any notes regarding deviations from the planned sampling protocol (e.g. limited volume precluded collecting the full volume required).

Table 3-8: Guidelines for Water Sample Container Preparation and Preservation

Parameter	Sample Container	Sample Volume	Storage Requirement	Preservative	Sample Holding Time	Analytical Method	Detection Limit
Fecal coliform	Plastic-Sterile	125 ml	Refrigerate to ≤6°C	Sodium Thiosulfate	8 Hours	SM 9222D	10 no./100 ml
E coli	Plastic-Sterile	125 ml	Refrigerate to ≤6°C	Sodium Thiosulfate	8 Hours	EPA 1603	10 no./100 ml
Enterococcus	Plastic-Sterile	125 ml	Refrigerate to ≤6°C	Sodium Thiosulfate	8 Hours	EPA 1600	10 no./100 ml

3.6.2 Sample Transport

Samples will be properly packaged for transport to the laboratory as summarized below.

1. Using packaging tape, secure the outside and inside of the drain plug at the bottom of the cooler that is used for sample transport;
2. Place the sealed container upright in the cooler;
3. Place additional cushioning material around the sides of each sample container as needed;
4. Place ice on top of sample containers. Do not pack ice so tightly that it may prevent the addition of sufficient cushioning material. Ensure that bottle caps will not be submerged in water if ice melts;
5. Fill the remaining space in the cooler with vermiculite or other cushioning material if the coolers are being shipped;
6. Place the chain-of-custody forms in a large Ziploc© type bag and tape the forms to the inside of the cooler lid; and,
7. Close the cooler lid and fasten with packaging tape. Wrap strapping or packaging tape around both ends of the cooler at least twice, if coolers are being shipped.

All shipments will be accompanied by the chain-of-custody form identifying the contents. It is preferred that a separate chain-of-custody form be completed for and placed in each shipping container/cooler. The original form will accompany the shipment and copies will be retained by the sampler for the project records.

During the dry weather and wet weather sampling events, representatives from the firm conducting the field sampling will be responsible for delivering the samples to the laboratory quickly enough so that hold times can be achieved for the bacteria parameters (8 hours from the time of sample collection). The Field Manager will manage the coordination of field crews and couriers during the sampling event.

3.7 Sample Documentation

3.7.1 Field Data Collection Forms

The field log book will serve as a daily record of events, observations and measurements during all field activities. All information pertinent to sampling activities will be recorded in the field logs and will include:

- Names of field crew and specifically the author of the field log;
- Date and time of the sample round beginning and ending;
- Location of sampling activity;
- Date and time of collection;
- Sample identification numbers; and,
- Field measurements.

Field observations and details related to analysis or integrity of samples (e.g., weather conditions, noticeable odors, colors, stream flow description, etc.)

The field log book may also include:

- Sampling method;
- Sampling equipment used;
- Number and volume of samples collected ;
- Type of sample;
- Summary of any meetings or discussions with the public, state agency, etc.; and,
- Levels of safety protection.

Field meters will be calibrated daily in accordance with the manufacturer's recommendations. Standards, solutions used, concentrations and readings taken will be recorded daily in Instrument Calibration Sheet.

3.7.2 Sample Chain-of-Custody Forms

A chain-of-custody is a legally-binding record of the date and time periods that samples were in the possession (e.g. custody) of the parties indicated. Transfers between parties are documented by the custodial party signing over custody to the receiving party and the receiving party signing for receipt of the samples. Completed chain-of-custody forms will be required for all samples to be analyzed.

Chain-of-custody forms will be prepared in advance by the laboratory for each sampling location and round of sampling. Chain-of-custody forms will be initiated by the sampling crews in the field

during the sampling events and must remain with the samples at all times. The samples and signed chain-of-custody form will remain in the possession of the sampling crew until samples are either delivered to the lab or placed in the custody of the personnel responsible for their delivery to the laboratory.

The chain-of-custody form will contain the sample's unique identification number, sample date and time, sample description, sample type and analyses required. Copies will be made prior to shipment for field documentation. The original chain-of-custody form will accompany the samples to the laboratory.

3.7.3 Data Submittal

Instrument Calibration Sheets and copies of the field log book will be turned over to the LimnoTech Water Quality Monitoring Program Task Manager following each monitoring event. Following review by the LimnoTech Water Quality Monitoring Program Task Manager, all field logs, photographs and chain-of-custody forms will be included in the project database.

3.8 Quality Control

The purpose of any quality assurance/quality control (QA/QC) program is to ensure that all sampling protocols and procedures are followed such that samples are representative of the water quality to which they are associated. The monitoring data that will be collected is intended to meet the quality assurance objectives described in the QAPP. Data quality will be measured in terms of accuracy and precision, completeness, representativeness, comparability, and the required detection limits for the analytical methods. Each of these data quality indicators is defined in the QAPP. QC samples will be collected in the field to support the assessment of data quality. The QA/QC program includes the following elements:

- Training of all field staff;
- Field quality control procedures;
- QA/QC samples; and,
- Equipment calibration.

3.8.1 Training

All field staff will receive training covering the QAPP and this Water Quality Monitoring Work Plan. The training will include proper procedures for sample collection, handling and submission and general field procedures. Specific emphasis will be placed on QA/QC issues as well as on health and safety. The training will also cover the operation, maintenance, and calibration of field equipment including multi-parameter sondes and all other on-site equipment used throughout the field program. SOPs for all program elements will be distributed to staff and will be available at all times.

3.8.2 Field Quality Control

The quality of data generated in a laboratory depends primarily on the integrity of the samples that arrive at the laboratory. Consequently, necessary precautions must be taken to protect samples from contamination and deterioration. Procedures detailed in SOPs for Collection of Discrete Water Samples and SOPs for Water Quality Field Measurements will be followed to ensure field quality control.

3.8.3 QA/QC Samples

This section describes the type and frequency of QC samples for the monitoring program.

3.8.3.1 Field Blanks

Field accuracy will be assessed through the use of field or equipment blanks. In order for the accuracy assessment to be relevant, all appropriate protocols concerning sample collection, handling, preservation, and hold times must be maintained. Equipment that is used to collect samples for analysis may become cross-contaminated through the normal course of monitoring. If not properly cleaned and rinsed, samples may be contaminated during sampling from previous locations.

Field blanks will consist of a distilled water rinse of sampling equipment collected into separate sample containers and submitted to the laboratory to assess the quality of the data resulting from the monitoring program. Field blanks should be collected after the sampling equipment has been cleaned in accordance with appropriate specified cleaning procedures. The laboratory will provide the sampling crews with the water to be used to prepare the field blanks.

Field blanks will be collected at a frequency of one blank during each sampling event per sampling crew.

3.8.3.2 Field Duplicates

Precision is a measure of the agreement between two or more measurements. Duplicate or replicate samples will be taken for a portion of the samples to assess field precision. A field duplicate is defined as a sample produced when a single sample is split into two or more aliquots immediately after the sample is collected. Each aliquot is placed into a separate container and analyzed separately.

Field duplicates will be collected at a frequency at least one field duplicate per sampling crew.

3.8.4 Calibration of Field Equipment

Instantaneous water quality measurements (such as salinity, temperature, and conductivity) using field instruments will be collected as specified in the preceding sections of this Water Quality Monitoring Work Plan. Salinity, temperature, and conductivity will be measured at the specified sampling locations using an YSI 6920 or similar instrument, prior to sample collection. All field

instruments will be calibrated at the beginning of the day of sampling and checked again at the end of each day, as required by the QAPP. Field instrument calibration and sample measurement data will be recorded on the Instrument Calibration Sheet and in the field log book, respectively.

The field instrument calibration must be conducted in accordance with the SOP included in Appendix C of the Water Quality Modeling and Monitoring QAPP.

3.9 Program Safety

The most critical component of a sampling program is crew safety. Safety is of paramount importance as stream sampling can be extremely dangerous. The conditions are often wet and dark adding to the dangers. The element of danger is accentuated if personnel are unfamiliar with their surroundings and/or procedures. Consequently, staff must be properly trained in both safety and monitoring procedures, following a well thought out program.

Field Safety Instructions (FSI) have been developed by LimnoTech for the Water Quality Monitoring Program. The FSI include safety precaution information and emergency procedures. The LimnoTech FSI is the governing health and safety document for the sampling program.

RE: Civil Action 2:15-cv-04652-RB

Dear Mr. Willert:

The United States Environmental Protection Agency (EPA) has received the Delaware County Regional Quality Control Authority (DELCORA) Water Quality Modeling and Monitoring Work Plan Update WQMMWP dated July 31, 2017. EPA has consulted with the Pennsylvania Department of the Environment (PaDEP). This letter served to iterate the original approval and formally notify you that EPA accepted the updated WQMMWP and is approved.

Sincerely,

Andrew F. Seligman, Environmental Scientist
Water Enforcement Branch

Section 1 Introduction

1.1 Background of DELCORA's Facilities

Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities serve residential, commercial, institutional, and industrial customers in Delaware County. DELCORA owns and operates an extensive system of pump stations, force mains, and sewers that provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia as shown diagrammatically in Figure 1-1. The total service area served by DELCORA, as shown on Figure 1-2, is approximately 82,977 acres which illustrates that DELCORA serves a significant and widespread portion of Delaware County.

The combined sewer area simulated in DELCORA's existing Hydrologic and Hydraulic model is located within the City of Chester and consists of a drainage area of approximately 1,510 acres. It comprises approximately half of Chester City's serviced area. To support the service area, DELCORA owns and operates over 129 miles of separate and combined sewers. Included in the 129 miles of sewers are: 11.7 miles of an interceptor system; 3,209 manholes; and twenty-five (25) combined sewer outfall regulators controlling storm overflows. The location of Chester City's service area is illustrated on Figure 1-2.

Historically, DELCORA has characterized its service areas as "Eastern" and "Western." The Western service area discharges to DELCORA's Western Regional Treatment Plant (WRTP). The Eastern service area discharges to the Philadelphia Water Department's Southwest Water Pollution Control Plant (PWDSWPCP). In 2002, DELCORA completed the installation of a force main that connects the Eastern Service Area's Central Delaware Pump Station (CDPS) to the Chester Force Main. This connection allows DELCORA to send flow from the CDPS to the WRTP. Flows above 20 MGD are directed to the PWDSWPCP. As such, dry weather flows and a portion of the wet weather flows (total flow less than 20 MGD) from the Central Delaware County Authority in the Eastern Service Area are discharged to the WRTP.

There are a total of 26 combined sewer overflow outfalls listed with 25 discharge points (Outfall #009 and #010 both discharge at Outfall #009) in DELCORA's existing National Pollutant Discharge Elimination System (NPDES) Permit. Under its NPDES Permit No. PA0027103, issued and administered by the Pennsylvania Department of Environmental Protection (PADEP), DELCORA is authorized to discharge from the Western Regional Treatment Plant (Outfall #001), four storm water outfalls at the WRTP (028-031) and from 26 combined sewer overflow outfalls (#002-#026, #032, #033) that ultimately discharge to the Delaware River, Chester Creek and/or Ridley Creek.

Figure 1-1: DELCORA's Conveyance System

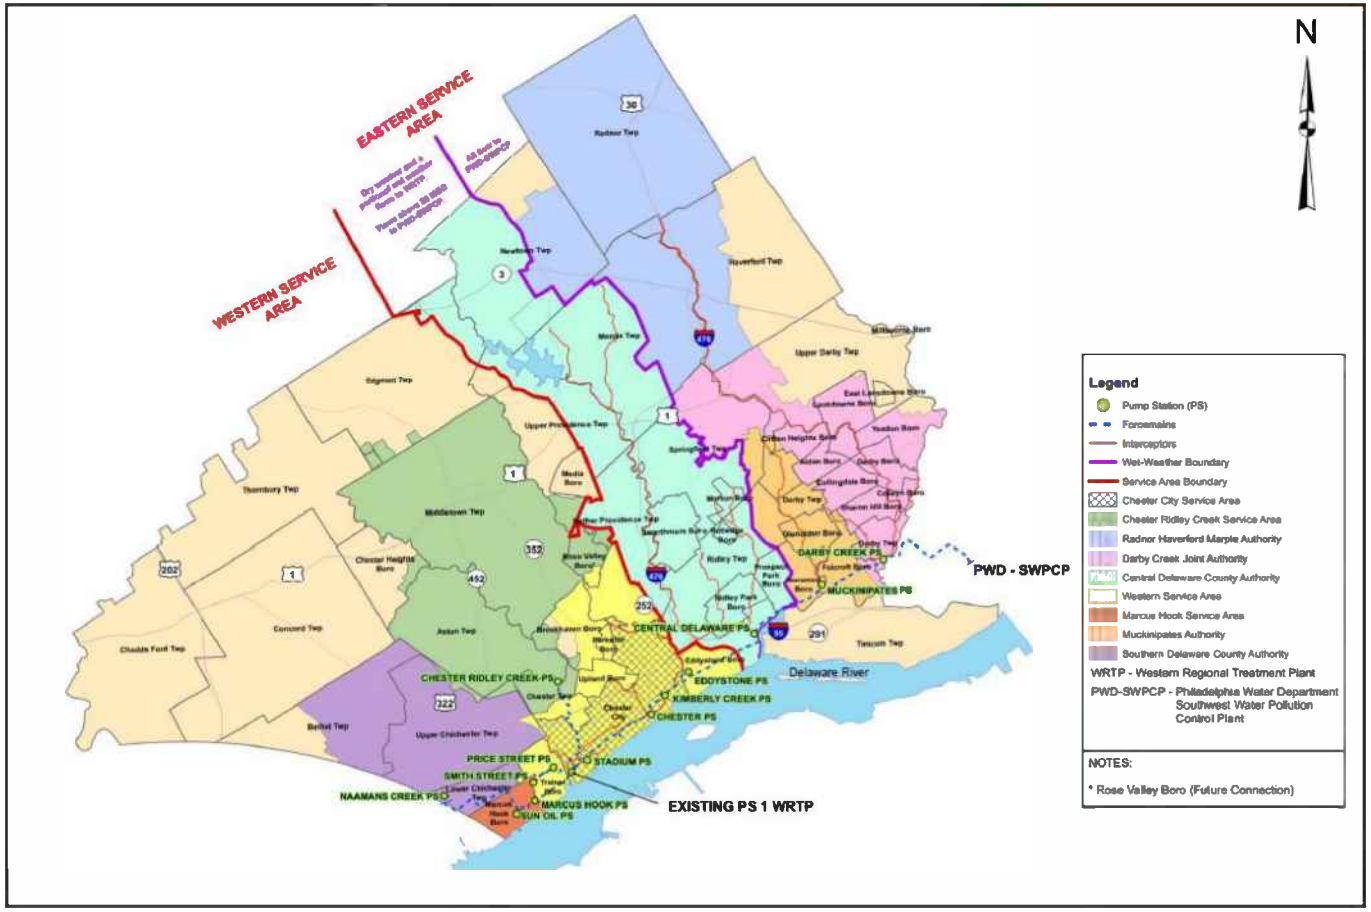
Figure 1-2: DELCORA's Service Area



CSO Long-Term Control Plan Delaware County Regional Water Quality Control Authority	GREELEY AND HANSEN	Figure 1-2 DELCORA'S SERVICE AREA

Part C – Other Requirements, Section V – Combined Sewer Overflows of the NPDES Permit details DELCORA's responsibilities with respect to the CSO system including reporting, continued implementation of and continued compliance with the Nine Minimum Controls (NMC), and implementation of the existing Long-Term Control Plan (LTCP) dated April 1999 and the July 2008 addendum to the LTCP until the updated LTCP is approved.

1.2 DELCORA Facilities

DELCORA's Western service area wastewater is treated at the WRTP located at 3201 W. Front Street in Chester, Pennsylvania. The WRTP treats all wastewater from Southern Delaware County Authority, Marcus Hook Borough, Trainer Borough, Upland Borough, Parkside Borough, Eddystone Borough, Chester Township and the City of Chester as well as a portion of the wastewater from Brookhaven Borough and Nether Providence Township. The City of Chester CSO system is described in detail in Section 1.3.2.

One of the facilities in the City of Chester is the 40-MGD Chester Pump Station and the 48-inch-diameter, PCCP force main that runs to the WRTP. DELCORA has completed construction of a 54-inch-diameter ductile iron force main to replace the existing force main. In 2002, DELCORA completed a force main that connects the Central Delaware Pump Station via a 3.4-mile, 24-inch ductile iron force main to the Chester Force Main. This connection allows DELCORA to send up to 27 MGD of flow from the CDPS to the WRTP, however, DELCORA's operating policy limits this flow to 20 MGD, with flows above this point to be directed to PWD SWPCP. Figure 1-1 shows the interconnections in DELCORA's system. The left side of the figure indicates the Western service area and the right side indicates the Eastern service area. This interconnectivity coupled with the legal agreements DELCORA maintains with the municipalities and conveyance authorities in Delaware County creates the complicated legal/financial framework under which DELCORA operates.

1.2.1 City of Chester CSO System

As noted in Section 1.1, the combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's service area. The combined wastewater/stormwater system in the City of Chester is complicated by the fact that parts of the system are owned, operated and maintained by two governmental entities, the City and DELCORA. DELCORA owns, operates and maintains the parts of the system that convey wastewater, such as the street sewers, collectors, interceptors, and CSO regulators and CSO outfalls. The City owns, operates and maintains the inlets, stormwater-only sewers that connect to the combined sewer system and any stormwater-only outfalls. The City is also responsible for the maintenance and cleaning of the streets, planning, zoning, and development controls.

The Chester CSO system contains 26 permitted outfalls as listed in Table 1-1, and they discharge to three receiving water bodies: the Delaware River, Chester Creek, and Ridley Creek. Figure 1-1 depicts the locations of CSO regulators and outfalls that are DELCORA's responsibility.

Table 1-1: Permitted CSOs in the City of Chester

Name of Receiving Stream	CSO Outfall	Interceptor/CSO Regulator Location	Latitude	Longitude

1.3 Consent Decree

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated LTCP to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. Consent Decree Paragraphs V.A.10.e and V.A.10.f require that the development of the LTCP include:

V.A.10.e. Develop and implementation of a Water Quality Model;

V.A.10.f Characterization of the service area and the Receiving Waters as required by CSO Control Policy Paragraph II.C.1 and associated guidance.

Consent Decree Paragraph V.A.15 (Water Quality Model Plan) requires that within 90 days after review and approval of the Alternatives Evaluation Approach, DELCORA shall submit a report to the USEPA and PADEP that describes the use of the Water Quality Model to support the Demonstration Approach consistent with Section II.C.4 of the CSO Control Policy and the Paragraph V.13 of the Consent Decree (Alternatives Evaluation). Section V.A.15.a of the Consent Decree specifically states:

For each water body in which the Demonstration Approach is to be used, the Water Quality Model Plan shall address:

(i) Background, Scope and Purpose, Description of the System;

(ii) Water quality modeling software to be employed;

(iii) Model configuration and development, including reaches to be modeled, and segmentation and boundary conditions;

(iv) Calibration and validation (dry and wet weather), including events and data to be employed, detailed information regarding all additional data collection activities (if needed), quantitative and qualitative calibration criteria, and utilization of H&H Model outputs;

(v) Use of the Water Quality Model to evaluate Typical Year in-stream conditions for each identified pollutant of concern;

(vi) Schedule for model development and implementation, including integration into LTCP development consistent with other dates required pursuant to this Consent Decree.

1.4 QAPP Purpose and Objectives

This Quality Assurance Project Plan (QAPP) has been developed to meet the requirements of the DELCORA Consent Decree Paragraph Section V.A.15.a.(iv) requiring detailed information regarding all additional data collection and water quality modeling activities. The purpose of the QAPP is to document the necessary procedures required to assure that the project is executed in a manner consistent with applicable U.S. EPA guidance documents and with generally accepted and approved quality assurance objectives. This QAPP is organized in accordance with the basic groups and subgroup elements discussed in the U.S. EPA guidance for QAPPs. The four basic groups include project management (Group A); data generation and acquisition (Group B); assessment and oversight (Group C); and data validation and usability activities (Group D). The groups are subdivided into elements covering specific topics related to each group. The Section and Subsection headings of this QAPP include references to the U.S. EPA QAPP Guidance group letters and element numbers to facilitate cross-reference with the Guidance.

The QAPP integrates quality control policies and project-specific work tasks to successfully conduct water quality monitoring and modeling to support the CSO Long Term Control Plan update. Greeley & Hansen will serve as the contracting authority for the project and provide overall project management. LimnoTech will serve as technical advisors for the sampling program and to provide the data integration and interaction role. The field contractor (Weston Solutions) will conduct the actual sampling program. The laboratory contractor (Eurofin QC) will perform laboratory analysis for the project.

The QAPP has been designed and organized in terms of compliance with U.S. EPA requirements. It is the overall intent of the QAPP to provide professional guidelines for activities by all personnel on the project and to ensure that quality assurance/quality control QA/QC procedures are followed.

Page intentionally left blank for double-sided printing

Section 2 Project Management (Group A)

2.1 Project/Task Organization (A.4)

Each of the organizations included in the project team has established an organizational structure for providing technical direction and administrative control to accomplish quality-related activities for the development of the project. Key project personnel and their corresponding responsibilities are listed in Table 2-1 below and shown in Figure 2-1.

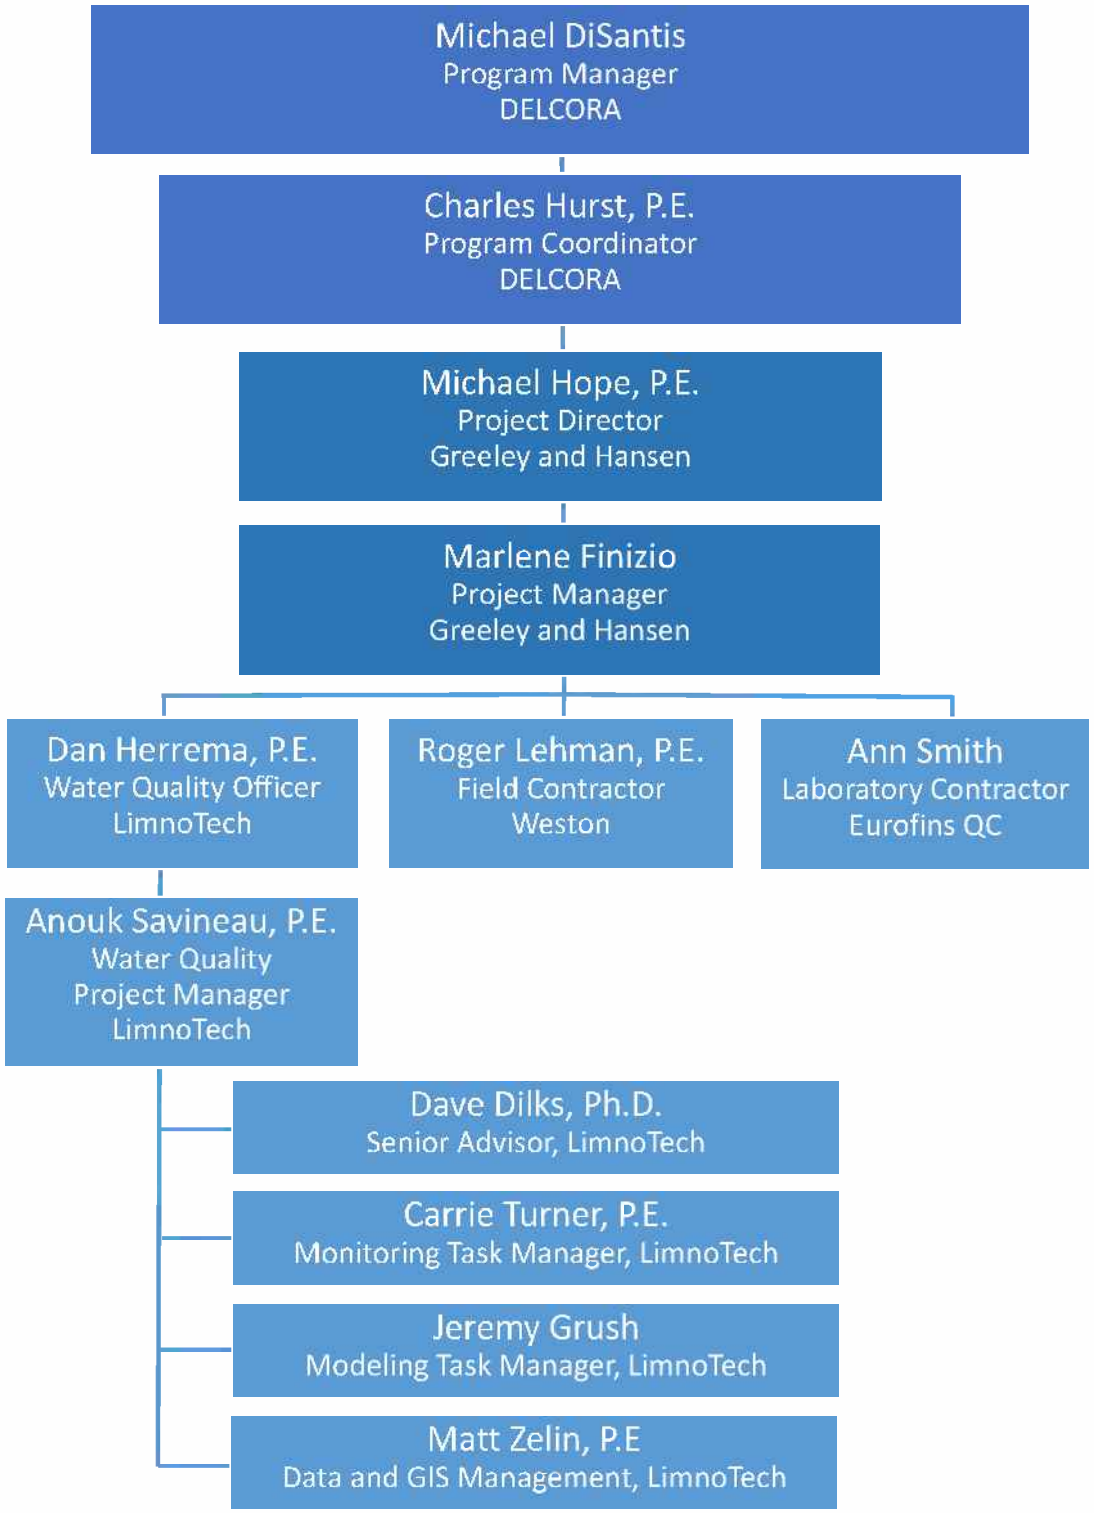
Table 2-1: Key Personnel for the Water Quality Monitoring and Modeling QAPP

Name/Affiliation	Project Title	Responsibility
Michael DiSantis DELCORA	Program Manager	Project oversight
Charles Hurst, P.E. DELCORA	Program Coordinator	Program management and coordination between contractors and DELCORA staff
Michael Hope, P.E. Greeley and Hansen	Project Director	Project direction, review/approval of work products
Marlene Finizio Greeley and Hansen	Project Manager	Project management, coordination of overall work
Anouk Savineau, P.E. LimnoTech	Water Quality Monitoring and Modeling Program Manager	Overall water quality monitoring and modeling task coordination.
Carrie Turner, P.E. LimnoTech	Water Quality Monitoring Program Task Leader	Monitor conditions, decisions to initiate sampling events, compare data to QAPP objectives.
Roger Lehman, P.E. Weston Solutions, Inc.	Field Project Manager	Receiving water and overflow sample collection, manage field staff and equipment development.
Ann Smith Eurofins QC	Laboratory Technical Director	Supply sample bottles and chain-of-custodies. Ensure sample analysis is conducted to meet objectives of QAPP, coordinate sample transfer.
Ray Fratti Eurofins QC	Laboratory QA/QC Manager	QA/QC review of laboratory data to ensure QAPP objectives are met.
Jeremy Grush LimnoTech	Water Quality Modeling Task Leader	Develop, calibrate and validate water quality model consistent with Work Plan.
Matt Zelin, P.E. LimnoTech	Water Quality Data Management Task Leader	Develop, manage, and maintain the water quality database. All data collected during the course of the study will be entered into a database.

The remainder of the project team is made up of engineers, scientists, and technicians. The disciplines represented include environmental assessment and modeling. Staff members within each organization will report to their project manager for technical and administrative direction. Each staff member has responsibility for performance of assigned quality control duties in the course of accomplishing identified sub-tasks. The quality control duties include:

- Completing the assigned task on or before schedule and in a quality manner in accordance with established procedures; and
- Ascertaining that the work performed is technically correct and meets all aspects of the QAPP.

Figure 2-1: Project Team Organization



2.2 Problem Definition/Background (A.5)

The Delaware County Regional Water Quality Control Authority (DELCORA) is responsible for the collection, transmission, treatment and disposal of approximately 65 million gallons per day (MGD) of wastewater generated in southeastern Pennsylvania. DELCORA's facilities, described in Section 1.2 and shown diagrammatically in Figure 1-1, provide the core infrastructure for the transmission of wastewater to treatment facilities in Delaware County and the City of Philadelphia. DELCORA serves a significant and widespread portion of Delaware County and has a total service area of approximately 82,977 acres (Figure 1-2).

The combined portion of DELCORA's sewer system is located within the City of Chester (City), and it comprises approximately half of the City's serviced area. The Chester combined sewer system includes 25 combined sewer overflow outfall locations that discharge to three receiving water bodies: the Delaware River, Chester Creek and Ridley Creek. The combined wastewater/stormwater system in the City of Chester is complicated by the fact that parts of the system are owned, operated, and maintained by two governmental entities, the City and DELCORA. Figure 1-3 shows the CSO regulators and outfalls that are DELCORA's responsibility. DELCORA's responsibilities with respect to the CSO system include reporting, continued implementation of and continued compliance with the Nine Minimum Controls (NMC), and implementation of the existing Long-Term Control Plan (LTCP) dated April 1999 and the July 2008 addendum.

On August 17, 2015, a Consent Decree was lodged in the United States District Court for the Eastern District of Pennsylvania that requires DELCORA to complete and submit a revised and updated LTCP to the United States Environmental Protection Agency (USEPA or EPA) and the Pennsylvania Department of Environmental Protection (PADEP or DEP) for review and approval. The Water Quality Monitoring Program is one component of this Water Quality Model requirements in the Consent Decree (see Section 1.3) that will provide DELCORA with reliable and technically sound data to inform the development, calibration and validation of the Water Quality Model and decisions on CSO control alternatives.

As part of DELCORA's LTCP requirements, pollutants of concern (POCs) were identified and documented in the "Identification of Sensitive Areas and Pollutants of Concern Report" (Greeley and Hansen 2016). Three POCs were identified: fecal coliform, *Escherichia coliform* (*E. coli*), and Enterococcus. Available data for the POCs in the DELCORA combined sewer service area and adjacent watersheds are insufficient for developing a Water Quality Model that meets the requirements of the Consent Decree.

A Water Quality Monitoring Work Plan has been developed to ensure that additional monitoring activities undertaken to support the development of the Water Quality Model and the LTCP update result in representative water quality and quantity information. A Water Quality Model Work Plan has also been developed to ensure that the Water Quality Model meets the requirements set forth in the Consent Decree (Section 1.3). This portion of the work plan describes the water quality model development, methods used to specify CSO and background sources, and the approach to model calibration and validation. This QAPP

describes the quality assurance/quality control component of the sampling program and the water quality model development.

2.2.1 Water Quality Monitoring Objectives

Under the Consent Decree requirements, DELCORA submitted a Pollutant of Concern report in February 2016, subsequently revised in May 2016 (Greeley and Hansen, 2016) that identified three indicator bacteria (fecal coliform, *Escherichia coliform* (*E. coli*), and enterococcus) as pollutants of concern (POC) that are potentially impacting the river during CSO discharges. The water quality monitoring objectives are to collect water quality data for the POCs during dry and wet weather event periods that can be used to characterize the bacteria sources in the Delaware River, Chester Creek, and Ridley Creek in the vicinity of the City of Chester, PA, and to calibrate and validate the Water Quality Model, consistent with the Consent Decree requirements in Paragraph V.A.15.a. Additional in situ parameters, such as salinity, temperature, and conductivity will also be collected to inform the development of the Water Quality Model.

2.2.2 Water Quality Modeling Objectives
