Studies that provide information at 'new levels of observed effect' have been identified. These serve as scientific benchmarks for possible risk to health and well-being. Next, we indentify reduction factors to compensate for sensitive subpopulations and apply them to the scientific benchmarks (lowest observed effect levels).

A ten-fold reduction factor is warranted (or higher) for studies that report effects from only shortp-term (i.e., acute) rather than chronic (i.e., long-term) exposures. Longer duration of exposure can cause bioeffects at lower exposures where these effects are NOT seen with shorter (acute) exposures (Belyaev, 1997; Belyaev, 2012). Chronic exposures with longer durations of weeks, months or years is what most populations face with respect to wireless classrooms, wireless offices and locations near base stations.

A second ten-fold reduction (or higher) is justified as a buffer for sensitive populations including children, the elderly and other adult groups that may be ill, already sensitized, in remission or suffer from ailments made worse by physiological stress and insomnia.

Studies which contribute together can reasonably contribute to delineating a new RFR lower effects level are primarily mobile phone (cell phone) base station studies of healthy human populations and studies of sperm damage in men who use and/or wear their wireless devices on or around the belt or pants pocket.

Power Density Studies (Mobile Phone Base Stations and Sperm/Fertility Studies)

A scientific benchmark of 0.003 uW/cm2 or three nanowatts per centimeter squared for 'lowest observed effect level' for RFR is based on mobile phone base station-level studies. The Thomas et al (2008) study shows effects at a LOEL of 0.005 uW/cm2 on adults exposed to short-term cell phone radiation only (it is not a chronic exposure study). Other studies that are relevant are Thomas et al (2010) with a LOEL of 0.003 uW/cm2 and Heinrich et al, (2010) with a LOEL of 0.003 uW/cm2. Both studied mixed child/adolescent populations of students, but have short-term test periods (are not chronic exposure studies) and have LOELs of 0.003 uW/cm2. Buchner et al (2012) shows a 0.006 uW/cm2 'effect level' and tests adult populations, but achieves 'chronic' exposure testing criterion (over 18 months). Applying a ten-fold reduction to compensate for the lack of long-term exposure (to provide a safety buffer for chronic exposure) or for children as a sensitive subpopulation yields a 300 to 600 picowatts per square centimeter precautionary action level. This is also equal to a 0.3 nanowatts to 0.6 nanowatts per square centimeter as a reasonable, precautionary action level.

Of the studies that deal with children and base-station level RFR exposures, none studied children exclusively, so the results may dilute out any apparent effects acruing to the younger test subjects. Thomas et al (2010) is a short-term exposure study of children and adolescents 8 to 17 years in age. Heinrich et al (2010) is a further study of the same population of 8 to 17 year olds over the short-term. A 100-fold reduction could be defended as reasonably conservative in this instance.

Behari et al (2006) provides the one sperm study expressed in power density units with a LOEL of 0.00034 uW/cm2. It is a chronic exposure study. The majority of sperm studies with good exposure information are expressed in SARs (W/kg). These range from LOELs of 0.014 (Kumar et al, 2012) to 0.091 W/kg (Atasoy et al, 2012) to 0.43 W/kg (Salama et al, 2008) to 0.795 W/kg (Panagopoulous et al, 2012) to 0.9 W/kg (Kesari et al, 2012). All the other sperm damage or ovarian damage studies have SARs

of greater than 1.0 W/kg (7 more studies). All are short-term studies. There are more sperm damage studies but without any measurements or other specific exposure information. These are studies that place sperm, or mice, or give prenatal exposures to animals close to sources of cell phone radiation. Such studies give weight to the argument that low-intensity RFR exposures can cause damage, but do not help in delineating LOELs because they have no specific exposure numbers, just distances.

Most of the sperm studies and base station studies which have exposures expressed power density (microwatts per square centimeter) have 'effect' levels in the nanowatt range (0.34 nanowatt/cm2 to 100 nanowatt/cm2)*. They include Behari and Kesari, 2006; Buchner and Eger, 2012; Oberfeld et al, 2004; Thomas et al, 2008, 2010; Heinrich et al, 2010; Navarro et al, 2003; and Otitoloju et al 2010. Avendano et al (2012) report that WI-FI exposure from a 4-hr laptop exposure decreased sperm viability and caused DNA fragmentation in human sperm samples (exposure in petri dishes) at 0.5 to 1.0 uW/cm2. The Kundi-Hutter 2009 Pathophysiology Journal review paper of base station studies through 2006 reports an overall NOEL below 0.05 to 0.1 uW/cm2. Overall, the new 2007-2012 power density studies are reporting 'lowest effects levels' two or three orders of magnitude lower than in 2006, down from the microwatt/cm2 range to the nanowatt/cm2 range.

SAR Studies (Sperm Studies and Ovarian Damage with Cell Phone Radiation Exposures)

Studies on male fertility (adverse effects on sperm, on the testes size and morphology, etc) coming from cell phone-in-the-pocket-on-stand-by-mode and wireless laptop studies provide us with a flood of new data showing very low-intensity effects to guide precautionary actions and to educate the public about potential risks to health, fertility and reproduction.

*The RF Color Charts in this Report are a guide to reported biological effects and those RFR levels reported to cause them.

Sperm and fertility studies with 'effects levels' in the 9 microwatt/kg to 80 milliwatt/kg range are Kumar et al, 2012 (male infertility) and Aitken et al, 2005 (sperm DNA damage). Sperm studies with 'effect levels' in the 90 to 900 milliwatt/kg range are De Iuliis et al, 2009 (human sperm cell damage), Salama et al, 2008 (decrease in sperm mobility and concentration), Panagopoulous et al, 2012 (ovarian damage) and Kesari et al, 2012 (sperm damage). Studies from 1 W/kg to 1.8 W/kg that report sperm or reproductive damage are Gul et al, 2009 (toxic effect on ovaries), Agarwal et al, 2008 (sperm damage), Agarwal et al, 2009 (sperm damage) and Yan et al, 2007 (deformed sperm cells, disabled for swimming).

The WI-FI laptop study by Atasoy et al (2012) reports that exposures to laptops estimated at 0.091 W/kg increase DNA damage and reduce DNA repair in damaged sperm, and "*raise questions about safety of radiofrequency exposure from WI-FI internet access dvices for growing organisms of reproductive age, with a potential effect on fertility and integrity of germ lines.*"

Altered fetal development in mice exposed to RFR at SARs of 0.3 to 60 milliwatt/kg is reported to result in consequent adverse effects on learning and behavior (Aldad et al, 2012). Fragopoulou et al (2009) reported changes at 600 to 900 milliwatts/kg in mouse embryos.

General Approach to Delineating a Precautionary Action Level

As a methodology, is not necessary or wise to use an averaging approach among studies. The technique itself is too vulnerable to weighting problems by the older studies that did not test for effects at the lowest range of exposures to RFR (or did not have the power to assess effects). Averaging also is insensitive to giving proper visibility to important NEW results at the very low-intensity (nanowatt, picowatt and femtowatt/cm2 range). Even when they are averaged together, these studies contribute vanishingly small influence when averaged together with studies of much higher power density to determine a scientific benchmark for harm.

One limitation of the sperm studies using base station-level RFR exposures is that good estimates of exposure are available if sperm are tested outside the body (in petri dishes), but that does not reflect the more realistic situation of sperm exposed in humans themselves (using or carrying a mobile phone near the testes) where exposure estimates are more difficult to determine. So, it is useful and informative to observe the combined results of both in-vivo and ex-vivo studies as a guide. For base station studies on human populations, the quality of exposure assessments is variable, and in some cases inadequate. Further, very few base station studies are conducted so that test subjects do not know if/when they are subjected to elevated RFR (blinded studies), so that some bias may influence results. People often report more ill effects because they are aware of the exposure (from a nearby base station, for example). These variations in quality across the studies, however, do not offset their usefulness in the aggregate for delineating what the lowest observable effect exposures are, and helping to guide decision-making for public health and precautionary actions.

A further concern is that time-averaging of RFR to give a single numeric recommendation for a precautionary action guideline does not address the critical difference between peak power levels (RFR spikes that occur intermittently) and measurements that hide how high peak power spikes are by dilution. Since biological responses can last over seconds of time, or have even longer effects on proteins and enzymes, while the RFR pulses may be in microseconds or milliseconds in duration, it is entirely possible that what causes bioeffects is the high, intermittent RFR spikes that the body perceives and responds to as one continuous, high-power assault. For example, the DECT phone peak power is about 100 times larger than what RFR is measured with time-averaging. A person near a cell tower that produces an RFR measurement of 0.1 microwatts/cm2 is probably getting RFR power density spikes of eight times higher, if you could measure the spikes individually. None of the studies profiled in this section deal with peak power pulses and biological response times that are longer than the 'intermission' between RFR spikes. Thus, precautionary action levels should err on the side of being conservative.

The planning of base stations, and other site evaluations needs to have a scientific benchmark below which effects have not (not yet) been characterized, published or vetted. Then, a reasonable safety buffer should be added - remembering that the design life of such facilities may be 30-50 years long. This is standard procedure for environmental planning constraints.

Health Agencies Should Act Now

Health agencies and regulatory agencies that set public safety standards for ELF-EMF and RFR should act now to adopt new, biologically-relevant safety limits that key to the lowest scientific benchmarks for harm coming from the recent studies, plus a lower safety margin. Existing public safety limits are too high by several orders of magnitude, if prevention of bioeffects and resulting adverse health effects are to be minimized or eliminated. Most safety standards are a thousand times or more too high for healthy populations, and even less effective in protecting sensitive subpopulations.

New, biologically-based public exposure standards are critically needed now and should key to scientific benchmarks for harm, plus a safety margin below that level.

Standard of Evidence for Judging the Science

The standard of evidence for judging the scientific evidence should be based on good public health principles rather than demanding scientific certainty before actions are taken.

Sensitive Populations Require Special Protections

Safety standards for sensitive populations will need to be set at lower levels than for healthy adult populations to protect the developing fetus, the infant and young child, school-age children, the elderly, those with pre-existing chronic diseases, and those with developed electrical sensitivity (EHS). Men of child-bearing age should not wear

wireless devices on their body in order to protect the integrity of sperm DNA. Sperm should be considered a 'sensitive population'. Scientific benchmarks for lowest effect levels should be identified, and applied with additional safety margin reductions to safeguard populations against excessively high exposure to chronic ELF-EMF and RFR.

Protect Children Against Chronic Exposure to Wireless Devices

Strong precautionary action and clear public health warnings are universally warranted for use of cordless and cell phones to help prevent a global epidemic of brain tumors. This is especially important for children, adolescents and young adults, while new safety standards are established and implemented. Children should not use wireless devices except in the case of emergencies, or be exposed on an involuntary and chronic basis to wireless in their living, sleeping or learning environments.

Common Sense Precautionary Measurees are Warranted Now

Common sense measures to limit both ELF-EMF and RFR in the fetus and newborn infant are needed, especially with respect to avoidable exposures like baby monitors in the crib and baby isolettes (incubators) in hospitals that can be modified; and where education of the pregnant mother with respect to laptop computers, mobile phones and other sources of ELF-EMF and RFR are easily instituted.

Wireless laptops and other wireless devices should be strongly discouraged in schools for children of all ages, and wireless systems already installed should be replaced with wired (cable) alternatives. While without question it is important for children to have access to the internet, wired computer laboratories will have no elevated exposure to RFR. What might be lost in flexibility of moving rooms arounds will be more than gained by reducing exposure to RFR if wired connections, rather than wireless, are used. Pregnant women should be strongly cautioned not to use wireless devices during pregnancy. If a school already has wireless facilities, classrooms without wireless should be made available to students, teachers and staff during the transition if sensitivities to

EMF are reported by the individual. Special education classroom teaching environments should offer wired teaching environments (not wireless), nor should they be exposed to off-site wireless radiofrequency radiation from other sources that elevate interior levels for children.

Special Protections for the Integrity of the Genome and Reproduction

Reducing life-long health risks should begin in the earliest stages of embryonic and fetal development. Development pace is accelerated for the infant and very young child compared to adults, and is not complete in young people (as far as brain and nervous system maturation) until the early 20's. Windows of critical development mean that risk factors once laid down in the cells, or in epigenetic changes in the genome may have grave and life-long consequences for health or illness for every individual, and furthermore these genetic and epigenetic changes may be passed to the next generation. All relevant environmental conditions, including biologically active exposures to EMF and RFR that can degrade the human genome, and impair normal health and development of all species including humans - should be given weight in defining and implementing strong precautionary actions now to protect public health. The consequence of ignoring clear evidence of large-scale health risks to global populations, when the risk factors are largely avoidable or preventable is too high a risk to take.

SECTION 26

Glossary of Terms and Abbreviations

Prepared for the BioInitiative Working Group

July 2007

Absorption. In radio wave propagation, attenuation of a radio wave due to dissipation of its energy, i.e., conversion of its energy into another form, such as heat.

Athermal effect. Any effect of electromagnetic energy on a body that is not a heat-related effect.

Blood–brain barrier. A functional concept developed to explain why many substances that are transported by blood readily enter other tissues but do not enter the brain; the "barrier" functions as if it were a continuous membrane lining the vasculature of the brain. These brain capillary endothelial cells form a nearly continuous barrier to entry of substances into the brain from the vasculature.

Conductance. The reciprocal of resistance. Expressed in siemens (S).

Conductivity: A property of materials that determines the magnitude of the electric current density when an electric field is impressed on the material.

Continuous wave. A wave whose successive oscillations are identical under steady-state conditions.

Current density. A vector of which the integral over a given surface is equal to the current flowing through the surface; the mean density in a linear conductor is equal to the current divided by the cross-sectional area of the conductor. Expressed in ampere per square metre (A $m^{!2}$).

Depth of penetration. For a plane wave electromagnetic field (EMF), incident on the boundary of a good conductor, depth of penetration of the wave is the depth at which the field strength of the wave has been reduced to 1/e, or to approximately 37% of its original value.

Dielectric properties: In the context of this document the properties of materials conductivity and permeability.

Dosimetry. Measurement, or determination by calculation, of internal electric field strength or induced current density, of the specific energy absorption, or specific energy absorption rate distribution, in humans or animals exposed to electromagnetic fields.

Electric field strength. The force (**E**) on a stationary unit positive charge at a point in an electric field; measured in volt per metre (V $m^{!1}$).

Electrosensitivity (Electrohypersensitivity): A working definition of EHS from Bergqvist et al. (1997) is "a phenomenon where individuals experience adverse health effects while using or being in the vicinity of devices emanating electric, magnetic or electromagnetic fields (EMFs)".

Electromagnetic energy. The energy stored in an electromagnetic field. Expressed in joule (J).

Electric field strength (E): The magnitude of a field vector at a point that represents the force (F) on a charge (q). E is defined as E = F/q and is expressed in units of Volt per meter (V/m).

Electromagnetic field: Electromagnetic phenomena expressed in vector functions of space and time.

Electromagnetic radiation: The propagation of energy in the form of electromagnetic waves through space.

EMF. Electric, magnetic, and electromagnetic fields.

Exposure: Exposure occurs wherever a person is subjected to electric, magnetic or electromagnetic fields or contact currents other than those originating from physiological processes in the body.

Extra low frequency (ELF): Extra low frequency fields include, in this document, electromagnetic fields from 1 to 300 Hz. Alternately, **ELF-** Extremely low frequency where the European convention is extremely low frequncy, US is extra-low frequency.

Frequency modulation (FM): Frequency Modulation is a type of modulation representing information as variations in the frequency of a carrier wave. FM is often used at VHF frequencies (30 to 300 MHz) for broadcasting music and speech.

Far field. The region where the distance from a radiating antenna exceeds the wavelength of the radiated EMF; in the far-field, field components (**E** and **H**) and the direction of propagation are mutually perpendicular, and the shape of the field pattern is independent of the distance from the source at which it is taken.

Frequency. The number of sinusoidal cycles completed by electromagnetic waves in 1 second; usually expressed in hertz (Hz).

Impedance, wave. The ratio of the complex number (vector) representing the transverse electric field at a point to that representing the transverse magnetic field at that point. Expressed in ohm (S).

Magnetic flux density (B): The magnitude of a field vector at a point that results in a force (F) on a charge (q) moving with the velocity (v). The force F is defined by $F = q*(v \times B)$ and is expressed in units of Tesla (T).

Magnetic field strength (H): The magnitude of a field vector that is equal to the magnetic flux density (B) divided by the permeability (μ) of the medium. H is defined as $H = B/\mu$ and is expressed in units of Ampere per metre (A/m).

Magnetic permeability. The scalar or vector quantity which, when multiplied by the magnetic field strength, yields magnetic flux density; expressed in henry per metre ($H\ m^{-1}$). *Note:* For isotropic media, magnetic permeability is a scalar; for anisotropic media, it is a tensor quantity.

Microwaves: Microwaves are defined in the frame of this expertise as electromagnetic waves with wavelengths of approximately 30 cm (1 GHz) to 1 mm (300 GHz).

Milligauss (mG): A milligauss is a measure of ELF intensity and is abbreviated mG. This is used to describe electromagnetic fields from appliances, power lines, interior electrical wiring.

Milliwatt (mW): A unit of power equal to 10^{-3}.

Microwatt (uW): A unit of power equal to 10^{-6}

Microwatts per centimeter squared (μW/cm2)

Radiofrequency radiation in terms of power density is measured in microwatts per centimeter squared and abbreviated (μW/cm2). It is used when talking about emissions from wireless facilities, and when describing ambient RF in the environment. The amount of allowable RF near a cell tower is 1000 μW/cm2 for some cell phone frequencies, for example.

Nanowatt (nW): A unit of power equal to 10^{-9} Watt.

Non – thermal effects (or athermal effects): An effect which can only be explained in terms of mechanisms other than increased molecular motion (i.e. heating), or occurs at absorbed power levels so low, that a thermal mechanism seems unlikely, or displays so unexpected a dependence upon some experimental variable that it is difficult to see how heating could be the cause.

Near field. The region where the distance from a radiating antenna is less than the wavelength of the radiated EMF. *Note:* The magnetic field strength (multiplied by the impedance of space) and the electric field strength are unequal and, at distances less than one-tenth of a wavelength from an antenna, vary inversely as the square or cube of the distance if the antenna is small compared with this distance. Near field exposures are unreliable for estimation of exposures by calculation. The can zero out or be additive and nearly infinite, thus creating problems for exposure assessment.

Non-ionizing electromagnetic radiation (NIER). Includes all radiations and fields of the electromagnetic spectrum that do not normally have sufficient energy to produce ionization in matter; characterized by energy per photon less than about 12 eV, wavelengths greater than 100 nm, and frequencies lower than 3×10^{15} Hz.

Occupational exposure. All exposure to EMF experienced by individuals in the course of performing their work. Safety limits are five times higher for allowable occupational exposures than for general public exposures in the US.

Permeability (μ): A property of materials that indicates how much polarisation occurs when an electric field is applied.

Permittivity. A constant defining the influence of an isotropic medium on the forces of attraction or repulsion between electrified bodies, and expressed in farad per metre ($F\ m^{-1}$); *relative permittivity* is the permittivity of a material or medium divided by the permittivity of vacuum.

Public Exposure. All exposure to EMF experienced by the general public excluding exposure during medical procedures and occupational work environments. Public exposure limits in the US are five times lower than for occupational exposures, where informed consent by employees is required.

Power Density. The power as measured in free space (ambient) as opposed to measured by SAR or specific absorption rate (within tissues or the body). The unit of measurement can be watts per square meter, milliwatts per square meter or microwatts per centimeter squared. Radiofrequency (RF). Any frequency at which electromagnetic radiation is useful for telecommunications, or broadcasting for radio and television. Frequency range is usually defined as 300 Hz (300 hertz) to 300 GHz (300 gigahertz).

Radiofrequency (RF): The frequencies between 100 kHz and 300 GHz of the electromagnetic spectrum.

Reasonance. The change in amplitude occurring as the frequency of the wave approaches or coincides with a natural frequency of the medium; whole body absorption of electromagnetic waves presents its highest value, i.e., the reasonance. for frequencies (in MHz or megahertz) corresponding to approximately 114/L where L is the height of the individual in meters. Reasonance can also be applicable to organs, tissues, or other body parts.

Specific Absorption Rate (SAR is measured in watts per kilogram or W/Kg)
SAR stands for specific absorption rate. It is a calculation of how much RF energy is absorbed into the body, for example when a cell phone or cordless phone is pressed to the head. SAR is expressed in watts per kilogram of tissue (W/Kg). The amount of allowable energy into 1 gram of brain tissue from a cell phone is 1.6 W/Kg in the US. For whole body exposure, the exposure is 0.8 W/Kg averaged over 30 minutes for the general public. International standards in most countries are similar, but not exactly the same.

Static electric field: Static fields produced by fixed potential differences.

Static magnetic fields: Static fields established by permanent magnets and by steady currents.

VDU: Video display units for computers, videos, TV and some measurement devices using cathode ray tubes

WI-FI: Stands for wireless fidelity. WI-FI systems create zones of wireless RF that allow access to wireless internet for computers, internet phone access and other wireless services. Access points that provide WI-FI to access Land Area Networks (LANs) can be installed on streets (for city-wide coverage) or indoors in buildings, Restaurants, hotels, coffee shops, airports, malls and other commercial enterprises are widely installing WI-FI. The range of typical WI-FI systems is about 300 feet.

WI-MAX: Stands for "Wireless interoperability for Microwave Access" and is a telecommunications technology aimed at providing wireless data over long distances. Like WI-FI, WI-MAX systems are designed to provide wireless access but over much broader geographic areas, with some systems transmitting signal up to 10 miles. Higher levels of RF are produced at the wireless transmission facilities than for WI-FI.s

Section 20 LIST OF ABBREVIATIONS

µT	microtesla
µW	microwatt
AC	Alternating current

MF	Magnetic Field (sometimes MF-ELF)
MHz	Megahertz
ms	Milliseconds
mT	Millitesla
mG	Milligauss
mW	Milliwatt
nT	Nanotesla

nW Nanowatt

NRPB National Radiation Protection Board (HPA)

OR Odds Ratio (measure of increased risk of disease)

REFLEX European Research Program for Radiofrequency Hazards

RF Radiofrequency Radiation (also written as RFR or RF-EMF)

SCENIHR Scientific Committee on Emerging and Newly Identified Health Risks

TNO Nederlandse Onderzoek (Netherlands Organisation Applied Scientific Research

UMTS Universal Mobile Telephony System **UNEP** United Nations Environmental

VDT Video display terminal (VDU – for computers, videos, TV, that use cathode ray tubes).

Wi-Fi Short for wireless fidelity – wireless internet access - works for short- distances for cell phone and laptop computer access without wires.

WLAN Wireless Local Area Network (wireless internet coverage usually up to 300' provided by access points that create elevated radiofrequency radiation for that service zone.

WiMAX Worldwide Interoperability for Microwave Access (wireless service up to 10 miles in comparison to Wi-Fi that may serve 300' area)

WHO World Health Organisation

FCC The Federal Communications Commission (FCC) is an independent United States government agency, created, directed, and empowered by Congressional statute to oversee the regulation of radio and TV broadcasting and wireless technologies. It is not a health agency.

HPA Health Protection Agency (UK) that was formerly the National Radiation Protection Division Board). The Health Protection Agency (HPA) is an independent body that protects the health and well-being of the population. The Agency plays a critical role in protecting people from infectious diseases and in preventing harm when hazards involving chemicals, poisons or radiation occur.

DNA Deoxyribonucleic acid, or DNA is a nucleic acid molecule that contains the genetic instructions used in the development and functioning of all living things.

Melatonin Melatonin is a hormone produced in the brain by the pineal gland, It is a potent anti-oxidant that protects against oxidative damage from free radicals that can cause DNA damage.

Alzheimer's Alzheimer's disease is a progressive brain disorder that gradually destroys a person's memory and ability to learn, reason, make judgments, communicate and carry out daily activities. As Alzheimer's progresses, individuals may also experience changes in personality and behavior, such as anxiety, suspiciousness or agitation, as well as delusions or hallucinations.

RFIAWG Radiofrequency Interagency Working Group (US) composed of members from federal agencies with some interest in radiofrequency radiation issues. This Working Group was made up of representatives from the US government's National Institute for Occupational Safety and Health (NIOSH), the Federal Communications Commission (FCC), Occupational Health and Safety Administration (OSHA), the Environmental Protection Agency (US EPA), the National Telecommunication and Information Administration, and the US Food and Drug Administration (FDA).

ICNIRP International Commission on Non-Ionizing Radiation. It is a body of independent scientific experts consisting of a main Commission of 14 members, 4 Scientific Standing Committees covering Epidemiology, Biology, Dosimetry and Optical Radiation and a number of consulting experts. This expertise is brought to bear on addressing the important issues of possible adverse effects on human health of exposure to non-ionising radiation.

SECTION 27

Appendix 20-A Average Residential Exposures to ELF (Power Frequency Fields)

Prepared for the BioInitiative Working Group

July 2007

What are Ambient ELF and RF Levels?

A nation-wide survey in the United States by Zaffanella et al (1993) collected engineering data on sources and levels of 60 Hz electric power magnetic fields that exist inside residences in the United States.

Approximately 1000 residences were randomly selected for the survey. The goals were to 1) identify all significant sources of magnetic field, 2) estimate for each source the percentage of residences where magnetic fields exceeded specified levels, 3) to determine the relation between magnetic field and sources and 4) to characterize the field varations in time.

The median field was identified as 0.5 mG and the average field was 0.9 mG. Thus, this confirms that average residential magnetic fields based on the 1000-home study is less than 1 mG.

Appliances produce magnetic fields but these diminish rapidly with distance (at $1/R^3$),

Power lines generally produce the largest average residential magnetic field when the entire living space of a residence and a 24-hour period are considered. Power line magnetic field exceeds 1 mG in 17%, exceed 2.5 mG in 9.5% and exceed 5 mG in 0.3% of all the residences surveyed.

Zaffanella (1998) conducted measurements to characterize typical EMF exposure levels in persons living in the United States - a study called the 1000-Person Study. Table A-S.2 shows that about half of all people in the US have EMF exposures at home under 0.75 mG; in bed are 0.48 mg; at school 0.60 mG; at work 0.99 mG; and 0.87 mG is the median EMF exposure for an average 24-hour day.

Table A-S.2

Table S.2 Descriptive Statistics for Different Activity Periods

Parameter	Home not in Bed	In Bed	Work	School	Travel	24-Hour
Number of Valid Data Sets	1011	996	525	139	765	1012
1st Percentile	0.10 mG	0.01 mG	0.14 mG	0.13 mG	0.13 mG	0.18 mG
5th Percentile	0.20 mG	0.08 mG	0.24 mG	0.18 mG	0.29 mG	0.27 mG
10th Percentile	0.27 mG	0.12 mG	0.30 mG	0.29 mG	0.41 mG	0.35 mG
25th Percentile	0.44 mG	0.24 mG	0.60 mG	0.35 mG	0.66 mG	0.51 mG
50th Percentile	0.75 mG	0.48 mG	0.99 mG	0.60 mG	0.98 mG	0.87 mG
75th Percentile	1.39 mG	1.24 mG	1.78 mG	1.01 mG	1.46 mG	1.41 mG
90th Percentile	2.49 mG	2.44 mG	3.32 mG	1.64 mG	2.18 mG	2.38 mG
95th Percentile	3.89 mG	3.63 mG	5.00 mG	1.77 mG	2.73 mG	3.38 mG
99th Percentile	9.50 mG	9.19 mG	13.5 mG	3.55 mG	5.43 mG	6.16 mG
Mean	1.29 mG	1.11 mG	1.73 mG	0.82 mG	1.22 mG	1.25 mG
Standard Deviation	2.54 mG	2.06 mG	3.09 mG	0.70 mG	0.99 mG	1.51 mG
Geometric Mean	0.80 mG	0.52 mG	1.03 mG	0.64 mG	0.96 mG	0.89 mG
Geometric Standard Deviation	2.50	3.52	2.57	2.06	2.03	2.18

In Sweden, Mild et al (1996) report that overall mean residential ELF exposures are 0.4 mG, and in Norway are 0.13 mG.

Average Occupational Exposures to ELF

Average occupational exposures in commercial office buildings are 1-2 mG or less and have been reported fairly consistently across numerous studies of exposure assessment (Table 1). Powerline and electrical workers have higher average occupational exposures from 10 mG to 16.6 mG.

Table A-2: Average Occupational Exposures to ELF

EMF RAPID Program – Questions and Answers, NIEHS, June 2002	
Office buildings (median)	0.6 mG
Support staff	0.5 mG
Professional staff	0.6 mG
Maintenance staff	0.6 mG
Visitors	0.6 mG
EMF RAPID Program Engineering Project #3 Executive Summary, May 1996	
Office building (average)	0.7 mG
Office building (median)	0.4 mG
Electric and Magnetic Field Fundamentals (EPRI Resource Paper, March 1994)	
Typical magnetic fields in offices	1 – 2 mG
Power line workers	10 mG
Occupational EMF Exposure Assessment (EPRI Resource Paper, February 1994)	
Office Worker Comparison Group	1.6 mG
All Occupationally Exposed Utility Workers	16.6 mG
Table 7 – Other Studies Cited	
Bracken Study (1990)	1.0 mG
Deadman Study (1988)	1.6 mG
Bowman Study (1992)	0.9 – 1.8 mG

Limits on Operation of Sensitive Electronic Equipment

Companies that manufacture or use equipment in nanotechnology and biotechnology and found 1.0 mG is generally the limit for proper operation of electron beam devices (mass spectrometers, scanning electron microscopes, lithography, etc) used in these technologies. Ten (10) milligauss (mG) is the EMF limit for normal computers – above 10 mG can introduce "computer jitter" and other problems.

What are Ambient Radiofrequency Radiation/Microwave Levels?

Prior to the rapid development of wireless communications for personal and business usage, RF power density levels were primarily related to AM, FM and television broadcasting signal in both urban and rural areas of the United States. Microwave frequencies used for wireless communications were negligible.

Original extra-planetary sources of microwave radiation were infinitesimally small, on the order of a billionth of a microwatt per centimeter squared (10^{-12} uW/cm^2). Human evolution took place without any appreciable exposure to microwave radiation from background sources. The human body has no evolutionary protection against microwave radiation, as it does for ultraviolet radiation from the sun (Johannson, 2000). Wireless voice and communications have introduced unprecedented levels of public exposure in the last decade.

Mantiply (1997) measured and reported common sources and levels of RF in the environment. He identified areas near cellular base stations on the ground near towers to be from 0.003 to 0.3 μW/cm2. Background level ambient RF exposures in cities and suburbs in the 1990's were generally reported to be below 0.003 μW/cm2.

Hamnerius (2000) reported that ambient RF power density measurements in twelve (12) large cities in Sweden were roughly ten times higher than in the United States for equivalent measurement locations by Mantiply in 1978 (when no cellular phone service existed in the US). He reported a total mean value of 26 measured sites in the study was 0.05 μW/cm2 and the median value was 40 μW/cm2. An office location with a base station nearby at about 300 feet distance tested 150 μW/cm2. A train station with antennas mounted indoors tested at about 3 μW/cm2. Both indoor and outdoor ambient RF power density measurements showed high variability depending on proximity to transmitting antennas.

Sage Associates reported on microwave frequency RF power density levels at outdoor locations both near and far from wireless antenna sites in the United States (Sage, 2000). Within the first 100-300 feet, power density levels have been measured at 0.01 to 3.0 μW/cm2. Elevated RF power density levels from a major wireless antenna site can often be detected at 1000 feet or more. Power density levels away from wireless antenna sites measure between 0.001 μW/cm2 to 0.000001 μW/cm2. Vegetation often reduces signal (and therefore the reach of elevated RF exposures) but dry building materials used to visually screen wireless sites do not appreciably diminish signal transmission. Therefore, many sites that are "out-of-sight" because of stealth design can still produce elevated RF levels in nearby areas where people live, work and go to

school. For purposes of this evaluation, a 10 dB attenuation has been incorporated to take building material shielding effects into account.

APPENDIX 20-B

STANDARDS OF EVIDENCE FOR DECISIONMAKING DIFFERS AMONG PROFESSIONS

There is a large difference between what constitutes causal evidence for purposes of achieving scientific consensus, what constitutes sufficient evidence for purposes of interim public health policy, and what constitutes "a more likely than not" case. A central confusion in this debate is whether prudent policy and public health decisions necessarily require conclusive scientific evidence first. This is not the case. The state of the science needs to be presented in an understandable and scientifically accurate manner, but prudent public health actions do not and should not require 100% proof of harm. In fact, precautionary and preventative actions are specifically justified at a point in time before scientific proof is established. If the growing weight of evidence is positive (although all studies need not report positive effects) then it may be essential to take preventative actions and implement policies that are protective of public health, safety and welfare rather than wait for absolute certainty. The following discussion is presented to highlight some of the main differences in professional approach and traditional ways of viewing and interpreting scientific evidence. In reality, the basis for taking action (preventative or precautionary action) is a continuum – there are no hard and fast rules. The bar for Public Health Policy may be higher or lower than shown in Figure 2; based on many factors, including how widespread the risk, how dread the disease, the cost of inaction (doing nothing until there is proof, but many may be harmed), etc.

A. Scientific Standard of Evidence

There are several levels of proof for adverse effects of environmental exposures. The most rigorous is a scientific standard, where virtual proof of causation is typically required by scientists to arrive at consensus about an effect. This approach works best in physics and chemistry. In biological systems this is rarely possible.

In this case, the 'scientific standard' refers to the overall evidence that the science community typically requires before rendering opinions on the strength of evidence, and what evidence they believe is necessary to establish a causal link (proof).

Figure 1 shows Standards of Evidence that are routinely employed by various interest groups in the EMF debate (Sage, 1997). It can be used to focus on various accepted standards for evidence that are legitimately used by scientific and professional groups to determine when an action is appropriate. The varying levels of certainty about an outcome will dictate different decision-making among different groups that may all be appropriate given their professional charge. Even though the evidence required to make a scientific determination about causality has a far higher standard than a legal determination on the 'weight of the evidence' or 'preponderance of evidence' (a legal standard), neither negates the correctness of the other in its proper jurisdiction. Scientists typically want all possible evidence (animal, cell and epidemiological studies, with replications) showing a high degree of consistency. This can generally be described as a 95% to

99% degree of certainty before drawing conclusions (it does not refer to the 95% confidence interval in epidemiology, except as a part of the overall proof).

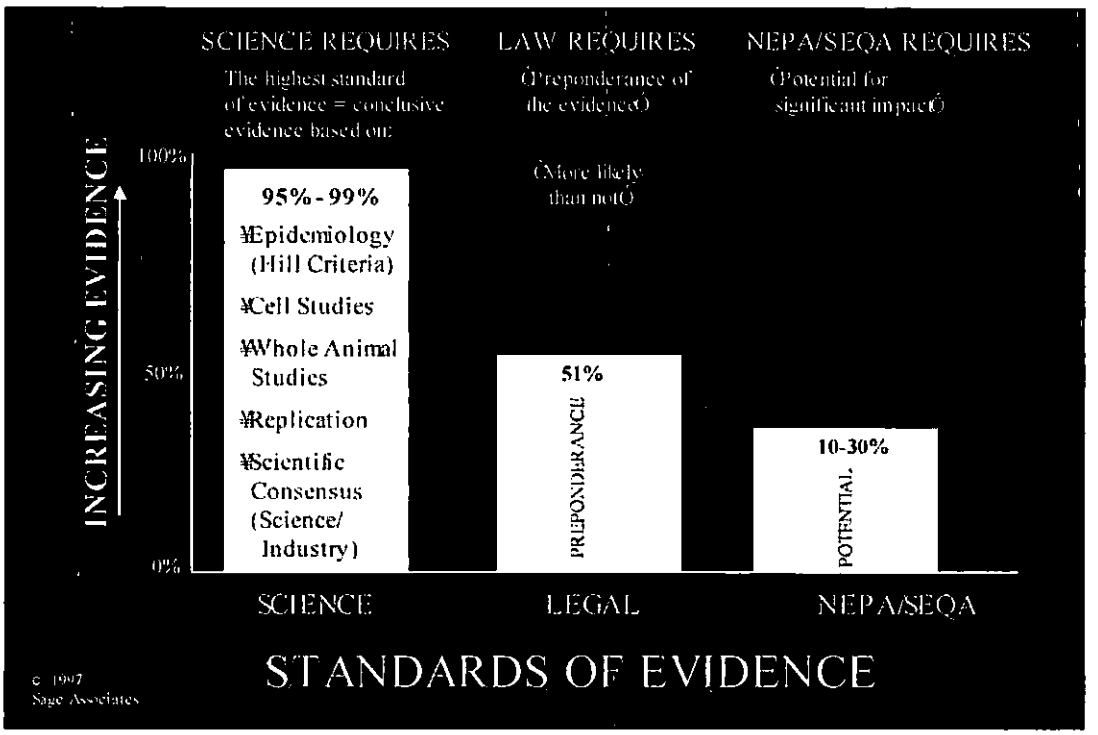

Figure 1 Variable Standards of Evidence (By Profession)

B. Legal Standard of Evidence

The second level of proof is the standard applied in legal proceedings, which is 'more likely than not' or 'preponderance of the evidence' (Figure 1). This is to say if there is a 50%+ likelihood of harm, this is taken as evidence for a relationship (Sage, 1997). At least this level of evidence is reached for the studies of adult cancer and neurodegenerative diseases and 50/60 Hz magnetic field exposures. As with childhood leukemia, while we have documented associations, this does not necessarily indicate causation. Failure to meet either the scientific or the legal standard of proof does not mean that there is no relationship between exposure and disease. In the case of EMF exposure, where everyone is exposed, the societal implications may be huge if there is a real risk whose magnitude has simply just not yet been clarified. Public policies are needed to address this issue of decision-making in the face of this scientific uncertainty.

C. Environmental Protection Standard of Evidence

National and state environmental quality acts (The National Environmental Policy Act) and various state environmental quality acts (SEQA) require that assessments use a standard of "potential for a significant impact on the environment which is a relatively low level of certainty (10% to 30%). The potential for a significant impact requires that mitigation strategies be developed, i.e, require precautionary or preventative actions when only the potential for risk is present (Figure 1).

For example, the potential for risk to humans from building on an active earthquake fault will require a finding of potentially significant impact, and will require mitigative action; even when there is no certainty (no causal evidence) that the fault will rupture and cause damage within the design lifetime of the building. Proof of harm is not a pre-condition for taking action, and the level of certainty is low in comparison to a scientific or legal standard of certainty. Nonetheless, each standard has validity, and will have a different level of evidence required to take action. What decision-makers need to address is what standard of evidence is appropriate now to guide them with respect to EMF exposures that are clearly of environmental and public health concern.

D. Public Health Standard of Evidence

The prudent approach from a public health point of view is to take preventive actions as if causation had been proven, while at the same time to continue to search for mechanisms of action. In the case of childhood leukemia and ELF exposure there is a consistent and statistically significant association in most studies, while for many of the other diseases the results are less consistent although strong associations are found in some studies (Figure 2). This bar graph should be considered illustrative only, since the level of certainty may be higher or lower (above or below 50%) depending on the circumstances of the potential risk, and costs of those risks to society.

Whether magnetic fields actually cause childhood leukemia and the other cancers and neurological diseases documented in this Report; or whether it is some other component in the electromagnetic environment that is responsible for the association is a subject of debate within the scientific community, but from a public health point of view it doesn't matter. The fact that there are unknowns does not negate or override the ultimate public health responsibility, which is to protect the population from exposures which cause disease. Those who make public health decisions, as well as policymakers who rely on them and who approve construction of new schools and homes near power lines, those who provide insurance or financing of new construction, those who must choose siting routes for new electrical facilities all face making decisions with some uncertainty about the potential health risks from EMF exposure. Important social issues must often be decided on the basis of incomplete or uncertain scientific information.

Acknowledgements

The BioInitiative Working Group gratefully acknowledges the many independent scientists, researchers and experts who have labored, some for decades - many of whom are no longer with us - to bring this body of science into the public arena. There would be no BioInitiative without their perseverance and generous contributions of intellect and resources.

We deeply appreciate the Santa Barbara Foundation for serving as our fiscal agent. Thanks go to Jan Campbell, Senior Vice President of Philanthropic Services, Communications and Marketing, and to Cheri Savage. Assistant Treasurer of the Santa Barbara Foundation for making this relationship possible. In addition, Mr. Nick Munday gave us brilliant technical help in refining our graphic products.

Web designer Julie Faber of Mountain Studio has our gratitude for her artful guidance in the redesign and layout of the BioInitiative 2012 website. She is both professional and intuitive, helping us communicate complex ideas with precision and flair.

Personally, I am indebted to my husband Dr. Orrin Sage and our family for their encouragement and understanding during the long months of immersion and irregular hours this project demanded. Working with colleagues in time zones spanning Russia, Sweden, Canada, Austria, the Slovak Republic, Italy, Greece, and India makes a 24-hr workday seem normal. Finally, gratitude to Avery, Drake, Ford, Jenner, Luke, Solei, and all the children whose trusting faces remind us that we hold their future in our hands. (Cindy Sage).

13. ABSTRACT

More than 2300 references on the biological responses to radio frequency and microwave radiation, published up to April 1972, are included in this bibliography of the world literature. Particular attention has been paid to the effects on man of non-ionizing radiation at these frequencies. The citations are arranged alphabetically by author, and contain as much information as possible so as to assure effective retrieval of the original documents. Soviet and East European literature is included in detail. An outline of the effects which have been attributed to radio frequency and microwave radiation is included as Chapter 1. The revised report (which supersedes DDC report AD#734391) is updated with the inclusion of three supplementary listings, and has incorporated many corrections and additions to the original 2100 citations.

ABSTRACT

More than 2000 references on the biological responses to radio frequency and microwave radiation, published up to June 1971, are included in the bibliography.* Particular attention has been paid to the effects on man of non-ionizing radiation at these frequencies. The citations are arranged alphabetically by author, and contain as much information as possible so as to assure effective retrieval of the original documents. An outline of the effects which have been attributed to radio frequency and microwave radiation is also part of the report.

*Three supplementary listings bring the number of citations to more than 2300.

The author welcomes information which will correct errors and omissions (both of which no doubt exist). Copies of new papers would be greatly appreciated, and would encourage updating and revising the bibliography periodically.

ACKNOWLEDGMENTS

The assistance and support received during the preparation of this bibliography have been considerable, and I am happy to acknowledge my indebtedness and gratitude. Drs. John Keesey and Dennis Heffner, former and present Heads of the Biophysics Division, and Dr. Seymour Friess, Director of the Environmental Biosciences Department of the Naval Medical Research Institute, permitted me the opportunity to work on the bibliography, and offered frequent encouragement.

Acknowledgment is also due to many friends and associates for their helpful suggestions, comments, and loans and/or gifts of reports or other material, which have been invaluable in the course of the work. Mr. Glenn Heimer of the Naval Ship Engineering Center contributed an extensive collection of government reports and documents, many of which had not previously been cited in the open literature.

Special help in tracing and in the acquisition of relevant papers has been received from the librarians and staff members of the NMRI library: Mrs. Thelma Robinson, Mrs. Ernestine Gendleman, Mrs. Eleanor Capps, and Miss Deborah Grove. Their diligence and resourcefulness in tracing and obtaining copies of a large number of papers and reports, often in spite of incomplete and/or inaccurate citations given in other sources, enabled me to include many relevant items in the bibliography.

Mr. Christopher Dodge of the Scientific and Technical Center, Department of the Navy, provided much of the Soviet Bloc literature, linguistic and other technical assistance, and in addition offered valuable comments and encouragement throughout the preparation of this report. Especially noteworthy were the corrections and improvements suggested by Chris following his reading of the entire manuscript.

Helpful also in locating some of the Soviet literature was Mr. E. S. Serebrennikov, of the Science and Technology Division, The Library of Congress.

Credit is due Mrs. Anna Woke (of this Institute) for translating many of the German papers; to Dr. Emilio Weiss, who translated from the Italian, and to Mrs. Edith Pugh who typed many "first drafts"; also to Mrs. Rhoda Glaser for her help in many aspects of the work.

Mrs. Fannie Epstein deserves special mention for her outstanding editorial assistance, and especially for the heroic typing, organization, and checking of the entire report.

Foreword

It is the hope of the author that this bibliography will provide guidance to the diffuse and conflicting literature on the biological responses to electromagnetic radiation at radio- and microwave-frequencies, with particular reference to the effects of concern to man. Such guidance is needed in the formulation and appraisal of criteria and limits of human exposure to "non-ionizing" radiation, and in the planning and conduct of future research.

The original plans were to categorize and key the literature citations to the "outline of biological and clinical effects" (Chapter 1). This proved to be a much more difficult and time-consuming task than anticipated, and was actually completed only for about 400 papers. Thus, the letter-number combinations given in square brackets for some of the "A" through "C" citations refer to the outline. [NV] indicates the citation was "not verified".

The standard format used throughout the bibliography is: author, (date), journal, volume, (issue): page, "title". The authors are alphabetized, and in chronological order. Multiple authors are also alphabetically ordered according to the second, third, etc., author. Inclusive pagination is given where possible, as is the original language of the citation. Report accession and translation numbers (some of which are cited in Appendix A), and alternate sources are listed when known. The title of books is underlined. When the title of the report was not available (or not given), a short (one line) description of the paper is listed whenever possible. Reports in which the name of the author was not given are listed chronologically using the format, "title", reference, source, (date). In many cases the citation was obtained from secondary (and tertiary) sources. For this reason it was impossible to put every citation into a consistent format.

In a few cases, papers have been cited which were presented at symposia or meetings devoted to the present topic, even when the report title suggests that it does not pertain directly to the topic. This has been done to show the wide range of items considered relevant (at least at the time of the meeting, and by the organizing chairman) in past years. An example is "electroanesthesia".

A few citations of marginal and/or peripheral relationship have also been included so that the reader may judge the applicability to his individual research needs. Examples are reports dealing with the biological effects of static and alternating magnetic fields, experimental techniques using radio frequency and microwave radiation (e.g., electron spin resonance, and nuclear magnetic resonance spectroscopy), and microwave exposure limits, regulations, and standards.

References for a few limited-distribution government reports are available upon request.

CHAPTER 1

Reported Biological Phenomena ("Effects") and Some Clinical Manifestations Attributed to Microwave and Radio-Frequency Radiation (See Note)

A. Heating of Organs* (Applications: Diathermy, Electrosurgery, Electrocoagulation, Electrodesiccation, Electrotomy)

1. Whole Body (temperature regulation defects), Hyperpyrexia
2. Skin
3. Bone and Bone Marrow
4. (a) Lens of Eye (cataractous lesions - due to the avascular nature of the lens which prevents adequate heat dissipation.) (b) Corneal damage also possible at extremely high frequencies.
5. Genitalia (tubular degeneration of testicles)
6. Brain
7. Sinuses
8. Metal Implants (burns near hip pins, etc.)

The effects are generally reversible except for 4a.

B. Changes in Physiologic Function

1. Striated Muscle Contraction
2. Alteration of Diameter of Blood Vessels (increased vascular elasticity), Dilation
3. Changes in the Oxidative Processes in Tissues and Organs
4. Liver Enlargement
5. Altered Sensitivity to Drug Stimuli
6. Decreased Spermatogenesis (decreased fertility, to sterility)
7. Altered Sex Ratio of Births (more girls!)
8. Altered Menstrual Activity
9. Altered Fetal Development
10. Decreased Lactation in Nursing Mothers
11. Reduction in Diuresis (Na^+ excretion via urine output)
12. Altered Renal Function (decreased filtration in tubules)
13. Changes in Conditioned Reflexes
14. Decreased Electrical Resistance of Skin
15. Changes in the Structure of Skin Receptors of the (a) Protective, and (b) Blood-Carrying Systems
16. Altered Blood Flow Rate

---

* It is also reported that low levels of irradiation produce a cooling effect - "hypercompensation".

Note: These effects are listed without comment or endorsement since the literature abounds with conflicting reports. In some cases the basis for reporting an "effect" was a single or a non-statistical observation which may have been drawn from a poorly conceived (and poorly executed) experiment.

The Outline of Reported Biological Phenomena ('Effects') and Clinical Manifestations Attributed to Microwave and Radio-Frequency Radiation, is patterned after that given by R. Murray, et al., in an article entitled, "How safe are microwaves", which appeared in Non-Ionizing Radiation 1(1):7-8 (1969). Some of the "effects" were listed in the report by S. F. Cleary and W. T. Ham, Jr., entitled, "Considerations in the evaluation of the biological effects on exposure to microwave radiation", (Background document, Part I, 1969, for the Task Force on Research Planning in Environmental Health, Subtask Force on Physical Factors in the Environment). The discussion and suggestions offered by Byron McLees, Edward Finch, Lewis Gershman, and Christopher Dodge relating to the Outline are also gratefully acknowledged.

Preparation of the bibliography was supported by the Bureau of Medicine and Surgery, Department of the Navy, under work unit MF12.524.015-0004B.

17. Alterations in the Biocurrents (EEG?) of the Cerebral Cortex (in animals)
18. Changes in the Rate of Clearance of Tagged Ions from Tissue
19. Reversible Structural Changes in the Cerebral Cortex and the Diencephalon
20. Electrocardiographic (EKG) Changes
21. Alterations in Sensitivity to Light, Sound, and Olfactory Stimuli
22. Functional (a) and Pathological (b) Changes in the Eyes: (a) decrease in size of blind spot, altered color recognition, changes in intraocular pressure, lacrimation, trembling of eyelids; (b) lens opacity and coagulation, altered tissue respiration, and altered reduction-oxidation processes
23. Myocardial Necrosis
24. Hemorrhage in Lungs, Liver, Gut, and Brain } At Fatal Levels
25. Generalized Degeneration of all Body Tissue } of Radiation
26. Loss of Anatomical Parts
27. Death
28. Dehydration
29. Altered Rate of Calcification of Certain Tissue

C. Central Nervous System Effects

1. Headaches
2. Insomnia
3. Restlessness (Awake and During Sleep)
4. Electroencephalographic (EEG) Changes
5. Cranial Nerve Disorders
6. Pyramidal Tract Lesions
7. Conditioned Reflex Disorders
8. Vagomimetic Action of the Heart; Sympaticomimetic Action
9. Seizures, Convulsions

D. Autonomic Nervous System Effects

1. Neuro-vegetative Disorders (e.g., alteration of heart rhythm)
2. Fatigue
3. Structural Alterations in the Synapses of the Vagus Nerve
4. Stimulation of Parasympathetic Nervous System (Bradycardia), and Inhibition of the Sympathetic Nervous System

E. Peripheral Nervous System Effects

Effects on Locomotor Nerves

F. Psychological Disorders ("Human Behavioral Studies") - the so-called "Psychophysiologic (and Psychosomatic) Responses"

1. Neurasthenia - (general "bad" feeling)
2. Depression
3. Impotence
4. Anxiety
5. Lack of Concentration
6. Hypochondria
7. Dizziness
8. Hallucinations
9. Sleepiness
10. Insomnia
11. Increased Irritability
12. Decreased Appetite
13. Loss of Memory
14. Scalp Sensations
15. Increased Fatigability
16. Chest Pain
17. Tremor of the Hands

G. Behavioral Changes (Animal Studies)

Reflexive, Operant, Avoidance, and Discrimination Behaviors

H. Blood Disorders

(V = in vivo)
(v = in vitro)

Changes in:

1. Blood and Bone Marrow
2. Phagocytic (polymorphs) and Bactericidal Functions of Blood (V,v)
3. Hemolysis Rate (increase), (a shortened lifespan of cells)
4. Sedimentation Rate (increase), (due to changes in serum protein levels or amount of fibrinogen (?))
5. Number of Erythrocytes (decrease), also number of Lymphocytes
6. Blood Glucose Concentration (increase)
7. Blood Histamine Content
8. Cholesterol and Lipids
9. Gamma (also α and β) Globulin, and Total Protein Concentration
10. Number of Eosinophils
11. Albumin/Globulin Ratio (decrease)
12. Hemopoiesis (rate of formation of blood corpuscles)
13. Leukopenia (increase in number of white cells), and Leukocytosis
14. Reticulocytosis

I. Vascular Disorders

1. Thrombosis
2. Hypertension

J. Enzyme and Other Biochemical Changes

Changes in activity of:
1. Cholinesterase (V,v)
2. Phosphatase (v)
3. Transaminase (v)
4. Amylase (v)
5. Carboxydismutase

6. Protein Denaturation
7. Toxin, Fungus, and Virus Inactivation (at high radiation dose levels), Bacteriostatic Effect
8. Tissue Cultures Killed
9. Alteration in Rate of Cell Division
10. Increased Concentration of RNA in Lymphocytes, and Decreased Concentration in Brain, Liver, and Spleen
11. Changes in Pyruvic Acid, Lactic Acid, and Creatinine Excretions
12. Change in Concentration of Glycogen in Liver (Hyperglycemia)
13. Alteration in Concentration of 17- Ketosteroids in Urine

K. Metabolic Disorders

1. Glycosuria (sugar in urine; related with blood sugar?)
2. Increase in Urinary Phenol (derivatives? DOPA?)
3. Alteration of Rate of Metabolic Enzymatic Processes
4. Altered Carbohydrate Metabolism

L. Gastro-Intestinal Disorders

1. Anorexia (loss of appetite)
2. Epigastric Pain
3. Constipation
4. Altered Secretion of Stomach "Digestive Juices"

M. Endocrine Gland Changes

1. Altered Pituitary Function
2. Hyperthyroidism
3. Thyroid Enlargement
4. Increased Uptake of Radioactive Iodine by Thyroid Gland
5. Altered Adrenal Cortex Activity
6. Decreased Corticosteroids in Blood
7. Decreased Glucocorticoidal Activity
8. Hypogonadism (usually decreased testosterone production)

N. Histological Changes

1. Changes in Tubular Epithelium of Testicles
2. Gross Changes

O. Genetic and Chromosomal Changes

1. Chromosome Aberrations (e.g., linear shortening, pseudochiasm, diploid structures, amitotic division, bridging, "sticky" chromosomes, irregularities in chromosomal envelope)
2. Mutations
3. Mongolism
4. Somatic Alterations (changes in cell not involving nucleus or chromosomes, cellular transformation)
5. Neoplastic Diseases (e.g., tumors)

P. Pearl Chain Effect (Intracellular orientation of subcellular particles, and orientation of cellular and other (non-biologic) particles)

Also, orientation of animals, birds, and fish in electromagnetic fields

Q. Miscellaneous Effects

1. Sparking between dental fillings
2. Peculiar metallic taste in mouth
3. Changes in Optical Activity of Colloidal Solutions
4. Treatment for Syphilis, Poliomyelitis, Skin Diseases
5. Loss of Hair
6. Brittleness of Hair
7. Sensations of Buzzing, Vibrations, Pulsations, and Tickling About the Head and Ears
8. Copious Perspiration, Salivation, and Protrusion of Tongue
9. Changes in the Operation of Implanted Cardiac Pacemakers
10. Changes in Circadian Rhythms

CHAPTER 2

BIBLIOGRAPHY OF REPORTED BIOLOGICAL PHENOMENA ('EFFECTS') AND CLINICAL MANIFESTATIONS ATTRIBUTED TO MICROWAVE AND RADIO-FREQUENCY RADIATION

APPENDIX A

ACCESSION NUMBERS

Prefix of Report Number	Agency Assigning Number
AD-	Defense Documentation Center (DDC), formerly Armed Services Technical Information Agency (ASTIA)
JPRS-	Joint Publications Research Service
LC-ATD-	Library of Congress - Aerospace Technology Division
PB-	National Technical Information Service (NTIS), U. S. Dept. of Commerce
RADC-TR-	Rome Air Development Center, Griffiss Air Force Base, N. Y.
OTS-	Office of Technical Services, U. S. Dept. of Commerce
DA-	Department of the Army
SC-	Sandia Laboratory, Albuquerque, New Mexico
ACSI-	Assistant Chief of Staff for Intelligence (Army, Washington, D. C.)
CR-	National Aeronautics and Space Administration
N-	Scientific & Technical Aerospace Reports (STAR) of NASA
A-	International Aerospace Abstracts of Amer. Inst. of Aeronautics & Astronautics
X-	Classified NASA document (avail. from NASA Sci. & Tech. Info. Facility, P. O. Box 33, College Park, Md., 20740)
NLL-	National Lending Library for Science & Technology, Boston Spa, England

SECOND SUPPLEMENTARY LISTING

Bibliography of Reported Biological Phenomena ("Effects"), and Clinical Manifestations Attributed to Microwave and Radio-Frequency Radiation; Naval Medical Research Institute Research Report No. 2 on Project MF12.524-0004B, dated 4 October 1971, by Zorach R. Glaser.

2073. BARANSKI, S. (1971) Aerospace Medicine 42(11):1196-1199, "Effect of chronic microwave irradiation on the blood forming system of Guinea pigs and rabbits"

2074. BOSISIO, R. G., & BARTHAKUR, N. (1969) J. of Microwave Power 4:190-, (Abstr. in: Non-ionizing Rad. 1(4):193 only, (1970)), "Microwave protection of plants"

2075. BOSISIO, R. G., BARTHAKUR, N., & SPOGNER, J. (1970) J. of Microwave Power 5:47-53, (Abstr. in: Non-ionizing Rad. 1(4): 193 only, (1970)), "Microwave protection of a field crop against cold"

2076. BREYSSE, P. A. (1969) J. Microwave Power 4:25-29, (Abstr. in: Non-ionizing Rad. 1(2):102-103, (1969), Abstract #43), "Microwave uses on the Campus; a study of environmental hazards"

2077. CLEARY, S. F. (1970) Critical Reviews in Environmental Control 1 (Chemical Rubber Co.):257-304, (Abstr. in: Non-ionizing Rad. 1(4):194 only, (1970)), "Biological effects of microwave and radio frequency radiation"

2078. DAVIS, F. S., WAYLAND, J. R., & MERKLE, M. G. (1971) Science 173:535-537, (6 Aug.), "Ultrahigh-frequency electromagnetic fields for weed control: Phytotoxicity and selectivity"

2079. DUBREV, B., et al. (196?) Works of the Scientific Research Institute of Labour Protection and Occupational Diseases (Sofia, Bulgaria), 17:31-40, (Abstr. in: Non-ionizing Rad. 2(1):43 only, 1971)), "High frequency electromagnetic waves and (p[illegible]ction of) ozones"

2080. HAMID, M. A. K., BOENER, W. N., & TONG, S. C. (1970) J. of Microwave Power 5:44-46, (Abstr. in: Non-ionizing Rad. 1(4): 193 only, (1970)), "Microwave irradiation of potato-waste water"

2081. HAMID, M. A. K., & BOULANGER, R. J. (1969) J. Microwave Power 4:11-18, (Abstr. in: Non-ionizing Rad. 1(2):102 only, (1969), Abstract #40), "New method for control of moisture and insect infestations of grain by microwave power"

2082. HEYDENREICH, A. (196?) beitsmedizin - Sozialmedizin - Arbeitshygiene, (Stuttgart), 6:280-284, (Abstr. in: Non-ionizing Rad. 2(1):44 only, (1971)), "Radiation-induced eye lesions"

2083. IIZUKA, K. (196?) Report (AD 667729) Avail. from DDC Clearing House, "Photographing microwave fields"

2084. JAMES, D. E., LEACH, W. M., MILLS, W. A., MOORE, R. T., & SHORE, M. L. (1969) Non-ionizing Rad. 1(3):125-130, "Effects of 2450 MHz microwaves on protein synthesis and on chromosomes in Chinese hamsters"

2085. JOLY, R., et al. (196?) Revue des corps de sante des armees, (Paris), 10.235-259, (Abstr. in: Non-ionizing Rad. 2(1):43 only, (1971)), "Possible biological and physiopathological effects of v.h.f. electromagnetic radiations from radar aerials"

2086. McLEES, B. D., & FINCH, E. D. (1972) In: Advances in Biological and Medical Physics, 14, Academic Press, N. Y., "Analysis of the reported physiologic effects of microwave radiation"

2087. MAY, K. N. (1969) J. Microwave Power 4:54-59, (Abstr. in: Non-ionizing Rad. 1(3):151 only, (1969), Abstract #67), "Applications of microwave energy in preparation of poultry convenience foods"

2088. MICHAELSON, S. M. (1970) Non-ionizing Rad. 1(4):169-176, "Pathophysiological aspects of microwave irradiation, Part 1 - Thermal effects"; Part 2, ibid. (1971) 2(1):27-38, "Critical analysis of the literature"

2089. PAZDEROVA, J. (1968) Pracovni Lek. 20:10-, "Effects of electromagnetic radiation of the order of centimeter and meter waves on human's health"

2090. PLHAK, M., SERVUS, V., & SCHUBERTOVA, J. (196?) Vojenske zdravotnicke listy (Prague), 38(1):7-9, (Abstr. in: Non-ionizing Rad. 1(4):194 only, (1970)), "Hazards associated with microwaves, and preventive examinations of radar specialists"

2091. PLISCHKE, L. W., & WOLFF, W. F. (196?) J. of the American Soc. of Safety Engineers 14(6):12-15, (Abstr. in: Non-ionizing Rad. 2(1):43 only, (1971)), "Turned in or turned on -- r.f. radiation study"

2092. ROGERS, S. J., & KING, R. S. (1970) Non-ionizing Rad. 1(4):178-189. "Radio hazards in the m.f./h.f. band"

2093. ROSE, V. E., GELLIN, G. A., POWELL, C. H., & BOURNE, H. G. (1969) Amer. Industrial Hygiene Assoc. J. 30:137-, "Evaluation and control of exposures in repairing microwave ovens"

2094. SALINSKY, B., NEDBAL, J., & ZAKOVA, L. (196?) Pracovni lekarstvi 20:363-36n, (Abstr. in: Non-ionizing Rad. 1(3)152-[illegible], (1969)), (Also CIS abstract 562-1969), "State of health of workers exposed to radiofrequency radiation in industrial establishments at Brno"

2095. TAKAHASHI, K., VASISHTH, R. C., & COTE, W. A. (1969) J. Microwave Power 4:64-67, (Abstr. in: Non-ionizing Rad. 1(3):151 only, (1969), Abstract #69), "Uniform polymer distribution in paper saturated with polymer solution, via microwave power"

2096. TERRILL, J. G. (1970) Archives of Environmental Health 19:265-271, (Abstr. in: Non-ionizing Rad. 1(4):195 only, (1970)), "Microwaves, lasers and X-rays -- adverse reactions due to occupational exposures"

2097. URBAIN, W. M. (1969) J. Microwave Power 4:59-61, (Abstr. in: Non-ionizing Rad. 1(3):151 only, (1969), Abstract #68), "Some thoughts on the problems of microwave heating and food processing"

2098. "Non-ionizing radiation - an introduction", Non-ionizing Rad. 1(1):5-6, (1969)

2099. "Biological injuries and effects", Rept., Bur. of Rad. Health/DEP 70-3, Dept. of Health, Education and Welfare, (Abstr. in: Non-ionizing Rad. 2(1):41 only, (1971))

2100. "Consumer hazards: Why they happen and how they can be fixed", Electronics, 3 August 1970, pp. 54-67, (Abstr. in: Non-ionizing Rad. 2(1):44 only, (1971))

2101. "Microwave Oven Safety", in: Hospital Administration Notes, No. 41, Bureau of Medicine & Surgery, Department of the Navy, p. 7 only, Oct. 1971.

17 April 1972

THIRD SUPPLEMENTARY LISTING

to

Bibliography of Reported Biological Phenomena ('Effects') and Clinical Manifestations Attributed to Microwave and Radio-Frequency Radiation; Naval Medical Research Institute Research Report No. 2 on Project MF12.524.015-0004B, dated 4 October 1971, by Zorach R. Glaser. (AD #734391)

2102. ALLIS, J. W., & JANES, D. E. (1970) In: Radiation Bio-Effects Summary Report, Hodge, D. M., (ed.), for Jan-Dec 1970, Div. of Biological Effects, Bur. Rad. Health, DHEW, (Rept. No. BRH/DBE 70-7), pp. 131-136, "Ultraviolet spectral changes in bovine serum albumin after irradiation with microwaves at 2.45 GHz"

2103. BAERWALD, F. R. (1970) Wehrmedizinische Monatsschrift 14:249-257 (In German), (Abstr. #A71-12845), "Effects, precautionary measures, and medico-military aspects involved in handling microwaves"

2104. BAKER, K. F., & FULLER, W. H. (1965) Unpub. data cited in: OLSEN, C. M., DRAKE, C. L., & BUNCH, S. L., J. of Microwave Power 1:45-56, "Some biological effects of microwave energy"

2105. BALDWIN, M. T., & EDWARDS, W. P. (1970) In: Radiation Bio-Effects Summary Report, Hodge, D. M., (ed.), Jan-Dec 1969, Div. of Biological Effects, Bur. Rad. Health, DHEW (Rept. No. DBE 70-1), pp. 83-94, "Cerebral effects of radio frequency energy"

2106. BARTSEVICH, B. N., ILIN, A. V., KRIVENKO, V. N., ROGOSSKII, S. S., & ULITSKII, L. A. (1970) Voenno-Meditsinskii Zhurnal :39-41 (In Russ.), (Abstr. #A70-20489), "Results of dynamic observation of persons working in the region of influence of a microwave field" [Study of behavior and blood chemistry (including proteins)]

2107. BILLING, U. H. (1969) Report (7 pages), U.S. Dept. Health, Education, & Welfare, Public Health Service, Consumer Protection & Environ. Health Service, Radiation Control Admin., Bur. of Rad. Health, "Biological effects of radio- and low-frequency electromagnetic radiation" (Preliminary Draft)

List of 155 Reviews on Non-thermal Effects of Microwave/Intermediate Frequency EMFs

Martin L. Pall

Among the scientific reviews documenting these various non-thermal health effects are 155 that follow. Each of these reviews cites at least a dozen primary literature citations showing non-thermal effects, with many citing 100 or more going up to the 3rd reference which cites over 1000 such citations. It can be seen from this that the primary literature citations supporting the existence of various non-thermal health effects cited in these reviews go into several thousands. This list is not and is not intended to be a list of all important such reviews. However it gives some measure of the size of the literature that contradicts the industry contention that there are no non-thermal effects of microwave frequency EMFs.

Received 10 February 2013; received in revised form 6 May 2013; accepted 15 July 2013

Abstract

Although autism spectrum conditions (ASCs) are defined behaviorally, they also involve multileveled disturbances of underlying biology that find striking parallels in the physiological impacts of electromagnetic frequency and radiofrequency exposures (EMF/RFR). Part I of this paper will review the critical contributions pathophysiology may make to the etiology, pathogenesis and ongoing generation of core features of ASCs. We will review pathophysiological damage to core cellular processes that are associated both with ASCs and with biological effects of EMF/RFR exposures that contribute to chronically disrupted homeostasis. Many studies of people with ASCs have identified oxidative stress and evidence of free radical damage, cellular stress proteins, and deficiencies of antioxidants such as glutathione. Elevated intracellular calcium in ASCs may be due to genetics or may be downstream of inflammation or environmental exposures. Cell membrane lipids may be peroxidized, mitochondria may be dysfunctional, and various kinds of immune system disturbances are common. Brain oxidative stress and inflammation as well as measures consistent with blood–brain barrier and brain perfusion compromise have been documented. Part II of this paper will review how behaviors in ASCs may emerge from alterations of electrophysiological oscillatory synchronization, how EMF/RFR could contribute to these by de-tuning the organism, and policy implications of these vulnerabilities. Changes in brain and autonomic nervous system electrophysiological function and sensory processing predominate, seizures are common, and sleep disruption is close to universal. All of these phenomena also occur with EMF/RFR exposure that can add to system overload ('allostatic load') in ASCs by increasing risk, and worsening challenging biological problems and symptoms; conversely, reducing exposure might ameliorate symptoms of ASCs by reducing obstruction of physiological repair. Various vital but vulnerable mechanisms such as calcium channels may be disrupted by environmental agents, various genes associated with autism or the interaction of both. With dramatic increases in reported ASCs that are coincident in time with the deployment of wireless technologies, we need aggressive investigation of potential ASC – EMF/RFR links. The evidence is sufficient to warrant new public exposure standards benchmarked to low-intensity (non-thermal) exposure levels now known to be biologically disruptive, and strong, interim precautionary practices are advocated.

1. Introduction

The premise of this review is that although scant attention has been paid to possible links between electromagnetic fields and radiofrequency radiation exposures (EMF/RFR) and Autism Spectrum Conditions (ASCs), such links probably exist. The rationale for this premise is that the physiological impacts of EMF/RFR and a host of increasingly well-documented pathophysiological phenomena in ASCs have remarkable similarities, spanning from cellular and oxidative stress to malfunctioning membranes, channels and barriers to genotoxicity, mitochondrial dysfunction, immune abnormalities, inflammatory issues, neuropathological disruption and electrophysiological dysregulation – in short, multi-scale contributors to de-tuning the organism. Additional support may be found in the parallels between the rise in reported cases of ASCs and the remarkable increases in EMF/RFR exposures over the past few decades

Reviewing these similarities does not prove that these parallels imply causality. Moreover, the physiological processes affected by EMF/RFR are also impacted by other environmental factors, and are known to be present in myriad other chronic illnesses. A set of in-depth reviews on the

Complainant's Exhibit No. 6

science and public health policy implications of EMF/RFR has been published in a special issue of Pathophysiology 16 (2,3) 2009. This two-volume special issue of Pathophysiology offers a broad perspective on the nature of health impacts of man-made EMFs, documenting biological effects and health impacts of EMFs including genotoxicity, neurotoxicity, reproductive and developmental effects, physiological stress, blood–brain barrier effects, immune system effects, various cancers including breast cancer, glioma and acoustic neuroma, Alzheimer's disease; and the science as a guide to public health policy implications for EMF diseases [1]. Many of these reviews have been updated in the BioInitiative 2012 Report [2], with 1800 new papers added. Further reinforcement is published in seminal research reviews including the two-volume Non-Thermal effects and Mechanisms of Interaction between Electromagnetic Fields and Living Matter, Giuliani L and Soffritti, M (Eds.), ICEMS, Ramazzini Institute, Bologna, Italy (2010) [3]; the World Health Organization INTERPHONE Final Report (2010) [4]; and the WHO International Agency for Research on Cancer RFR Monograph [5] designating RFR as a Group 2B Possible Human Carcinogen. The National Academy of Sciences Committee on Identification of Research Needs Relating to Potential Biological or Adverse Health Effects of Wireless Communication Devices (2008) [6] called for health research on wireless effects on children and adolescents and pregnant women; wireless personal computers and base station antennas; multiple element base station antennas under highest radiated power conditions; hand-held cell phones; and better dosimetric absorbed power calculations using realistic anatomic models for both men, women and children of different height and ages. Yet EMF/RFR does not need to be a unique contributor to ASCs to add significantly to system overload ('allostatic load') and dysfunction [7]. Even so these pathophysiological overlaps do suggest that the potential for an EMF/RFR-ASC connection should be taken seriously, and that their biological fragility may make many with ASCs more likely to experience adverse EMF/RFR impacts. This is a sufficient basis to recommend that precautionary measures should be implemented, that further research should be prioritized, and that policy level interventions based on existing and emerging data should be designed and pursued. Moreover, pursuing this link could help us understand ASCs better and find more ways to improve the lives of people with ASCs and of so many others.

This paper is divided into two parts. Part I (http://dx.doi.org/10.1016/j.pathophys.2013.08.001) describes the pathophysiology and dynamism of common behavioral manifestations in autism, and pathophysiological damage to core cellular processes that is associated both with ASCs and with impacts of EMF/RFR. Part II (http://dx.doi.org/10.1016/j.pathophys.2013.08.002) reviews how behaviors in ASCs may emerge from alterations of electrophysiological oscillatory synchronization and how EMF/RFR could contribute to these by de-tuning the organism. Part II also discusses public health implications, and proposes recommendations for harm prevention and health promotion.

2. Physiological pathogenesis and mechanisms of autism spectrum conditions

2.1. How are biology and behavior related?

Appreciating the plausibility of a link between ASCs and EMF/RFR requires considering the relationship between ASC's behavioral and biological features. ASCs were first labeled as 'autism' in 1943 by Leo Kanner, a child psychiatrist who extracted several key behavioral features, related to communication and social interaction challenges and a tendency toward restricted interests and repetitive behaviors [8]. There has been some modification of the characterization of these behavioral features, but ASCs are still defined behaviorally, although sensory issues such as hypo- or hyper-reactivity have recently been included in the diagnostic criteria (Diagnostic and Statistical Manual of Mental Disorders or DSM-V) [9,10].

2.1.1. Transduction is fundamental but poorly understood

To evaluate how an environmental factor such as EMF/RFR could lead to autism and/or influence its severity or incidence, we examine how effects of EMF/RFR exposure may be transduced into changes in nervous system electrical activity, and how these in turn generate the set of behaviors we have categorized as 'autism.'[11] This means not taking behaviors as given, or as purely determined by genetics, but exploring the full range of biology that generates these features and challenges.

2.1.2. More than brain

Although 'autism' has long been considered to be a psychiatric or neurological brain-based disorder [12,13], people diagnosed with ASCs often have many biological features including systemic pathophysiological disturbances (such as oxidative stress, mitochondrial dysfunction and metabolic and immune abnormalities) [14–17] as well as symptomatic medical comorbidities (such as gastrointestinal distress, recurrent infections, epilepsy, autonomic dysregulation and sleep disruption) [18–26] in addition to the core defining behaviors [27]. Because of variability among individuals, the relevance of many of these biological features has been dismissed as secondary and not intrinsically related to the 'autism.'

2.1.3. Heterogeneity: more genetic and environmental than physiological

Presently large numbers of genes and environmental contributors to ASCs are under consideration. Over 800 genes have been associated with ASCs, and over 100 different rare genetic syndromes are frequently accompanied by ASCs, but

no clear unifying mechanism has been identified [28–33]. Similarly, a large number of potential environmental contributors are under investigation ranging from toxicants and Vitamin D deficiency or failure to take prenatal vitamins to air pollution and stress or infection in pregnancy [34–41].

By contrast, a smaller set of disturbances are showing up physiologically as common across substantial numbers of people with ASCs – as well as in myriad other chronic conditions whose prevalence also appears to be increasing [42,43]. These include oxidative stress, inflammation, and mitochondrial dysfunction. EMF/RFR exposure is associated with many of the same biological effects and chronic health conditions [1]. This environmentally vulnerable physiology [44], which may serve as final common pathways triggered by diverse genetic and environmental contributors, will be discussed in Section 3 of Part I as well as in Part II; it may or may not need to rest on underlying genetic vulnerability.

2.1.4. *EMF/RFR research may help us understand how ASCs 'work'*

Some correlations between biological and behavioral features have been identified – e.g., a higher level of immune abnormalities correlates with more aberrant behaviors [26,45–50]. In order to move beyond correlations to identifying *mechanisms* by which the *transduction of pathophysiology into behavior* might actually occur, an important component is studying the relationship between systemic pathophysiology and nervous system electrophysiology.

The brain is simultaneously a tissue-based physical organ that can be compromised by cellular pathophysiology as well as altered developmental processes and an information processing system that operates through networks of synchronized electrical oscillations (brain waves) – and EMF/RFR impacts may occur directly at both of these levels. To date the emphasis in ASC research has largely been on 'structure-function' relationships that have been anatomy-centered. Thus, exploring how EMF/RFR impacts ASCs may answer questions of how pathophysiological and electrophysiological information-processing interacts.

2.2. *Time courses of mechanisms*

Researchers have mainly looked for causes of autism in mechanisms that occur early and create permanent change or damage. This approach is logical if one assumes that genetic influences are overwhelmingly predominant, and 'autism' is a fixed lifelong trait. However evidence is emerging that ASCs may be more state-like and variable than trait-like and fixed.

2.2.1. *Plasticity*

A remarkable shift is occurring in conceptual thinking about ASCs and brain plasticity [51]. There are growing numbers of reports of improvement and loss of diagnosis, reversal of neurological symptoms in a growing number of mouse models of genetic syndromes that in humans prominently feature autism [52–62], short-term pharmaceutically-induced improvement in brain connectivity [63], and transient reversal or abeyance of symptomatology under various circumstances (including fever, fluid-only diet, and certain antibiotic treatments [50,64]). Reversals undermine the idea that ASCs derive from an intrinsically 'broken brain', and short time frames of marked improvement cannot be accounted for by remodeling of the brain's anatomical substrate [65]. 'Brain waves' and their synchronization, on the other hand, could easily vary over short time periods.

Also, evidence of average to superior intelligence in most people with autism [66,67], as well as of domains of perceptual superiority [68–76], call into question the assumption that ASCs are intrinsically associated with cognitive deficits.

2.2.2. *Mechanisms that operate actively throughout the life-course*

EMF/RFR effects can occur within minutes (Blank, 2009) and may, in part, explain clinical reports of 'intermittent autism' – for example, some children with mitochondrial disease who have ups and downs of their bioenergetics status 'have autism' on their bad days but don't display autistic features on their good days [77]. These children with their vulnerable, barely compensated mitochondria could very well be teetering right at the brink of a minimally adequate interface of metabolic and electrophysiological dysfunction. Everyday exposures to allergens, infection, pesticide on the school playground, as well as EMF/RFR interference with electrophysiology might reasonably contribute to the bad days. Stabilizing more optimal nervous system performance [78] including through environmental control of excessive EMF/RFR exposure could perhaps achieve more 'good days'.

2.2.3. *Pathophysiology and allostatic load*

The model of 'allostatic load' – the sum total of stressors and burdens [79]– may be central to understanding how the many risk factors interact to create autism – and to create a spectrum of levels of severity across so many of ASD's associated features. This accumulation increases chronic stress, and a growing number of papers document indicators of chronic stress in individuals with ASCs (as will be discussed in Part II). The 'allostatic load' concept dovetails well with a model of progressive exacerbation of pathophysiological disturbances that occurs in the pathogenesis of many chronic diseases [43]. It is also critical to understand that many different environmental factors converge upon a much smaller number of environmentally vulnerable physiological mechanisms [44], so that large numbers of small exposures may have effects from small numbers of large exposures.

EMF/RFR exposures have demonstrated biological effects at just about every level at which biology and physiology have been shown to be disrupted in ASCs. Further EMF/RFR has been shown to potentiate the impact of various toxicants when both exposures occur together [80]; this may be additive or more than additive. This suggests that EMF/RFR may synergize with other contributors and make things worse. A cascade of exposures interacting with vulnerabilities in

an individual can potentially lead to a tipping point for that person, such as the phenomenon of autistic regression experienced by a substantial subset of people with ASCs.

Just a few decades ago, EMF/RFR exposures were not present in the environment at today's levels. Levels have increased several thousand-fold or more in the past two decades from wireless technology alone; with unplanned side effects from pulsed RFR that is a newly classified Group 2B possible human carcinogen [5]. Nearly six billion people globally own wireless phones. Many millions are exposed to wireless exposures from use of wireless devices and wireless antenna facilities [81]. For this as well as for physiological reasons, 'allostatic loading' as a viable concept for the study of ASCs should reasonably address EMF/RFR as one of the exposures of relevance to the overall stress load, since it is now a chronic and unremitting exposure in daily life at environmentally relevant levels shown to cause bioeffects from preconception and pregnancy through infancy, childhood and the whole life-course.

3. Parallels in pathophysiology

This section will review parallels in pathophysiology between ASCs and impacts of EMF/RFR. It will begin with a review of mechanisms of direct impact and damage at the level of molecules, cells, tissues and genes. It will then move on to consider how these levels of damage lead to degradation of the integrity of functional systems including mitochondrial bioenergetics, melatonin metabolism, immune function and nervous system physiology. The review of parallels concludes with electromagnetic signaling and synchronized oscillation from membranes to nervous system. It will discuss how the ensemble of pathophysiological disturbances, which are themselves final common pathways that can be caused or worsened by many stressors, combine to converge upon electrophysiology. This leads to the implication that 'aberrant' neural systems and somatic function and behaviors might be better understood as consequences or 'outputs' of disturbed underlying physiology to which EMF/RFR is a plausible contributor.

3.1. Damage: means and domains

ASCs have been conceptualized as 'neurodevelopmental' which has focused attention on how genes and environment could alter brain development. This leads to the unstated presumption that virtually everything important about the brain in ASCs has to do with differences in the way it was formed, and that all "malfunction" derives from this "malformation." In genetics this has led to a hunt for neurodevelopmental genes. There is no question that environmental impacts can alter brain development, and impact brain function across the lifespan.

However the influence of the environment on neurodevelopmental conditions such as ASCs does not stop there. Evidence is accumulating showing that increased expression of genes associated with physiological dysregulation, as well as *single-nucleotide polymorphisms* (SNPs) associated with these issues, may be if anything more prominent than alterations of 'neurodevelopmental' genes [82]. In a study of gene expression in ASCs, Down syndrome and Rett syndrome, these authors state, *"(O)ur results surprisingly converge upon immune, and not neurodevelopmental genes, as the most consistently shared abnormality in genome-wide expression patterns. A dysregulated immune response, accompanied by enhanced oxidative stress and abnormal mitochondrial metabolism seemingly represents the common molecular underpinning of these neurodevelopmental disorders."* Others have also found pathophysiology-related genes as figuring most prominently in alterations of gene expression in ASC [83–86]. SNPs associated with methylation abnormalities, impaired glutathione synthesis and mitochondrial dysfunction also have been identified as significant risk factors.

Genetics may create risk, but the actual nervous system and health consequences probably come from dysfunction at the physiological level. As mentioned, evidence for pathophysiological dysfunction in ASCs increasingly abounds. In particular, a growing body of evidence widely reported in both the EMF/RFR and ASC literature documents immune aberrations, low total and reduced glutathione levels, lower activity of the anti-oxidative stress system and mitochondrial dysfunction. These phenomena may be both genetically and environmentally modulated. As will be discussed further below, they are certainly pertinent to the neurodevelopment of the brain, which has been by far the dominant focus autism research, but it does not stop there as they can significantly modulate brain function in real time, as well as shape the function of the entire organism, including the autonomic system, the cardiovascular, endocrine, immune, gastrointestinal and reproductive systems and more. These systemic impacts may in turn feed back into the nervous system, modulating how it functions.

3.1.1. Cellular stress

3.1.1.1. Oxidative stress. Autism (ASC) research indicates that oxidative stress may be a common attribute amongst many individuals with autism. In the past decade the literature on this has moved from a trickle to a flood. Studies document reduced antioxidant capacity, increased indicators of oxidative stress and free radical damage, alterations in nutritional status consistent with oxidative stress, altered lipid profiles, and pertinent changes not only in blood but also in brain tissue. Associations of ASCs with environmental exposures such as air pollution and pesticides are indirectly supportive as well, since such exposures are linked in other literature to oxidative stress [43,87–101].

Reactive oxygen species are produced as a normal consequence of mitochondrial oxidative metabolism as well as other reactions, but when their number exceeds the cell's antioxidant capacity a situation of oxidative stress develops. It

is certainly the case that oxidative stress can be a consequence of exposures to chemical toxicants, or of the interactive impacts of toxicants, nutritional insufficiencies and genetic vulnerabilities. This set of risk factors has received considerable attention for the potential roles each component and various possible combinations could play in causing or exacerbating autism.

Less often mentioned in the ASC pathophysiology literature is that it is also well established that EMF/RFR exposures can be associated with oxidative damage. Published scientific papers that demonstrate the depth of EMF and RFR evidence reporting oxidative damage in human and animal models are profiled by Lai and colleagues [102–104]. These cellular effects can occur at low-intensity, legal levels of exposure that are now 'common environmental levels' for pregnant women, the fetus, the infant, the very young child, and the growing child as well as for adults. Electromagnetic fields (EMF) can enhance free radical activity in cells [105,106] particularly via the Fenton reaction, and prolonging the exposure causes a larger increase, indicating a cumulative effect. The Fenton reaction is a catalytic process of iron to convert hydrogen peroxides, a product of oxidative respiration in the mitochondria, into hydroxyl free radical, which is a very potent and toxic free radical [103,104]. Free radicals damage and kill organelles and cells by damaging macromolecules, such as DNA, protein and membrane components.

Further indications of a link to oxidative stress are findings that EMF and RFR at very low intensities can modulate glutamate, glutathione and GABA, and affect mitochondrial metabolism. Alterations in all these substances and processes have been documented in ASCs [25,86,89,90,92,107–127]. On the EMF/RFR side, Campisi et al. (2010) report that increased glutamate levels from 900 MHz cell phone frequency radiation on primary rat neocortical astroglial cell cultures induced a significant increase in ROS levels and DNA fragmentation after only 20 min with pulsed RFR at non-thermal levels [128].

Fragopoulou et al. (2012) conducted proteomics analysis of proteins involved in brain regulation in mice as a consequence of prolonged exposure to EMF [129]. They identified altered expression of 143 proteins, ranging from as low as 0.003-fold downregulation up to 114-fold overexpression with affected proteins including neural function-related proteins including Glial Fibrillary Acidic Protein (GFAP), alpha-synuclein, Glia Maturation Factor beta (GMF), apolipoprotein E (apoE), heat shock proteins, and cytoskeletal proteins (i.e., neurofilaments and tropomodulin), as well as proteins of brain metabolism such as aspartate aminotransferase and glutamate dehydrogenase. The authors pointed out that oxidative stress was consistent with some of these changes.

Aberrations in glutathione metabolism and deficiencies in reserves of reduced glutathione are increasingly associated with ASCs, both systemically and in the brain. The parallel with EMF/RFR impacts here is strong, since glutathione reduction associated with EMF/RFR is reported in at least twenty three relevant research studies in both human and animal studies since 1998, including the following citations [130–144]. It is increasingly appreciated that glutathione is a final common pathway, a critical piece of environmentally vulnerable physiology, as glutathione reserves are compromised by an enormous number of environmental stressors, so that the cumulative impact upon glutathione may be far greater than could be predicted by the magnitude of any specific exposure [145], which supports an 'allostatic loading' model.

Also of note are studies showing that the effects of EMF/RFR can be reduced by supplementation with antioxidants and radical scavengers. As an example, Vitamins E and C reduced adverse impacts on rat endometrium from 900 MHz EMR exposure [137]. Gingko biloba has also prevented mobile phone-induced increases in malondialdehyde and nitric oxide levels in brain tissue as well as decreases in brain superoxide dismutase and glutathione peroxidase activities and increases in brain xanthine oxidase and adenosine deaminase activities, and treated rats were spared the histopathological cell injury found in the untreated rats [146]. Substantial further literature on antioxidants and radical scavengers is reviewed in Belyaev's contribution to the Bioinitiative 2012 Report [147].

3.1.1.2. Stress protein (heat shock protein) responses. Another well-documented effect of exposure to low-intensity extremely low frequency and RFR is the creation of stress proteins (heat shock proteins) indicating that a cell is being placed under physiological stress [148–154]. Heat shock proteins are in a family of inducible proteins that are initiated when any increased need for protection from stray electrons occurs [155,156]. The HSP response is generally associated with heat shock, exposure to toxic chemicals and heavy metals, and other environmental insults. HSP is a signal of cells in distress. Plants, animals and bacteria all produce stress proteins to survive environmental stressors like high temperatures, lack of oxygen, heavy metal poisoning, and oxidative stress. It should also be noted that the generation of HSP stress proteins can have constructive medical applications, such as protection from reperfusion of the heart following ischemic injury [157]. Another concomitant impact of cellular stress can be protein misfolding, which has been documented in association with exposure to EMF/RFR [158,159].

Although a number of papers have demonstrated increases in HSPs in people with ASCs [160–164], it has been investigated far less often than oxidative stress. Part of the research needed to study possible influences of EMF/RFR on ASCs would be more careful study of HSPs in ASCs.

3.1.2. Membranes and channels

3.1.2.1. Cell membranes and lipid peroxidation. Cell and organelle membranes play roles in partitioning cells from the extracellular milieu as well as in sustaining boundaries and regulating flow of materials between cellular compartments needing different metabolic parameters for their activities.

They also play critical roles in maintaining electrical differences and the flow of electricity.

Adey (2002) summarized studies that report cell membranes as the site of initial field transductive coupling.

"*Collective evidence points to cell membrane receptors as the probable site of first tissue interactions with both ELF and microwave fields for many neurotransmitters* [165], *hormones* [166,167], *growth-regulating enzyme expression* [168–171], *and cancer-promoting chemicals* [172,173]. *In none of these studies does tissue heating appear involved causally in the responses.*" [174]

Membranes are well-known targets of oxidative stress. Membrane damage is a major route through which free radical damage proliferates through the cellular system. Lipid peroxidation of membranes most often affects polyunsaturated fatty acids such as EPA and DHA which are the most abundant and vulnerable lipids in the brain where the damage they sustain can have serious impacts – DHA is 40% of PUFAs (brain polyunsaturated fatty acids). Lipid peroxidation of membranes has been identified as an effect of EMF/RFR in multiple studies [175,176]. A variety of other mechanisms for membrane alteration related to EMF/RFR have been intimated in the literature. Physicochemical properties of membranes such as phase transition of phosphatidylcholine can be shifted by non-thermal effects of microwave radiation [177]. Membrane potential and currents may also be impacted by pulsed radiofrequency fields [178]. This has been observed graphically in altered cellular movement in Paramecium caudatum, with these cells becoming broader, with a broader-appearing cytopharynx, with their pulse vesicles having difficult in expelling their content outside the cell, and with less efficient movement of cilia [179] which the authors suggested might be due to targeting of the cellular membrane. The impacts on this unicellular organism may help us imagine what the impact of EMF/RFR might be on cells with some structural similarities, such as columnar epithelial cells and ciliated cells in mucosal surfaces in the respiratory system, digestive tract, uterus and fallopian tubes and central spinal cord.

Indications of lipid peroxidation of membranes has been documented in ASCs, including malonaldehyde and isoprostanes, as well as alteration of membrane phospholipids and prostaglandins [98,100,115,162,180–184]. In one study the isoprostane levels showed a biomodal distribution with the majority of ASC subjects showing moderate increase but a smaller group showing dramatic increases [183]. Thromboxane, reflecting platelet activation, was also elevated in one study [98]. Given that this phenomenon has been identified in many people with ASCs, it is plausible that such individuals will likely be more vulnerable to having such cellular injuries caused, worsened or both by EMF/RFR exposures.

3.1.2.2. Calcium channels. EMF/RFR exposures have been shown to alter or disturb calcium signaling [185] through a variety of mechanisms, including membrane leakage [186], alteration of calcium-binding proteins and GFAP reactivity [187,188], and altered ultrastructural distribution of calcium and calcium-activated ATPases after exposure [189]. Adey (2002) provided an overview of key studies on calcium efflux and the importance of calcium in cell signaling. "*Early studies described calcium efflux from brain tissue in response to ELF exposures* [190,191], *and to ELF-modulated RF fields* [190–193]. *Calcium efflux from isolated brain subcellular particles (synaptosomes) with dimensions under 1.0 μm also exhibit an ELF modulation frequency-dependence in calcium efflux, responding to 16 Hz sinusoidal modulation, but not to 50 Hz modulation, nor to an unmodulated RF carrier* [194]. *In the same and different cell culture lines, the growth regulating and stress responsive enzyme ornithine decarboxylase (ODC) responds to ELF fields* [170,195] *and to ELF-modulated RF fields.*" [168,170,171,196].

Dutta et al. (1992) reported:

"*Radio-frequency electromagnetic radiation (RFR) at 915 and 147 MHz, when sinusoidally amplitude modulated (AM) at 16 Hz, has been shown to enhance release of calcium ions from neuroblastoma cells in culture. The dose-response relation is unusual, consisting of two power-density "windows" in which enhanced efflux occurs, separated by power-density regions in which no effect is observed. Thus RFR affects both calcium-ion release and AChE activity in nervous system-derived cells in culture in a common dose-dependent manner.*" [197]

Alterations in calcium signaling impacts are of central importance in ASC pathophysiology, and have been documented to occur with some EMF/RFR exposures. Calcium channels play an important role in regulating neuronal excitability. Disturbance during development may be contributory to the development of ASCs, and is often associated with vulnerability to seizures. Gene alterations associated with a number of voltage-gated calcium channels have been identified in ASCs [198–202]. However, based on an examination of patient laboratory and phenotype data it has been argued that aberrant calcium signaling could be downstream: Palmieri and Persico (2010) suggest that "*an abnormal neuroimmune response as a relevant player in elevating intracellular Ca^{2+} levels, deranging neurodevelopment, driving oxidative stress, and ultimately affecting synaptic function and neural connectivity especially in long-range neuronal pathways physiologically responsible for integrated information processing*" [203]. Peng and Jou (2010) have in turn shown how increased intracellular calcium can cause oxidative stress, and a vicious circle: "... *mitochondrial ROS [reactive oxygen species]rise can modulate Ca^{2+} dynamics and augment Ca^{2+} surge. The reciprocal interactions between Ca^{2+} induced ROS increase and ROS modulated Ca^{2+} upsurge may cause a feedforward, self-amplified loop creating cellular damage far beyond direct Ca^{2+} induced damage*" [204].

Environmental as well as genetic routes to calcium signaling dysfunction have been identified [205] including chemicals such as the polyaromatic hydrocarbons.

PCB-95 in particular modulates the calcium-dependent signaling pathway responsible for activity-dependent dendritic growth [206,207]. In fact, once a genetic mutation has been associated with altering a critical signaling pathway and conferring risk for autism, chemicals or other environmental agents can be identified that target the same pathways and also confer ASC risk. Stamou et al. (2012) have reviewed this strategy of identifying multiple mechanisms converging on common signaling pathways regarding Ca(2+)-dependent mechanisms as well as extracellular signal-regulated kinases (ERK)/phosphatidylinositol-3-kinases (PI3K) and neuroligin-neurexin-SHANK [208]. From this point of view, there may be no particular reason to privilege genetic mutations in their contribution to a disturbance of calcium signaling, since whether this function becomes derailed due to a genetic mutation, from a chemical toxin or from EMF/RFR perturbation of calcium signaling, the functional effect is comparable.

3.1.3. Junctions and barriers

The damage discussed so far has been at the molecular and subcellular level. However impacts from this level reverberate up to larger scales in the system. Where membranes create boundaries between cells and subcellular compartments, barriers do this at a larger scale. Cells become capable of forming barriers between each other through tight junctions which block substances and cells from 'slipping through the cracks,' so to speak, between the cells. Conversely, gap junctions are subcellular structures providing openings that allow physical passage of materials between cells otherwise separated by membranes.

Such connections between cells can also be altered by electromagnetic fields and radiofrequency exposures, at least under certain circumstances. High frequency magnetic fields have been observed to be associated with a sharp decrease in intercellular gap junction-like structures, in spite of increased gene expression for pertinent proteins [209]. Changes in tight junctions have been observed upon exposure to microwave and x-ray irradiation [210].

A number of papers in the ASC research field document problems pertinent to junctions. Connexin abnormalities have been documented in neuropathological studies [211] and MacFabe and colleagues identified lipid alterations associated with oxidative stress, membrane fluidity and the modulation of gap junction coupling [212]. Decrease in platelet endothelial cell adhesion molecule-1 were reduced and this reduction correlated with repetitive behavior and abnormal brain growth; adhesion molecules modulate permeability and signaling at the blood–brain barrier as well as leukocyte infiltration into the central nervous system [213].

EMF and RFR might also compromise biologically important barrier structures that separate blood flow from organs like the brain [214]. This raises important questions regarding whether other 'barriers' that keep blood flow separate from the gut (gut-blood barrier), or the placenta (blood–placenta barrier) or the eye (ocular-blood barrier) may also be rendered pathologically leaky, and allow albumin, toxins, pro-inflammatory cytokines and infectious agents to cross these barriers, which may invoke immune responses in the intestines, and may impact the developing fetus [215]. While there are a fair number of negative studies, there are also many studies showing and association between EMF/RFR and pathological leakage of the blood–brain barrier (BBB), as well as evidence in animal studies of damage to brain cells and damage to or death of neurons. Such leakage has been shown to be potentiated by physiological factors such as diabetes and insulin (Gulturk et al., 2010) and has also potentiated viral lethality in a dose-dependent fashion (Lange et al., 1991). Many of the positive findings were associated with non-thermal exposures comparable to normal cell phone radiation exposure [216–222]. There are scattered reports of increased permeability across other membranes and barriers, such as the blood–testicle barrier in mice (Wang, 2008; Wang et al., 2010 and the rat liver canalicular membrane [223]). A 1992 study by Kues et al. reported that "*studies in our laboratory have established that pulsed microwaves at 2.45 GHz and 10 mW/cm^2 are associated with production of corneal endothelial lesions and with disruption of the blood–aqueous barrier in the non-human primate eye*" [224]. A recent study showing impact of high-frequency electromagnetic fields on trophoblastic connexins [209] may indicate the vulnerability of the placenta and placental barrier function to electromagnetic fields. A thorough review and methodological discussion of literature regarding EMF/RFR impacts on the BBB is provided by Salford in Section 10 of the BioInitiative 2012 Report [214].

BBB integrity can be compromised by oxidative stress which can lead to increased permeability [225], and the resultant extravasation of albumin into brain parenchyma can be excitotoxic and neurotoxic [226,227]. The interaction of these factors may contribute to a feed-forward vicious cycle that can result in progressive synaptic and neuronal dysfunction as seen in various neurodegenerative diseases [228].

The evidence suggesting possible existence of barrier function compromise in people with ASCs is largely indirect. The existence of brain neuroinflammation in ASCs has been documented in a growing number of studies [160,229,230], and this is known to be associated with BBB permeability [231–233]. In a review of clinical MRI findings in ASCs 19/59 showed white matter signal abnormalities [234], which in other settings have been associated with cerebral hypoperfusion, though not necessarily in the same locations as the hyperintensities [235,236]. Blood flow abnormalities, predominantly hypoperfusion, documented in a few dozen PET and SPECT studies, could also be caused by and/or associated with physiological phenomena associated with vascular permeability as will be revisited below. Increased intestinal permeability has been documented (although its absence has also been documented) [237–243] and discussed in the context of food exposures, particularly gluten [244–250]. The reactivity to large numbers of different foods, clinically observed in many children with autism, has been framed by

some as a manifestation of indiscriminate exposure of the immune system and the brain to food proteins on account of intestinal permeability as well as BBB permeability [251]. This reactivity could in turn feed in to aberrant immune responsivity which in turn could further amplify barrier vulnerability [248].

A number of studies have made an association between an increased risk of having a child with autism and maternal infection during pregnancy. This phenomenon looks like it is a result of the maternal immune system response rather than being due to an impact deriving from a specific infectious agent; but the potential for an accompanying compromise of the placental barrier is also conceivable in this setting. Under these circumstances the fetal risk of exposure to maternal blood toxins, cytokines and stress proteins in utero could potentially be increased if placenta barrier (BPB) function were impaired. The integrity, or compromise thereto, of the maternal-fetal interface via the placenta is an important modulator of brain development [252].

3.1.4. Genetic alterations and reproductive impacts

The overwhelming emphasis in recent decades in autism research has been on genetics, and on finding linkages between genes, brain and behavior, in part because of the high heritability of autism that was calculated from the concordance rates of monozygotic (identical) vs. dizygotic (fraternal) twins found in by a series of small twin studies performed some decades ago. In recent years the genetic premises of this seemingly obvious framing of autism as overwhelmingly genetic have been undermined at several levels [253]. First, the number of reported cases is increasing, making it more difficult to maintain that ASCs are purely genetic because these increases can only be partly explained away by greater awareness or other data artifacts [254,255]. Second, the complexity of the ways we understand how genes might relate to autism has grown, from an expectation a decade ago that a small number of genes (even less than a dozen) would explain everything to an identification of close to a thousand genes associated with autism with common threads linking only a small subset [256,257], as well as 'de novo' mutations present in ASC children but not their parents and even 'boutique' mutations not shared beyond an individual family. Moreover, a recent twin study that was much larger than any of the prior such studies identified a modest genetic role but a substantial environmental role [258]. Indeed even concordance between identical twins appears to be influenced by whether the twins shared a placenta [259]. All of this calls into question the idea that genetics can be presumed to be the 'cause' of autism simply based upon heritability calculations, and upgrades the importance of looking not only at the environment and environmentally vulnerable physiology, but also at acquired mutations.

3.1.4.1. Genotoxicity. Genotoxicity has been proposed as a mechanism for the generation of 'de novo' mutations (found in children but not their parents) being found in ASCs [260]. Reviews and published scientific papers on genotoxicity and EMF report that both ELF-EMF and RFR exposures are genotoxic – i.e., damaging to DNA – under certain conditions of exposure, including under conditions of intermittent and/or chronic ELF and RFR exposure that are of low-intensity and below current world safety standards [104,105,261–266]. Types of genetic damage reported have included DNA fragmentation and single- and double-strand DNA breaks, micronucleation and chromosome aberrations, all of which indicate genetic instability [102,103].

Researchers have recently identified large numbers of de novo mutations, more likely to be transmitted by fathers than by mothers to their children [267–269]. This is consistent with the EMF/RFR literature that repeatedly documents DNA damage to sperm from cell phone radiation (see Section 3.1.4.1.2). The Eichler team at the University of Washington found that 39% of the 126 most severe or disruptive mutations map to a network associated with chromatin remodeling that has already been ranked as significant amongst autism candidate genes [268]. Although the relationship between the prominence of chromatin-related gene mutations and the impacts of EMF/RFR on chromatin condensation has not been clarified, the parallels support further investigation.

3.1.4.1.1. Contributors to genotoxicity.

- Oxidative stress and free radical damage to DNA

  Oxidative stress and excessive free radical production are very well known to be potentially genotoxic. They can be a consequence of myriad environmental factors, including but by no means limited to EMF/RFR. The DNA damage that can result could very well be one cause of 'de novo' mutations which to date have been found in only a small percentage of individuals with ASCs. Although there is not a consensus at this time about the rates or causes of de novo mutations in ASCs, environmentally triggered oxidative stress and free radical damage that we know are present in large numbers of people with ASCs can be genotoxic, and this warrants a serious investigation of the potential contribution of EMF and RFR to de novo mutations in ASC. Further, the huge increases in exposure to EMF/RFR in daily life due to electrification and the global saturation of RFR from wireless technologies [81] reinforce this need.
- Challenge to DNA repair mechanisms

  When the rate of damage to DNA exceeds the rate at which DNA can be repaired, there is the possibility of retaining mutations and initiating pathology. Failure to trigger DNA damage repair mechanisms, or incomplete or failed repair, may be a consequence of a variety of commonplace stressors, including EMF/RFR exposure. A decrease in DNA repair efficiency has been reported to result from exposure to low-intensity RFR in human stem cells, and other cells. Mobile phone frequency GSM exposure at the frequency of 915 MHz consistently inhibited DNA repair foci in lymphocytes [270–272]. Belyaev, Markova and colleagues (2005), and Markova et al. (2009)

reported that very low-intensity microwave radiation from mobile phones inhibits DNA repair processes in human stem cells. A significant reduction in 53BP1 (tumor suppressor p53 binding protein 1) foci was found in cells exposed to microwave radiofrequency radiation within one hour of exposure. Fibroblast cells were impacted in this fashion but adapted over time, whereas stem cells were similarly affected (inhibited 53BP1 foci) but did not adapt to microwave radiation during chronic exposure [270,271]. Additional challenges to DNA repair mechanisms include not only toxicants and other damaging inputs but also nutritional insufficiencies of substances important to the proper functioning of DNA repair mechanisms, including Vitamin D, essential fatty acids, and minerals such as selenium and molybdenum [273]. The high possibility that various such contributors may combine supports an 'allostatic load' model of environmental injury and genotoxicity.

- Chromatin condensation

The work of Markova, Belyaev and others has repeatedly shown that RFR exposure can cause chromatin condensation, which is a hallmark of DNA damage. Belyaev (1997) reported that super-low intensity RFR resulted in changes in genes, and chromatin condensation of DNA at intensities comparable to exposures from cell towers (typically at RFR levels of 0.1 to one microwatt per centimeter squared ($\mu W/cm^2$)) [274]. Significant microwave (MW)-induced changes in chromatin conformation were observed when rat thymocytes were analyzed between 30–60 min after exposure to MW [275].

In recent studies, human lymphocytes from peripheral blood of healthy and hypersensitive to EMF persons were exposed to non-thermal microwave radiation (NT MW) from the GSM mobile phones [270,271]. NT MW induced changes in chromatin conformation similar to those induced by heat shock, which remained up to 24 h after exposure. The same group has reported that contrary to human fibroblast cells, which were able to adapt during chronic exposure to GSM/UMTS low intensity RFR exposure, human stem cells did not adapt [272].

3.1.4.1.2. Gonadal and germline impacts. De novo mutations have been shown to be more of a problem related to paternal age [268,276–279], and this may be related to the impact of environmental factors such as EMF/RFR on the stem cell genome, particularly in sperm which have no DNA repair capacity. Vulnerability of testes and ova, and of sperm and egg cells, relates to the tissue milieu in which damage to the germline can take place, as well as on the greater vulnerability of stem cells. Several international laboratories have replicated studies showing adverse effects on sperm quality, motility and pathology in men who use and particularly those who wear a cell phone, PDA or pager on their belt or in a pocket [106,280–284]. Other studies conclude that usage of cell phones, exposure to cell phone radiation, or storage of a mobile phone close to the testes of human males affect sperm counts, motility, viability and structure [175,284,285]. Animal studies have demonstrated oxidative and DNA damage, pathological changes in the testes of animals, decreased sperm mobility and viability, and other measures of deleterious damage to the male germ line [134,286–290]. Of note, altered fatty acids consistent with oxidative stress have been found in sperm cells in male infertility [291,292].

There are fewer animal studies that have studied effects of cell phone radiation on female fertility parameters. Panagopoulous et al. (2012) report decreased ovarian development and size of ovaries, and premature cell death of ovarian follicles and nurse cells in *Drosophila melanogaster* [293]. Gul et al. (2009) report rats exposed to stand-by level RFR (phones on but not transmitting calls) caused decrease in the number of ovarian follicles in pups born to these exposed dams [294]. Magras and Xenos (1997) reported irreversible infertility in mice after five (5) generations of exposure to RFR at cell phone tower exposure levels of less than 1.0 $\mu W/cm^2$ [295].

3.1.4.1.3. Implications of genotoxicity. The issue of genotoxicity puts the contribution of genetic variation into a different light – as something that needs to be accounted for, not necessarily assumed as the starting point. In this regard it has been speculated that the apparent higher rates of autism in Silicon Valley, discussed in the past as related to 'geek genes'[296], might be conditioned by higher levels of exposure to EMF/RFR. The relationship between the greater vulnerability of male sperm than of female eggs to adverse effects of EMF/RFR exposure and the marked (4:1) predominance of paternal origin of de novo point mutations (4:1 bias), also deserves further careful attention [268].

3.1.5. Implications of damage

We have reviewed parallels between ASC and EMF/RFR in molecular, cellular and tissue damage, including cellular stress (oxidative stress, the heat shock response and protein misfolding), injury of membranes, aberrant calcium signaling, and compromise of cell junctions and barriers. The genotoxicity of EMF/RFR was reviewed in relation to issues of environmental contributions to autism and of the phenomenon of de novo mutations. The compromise of the tissue substrate appears to have many commonalities in ASCs and in EMF/RFR exposures. Also notable was the possibility of attenuating some of the damage through increasing antioxidant status.

Regarding Rett syndrome, a genetic syndrome often associated with autistic behaviors, these commonalities come to mind in considering the implications of a recent study documenting arrest of symptomatology in a mouse model of Rett syndrome through a bone marrow transplant of wild-type microglia [297,298]. The introduction of these competent microglia cells did not directly target the neuronal defect associated with the MECP2 gene mutation; instead the benefits of the transplant were due to overcoming the inhibition of phagocytosis caused by the MECP2 mutation that was absent in the wild-type microglia. Phagocytosis involves removing debris. This suggests that while research has focused on how

specific molecular defects, particularly in the synapse, may contribute to Rett pathophysiology, there may also be an important contribution from cellular debris, misfolded proteins and other disordered cellular structure and function. Such disorder could be accumulating in cells under the conditions of pathophysiological disarray reviewed above. Based on this study as well as on the levels of damage just reviewed, cellular problems that are pertinent to ASCs most likely go beyond any specific defect introduced by a mutation. Additionally it is conceivable that many of the mutations may be not part of normal background variation but instead collateral damage from the same environmental factors that are also driving the damage to the physiology.

3.1.6. Summary of Part I and preview of Part II

The data reviewed above in Part I of this two part paper documents a series of parallels between the pathophysiological and genotoxic impacts of EMF/RFR and the pathophysiological underpinnings of ASCs. DNA damage, immune and blood–brain barrier disruption, cellular and oxidative stress, calcium channel, disturbed circadian rhythms, hormone dysregulation, and degraded cognition, sleep, autonomic regulation and brainwave activity all have commonalities between ASCs and EMF/RFR, and the disruption of disruption fertility and reproduction associated with EMF/RFR may also be related to the increasing incidence of ASCs. All of this argues for reduction of exposures now, and better coordinated research in these areas.

These pathophysiological parallels are laid out after identifying the dynamic features of ASCs that could plausibly arise out of such pathophysiological dysregulation. The importance of transduction between levels was also discussed in Part I, and will be elucidated in much more detail in Part II where more detail will be given about the possible interfaces between the cellular and molecular pathophysiology reviewed above and the higher-level disruption of physiological systems, brain tissue and nervous system electrophysiology.

The emergence of ever larger amounts of data is transforming our understanding of ASCs from static encephalopathies based on genetically caused brain damage to dynamic encephalopathies where challenging behaviors emanate from physiologically disrupted systems. In parallel, the emergence of ever larger bodies of evidence supporting a large array of non-thermal but profound pathophysiological impacts of EMF/RFR is transforming our understanding of the nature of EMF/RFR impacts on the organism.

At present our policies toward ASCs are based on outdated assumptions about autism being a genetic, behavioral condition, whereas our medical, educational and public health policies related to treatment and prevention could be much more effective if we took whole-body, gene-environment considerations into account, because there are many lifestyle and environmental modifications that could reduce morbidity and probably incidence of ASCs as well.

At present our EMF/RFR standards are based on outdated purely thermal considerations, whereas the evidence is now overwhelming that limiting regulations in this way does not address the much broader array of risks and harm now known to be created by EMF/RFR.

In particular, the now well-documented genotoxic impacts of EMF/RFR, placed in parallel with the huge rise in reported cases of ASCs as well as with the de novo mutations associated with some cases of ASCs (as well as other conditions), make it urgent for us to place the issue of acquired as well as inherited genetic damage on the front burner for scientific investigation and policy remediation.

With the rising numbers people with ASCs and other childhood health and developmental disorders, and with the challenges to our prior assumptions posed ever more strongly by emerging evidence, we need to look for and act upon risk factors that are largely avoidable or preventable. We would argue that the evidence is sufficient to warrant new public exposure standards benchmarked to low-intensity (non-thermal) exposure levels causing biological disruption and strong, interim precautionary practices are advocated. Further evidence to support the pathophysiological support for parallels between ASCs and EMF/RFR impacts and for taking action will be offered in Part II.

Abstract

Autism spectrum conditions (ASCs) are defined behaviorally, but they also involve multileveled disturbances of underlying biology that find striking parallels in the physiological impacts of electromagnetic frequency and radiofrequency radiation exposures (EMF/RFR). Part I (Vol 776) of this paper reviewed the critical contributions pathophysiology may make to the etiology, pathogenesis and ongoing generation of behaviors currently defined as being core features of ASCs. We reviewed pathophysiological damage to core cellular processes that are associated both with ASCs and with biological effects of EMF/RFR exposures that contribute to chronically disrupted homeostasis. Many studies of people with ASCs have identified oxidative stress and evidence of free radical damage, cellular stress proteins, and deficiencies of antioxidants such as glutathione. Elevated intracellular calcium in ASCs may be due to genetics or may be downstream of inflammation or environmental exposures. Cell membrane lipids may be peroxidized, mitochondria may be dysfunctional, and various kinds of immune system disturbances are common. Brain oxidative stress and inflammation as well as measures consistent with blood–brain barrier and brain perfusion compromise have been documented. Part II of this paper documents how behaviors in ASCs may emerge from alterations of electrophysiological oscillatory synchronization, how EMF/RFR could contribute to these by de-tuning the organism, and policy implications of these vulnerabilities. It details evidence for mitochondrial dysfunction, immune system dysregulation, neuroinflammation and brain blood flow alterations, altered electrophysiology, disruption of electromagnetic signaling, synchrony, and sensory processing, de-tuning of the brain and organism, with autistic behaviors as emergent properties emanating from this pathophysiology. Changes in brain and autonomic nervous system electrophysiological function and sensory processing predominate, seizures are common, and sleep disruption is close to universal. All of these phenomena also occur with EMF/RFR exposure that can add to system overload ('allostatic load') in ASCs by increasing risk, and can worsen challenging biological problems and symptoms; conversely, reducing exposure might ameliorate symptoms of ASCs by reducing obstruction of physiological repair. Various vital but vulnerable mechanisms such as calcium channels may be disrupted by environmental agents, various genes associated with autism or the interaction of both. With dramatic increases in reported ASCs that are coincident in time with the deployment of wireless technologies, we need aggressive investigation of potential ASC—EMF/RFR links. The evidence is sufficient to warrant new public exposure standards benchmarked to low-intensity (non-thermal) exposure levels now known to be biologically disruptive, and strong, interim precautionary practices are advocated.

1. Recap of part I and summary of part II

Part I of this two-part article previously documented a series of parallels between the pathophysiological and genotoxic impacts of EMF/RFR and the pathophysiological, genetic and environmental underpinnings of ASCs. DNA damage, immune and blood–brain barrier disruption, cellular and oxidative stress, calcium channel dysfunction, disturbed circadian rhythms, hormone dysregulation, and degraded cognition, sleep, autonomic regulation and brainwave activity—all are associated with both ASCs and EMF/RFR; and the disruption of fertility and reproduction associated with EMF/RFR may also be related to the increasing incidence of ASCs. All of this argues for reduction of exposures now, and better coordinated research in these areas. These

pathophysiological parallels are laid out after identifying the dynamic features of ASCs that could plausibly arise out of such pathophysiological dysregulation. The importance of transduction between levels was also discussed in Part I.

Part II elucidates in much more detail the possible interfaces between the cellular and molecular pathophysiology reviewed above and the higher-level disruption of physiological systems, brain tissue and nervous system electrophysiology. It addresses mitochondrial dysfunction, immune system disregulation, neuroinflammation and brain blood flow alterations, altered electrophysiology, disruption of electromagnetic signaling, synchrony, and sensory processing, de-tuning of the brain and organism, and behavior as an emergent property. The emergence of ever larger amounts of data is transforming our understanding of ASCs from static encephalopathies based on genetically caused brain damage to dynamic encephalopathies where challenging behaviors emanate from physiologically disrupted systems. In parallel, the emergence of ever larger bodies of evidence supporting a large array of non-thermal but profound pathophysiological impacts of EMF/RFR is transforming our understanding of the nature of EMF/RFR impacts on the organism. At present our policies toward ASCs are based on outdated assumptions about autism being a genetic, behavioral condition, whereas our medical, educational and public health policies related to treatment and prevention could be much more effective if we took whole-body, gene-environment considerations into account, because there are many lifestyle and environmental modifications that could reduce morbidity and probably incidence of ASCs as well. Our EMF/RFR standards are also based on an outdated assumption that it is only heating (thermal injury) which can do harm. These thermal safety limits do not address low-intensity (non-thermal) effects. The evidence is now overwhelming that limiting exposures to those causing thermal injury alone does not address the much broader array of risks and harm now clearly evident with chronic exposure to low-intensity (non-thermal) EMF/RFR. In particular, the now well-documented genotoxic impacts of EMF/RFR, placed in parallel with the huge rise in reported cases of ASCs as well as with the de novo mutations associated with some cases of ASCs (as well as other conditions), make it urgent for us to place the issue of acquired as well as inherited genetic damage on the front burner for scientific investigation and policy remediation. With the rising numbers people with ASCs and other childhood health and developmental disorders, and with the challenges to our prior assumptions posed ever more strongly by emerging evidence, we need to look for and act upon risk factors that are largely avoidable or preventable. We argue that the evidence is sufficient to warrant new public exposure standards benchmarked to low-intensity (non-thermal) exposure levels causing biological disruption and strong, interim precautionary practices are advocated. The combined evidence in Parts I and II of this article provide substantial pathophysiological support for parallels between ASCs and EMF/RFR health impacts.

2. Parallels in pathophysiology

2.1. Degradation of the integrity of functional systems

EMF/RFR exposures can yield both psychological and physiological stress leading to chronically interrupted homeostasis. In the setting of molecular, cellular and tissue damage, one would predict that the organization and efficiency of a variety of organelles, organs and functional systems would also be degraded. In this section we will review disturbances from EMF/RFR in systems (including include oxidative and bioenergetics metabolism, immune function and electrophysiological oscillations) that include molecular and cellular components subject to the kinds of damage discussed in the previous section. We will review disturbances that have been associated with EMF/RFR, and consider the parallel disturbances that have been documented in ASCs.

2.1.1. Mitochondrial dysfunction

Mitochondria are broadly vulnerable, in part because the integrity of their membranes is vital to their optimal functioning—including channels and electrical gradients, and their membranes can be damaged by free radicals which can be generated in myriad ways. Moreover, just about every step in their metabolic pathways can be targeted by environmental agents, including toxicants and drugs, as well as mutations [1]. This supports a cumulative 'allostatic load' model for conditions in which mitochondrial dysfunction is an issue, which includes ASCs as well as myriad other chronic conditions.

Mitochondria are commonly discussed in terms of the biochemical pathways and cascades of events by which they metabolize glucose and generate energy. But in parallel with this level of function there also appears to be a dimension of electromagnetic radiation that is part of the activity of these organelles. For example, electromagnetic radiation can be propagated through the mitochondrial reticulum, which along with the mitochondria has a higher refractive index than the surrounding cell and can serve to propagate electromagnetic radiation within the network [2]. It is also the case that "*The physiological domain is characterized by small-amplitude oscillations in mitochondrial membrane potential (delta psi(m)) showing correlated behavior over a wide range of frequencies.... Under metabolic stress, when the balance between ROS [reactive oxygen species, or free radicals] generation and ROS scavenging [as by antioxidants] is perturbed, the mitochondrial network throughout the cell locks to one main low-frequency, high-amplitude oscillatory mode. This behavior has major pathological implications because the energy dissipation and cellular redox changes that occur during delta psi(m) depolarization result in suppression of electrical excitability and Ca2 + handling...*" [3].

These electromagnetic aspects of mitochondrial physiology and pathophysiology could very well be impacted by EMF/RFR.

Other types of mitochondrial damage have been documented in at least some of the studies that have examined the impacts of EMF/RFR upon mitochondria. These include reduced or absent mitochondrial cristae [4–6], mitochondrial DNA damage [7], swelling and crystallization [5], alterations and decreases in various lipids suggesting an increase in their use in cellular energetics [8], damage to mitochondrial DNA [7], and altered mobility and lipid peroxidation after exposures [9]. Also noted has been enhancement of brain mitochondrial function in Alzheimer's transgenic mice and normal mice [10]. The existent of positive as well as negative effects gives an indication of the high context dependence of exposure impacts, including physical factors such as frequency, duration, and tissue characteristics [11].

By now there is a large amount of evidence for biochemical and other abnormalities in a large portion of children with autism that are consistent with mitochondrial dysfunction [12–14]. Recently published postmortem brain tissue studies that have added a new dimension of evidence for mitochondrial abnormalities in ASCs will be reviewed in the section on alteration of brain cells below.

Secondary mitochondrial dysfunction (i.e. environmentally triggered rather than rooted directly in genetic mutations) [15–18] could result among other things from the already discussed potential for EMF/RFR to damage channels, membranes and mitochondria themselves as well as from toxicant exposures and immune challenges. In a meta-analysis of studies of children with ASC and mitochondrial disorder, the spectrum of severity varied, and 79% of the cases were identified by laboratory findings without associated genetic abnormalities [16].

2.1.2. Melatonin dysregulation

2.1.2.1. Melatonin, mitochondria, glutathione, oxidative stress. Melatonin is well-known for its role in regulation of circadian rhythms, but it also plays important metabolic and regulatory roles in relation to cellular protection, mitochondrial malfunction and glutathione synthesis [19–21]. It also helps prevent the breakdown of the mitochondrial membrane potential, decrease electron leakage, and thereby reduce the formation of superoxide anions [22]. Pharmacological doses of melatonin not only scavenge reactive oxygen and nitrogen species, but enhance levels of glutathione and the expression and activities of some glutathione-related enzymes [21,23].

2.1.2.2. Melatonin can attenuate or prevent some EMF/RFR effects. Melatonin may have a protective effect in the setting of some EMF/RFR exposures, apparently in relation to these functions just described. EMF/RFR can impact melatonin; one example is exposure to 900 MHz microwave radiation promoted oxidation, which reduced levels of melatonin and increased creatine kinase and caspase-3 in exposed as compared to sham exposed rats [24].

Melatonin can attenuate or prevent oxidative damage from EMF/RFR exposure. In an experiment exposing rats to microwave radiation (MW) from a GSM-900 mobile phone with and without melatonin treatment to study renal impacts [25], the untreated exposed rats showed increases of lipid peroxidation markers as reduction of the activities of superoxide dismutase, catalase and glutathione peroxidase indicating decrement in antioxidant status. However these negative effects were inhibited in the exposed rats treated with melatonin. Melatonin also inhibited the emergence of preneoplastic liver lesions in rats exposed to EMFs [26]. The development of DNA strand breaks was observed in RFR exposed rats; this DNA damage was blocked by melatonin [27]. Exposure of cultured cortical neurons to EMF led to an increase in 8-hydroxyguanine in neuronal mitochondria, a common biomarker of DNA oxidative damage, along with a reduction in the copy number of mitochondrial DNA and the levels of mitochondrial RNA transcripts; but these effects could all be prevented by pretreatment with melatonin [7]. In a study of skin lesion induced by exposure to cell phone radiation, the skin changes in the irradiated group (which included thicker stratum corneum, epidermal atrophy, papillamatosis, basil cell proliferation, increased epidermal granular cell layer and capillary proliferation, impaired collagen tissue distribution and separation of collagen bundles in dermis) were prevented (except for hypergranulosis) by melatonin treatment [28]. Melatonin as well as caffeic acid phenyethyl ester (an antioxidant) both protected against retinal oxidative stress in rates exposed long-term to mobile phone irradiation [29]. Nitric oxide (NO) was increased in nasal and sinus mucosa in rats after EMF exposure, with this NO possibly acting as a defense mechanism suggesting tissue damage; but this was prevented by pretreatment with melatonin [30]. Melatonin treatment significantly prevented the increase in the MDA (malondyaldehyde, a marker of lipid peroxidation) content and XO (xanthine oxidase) activity in rat brain tissue after 40 days of exposure, but it was unable to prevent the decrease of CAT activity and increase of carbonyl group contents [31].

Of note, the melatonin production of infants in isolettes in neonatal intensive care units appears to be impacted by the high ELF-EMF environment, in that when infants were removed from those exposures they showed an increase in melatonin levels [32]. There is an increased prevalence of ASCs in children who were born prematurely [33–43]. There are many potential prematurity-associated factors that could contribute to increased risk for ASCs, but proper melatonin regulation warrants EMF/RFR controls in the newborns' environment.

2.1.2.3. Melatonin and autism. Regarding melatonin status in people with ASCs, a recent meta-analysis summarized the current findings as indicating that "*(1) Physiological levels of melatonin and/or melatonin derivatives are commonly below average in ASC and correlate with autistic behavior, (2) Abnormalities in melatonin-related genes may be a cause of low melatonin levels in ASD, and (3) ... treatment with melatonin significantly improves sleep duration and sleep onset latency in ASD.*" [44].

The meta-analysis also showed that polymorphisms in melatonin-related genes in ASC could contribute to lower melatonin concentrations or an altered response to melatonin, but only in a small percentage of individuals, since pertinent genes were found in only a small minority of those screened.

Based on the common presence of both sleep disorders and low melatonin levels, Bourgeron [45] proposed that synaptic and clock genes are important in ASCs, and that future studies should investigate the circadian modulation of synaptic function [45]. A number of melatonin-related genetic variants have been identified as associated with ASCs. Polymorphisms and deletions in the ASMT gene, which encodes the last enzyme of melatonin synthesis, have been found [46–48], and variations have been found as well for melatonin receptor genes [46,47,49]. CYP1A2 polymorphisms have been found in slow melatonin metabolisers, in whom melatonin levels are aberrant and initial response to melatonin for sleep disappeared in a few weeks [50].

2.1.2.4. Autism AND melatonin AND glutathione. Whereas PubMed searches for "autism AND melatonin" and "autism AND glutathione" each coincidentally yielded 72 citations, and "melatonin AND glutathione" yielded 803 citations, the search for "autism AND melatonin AND glutathione" yielded zero citations. This is interesting given the strong connection of melatonin and glutathione metabolically, as discussed above, alongside of the strongly established interest in both glutathione and melatonin in ASC research and increasingly in clinical practice. Hopefully one contribution of an investigation of EMF/RFR links to ASCs will be to help bring attention to this relationship, which may help identify potential environmental and physiological causes for low melatonin in those without pertinent mutations. Of pertinence, tryptophan hydroxylase (TPH2) – the rate limiting enzyme in the synthesis of serotonin, from which melatonin is derived – is extremely vulnerable to oxidation, and tends to misfold when its cysteine residues are oxidized, with the enzyme being converted to a redox-cycling quinoprotein [51–54].

2.1.3. Disturbed immune function

There is by now a broad appreciation of the presence of immune disturbances in ASCs, to the point where there is an emerging discussion of ASCs as neuroimmune disorders [55,56]. Research identifying immune features in ASCs spans from genetics where risk genes have been identified to epigenetics where altered expression of immune genes is being reported as prominent in ASC epigenetics [57–59], and also includes prenatal infectious and immune disturbances as risk factors for autism as well as other neurodevelopmental and neuropsychiatric diseases as well as other conditions such as asthma [60–62]. Immune disturbances in infants and children with ASC are heterogeneous, with some but not all manifesting autoimmunity [63,64]. Anecdotally, recurrent infection is common while on the other hand some get sick less often than their peers. It is common for people with autism to have family members with immune or autoimmune diseases [65]. The immune system is turning out to have an important role in brain development [66–68]. As mentioned, glial activation associated with brain immune response has been identified in a growing number of studies. Whether or not EMF/RFR contributes to these features of ASCs causally, based on the evidence below regarding immune impacts of EMF/RFR exposure [69], it is certainly plausible that such exposures could serve as aggravating factors.

2.1.3.1. Low-intensity exposures. The body's immune defense system is now known to respond to very low-intensity exposures [70]. Chronic exposure to factors that increase allergic and inflammatory responses on a continuing basis is likely to be harmful to health, since the resultant chronic inflammatory responses can lead to cellular, tissue and organ damage over time. Many chronic diseases are related to chronic immune system dysfunction. Disturbance of the immune system by very low-intensity electromagnetic field exposure is discussed as a potential underlying cause for cellular damage and impaired healing (tissue repair), which could lead to disease and physiological impairment [71,72]. Both human and animal studies report that exposures to EMF and RFR at environmental levels associated with new technologies can be associated with large immunohistological changes in mast cells as well as other measures of immune dysfunction and dysregulation. Mast cells not only can degranulate and release irritating chemicals leading to allergic symptoms; they are also widely distributed in the body, including in the brain and the heart, which might relate to some of the symptoms commonly reported in relation to EMF/RFR exposure (such as headache, painful light sensitivity, and cardiac rhythm and palpitation problems).

2.1.3.2. Consequences of immune challenges during pregnancy. As mentioned, infection in pregnancy can also increase the risk of autism and other neurodevelopmental and neuropsychiatric disorders via maternal immune activation (MIA). Viral, bacterial and parasitic infections during pregnancy are thought to contribute to at least 30% of cases of schizophrenia [73]. The connection of maternal infection to autism is supported epidemiologically, including in a Kaiser study where risk was associated with psoriasis and with asthma and allergy in the second trimester [65], and in a large study of autism cases in the Danish Medical registry [74] with infection at any point in pregnancy yielding an adjusted hazard ration of 1.14 (CI: 0.96 – 1.34) and when infection occurred during second trimester the odds ratio was 2.98 (CI: 1.29 – 7.15). In animal models, while there is much variation in study design, mediators of the immune impact include oxidative stress, interleukin-6 and increased placental cytokines [61,68,75]. Garbett et al. [76] commented on several mouse models of the effects of MIA on the fetal brain that "The overall gene expression changes suggest that the response to MIA is a neuroprotective attempt by the

developing brain to counteract environmental stress, but at a cost of disrupting typical neuronal differentiation and axonal growth." [76]. Maternal fetal brain-reactive autoantibodies have also been identified in some cases [62,77–82].

Although we have evidence of immune impacts of EMF/RFR, the impact of repeated or chronic exposure to EMF and RFR during pregnancy is poorly studied; could this trigger similar immune responses (cytokine production) and stress protein responses, which in turn would have effects on the fetus? Although this has been poorly studied, we do have data that very low cell phone radiation exposures during both human and mouse pregnancies have resulted in altered fetal brain development leading to memory, learning, and attention problems and behavioral problems [83].

2.1.3.3. Potential immune contributions to reactivity and variability in ASCs. Immune changes in ASCs appear to be associated with behavioral change [84–88], but the mechanisms are complex and to date poorly understood [89] and likely will need to be elucidated through systems biology methods that capture multisystem influences on the interactions across behavior, brain and immune regulation [90], including electrophysiology.

Two of the particularly difficult parts of ASCs are the intense reactivity and the variability in assorted symptoms such as tantrums and other difficult behaviors. Children with ASCs who also have gastrointestinal symptoms and marked fluctuation of behavioral symptoms have been shown to exhibit distinct innate immune abnormalities and transcriptional profiles of peripheral blood monocytes [91]. It is worth considering EMF/RFR exposures could be operating through related mechanisms so as to add to 'allostatic loading' in ways that exacerbate behavior. In Johansson 2006 and 2007 a foundation is provided for understanding how chronic EMF/RFR exposure can compromise immune function and sensitize a person to even small exposures in the future [72,92]. Johansson discusses alterations of immune function at environmental levels resulting in loss of memory and concentration, skin redness and inflammation, eczema, headache, and fatigue. Mast cells that degranulate under EMF and RFR exposures and substances secreted by them (histamine, heparin and serotonin) may contribute to features of this sensitivity to electromagnetic fields [92]. Theoharides and colleagues have argued that environmental and stress related triggers might activate mast cells, causing inflammatory compromise and leading to gut–blood–brain barrier compromise, seizures and other ASC ASC symptoms [93,94], and that this cascade of immune response and its consequences might also be triggered in the absence of infection by mitochondrial fragments that can be released from cells in response to stimulation by IgE/anti-IgE or by the proinflammatory peptide substance P [95].

Seitz et al. [96] reviewed an extensive literature on electromagnetic hypersensitivity conditions reported to include sleep quality, dizziness, headache, skin rashes, memory and concentration impairments related to EMF and RFR [96]. Some of these symptoms are common in ASCs, whether or not they are due to EMF/RFR exposure, and the experience of discomfort may be hard to document due to difficulties with self-reporting in many people with ASCs.

Johansson [72] also reports that benchmark indicators of immune system allergic and inflammatory reactions occur under exposure conditions of low-intensity non-ionizing radiation (immune cell alterations, mast cell degranulation histamine-positive mast cells in biopsies and immunoreactive dendritic immune cells) [71,72]. In facial skin samples of electro-hypersensitive persons, the most common finding is a profound increase in mast cells as monitored by various mast cell markers, such as histamine, chymase and tryptase [97]. In ASCs, infant and childhood rashes, eczema and psoriasis are common, and they are common in family members as well [98].

2.1.4. Alteration of and damage to cells in the brain

Brain cells have a variety of ways of reacting to environmental stressors, such as shape changes, metabolic alterations, upregulation or downregulation of neurotransmitters and receptors, other altered functionality, structural damage, production of un-metabolizable misfolded proteins and other cellular debris, and apoptosis; these range along a spectrum from adaptation to damage and cell death. These types of alterations can be looked at in animals under controlled conditions, but in human beings direct cellular examination can only be done on surgical biopsy tissue – which is hardly ever available in people with ASCs – or after death, at which point there has been a whole lifetime of exposures that are generally impossible to tease apart if there were even motivation to do so. This complicates the comparison of brain cell and tissue-related pathophysiology between what is seen in ASCs and what is associated with EMF/RFR exposures.

2.1.4.1. Brain cells. Impact of EMF/RFR on cells in the brain has been documented by some of the studies that have examined brain tissue after exposure, although the interpretation of inconsistencies across studies is complicated by sometimes major differences in impact attributable to differences in frequencies and duration of exposure, as well as to differences in resonance properties of tissues and other poorly understood constraints on cellular response. These studies and methodological considerations have been reviewed in depth in several sections of the 2012 BioInitiative Report [11,99]. A few examples of observations after exposure have included dark neurons (an indicator of neuronal damage), as well as alteration of neuronal firing rate [100], and upregulation of genes related to cell death pathways in both neurons and astrocytes [101]. Astrocytic changes included increased GFAP and increased glial reactivity [102–105], as well as astrocyte-pertinent protein expression changes detected by Fragopoulou et al. [322] as mentioned above. Also observed has been a marked protein downregulation of the nerve growth factor glial maturation factor beta (GMF) which is

considered as an intracellular signal transduction regulator in astrocytes, which could have significant impact on neuronal-glial interactions as well as brain cell differentiation and tumor development. Diminution of Purkinje cell number and density has also been observed, [106] including in two studies of the impacts of perinatal exposure [107,108]. Promotion of pro-inflammatory responses in EMF-stimulated microglial cells has also been documented [109].

Neuropathology findings in ASCs have been varied and have been interpreted according to various frameworks ranging from a regionalized approach oriented to identifying potential brain relationships to ASC's behavioral features [110] to identifying receptor, neurotransmitter and interneuron abnormalities that could account for an increased excitation/inhibition ratio [111–115]. Studies have documented a range of abnormalities in neurons, including altered cellular packing in the limbic system, reduced dendritic arborization, and reductions in limbic GABAergic systems [116]. Over the past decade a shift has occurred from presuming that all pertinent brain changes occurred prior to birth, to an acknowledgement that ongoing cellular processes appear to be occurring not only after birth but well into adulthood [117]. One of the reasons for this shift was the observation that head size (as well as brain weight and size) was on average larger in children with autism, and the head sizes of children who became diagnosed with autism increased in percentile after birth [118].

2.1.4.2. Neuroinflammation, glial activation and excitotoxicity. Although much attention has been paid in ASC brain literature to specific regions manifesting differences in size and activity in comparison to those without ASCs, there are other observations that are not strictly regional in nature, such as more widely distributed scaling differences (e.g. larger brains, wider brains, increased white matter volume, along with altered functional connectivity and coherence to be discussed below). Recently more studies have appeared identifying pathophysiological abnormalities such as neuroinflammation, mitochondrial dysfunction and glutathione depletion in brain tissue. Neuroinflammation was first identified in a study of postmortem samples from eleven individuals aged 5–44 who had died carrying an ASC diagnosis, in which activated astrocytes and microglial cells as well as abnormal cytokines and chemokines were found. Other research has identified further astrocyte abnormalities such as altered expression of astrocyte markers GFAP abnormalities, with elevation, antibodies, and altered signaling having been documented [119–121]. Increased microglia activation and density as well as increased myeloid dendritic cell frequencies have also been documented [87,122,123], as has abnormal microglial-neuronal interactions [124]. Recently, through use of the PET ligand PK11105, microglial activation was found to be significantly higher in multiple brain regions in young adults with ASCs [125]. Genes associated with glial activation have been documented as upregulated. Garbett et al measured increased transcript levels of many immune genes, as well as changes in transcripts related to cell communication, differentiation, cell cycle regulation and chaperone systems [126]. Voineaugu and colleagues performed transcriptomic analysis of autistic brain and found a neuronal module of co-expressed genes which was enriched with genetically associated variants; an immune-glial module which showed no such enrichment for autism GWAS signals was interpreted as secondary [127], but this seems to involve circular thinking, since it implies that the primary cause must be genetic, which is an assumption deriving from a dominant model, but is not a proven fact.

Neuroinflammation also does not appear to be strictly localized in a function-specific fashion, and it may contribute both to more broadly distributed and more focal features for tissue-based reasons. It may be that brain regions with particular prominence in ASCs may have distinctive cellular characteristics—e.g. the amygdala [128–138], which may have a larger or more reactive population of astrocytes [139] or the basal ganglia which may have greater sensitivity to even subtle hypoxia or perfusion abnormalities. In this case it may be the histology of these areas that makes them vulnerable to environmental irritants, and this may contribute to how environmental factors such as EMF/RFR might trigger or aggravate some of ASC's features. More widely distributed brain tissue pathology be part of what leads to differences in ASCs in brain connectivity. However these types of tissue-function relationships have been poorly investigated. Belyaev has intensively reviewed physical considerations including the contribution of tissue differences to variability in measured EMF/RFR impacts [11].

Various signs of mitochondrial dysfunction and oxidative stress have also been identified in the brain. Findings include downregulation of expression of mitochondrial electron transport genes [140] or deficit of mitochondrial electron transport chain complexes [141], brain region specific glutathione redox imbalance [142], and evidence of oxidative damage and inflammation associated with low glutathione redox status [143]. Oxidative stress markers were measured as increased in cerebellum [144].

Additional support for the presence of tissue pathophysiology-based changes in brains of people with ASCs comes from the various studies documenting reduction in Purkinje cell numbers [117,145–150], possibly due to oxidative stress and an increased excitation/inhibition ratio that could potentially be acquired [150]. Also of note are changes in the glutamatergic and GABAergic systems, which when imbalanced can disturb the excitation/inhibition ratio and contribute to seizure disorders; reductions in GABA receptors as well as in GAD 65 and 67 proteins that catalyse the conversion of glutamate into GABA have been measured [151–153]. A consensus statement on the cerebellum in ASCs stated that, *"Points of consensus include presence of abnormal cerebellar anatomy, abnormal neurotransmitter systems, oxidative stress, cerebellar motor and cognitive deficits, and neuroinflammation in subjects with autism"* [150].

Some indirect corroboration for these findings has come from neuroimaging, where the initial hypothesis regarding the tissue basis of the larger size of brains in so many people with autism – that it was due to a higher density of neurons and more tightly packed axons – came under question with the emergence of contradictory findings, well reviewed a few years ago by Dager and colleagues [154]. These include reduced rather than increased density of NAA (*n*-acetylaspartate, a marker of neuronal integrity and density that is produced in the mitochondria), reduced rather than increased fractional anisotropy suggesting less tightly packed axonal bundles [155–161] and greater rather than lower diffusivity, all of which may be more consistent with lower density of tissue and tissue metabolites and more fluid, which could be consistent with neuroinflammation and/or oxidative stress. The early postnatal development of such lower fractional anisotropy and increased diffusivity was measured in the process of occurring recently, in the first large prospective longitudinal imaging study of infants, who trended from 6 months to 2 years in the direction of these findings becoming more pronounced—but still with substantial overlap with those infants who did not develop autism [160]. This trend was consistent with prior studies showing increase in head size after birth, and added some information about what was happening in the brain to drive this size increase, although due to its methods it could only indirectly address the possibility that emergence during the first few years of life of tissue pathophysiology disturbances such as neuroinflammation might be contributing to these trends [162].

There is also substantial variability across many different types of brain findings. Of interest is that a number of functional brain imaging and electrophysiology studies have identified greater heterogeneity in response to stimuli between individuals in the ASC group than individuals in the neurotypical control group [163,164]. This may make more sense from the point of view of non-linear response—i.e. a disproportionality between output and input (as well as state and context sensitivity), in a pathophysiologically perturbed brain system. Nonlinearity has also been a significant methodological issue in EMF/RFR research because linear methods of study design and data analysis have often been insensitive to effects, whereas nonlinear methods have been argued to show greater sensitivity [165–175].

It is important to entertain how environmental agents could contribute individually and synergistically to brain changes in ASCs, how different exposures may disturb physiology similarly or differently, and how these changes may develop over progress over time after the earliest periods in brain development. EMF/RFR exposures could be preconceptional, prenatal or postnatal—or all of the above; it is conceivable that this could be the case in ASCs as well.

2.1.4.3. Altered development. There is some evidence for altered brain and organism development in relation to EMF/RFR exposure. Aldad et al. [83] exposed mice in-utero to cellular telephones, with resultant aberrant miniature excitatory postsynaptic currents, and dose-responsive impaired glutamatergic synaptic transmission onto layer V pyramidal neurons of the prefrontal cortex [83]. Lahijani exposed preincubated chicken embryos to 50 Hz EMFs, and made the following morphological observations: "*exencephalic embryos, embryos with asymmetrical faces, crossed beak, shorter upper beak, deformed hind limbs, gastroschesis, anophthalmia, and microphthalmia. H&E and reticulin stainings, TEMS, and SEMs studies indicated EMFs would create hepatocytes with fibrotic bands, severe steatohepatitis, vacuolizations, swollen and extremely electron-dense mitochondria, reduced invisible cristae, crystalized mitochondria with degenerated cristae, myelin-like figures, macrophages engulfing adjacent cells, dentated nuclei, nuclei with irregular envelopes, degenerated hepatocytes, abnormal lipid accumulations, lipid droplets pushing hepatocytes' nuclei to the corner of the cells, abundant cellular infiltrations cellular infiltrations inside sinusoid and around central veins, disrupted reticulin plexus, and release of chromatin into cytosol, with partially regular water layers, and attributed cell damage to elevated free radical induced cell membrane disruptions*" [5].

Although it is of great interest to characterize the changes in development associated with ASCs, it is also difficult to do in human beings because at present diagnosis is not possible until at least 2–3 years after birth. By now there have been a lot of prospective studies of infants at high risk for autism, but the in vivo brain imaging and electrophysiology data from these studies is only starting to be published, and so the for now the main sources of information are still inference backwards from post-mortem or imaging data, and animal models, both of which have clear limitations. Thus it is impossible to seek precise parallels here between what we know about the development of ASCs compared with the impacts of EMF/RFR exposures.

Nevertheless it is of real concern that such exposures have elicited some of the brain tissue changes that have been documented in ASCs, both in early development and subsequently. Already noted above is the question of whether high exposures of neonates to monitoring equipment may affect the melatonin levels of neonates [32]; these exposures also impact heart rate variability [258]. There are no studies yet on infants exposed to baby surveillance monitors or DECT wireless phones. However there are good laboratory testing studies yielding actual measurements of these devices that conclude: "*Maximum incident field exposures at 1 m can significantly exceed those of base stations (typically 0.1–1 V/m). At very close distances the derived or reference exposure limits are violated for baby surveillance monitors and DECT phones. Further, the authors conclude that, based on very strictly controlled laboratory testing of everyday devices like baby monitors and some cordless phones (W)orse case peak spatial SAR values are close to the limit for the public or uncontrolled environments, e.g., IEEE 802.11b and Bluetooth Class I*" [176].

Even exposure of the fetus to laptop computer wireless emissions through the pregnant mother's use of this device on her lap may involve induction of strong intracorporeal electric current densities from the power supply possibly even more than the device itself [177].

2.1.4.4. Brain blood flow and metabolism. Cerebral perfusion and metabolism abnormalities have been identified in close to two dozen papers studying autistic cohorts. Cerebral perfusion refers to the quantity of blood flow in the brain. Abnormal regulation of cerebral perfusion is found in a range of severe medical conditions including tumors, vascular disease and epilepsy. Cerebral hypoperfusion has also been found in a range of psychiatric disorders [178]. Neurocognitive hypotheses and conclusions, as well as localization of perfusion changes, have been heterogeneous across these papers. Hypoperfusion or diminished metabolism has been identified in frontal regions [179–184], temporal lobes [179,181,183–190], as well as a variety of subcortical regions including basal ganglia [181,188,189], cerebellum [188], limbic structures [184,191] and thalamus [188,189,191]—i.e. in a widely distributed set of brain regions. Possibly because virtually all of these studies were oriented toward testing neuropsychological rather than pathophysiological hypotheses, there were no probes or tests reported to unearth the tissue level alterations that might be underlying these reductions in blood flow in these brains.

While a large number of animal studies have documented blood–brain barrier (BBB) abnormalities from EMF/RFR exposures, only a few PET studies have been performed evaluating EMF exposure effects upon brain glucose metabolism. Volkow et al. performed PET scans both with and without EMF exposure (50 min of GSM-900 with maximum SAR of 0.901 W/kg), and the participants were blinded to the exposure situation [192]. A 7% increase in metabolism in the exposure situation compared to controls was identified regionally on the same side of the head as where the mobile phone was placed. The strength of the E-field from the phones correlated positively with the brain activation, which the authors hypothesized was from an increase in brain neuron excitability. A subsequent smaller study by Kwon et al. demonstrated not increased but decreased brain ^{18}FDG uptake after GSM-900 exposure [193].

Many possible mechanisms could be involved in the metabolic and perfusion abnormalities identified, ranging from altered neuronal activity that was hypothesized in the Volkow et al. [192] ^{8}FDG PET study to narrowing of vascular lumen in the setting of reduced perfusion. Underlying tissue pathophysiology-based phenomena could influence the measurable metabolism and perfusion abnormalities, via mechanisms such as excitotoxicity, cell stress response, constriction of capillary lumen by activated astrocytes, volume effects of vascular extravasation, subtle alterations in blood viscosity due to immune or oxidative stress-associated blood chemical changes, with other possibilities as well. Differences in findings between papers could relate at least in part to study design and nonlinearity issues.

2.1.5. Electrophysiology perturbations

At this stage the argument we hit a key pivot point, where we look at how the alterations in molecular, cellular and systems physiological function, which occur in the brain as well as in the body, impact the transduction into the electrical signaling activities of the brain and nervous system. Certainly the cells and tissues whose physiological challenges we have already discussed provide the material substrate for the electrical activity. Although ASC behaviors are influenced by many factors, they must in principle be mediated through nervous system electrophysiology.

If the cells responsible for generating synapses and oscillatory signaling are laboring under cellular and oxidative stress, lipid peroxidation, impaired calcium and other signaling system abnormalities, then mitochondrial metabolism will fall short, all the more so because of the challenges from the immune system which in turn be triggered to a major extent by environment. How well will synaptic signals be generated? How well will immune-activated and thereby distracted glial cells be able to modulate synaptic and network activity? [194–197].

At present we are in the early stages of being able to formulate these questions well enough to address them empirically. We do know that microglial activation can impact excitatory neurotransmission mediated by astrocytes [198]. We do know that the cortical innate immune response increases local neuronal excitability and can lead to seizures [199,200]. We do know that inflammation can play an important role in epilepsy [201]. We know less about lower levels of chronic or acute pathophysiological dysfunction and how they may modulate and alter the brain's electrophysiology.

2.1.5.1. Seizures and epilepsy. EEG signals in ASCs are abnormal on a variety of levels. At the most severe level, EEGs show seizure activity. Although less than 50% of people with ASCs clearly have seizures or epilepsy a much larger number have indications of epileptiform activity, and an even larger percent have subclinical features that can be noted by a clinical epileptologist though not necessarily flagged as of clinical concern. In addition to the association of some severe epilepsy syndromes (e.g. Landau Kleffner, tuberous sclerosis) with autism, the risk of epilepsy is substantially higher in people with ASCs than in the general population, with a large subset of these individuals experiencing seizure onset around puberty, likely in relation to aberrations in the dramatic and brain-impactful hormonal shifts of that phase of life. Epileptic seizures can be both caused by and cause oxidative stress and mitochondrial dysfunction. Seizures can cause extravasation of plasma into brain parenchyma [202–206] which can trigger a vicious circle of tissue damage from albumin and greater irritability, as discussed above. Evidence suggests that if a BBB is already disrupted, there

will be greater sensitivity to EMF/RFR exposure than if the BBB were intact [207,208], suggesting that such exposures can further exacerbate vicious circles already underway.

The combination of pathophysiological and electrophysiological vulnerabilities has been explored in relation to the impact of EMF/RFR on people with epilepsy EMF/RFR exposures from mobile phone emissions have been shown to modulate brain excitability and to increase interhemispheric functional coupling [209,210]. In a rat model the combination of picrotoxin and microwave exposure at mobile phone-like intensities led to a progressive increase in neuronal activation and glial reactivity, with regional variability in the fall-off of these responses three days after picrotoxin treatment [211], suggesting a potential for interaction between a hyperexcitable brain and EMF/RFR exposure.

One critical issue here is nonlinearity and context and parameter sensitivity of impact. In one study, rat brain slices exposed to EMF/RFR showed reduced synaptic activity and diminution of amplitude of evoked potentials, while whole body exposure to rats led to synaptic facilitation and increased seizure susceptibility in the subsequent analysis of neocortical slices [212]. Another study unexpectedly identified enhanced rat pup post-seizure mortality after perinatal exposure to a specific frequency and intensity of exposure, and concluded that apparently innocuous exposures during early development might lead to vulnerability to stimuli presented later in development [213].

2.1.5.2. Sleep. Sleep involves a profound change in brain electrophysiological activity, and EEG abnormalities including disrupted sleep architecture figure in sleep challenges in ASCs. Sleep symptoms include bedtime resistance, sleep onset delay, sleep duration and night wakings; and sleep architecture can involve significantly less efficient sleep, less total sleep time, prolonged sleep latency, and prolonged REM latency [214,215], with these sleep problems being worse in children with ASCs who regressed than in those who did not regress into their autism [215]. EEG abnormalities have also been associated with EMF/RFR exposure, including disrupted sleep architecture as well as changes in sleep spindles and in the coherence and correlation across sleep stages and power bands during sleep [216,217].

Sleep disturbance symptoms are also common in both situations. Insomnia is commonly reported in people who are chronically exposed to low-level wireless antenna emissions. Mann and Rosch reported an 18% reduction in REM sleep, which is key to memory and learning functions in humans [321]. In ASCs sleep difficulties are highly pervasive and disruptive not only to the affected individual but also to their whole family due to the associated problems such as noise (e.g. screaming at night) and the need for vigilance.

The multileveled interconnections involved in the modulation of sleep exemplify the interconnectedness of the many levels of pathophysiology reviewed here: "*Extracellular ATP associated with neuro- and glio-transmission, acting via purine type 2 receptors, e.g., the P2X7 receptor, has a role in glia release of IL1 and TNF. These substances in turn act on neurons to change their intrinsic membrane properties and sensitivities to neurotransmitters and neuromodulators such as adenosine, glutamate and GABA. These actions change the network input-output properties, i.e., a state shift for the network*" [218]. With disturbance simultaneously at so many of these levels, it is not surprising that sleep dysregulation is nearly universal in ASCs, and common in the setting of EMF/RFR exposures.

2.1.5.3. Quantitative electrophysiology. While clinical reading of EEG studies is done visually, a growing number of studies are examining EEG and MEG data using digital signal processing analysis to find not only epilepsy, but also abnormalities in the power spectrum, i.e. the distribution of power over the different frequencies present, with some studies showing impaired or reduced gamma-and activity [219–221] and others showing reduction of spectral power across all bands [222] while still others showed increased high-frequency oscillations [223]. Abnormalities in coherence and synchronization between various parts of the brain have been found [224–226], comparable to abnormal functional connectivity measured by fMRI [227] but measurable with higher temporal resolution using EEG or MEG [228–232]. Several studies have identified reduced complexity and increased randomness in EEGs of people with ASCs [233,234], as well as an increase in power but a reduction in coherence [229,235]. Some electrophysiological metrics are emerging as potential discriminators between brain signal from individuals with ASCs and those who are neurotypical, such as a wavelet-chaos-neural network methodology applied to EEG signal [236] and reduced cross-frequency coupling [237].

EMF/RFR also has impacts at levels of brain function measurable by these techniques. At various frequencies and durations of exposure it has been noted to impact alpha and beta rhythms [238], to increase randomness [170,239], to alter power, to modulate interhemispheric synchronization [240], to alter electrical activity in brain slices [241] and to alter the patterns of coordination (spectral power coherence) across the major power bands [242]. Bachman et al. [243] showed statistically significant changes in EEG rhythms and dynamics occurred in between 12% and 20% of healthy volunteers [243]. In children, exposures to cell phone radiation have resulted in changes in brain oscillatory activity during some memory tasks [97,102].

2.1.5.4. Sensory processing. Symptomatic level issues with sensory processing are highly prevalent in ASCs and can include hypersensitivity to external stimuli, hyposensitivity to internal sensations and difficulty localizing sensation including pain, and difficulty processing more than one sensory channel at one time [244–246]. There is now electrophysiological evidence of abnormalities at early (brainstem) stages of sensory processing, as well as in later stages of processing that occur in the cortex [247]. Some studies have

shown lower and some longer latencies of response to an auditory stimulus [247]. Domains of perception where the performance of people with ASCs is superior to that of neurotypical individuals have been identified [248]. *"It is ... probable that several mechanisms and neuronal abnormalities, most likely at multiple levels (from single neurons through to inter-area connections), all contribute to varying degrees to the abnormal sensory processing observed in ASD. It is also likely that no single mechanism is unique to one sensory modality, which is why we see such a widely distributed range of abnormalities across modalities"* [247].

It is also possible that the mechanisms may not simply be neural—they may also be modulated by glial, metabolic, immune, perfusional and other physiological processes by common underlying cellular abnormalities, and by physical properties as well. Yet there are few studies focusing upon the interface of tissue pathophysiology with electrophysiology.

Kenet et al. demonstrated environmental vulnerability of sensory processing in the brain by the exposure of rat dams to noncoplanar polychlorinated biphenyls (PCBs), during gestation and for three subsequent weeks of nursing [247]. The rat pups showed normal hearing sensitivity and brainstem auditory responses, but their tonotopic development of the primary auditory cortex was grossly distorted [249]. This study may be particularly relevant for EMF/RFR exposures, as Pessah, a co-author on this Kenet et al. [249] paper, was cited earlier as documenting how the noncoplanar PCBs used in this experiment target calcium signaling as do EMF/RFR exposures—i.e. they both converge upon a common particularly critical cellular mechanism [250,251].

2.1.5.5. Autonomic dysregulation. Although there are a fair number of negative studies regarding the impact of EMF/RFR exposure on the autonomic nervous system, increased HRV and autonomic disturbances have been documented [252–256]. Buchner and Eger [257], in a study in rural Germany of the health impacts of exposures from a new base station yielding novel exposure to EMF/RFR, saw a significant elevation of the stress hormones adrenaline and noradrenaline during the first six months with a concomitant drop in dopamine, with a failure to restore the prior levels after a year and a half. These impacts were felt by the young, the old and the chronically ill, but not by healthy adults [257].

Neonate vulnerability was documented by Bellieni et al. [258] who found that heart rate variability is adversely affected in infants hospitalized in isolettes or incubators where ELF-EMF levels are in the 0.8 to 0.9 μT range (8 to 9 mG). Infants suffer adverse changes in heart rate variability, similar to adults [258]. This electromagnetic stress may have lifelong developmental impacts, based on a study showing that in-utero beta 2 agonist exposure can potentially induce a permanent shift in the balance of sympathetic-to-parasympathetic tone [259].

Meanwhile clinical observation and a growing body of literature support a major role for stress in ASCs [260–263], with variability amongst individuals in the severity of the stress response but a tendency to have high tonic sympathetic arousal at baseline [264–269].

The impact of EMF/RFR exposure can also be greatly influenced by the stress system status of the individual being exposed. Tore et al. sympathecotomized some of his rats before exposure to GSM, to simulate cell phone exposure [207,208]. Sympathectomized rats, which were in a chronic inflammation-prone state, had more prominent albumin leakage than sham-exposed rats. However in the sympathecotmized rats who were exposed to GSM, albumin leakage was greatly increased, to levels resembling those observed in positive controls after osmotic shock. Salford et al. [99] suggest that *"...more attention should be paid to this finding, since it implicates that the sensitivity to EMF-induced BBB permeability depends not only on power densities and exposure modulations, but also on the initial state of health of the exposed subject"* [99].

The interconnection between stress and brain connectivity (or coherence) in ASCs is brought out by Narayanan et al. in a pilot study testing the impact of the beta blocker propranolol on brain functional connectivity measured using functional MRI [270]. A fairly immediate increase in functional connectivity was noted from propranolol—but not from nadolol which has the same vascular effects but does not cross the BBB. Propranolol decreases the burden of norepinephrine, thereby reducing the impact of stress systems on brain processing, and the authors interpreted these effects as creating an improvement of the brain's signal-to-noise ratio [271], allowing it to utilize and coordinate more remote parts of its networks. This suggests that stressors such as EMF/RFR, by adding biologically non-meaningful noise to the system, might have the opposite effects, degrading coherent integration.

2.2. De-tuning of the brain and organism

2.2.1. Electromagnetic signaling, oscillation and synchrony are fundamental, and vulnerable

While electrophysiological activity is an intrinsic property of the nervous system, electromagnetic signaling is a vital aspect of every cell and of molecular structure.

All life on earth has evolved in a sea of natural low-frequency electromagnetic (EM) fields. They originate in terrestrial and extraterrestrial sources. The ever-growing use of electric power over the last century has sharply modified this natural environment in urban settings. Exposure to power-frequency fields far stronger than the natural environment is now universal in civilized society. [272]

Adey published some of the earliest scientific studies on the "cooperativity" actions of cells in communication. Studies showing us that the flux of calcium in brain tissue and immune cells is sensitive to ELF-modulated radiofrequency fields is actually telling us that some of the most fundamental properties of cells and thus of our existence can be modulated by EMF/RFR. *"...in first detection of environmental*

EM fields in tissues, there appears to be a general consensus that the site of field action is at cell membranes. Strands of protein are strategically located on the surface of cells in tissue, where they act as detectors of electrical and chemical messages arriving at cell surfaces, transducing them and transmitting them to the cell interior. The structural basis for this transductive coupling by these protein strands is well known. Through them, cell membranes perform a triple role, in ***signal detection, signal amplification, and signal transduction to the cell interior***" [272].

Oscillation is also a universal phenomenon, and biological systems of the heart, brain and gut are dependent on the cooperative actions of cells that function according to principles of non-linear, coupled biological oscillations for their synchrony, and are dependent on exquisitely timed cues from the environment at vanishingly small levels [273,274]. The key to synchronization is the joint actions of cells that co-operate electrically - linking populations of biological oscillators that couple together in large arrays and synchronize spontaneously according to the mathematics described for Josephson junctions (Brian Josephson, the 1993 Nobel prize winner for this concept). This concept has been professionally presented in journal articles and also popularized in a book by Prof. Steven Strogatz, a mathematician at Cornell University who has written about 'sync' as a fundamental organizing principle for biological systems [274,275]. "*Organisms are biochemically dynamic. They are continuously subjected to time-varying conditions in the form of both extrinsic driving from the environment and intrinsic rhythms generated by specialized cellular clocks within the organism itself. Relevant examples of the latter are the cardiac pacemaker located at the sinoatrial node in mammalian hearts and the circadian clock residing at the suprachiasmatic nuclei in mammalian brains. These rhythm generators are composed of thousands of clock cells that are intrinsically diverse but nevertheless manage to function in a coherent oscillatory state. This is the case, for instance, of the circadian oscillations exhibited by the suprachiasmatic nuclei, the period of which is known to be determined by the mean period of the individual neurons making up the circadian clock. The mechanisms by which this collective behavior arises remain to be understood*" [274].

The brain contains a population of oscillators with distributed natural frequencies, which pull one another into synchrony (the circadian pacemaker cells). Strogatz has addressed the unifying mathematics of biological cycles and external factors disrupt these cycles. Others have discussed how this also applies to mitochondria: "*Organisation of mitochondrial metabolism is a quintessential example of a complex dissipative system which can display dynamic instabilities. Several findings have indicated that the conditions inducing instabilities are within the physiological range and that mild perturbations could elicit oscillations. Different mathematical models have been put forth in order to explain the genesis of oscillations in energy metabolism. One model considers mitochondria as an organised network of oscillators and indicates that communication between mitochondria involves mitochondrial reactive oxygen species (ROS) production acting as synchronisers of the energy status of the whole population of mitochondria. An alternative model proposes that extramitochondrial pH variations could lead to mitochondrial oscillations*" [276].

Mitochondrial dysfunction is important in ASCs but is usually conceptualized in purely biochemical terms without mentioning any oscillatory dimension to mitochondrial activity; it is conceivable that the interplay between biochemistry and oscillation could figure significantly in the mechanisms of impact of EMF/RFR in ASCs.

The field of bioelectromagnetics has studied exposure to very low levels of electromagnetic frequencies. Exposures can alter the magnetokinetics of the formation of a chemical bond, shifting the rate and amount of product produced [272].

Not just chemical reactions but synchronous biological oscillations in cells (pacemaker cells) can be disturbed and disrupted by artificial, exogenous environmental signals, which can lead to desynchronization of neural activity that regulates critical functions (including metabolism) in the brain, gut and heart and circadian rhythms governing sleep and hormone cycles [277]. Buzsaki in his book *Rhythms of the Brain* says "*rhythms can be altered by a wide variety of agents and that these perturbations must seriously alter brain performance.*" [273].

Disturbance can get increasingly disruptive as more damage occurs and more systems are thrown out of kilter and out of cooperativity. One can think of the kindling model in which repeated induction of seizures leads to longer and more severe seizures and greater behavioral involvement. The combination of disruptive and stimulatory effects of biologically inappropriate EMF/RFR exposures could contribute to disruption of synchronized oscillation and cooperativity at a myriad of levels but particularly in the brain, and this may contribute to the loss of coherence and complexity in the brain in autism, as well as dysregulation of multiple other bodily systems. Strogatz points out that there are many more ways of being desynchronized than of being synchronized [274] (which may relate to ASC's great heterogeneity). It has even been suggested that autism itself could be due to brain desynchronization [278].

2.2.2. *Behavior as an "emergent property"*

From a pathophysiological point of view one might hypothesize that a brain with greater indications of oxidative stress along with immune activation and mitochondrial dysfunction might generate different oscillatory activity than a brain in which those pathophysiological features were absent. From this vantage point it would make sense to propose that the compromised whole body health status of at least many with ASCs would make it harder for them to maintain the resilience of their brain cells and brain activities in the face of potentially disruptive exposures. Yet the investigation of how this might occur remains a largely unexplored frontier. But

from the point of view of making sense of the brain impact of environmental challenges – including but not limited to EMF-RFR – this investigation is crucial.

The pathophysiological perspective that guides this review would suggest a move away from considering the behavioral manifestations of ASCs as core, intrinsic, 'hard-wired traits.' *Instead behaviors may be better understood as 'outputs' or emergent properties – what the brain and body produce – when their physiological attributes are altered* in these fashions for whatever reasons—be they genetic, environmental or many combinations of both [279–284]. Sleep and consciousness have also been considered 'emergent properties' [285,286]. Brain oscillatory activity is critical for organizing behavior, and it arises from cells and subcellular features that are shaped by the environment and can act differently based on their functional status as well as on account of external sensory or psychosocial stimuli.

In particular, (a) brain oscillatory activity is intimately connected with underlying cellular, metabolic and immune status, (b) EMF/RFR is capable of perpetrating changes at each of these levels, and (c) problems at each of these levels can make other problems worse. And as mentioned earlier, EMF/RFR and various toxicants can co-potentiate damage [287–294], amplifying 'allostatic load'.

Put together, all of this implies that the combination of these EMF/RFR impacts may quite plausibly significantly contribute both to how ASCs happen in individuals and to why there are more reported cases of ASCs than ever before (1200–1500% increase in reported cases over the past 15–20 years, with studies showing that a substantial portion of this increase (45–65%) cannot be written off as artifact and may well represent true increases [295,296]).

The hopeful side of this framing of the problem comes from moving beyond the increasingly anachronistic idea that autism is determined overwhelmingly by genetic code about which we can do little or nothing. An emerging model that explains much more of what we now know frames ASCs as the dynamic, active outcomes of perturbed physiological processes – again, more like a chronic but changeable 'state' than a 'trait.' In the latter model, one is empowered – and motivated – to strongly reduce exposures and to make aggressive constructive environmental changes – particularly in diet and nutrition, given their protective potency discussed above [297]. In this way 'allostatic load' can be reduced, physiological damage can be repaired, homeostasis can be restored and resilience and optimal function can be promoted.

3. Implications

3.1. Exposures and their implications

Several thousand scientific studies over four decades point to serious biological effects and health harm from EMF and RFR [298,299]. These studies report genotoxicity, single-and double-strand DNA damage, chromatin condensation, loss of DNA repair capacity in human stem cells, reduction in free-radical scavengers (particularly melatonin), abnormal gene transcription, neurotoxicity, carcinogenicity, damage to sperm morphology and function, effects on behavior, and effects on brain development in the fetus of human mothers that use cell phones during pregnancy. Cell phone exposure has been linked to altered fetal brain development and ADHD-like behavior in the offspring of pregnant mice [83].

3.1.1. Exposures have outpaced precautions

There is no question that huge new exposures to EMF/RFRs have occurred over the past few decades. As discussed extensively in the BioInitiative 2012 update [299], there is much concern that regulations to date have been based on a very limited sense of the pertinent biology, and particularly that limiting concern to thermal impacts is no longer valid since there is a wealth of evidence by now that non-thermal impacts can be biologically very powerful. Only in the last two decades have exposures to RFR and wireless technologies become so widespread as to affect virtually every living space, and affect every member of societies around the world. Even as some disease patterns like brain tumors from cell phone use have become 'epidemiologically visible', there are no comprehensive and systematic global health surveillance programs that really keep up to report EMF/RFR health trends [300].

The deployment of new technologies is running ahead of any reasonable estimation of possible health impacts and estimates of probabilities, let alone a solid assessment of risk. However, what has been missing with regard to EMF/RFR has been an acknowledgement of the risk that is demonstrated by the scientific studies. There is clear evidence of risk, although the magnitude of the risk is uncertain, and the magnitude of doing nothing on the health effects cost to society is similarly uncertain. This situation is very similar to our history of dealing with the hazards of smoking decades ago, where the power of the industry to influence governments and even conflicts of interest within the public health community delayed action for more than a generation, with consequent loss of life and enormous extra health care costs to society. [301].

3.1.2. The population's exposure has increased

The very rapid global deployment of both old and new forms of emerging wireless technologies in the last two decades needs aggressive evaluation from a public health perspective, given the range of physiological impacts described in Section 2.

In the United States, the deployment of wireless infrastructure (cell tower sites) to support cell phone use has accelerated greatly in the last decades. The Cellular Telephone Institute of America (CTIA) estimated that in 1997 there were only 36,650 cell sites in the US; but increased rapidly to 131,350 in June 2002; 210,350 in June 2007 and 265,561 in June 2012 [302,303]. About 220,500 cell sites existed in 2008 [303–305]. These wireless facilities for cellular phone voice

and data transmission produce RFR over broad areas in communities and are an involuntary and unavoidable source of whole-body radiofrequency radiation exposure. Other new RFR exposures that did not exist before are from WI-FI access points (hotspots) that radiate 24/7 in cafes, stores, libraries, classrooms, on buses and trains, and from personal WI-FI enabled devices (iPads, tablets, PDAs, etc).

Not surprisingly, the use of cell phones has a parallel growth trend. In the late 1980s and early 1990's, only a few percent of the US population were cell phone users. By 2008, eighty-four percent (84%) of the population of the US owned cell phones. CTIA reports that wireless subscriber connections in the US increased from 49 million in June 1997 to 135 million in June 2002 to 243 million in June 2007 to 322 million in June 2012 [302,303]. This represents more than a 100% penetration rate in the US consumer market, up from just a few percent in the early 1990's. The number of wireless subscribers in June 1997 was 18%; in June 2002 it was 47%; in June 2007 it was 81% and in June 2012 it was 101%.

The annualized use of cell phones in the US was estimated to be 2.23 trillion minutes in 2008 and 2.296 trillion minutes in 2010 [303]. There are 6 billion users of cell phones worldwide in 2011 up from 2.2 billion in 2008 and many million more users of cordless phones.

The number of US homes with *only* wireless cell phones has risen from 10.5% in 2007 to 31.6% in June of 2012 [302,303]. There are no statistics for June 1997 nor for June 2002, since landline (non-wireless) phone use predominated. The shift to wireless communications, more minutes of use, and reliance on cell and cordless phones rather than corded phones is an extremely revealing measure of new EMF and RFR exposures for both adults and children.

The prevalence of autism has risen in parallel from one (1) in 5000 (1975) to 1 in 2500 (1985) to 1 in 500 (1995) to 1 in 250 (~2001) to 1 in 166 (~2004) to 1 in 88 (~2008) to 1 in 50 (~2013). All reflected birth cohorts born earlier[1,2]. Further research into autism prevalence studies have debunked the initial contention that higher numbers could be explained away by better diagnosis and broadening of diagnostic criteria[3-6].

3.1.3. Infants, children and childbearing families are highly exposed and vulnerable

The spread of cell towers in communities, often placed on pre-school, church day-care, and school campuses, means that young children may have hundreds of thousands of times higher RFR exposures in home and school environments than existed even 20–25 years ago. In addition, the nearly universal switch to cordless and cell phones, and away from corded landline phones, means that people are experiencing close and repetitive exposures to both EMF and RFR in the home [306]. Wireless laptops and wireless internet in schools, and home offices and for homework mean even more chronic exposures to RFR, a designated IARC 2B Possible Human Carcinogen [307,308]. The great utility of handheld devices as communication aids and engaging sources of information and satisfaction for people on the autism spectrum may come with a concerning biologically harmful underbelly.

Exposures prior to conception or during pregnancy and infancy can come from faulty wiring, proximity to power lines, or high-frequency transients from a proximate transformer on a utility pole. Sources of pulsed RFR inside the home include an electronic baby monitor in the crib, a wireless router in the next room, a DECT phone that pulses high emissions of RFR on a continuous basis 24/7, or conversion to all compact fluorescent bulbs that produce significant 'dirty electricity' for occupants due to low-kilohertz frequency fields on electrical wiring and in ambient space. Sick and vulnerable infants in neonatal intensive care units are heavily exposed from being surrounded by equipment, with negative metabolic and autonomic consequences documented [32,258].

Wireless phones and laptops exposures produce extremely low frequency pulses from the battery of the wireless device [301,306,309] and the exposures to pulsed radiofrequency microwave radiation when the wireless device is transmitting or receiving calls and emails.

Especially since EMF/RFR exposures are already classified as IARC 2B Possible Human Carcinogens, we should be actively investigating these sources of damage to DNA that could reasonably result in 'de novo mutations' but also be aware that common environmental exposures from EMF and RFR might play a role in the higher rates of concordance for autism (ASD) among twins and siblings.

Researchers also should be aware that common environmental exposures from EMF and RFR might play a role in the higher rates of autism (ASD) among twins and siblings, not solely because of maternal use of wireless devices during pregnancy and paternal sperm exposure to wireless devices peri-conception; but also because such oxidative damage to DNA can occur at levels introduced into the world of the fetus, and young developing infant and child via baby surveillance monitoring devices in the crib and wireless devices in the home. The deployment of technologies poses risks to human fertility and reproduction capacity, to the fetus, to children and adults [301].

3.1.4. ASC risk and genomic damage to future generations

Barouki and Grandjean make a persuasive case that public health interventions are critically needed in early childhood development to prevent adult diseases that appear decades later [310]. Although they do not include EMF or RFR but only chemicals, they do say that physiological stressors, which EMF and RFR certainly have been established, should be reduced during critical development windows. They say: "*The current pandemic of non-communicable diseases and the increased prevalence of important dysfunctions demand an open interrogation of why current interventions appear insufficient. We now know that disease risk can be induced very early in the life course and that it is modifiable by*

nutrients and environmental chemical exposures (along with drugs, infections, and other types of stresses)" [310].

Public health interventions are warranted now to protect the genetic heritage of humans, as well as the other stocks of genetic material in wildlife and plants in the face of what appears to be on-going impairment of these genomes. The risk of genomic damage for future generations is sufficiently documented to warrant strong preventative action and new public safety limits that observe EMF/RFR levels shown to cause adverse effects.

3.1.5. De-tuning the organism

Genetic mutations may lead to cancer and other diseases in the present and future generations, but the exposures that are capable of creating genotoxic impacts also compromise physiological function. Even genotoxicity can have not only specific but also non-specific effects due to molecular inefficiencies, misfolded proteins, and cellular debris [311,312].

In the setting of autism, a baby gestated or developing as a neonate in a milieu with excessively elevated EMF/RFR exposures is vulnerable to interference with the normal development processes, including the organization of information and experience in the brain. This baby's environment also often includes nutritional insufficiencies (processed denatured pesticide-laden food low in antioxidants, minerals and essential fatty acids essential to cellular protection). The baby's gestational period may have been complicated by the mother's own health issues such as conditions like obesity and diabetes [313] which converge upon on inflammation, oxidative stress and other common forms of physiological dysregulation. The exquisite 'tuning up' of the brain and body as it develops will integrate and respond to the environmental inputs it receives, and is particularly sensitive to environmental miscues (whether chemical like endocrine disruptors, EMF/RFR which can be both chemically and electromagnetically disruptive, or other environmental conditions whether hostile or nurturing). To the extent that the baby is burdened with more disorganized or hostile cues than nurturing and organizing cues, that baby may lose resiliency and become more physiologically vulnerable –perhaps approaching a tipping point into decompensation such as autistic regression or development of other chronic disease processes.

From a systems point of view, the phenomenon of 'autistic regression' can be understood as occurring after an accumulation of multisystem signaling interference leading to a tipping point of loss of some vital systems synchronization and increase in randomization. EMF/RFR exposures could plausibly contribute both to this vulnerability and to the decompensation/desynchronization process – as could other stressors such as infection, toxicity, acute stress. The vulnerability, then, is the 'allostatic load' – the total burden of stressors pressing toward disorganization. The tipping point may come in a variety of ways; but upon investigation one is likely to find that unless a stressor is severe, the trigger most proximally associated with the decompensation is likely to be the 'straw that breaks the camel's back' laid atop a prior accumulation of 'allostatic load.'

3.2. Conclusions and recommendations

The case has been made that ASCs involve physiological challenges at multiple levels, and that these challenges are paralleled in the physiological impacts of EMF/RFR exposure. Evidence has also been presented to suggest that the many levels of damage and degradation of physiological and functional integrity are profoundly related to each other. Although autism spectrum conditions (ASCs) are defined by problems with behavior, communication, social interaction and sensory processing, under the surface they also involve a range of disturbances of underlying biology that find striking parallels in the physiological impacts of electromagnetic frequency and radiofrequency radiation exposures (EMF/RFR). At the cellular and molecular level many studies of people with ASCs have identified oxidative stress and evidence of free radical damage, evidence of cellular stress proteins, as well as deficiencies of antioxidants such as glutathione. Elevated intracellular calcium in ASCs can be associated with genetic mutations but more often may be downstream of inflammation or chemical exposures. Cell membrane lipids may be peroxidized, mitochondria may function poorly, and immune system disturbances of various kinds are common. Brain oxidative stress and inflammation as well as measures consistent with blood–brain barrier and brain perfusion compromise have been documented. Changes in brain and autonomic nervous system electrophysiology can be measured and seizures are far more common than in the population at large. Sleep disruption and high levels of stress are close to universal. In parallel, all of these phenomena have also been documented to result from or be modulated by EMF/RFR exposure. Moreover, some people with ASCs have de novo mutations (that their parents do not have), and EMF/RFR exposures could contribute to this due to their potential genotoxicity. EMF/RFR exposure during pregnancy may send spurious signals to developing brain cells during pregnancy, altering brain development during critical periods, and may increase oxidative stress and immune reactivity that can increase risk for later developmental impairments, with further disruption later in development increasing risk, physiological dysregulation and severity of outcome.

All of this does not prove that EMF/RFR exposures cause autism, but it does raise concerns that they could contribute by increasing risk, and by making challenging biological problems and symptoms worse in these vulnerable individuals. Placed alongside the dramatic rise in reported cases of ASCs [333], that parallels the dramatic rise in deployment of wireless technologies, a strong case can be made for aggressively investigating links between ASCs and EMR/RFR, and minimizing exposures for people with autism as well as families preconceptionally, during pregnancy, and around infants and children at home, at school, and in health care centers and hospitals.

Please cite this article in press as: M.R. Herbert, C. Sage, Autism and EMF? Plausibility of a pathophysiological link part II, Pathophysiology (2013),

These arguments have implications for how we understand what ASCs 'are' and how they work, including an appreciation that it may be the physiological disturbance is what actually generates the 'autism' on a moment-to-moment basis—and that these physiological disturbances are profoundly driven by environmental insults. These implications call upon us to take the environmental contribution very seriously, which involves on the one hand a sobering appreciation of the vast array of exposures that can contribute to risk via perturbed development and physiological degradation, and on the other hand a sense that there are powerful things we can do to reduce risk and improve the situation.

3.2.1. Change our deployment of EMF/RFR

The deployment of RFR from wireless technologies has incredible momentum, and it has made many things easier and many other things possible for the first time. On the other hand this momentum can interfere with setting up the technology in a fashion truly respectful of biological tolerances. "*There is no question that global implementation of the safety standards proposed in the Bioinitiative (2007) Report, if implemented abruptly and without careful planning, have the potential to not only be very expensive but also disruptive of life and the economy as we know it. Action must be a balance of risk to cost to benefit. The major risk from maintaining the status quo is an increasing number of cancer cases, especially in young people, as well as neurobehavioral problems at increasing frequencies. The benefits of the status quo are expansion and continued development of communication technologies. But we suspect that the true costs of even existing technologies will only become much more apparent with time. Whether the costs of remedial action are worth the societal benefits is a formula that should reward precautionary behavior*" [301].

3.2.2. Encourage precautions right now based on present knowledge

Physicians and health care workers should raise the visibility of EMF/RFR as a plausible environmental factor in clinical evaluations and treatment protocols. Reducing or removing EMF and wireless RFR stressors from the environment is a reasonable precautionary action given the overall weight of evidence.

- Children with existing neurological problems that include cognitive, learning, attention, memory, or behavioral problems should as much as possible be provided with wired (not wireless) learning, living and sleeping environments,
- Special education classrooms should aim for 'no wireless' conditions to reduce avoidable stressors that may impede social, academic and behavioral progress.
- Adaptations to preserve the attractive design innovations of technologies such as tablet computers in a 'no wireless' environment should be developed.
- All children should reasonably be protected from the physiological stressor of significantly elevated EMF/RFR (wireless in classrooms, or home environments).
- School districts that are now considering all-wireless learning environments should be strongly cautioned that wired environments are likely to provide better learning and teaching environments, and prevent possible adverse health consequences for both students and faculty in the long-term.
- Monitoring of the impacts of wireless technology in learning and care environments should be performed with sophisticated measurement and data analysis techniques that are cognizant of the non-linear impacts of EMF/RFR and of data techniques most appropriate for discerning these impacts.
- There is sufficient scientific evidence to warrant the selection of wired internet, wired classrooms and wired learning devices, rather than making an expensive and potentially health-harming commitment to wireless devices that may have to be substituted out later, and
- Wired classrooms should reasonably be provided to all students who opt-out of wireless environments.

Broader recommendations also apply, related to reducing the physiological vulnerability to exposures, reduce 'allostatic load' and build physiological resiliency through high quality nutrition, reducing exposure to toxicants and infectious agents, and reducing stress [297], all of which can be implemented safely based upon presently available knowledge.

3.2.3. Build an environmentally physiologically centered research program in ASCs as a platform for investigating the EMR/RFR-ASC linkage

This review has been structured around the physiological parallels between ASCs and the impacts of EMF/RFR. What is missing from the autism research agenda is some cross-study of these two bodies of research evidence. To do this we will need both a recognition of the importance of these risks, and a collaborative multi-site research program centered around a "middle-out" physiological approach [314] that can transcend the limits of the gene-brain-behavior agenda that has dominated ASC research, by incorporating this now clearly limited approach into a broader framework [315]. This still dominant gene-brain-behavior approach has been based on an expectation of linear mapping across the levels on which it focuses, but instead the systems involved appear to be much more complex. The middle-out approach is an emerging more inclusive framework in systems biology that can incorporate complexity and nonlinear, multi-scale modeling [316–320]. The physiological levels largely left out in the gene-only approach are critically important to helping people with ASCs because they will help not only with understanding how environment impacts function but also with identifying leverage points.

3.2.4. Take the evidence as a call to action

Both EMF and RFR exposures are already classified as IARC Group 2B Possible Human Carcinogens. The substantial scientific literature on EMF and RFR effects on DNA, on immune and blood–brain barrier disruption, on stress proteins, on circadian rhythms and hormone disregulation, and on cognition, sleep, disruption of neural control and altered brainwave activity all argue for reduction of exposures now, and better coordinated research in these areas. The evidence is sufficiently documented to warrant strong preventative action and new public safety limits that observe EMF/RFR levels shown to cause adverse effects.

All relevant environmental conditions should be given weight in defining and implementing prudent, precautionary actions to protect public health, including EMF and RFR. Evidence is sufficient to add EMF/RFR prominently to the list of exposures that can degrade the human genome, and impair normal development, health and quality of our physiology. With the rising numbers people with ASCs and other childhood health and developmental disorders, we cannot afford to ignore this component of risk to our children and vulnerable populations. When the risk factors are largely avoidable or preventable, ignoring clear evidence of large-scale health risks to global populations poses unnecessary and unacceptable risks. Taking this evidence as a call to action will be challenging and disruptive in the short term, but constructive in the longer term as we learn to use EMF/RFR in healthier ways.

Curriculum Vitae

Date Prepared: November 18, 2009. Last modified September, 2017
Name: Martha R. Herbert
Office Address: TRANSCEND Research Program
Pediatric Neurology
Massachusetts General Hospital-East
Building 149, 2nd floor
Charlestown, MA 02129
Home Address: 31 Ames Street
Somerville, MA 02145
Work Phone: 617-334-7755
Work Email: martha.herbert@mgh.harvard.edu
Work FAX: (617) 812-6334
Place of Birth: New York City

RECEIVED
APR 27 2018
PA PUBLIC UTILITY COMMISSION
SECRETARY'S BUREAU

Education

1972	B.F.A.	Design and Social Theory	California Institute of the Arts, Los Angeles
1981	Ph.D.	Board of Studies in History of Consciousness	University of California, Santa Cruz
1983-1985		Science courses	City College of New York and University of California, Santa Cruz
1991	M.D.		Columbia University College of Physicians and Surgeons, New York City

Postdoctoral Training

7/1991-6/1992	Intern	Pediatrics	New York Hospital-Cornell University Medical Center
7/1992-6/1993	Junior Resident in Pediatrics	Pediatrics	New York Hospital-Cornell University Medical Center
7/1993-6/1994	Resident	Neurology	Massachusetts General Hospital
7/1994-6/1996	Fellow	Pediatric Neurology	Massachusetts General Hospital
7/1996-6/1998	Clinical/Research Fellow	Neurology	Massachusetts General Hospital

Faculty Academic Appointments

1975-1981	Graduate Teaching Assistant	Political Theory, Environmental Studies, Anthropology	University of California, Santa Cruz
19821986	Lecturer		College of New Rochelle
1982-1984	Lecturer		Empire State College, State University of New York
1982-1984	Lecturer	Division of Degree Studies	New York University
1986-1988	Lecturer		Iona College
1988-1989	Lecturer	New School for Social	Eugene Lang College

Complainant's
Exhibit No. 7

		Research	
1998-2003	Instructor	Neurology	Massachusetts General Hospital Harvard Medical School
2004-	Assistant Professor	Neurology	Harvard Medical School

Appointments at Hospitals/Affiliated Institutions

7/1996-6/1998	Fellow	Clinical and Research	Massachusetts General Hospital
7/1996-6/2003	Clinical Associate	Neurology	Massachusetts General Hospital
7/1996-6/2005	Assistant(position)	Neurology (Pediatrics)	McLean Hospital, Belmont, Massachusetts
7/2003-3/2012	Assistant Neurologist	Neurology	Massachusetts General Hospital
9/2005-5/2007	Active Associate	Pediatrics and Medicine	Cambridge Health Alliance
9/2005-5/2007	Consulting Neurologist	Neurology	Center for Child and Adolescent Development, Cambridge Health Alliance
4/2012-present	Assistant Neuroscientist	Neurology	Massachusetts General hospital

Other Professional Positions

1981-1982	Research Associate, Center for the Philosophy and History of Science	Boston University
1985	Visiting Scientist, Animal Behavior Division of the Department of Mammalogy	American Museum of Natural History
1995	Laboratory Instructor; Human Neural Science and Behavior Course	Harvard Medical School
2011-2017	President	Higher Synthesis Foundation
2011-	Director	Higher Synthesis Health
2017-	Secretary	Higher Synthesis Foundation

Major Administrative Leadership Positions

Local

2006-present	Director, TRANSCEND Research Program (Treatment Research And NeuroScience Evaluation of Neurodevelopmental Disorders)	Massachusetts General Hospital

Local

1998-2001	Brain Development Working Group	Coordinator, Harvard University Mind-Brain-Behavior Initiative
2003-2004	Subcommittee on research planning. Initiated monthly research planning meetings involving journal club and exploration of potential themes for	Autism Research Center Planning group, Massachusetts General Hospital Co-chair

	collaborative research projects.	
2005	Steering committee, Autism seminar planning	Massachusetts General Hospital
2006-2007	Research committee, Autism Center planning committee	Massachusetts General Hospital

National and International

2003	Planning Committee, Exploring Opportunities for Interdisciplinary Linkages in Neurodevelopment and Environmental Health Sciences.	The John Merck Fund invitational conference
	Multiple meetings over several months to plan agenda and choose attendees for this conference with approximately 25 attendees held at the Harvard Club in Boston, November 2003. Additionally, post-conference evaluation.	
2004-2007	Brain Development Initiative	Cure Autism Now Foundation Director
2004-present	Scientific Advisory Board	AGRE (Autism Genetic Resource Exchange)
2004-2005	Planning committee, White Matter Think Tank, Feb 4-6, 2005, Malibu, CA Planning process fall and winter 2004-2005	Cure Autism Now Foundation Chair
2005-2006	Organizing committee, CME course, "Clinical implications of environmental neurotoxicants for neurodevelopmental disabilities" November 2-3	UC Davis MIND Institute Co-chair, Chair of planning Robert Hendren, former Executive Director of the MIND Institute, UC Davis Medical School, then Vice Chair Psychiatry, UCSF
2006	Co-organizer of invitational conference: New Paradigms in Autism Research and Treatment November 3-5, 2006	Commonweal Institute Co-organizer
2006-2009	Autism Coalition for Treatment	Board of Directors
2006-2010	Environmental Health Advisory Board	Autism Society of America and John Merck Fund Co-Chair
2007-2010	Organizing committee for CME courses to follow up initial CME described above	UC Davis MIND Institute Co-chair
2007	Reviewer of John Merck Fund's	John Merck Fund

	Developmental Disabilities Program	
2007-2010	Treatment Guided Research Initiative	Autism Society of America
2007-		Director
2007	Autism and Environment Committee	Autism Speaks
2008	Biology Group	NIH Inter-Agency Coordinating Committee (IACC) Autism Strategy Process
2008	Strategic Planning Workgroup (SPWG)	NIH Interagency Autism Coordinating Committee (IACC)
2008-2014	Scientific Advisory Committee	Autism Speaks
2011-present	Consultant on neurodevelopmental and medical research and on development of Brain Research and Intervention program	The Center for Discovery, Sullivan County, New York State (largest residential facility in NY State for children and adults with special needs)
2013-	Co-Director of Medical Advisory Board for Research and Clinical Planning	Epidemic Answers Foundation, Canary Kids Movie Project
2013-2015	Consultant	Open Medicine Institute, Mountainview, CA
2013-	Board Member	Sherkow Foundation, New York City
2013-	Board Member	Zebrin Foundation, Cambridge, MA
2014-	Director of Medical and Scientific Advisory Board (and Principal Investigator)	Epidemic Answers Foundation, Documenting Hope Project
2014	Consultant hired by Bob Wright, founder of Autism Speaks, to analyze the merits and weaknesses of the organization's program on environment	Autism Speaks

Professional Societies

1986-1991	American Medical Student Association	President, Columbia University College of Physicians and Surgeons Chapter
	1987-1988	
1990-2001	American Neuropsychiatric Association	
1991-2004	American Academy of Pediatrics	
1991-2002	American Anthropological Association	
1993-2004	American Academy of Neurology	
1994-2005	Child Neurology Society	
	1996-2003	Electronic Communications Committee
1994-2003	Council for Responsible Genetics	
	1994-2003	Board of Directors
	1997-2003	Vice-Chair
1995-2000	International Society for Research on Emotion	Member

1996-1999	Society for Research in Child Development	Member
1996-1999	International Society on Infant Studies	Member
1998-2001	Brain Development Working Group, Harvard University Mind-Brain-Behavior Initiative	Member
1999	International Neuropsychological Society	Member
1999-present	Society for Neuroscience	Member

Grant Review Activities

2002	NIH Study Section, STAART (Studies to Advance Autism Research and Treatment) Centers Programs	NIH
2004	Grants Review	NAAR (National Alliance for Autism Research)
	2004	Reviewer
2006	Grants Review	Cure Autism Now
	2006	Reviewer
2007	Communications Program	Nancy Lurie Marks Family Foundation
	2007	Reviewer
2007-(year)	Child Pathology and Developmental Disabilities Study Section	NIH Ad Hoc Reviewer
2008	Missouri Life Sciences Research Board	American Association for the Advancement of Science (AAAS) Research Competitiveness Program
	2008	Remote reviewer
2008-2009	Special Emphasis Panel/Scientific Review Group 2008-20092009/10 ZRG1 BBBP-C (02)	NIH
2012	Child Pathology and Developmental Disabilities Study Section	NIH Ad Hoc Reviewer
2015	Developmental Brain Disorders	NIH Ad Hoc Reviewer

Other Editorial Roles

2006	Editorial advisor	Special issue of Autism Society of America magazine The Advocate, "Environmental Health and Autism," release date December 7, 2006.
2006-2007	Guest Editorial Board	American Journal of Biochemistry and Biotechnology, Special issue on Autism Spectrum Disorders
2008	Guest Editor	Autism Advocate, Special issue on Treatment Guided Research Initiative, Autism Society of America

Honors and Prizes

1968	National Merit Scholar	
1969	Richard F. Scholz Memorial Scholarship	Reed College
1985	T.C. Schneirla Award in Comparative Psychology	
1987-1991	Rhodebeck Scholarship	Columbia University College of Physicians and Surgeons
1998-1999	Warren-Whitman-Richardson Fellowship	Harvard Medical School
1998-2000	Research Scholar	Cure Autism Now
2004-2007	Innovator Award	Cure Autism Now
2007	Princeton Lecture Series Fellowship	Eden Institute Foundation
2009	Visiting Professor	Southwest Autism Research and Resource Center, Phoenix, AZ
2011	Most Inspirational Teacher	AutismOne
2013	Canary Award	Epidemic Answers Foundation, Documenting Hope Project

Report of Funded and Unfunded Projects

Funding Information

Past

1998-1999	Autism: Brain Morphometry and Cognitive Neuroscience Warren-Whitman-Richardson Fellowship PI: Martha Herbert *total grant $30,000.* Analysis of brain morphometry volumetric data from a dataset containing 93 MRI scans of children with autism, language impairment, low IQ and typical development.
1998-2000	Autism: Brain Morphometry and Cognitive Neuroscience Cure Autism Now Young Investigator Award

PI: Martha Herbert (indirect cost $7,272)
Analysis of brain morphometry volumetric data from a dataset containing 93 MRI scans of children with autism, language impairment, low IQ and typical development.

1999-2004 Autism: Brain Morphometry and Cognitive Neuroscience
NINDS K23 Mentored Clinical Scientist Development Award
PI: Martha Herbert ($48,529 indirect costs)
Analysis of brain morphometry volumetric data from a dataset containing 93 MRI scans of children with autism, language impairment, low IQ and typical development.

2002-2007 Neuroimaging of Young Children at High Risk for Autism (funding reallocated to allow pursuit of EEG in younger siblings at risk for autism)
NAAR (Nat'l Alliance for Autism Research) (indirect cost: $10,864)
PI: Martha Herbert
MRI scanning of infants at risk for autism, converted to EEG study.

2004-2007 Brain Development and White Matter Initiative
Innovator Award, CAN (Cure Autism Now Foundation)
PI; Martha Herbert (Indirect costs: 0)
Grant awarded to support innovate multidisciplinary research following the PI's contributions to autism with her white matter and her asymmetry findings.

2005-2006 Electrophysiological Indicators of Gating and Timing Abnormalities in Autism
Commonwealth Fund, Massachusetts
Co-PIs: Jerome Kagan, Martha Herbert
EEG studies of children with autism and typical controls focusing on early sensory processing ($100,000)

2005-2007 Unrestricted funds for autism research.
Bernard Fund for Autism Research, Harvard University
Co-PIs: Jerome Kagan and Martha Herbert (funds based with Dr. Kagan at Harvard FAS) ($250,000)
This funding was used to support the development of the TRANCEND Research Program's EEG research and the framing of its biomarker approach

2006-2008 Electrophysiological Indicators of Gating and Timing Abnormalities in Autism
Cure Autism Now Foundation
PI: Katherine Martien, Role on project: Co-Investigator
EEG studies of children with autism and typical controls focusing on early sensory processing

2006-2009 Gating, timing and Connectivity in Autism
Nancy Lurie Marks Family Foundation
Equipment grant: High Density 128 Lead Array EEG Machine, photogrammetry machine, eye-tracking machine, shielded room
PI: Martha Herbert ($188,500) equipment grant; 0 indirects)
This grant supported the purchase of a high density array 128 lead geodesic EEG, a photogrammetry machine, and an acoustic and electromagnetically shielded room, all of which are now housed at the MGH-Lurie Family Center for Autism in Lexington.

2007-2010 Treatment-Guided Research Initiative

Autism Society of America
Grant to plan information capture and dissemination related to individualized treatment of heterogeneous medical and behavioral issues in autism.

2006-2011 Multispectral MRI Imaging of White Matter in Autism
NINDS R01 NS 048455
PI: Martha Herbert ($2,539,706)(indirects: $1,479,807)
MRI imaging to assess tissue properties of white matter in autism and neurocognitive correlates related to simple and complex processing, utilizing volumetrics, diffusion tensor imaging and magnetic resonance spectroscopy along with neurocognitive assessment.

2007-2012 Coherence and Sensory Perception Deficits in Children with Autism – a Study of the 'Noisy Cortex' Hypothesis
Nancy Lurie Marks Family Foundation
PI: Tal Kenet, PhD; Role on Project: Co-Investigator
MEG study with MRI to study cortical noise, its impact on sensory processing, source localization via MRI, and structure-function correlation.

2007-2009 Coherence and Temporal Dynamics in Auditory Cortex of children with Autism
NIH R03
PI: Tal Kenet, PhD
Role on Project: Co-Investigator
Magneto encephalography study of auditory cortex.

2009-2011 Creating a Pediatric Imaging-Genomics Data Resource
NIH RC2
PI: Anders Dale, Terry Jernigan. Site PI: Bruce Rosen.
Role on Project: Investigator.
9-center study to build a database of ~1400 typically developing children ages 3-20, involving MRI, online neurocognitive assessment and salivary samples for genetics.

2011-2013 Retrospective Autism Recovery Documentation
Jane Botsford Johnson Foundation
PI ($98,1750)
To critically review and document detailed case reports of autism recovery and publish the findings in a peer-reviewed journal.

2010-2011 In vivo glutathione imaging: Spectral edited sequence development
Autism Research Institute
PI ($18,000)
To hire a programmer to develop a spectral edited sequence to perform in vivo magnetic resonance spectroscopy measures of glutathione in the brain

2011-2012 NIRS Imaging and its Utility and Importance in Infants
Nancy Lurie Marks Family Foundation
Equipment grant paying for purchase of Oxiplex frequency domain Near Infrared Spectroscopy machine
PI ($59,340)

2011-2013 Brain correlates of mitochondrial dysfunction in autism
Jane Botsford Johnson Foundation
PI ($154,238)
To perform multimodal analyses of existing clinical data comprised of EEG, MRI and laboratory data from children with autism with epilepsy and/or mitochondrial dysfunction

2011-2012 31Phosphorus Spectroscopy Imaging of lipid and bioenergetics metabolites: coil construction
Autism Research Institute and Parent's Collaborative
PI ($22,000)
To build a dual-tuned coil for the 3T Siemens magnet to allow in vivo measurement of phospholipids, ATP, phosphocreatine and other metabolites and to attempt to replicate the 1993 study showing positive findings with this method

2014 Autism and EMF: an EEG study: Silicon Valley Fund-Sullivan Fund. ($85,000)

2014-5 Magnetic Resonance Study of Brain Pathophysiology and Perfusion in Autism
Nancy Lurie Marks Family Foundation ($128,000 NCE)

2014-5 Data Collection and Outcomes: Infrastructure for Systems Medicine
Wallace Research Foundation ($100,000)

2015-2016 Data Capture and Data Pooling in Functional and Systems Medicine
Wallace Research Foundation ($100,000)

2016-2017 Customizing Practice-Based Research Network and Registry Design for Pooling Clinical Outcomes Data Across Diverse Functional and Systems Medicine Practices ($130,000)

Current

2008-2013 (in active data analysis) A prospective multi-system evaluation of infants at risk for autism.
Department of Defense Congressionally Directed Medical Research Program, Autism Spectrum Disorder Research Program, AS073092

PI: Martha Herbert, MD, PhD($656,250; total project $1,148,100) Partnering PI: Margaret Bauman, MD
A pilot study to develop infrastructure for prospective evaluation of medical/physiologial (including metabolic, immune, neuromotor) and electrophysiological (EEG, ERP, autonomics) as well as behavioral and language dimensions of development in infants at high risk for autism, hypothesizing that systemic physiological deficits will precede behavioral symptoms, and that proinflammatory immune and oxidative stress will correlate with EEG spikes, increased amplitude and reduced coherence.

2014- Principal Investigator, Documenting Hope Project (This is a virtual project in terms of management. Funding and in-kind corporate donations go through Epidemic Answers Foundation).

2016-2018 Autism, Environment, Brain, Biomarkers: Deterioration and Amelioration ($180,000 to Higher Synthesis Foundation)

2017-2018 Implementing a Data Capture Platform for Practice-Based Research About Integrative, Functional and Systems Approaches to Healthcare. Wallace Research Foundation

($100,000)

Current Unfunded Projects

2013-	Data analysis from DoD funded study that ended in 2013 – A multisystem assessment of Infants at High Risk for autism.
2013-	Practice-based research data capture consortium. Building consensus on practice data capture instruments to facilitate pooling data. This includes activities in addition to those funded by the Wallace Research Foundation (funding noted above).
2017-	Building a business plan for device development, and designing a replication study, following upon the based upon an EEG signature in 2-week-old infants who were studied in my DoD high Risk infant sibling study, that predicts autism outcome and severity at 30 months.

2016: Systems and Methods for Early Diagnosis of Autism Spectrum Disorders (Partners)

Report of Local Teaching and Training

Teaching of Students in Courses

1995:	Introduction to Neuroanatomy, section leader with 10 students. 2nd year medical students	Harvard Medical School Substantial weekly preparation for ten weeks.

Formal Teaching of Residents, Clinical Fellows and Research Fellows (post-docs)

1996-2003:	Institute of Health Professionals, Physical Therapy Lecture: Introduction to Pediatric Neurology Physical therapy students	Massachusetts General Hospital 2 two-hour lectures annually, approximately 50 students. Initial preparation was very extensive, over two months. Updates annually took one day each.
1996-2002	Annual lecture on Review of Pediatric Neurology.	McLean Hospital Review of Psychiatry and Neurology Substantial preparation 1996, 1997; course cancelled 2001. Course redesigned and lecture revised 2002; one day preparation. Approximately 60-70 students.
1997-2002:	Introduction to the Neurological Examination Harvard medical students	Harvard Medical School Participation in one-time bedside session with medical students. No preparation.
2002-2009	Summer Stock: Introductory lectures for new neurology residents	MGH: 1.5 hours per year introduction to autism clinical and research
2000-2004:	Predoctoral seminar in neuroscience Predoctoral neuropsychologists	Massachusetts Mental Health Two annual 1 ½ hour lectures: a) Introduction to Brain Development, b)

		Introduction to the Neurological Examination for Neuropsychologists. Substantial preparation for first two years. Lecture updated 2004, 2 hours, on basis of Learning and the Brain presentation, November 2003.
2003	"Autism Neuroimaging: A Review and Commentary." Continuing Medical Education Course in Pediatric Neurology.	Harvard Medical School 200+ attendees. One day preparation.
2003	"Autism: Do neurology, neuroscience and medicine implicate the environment?" Post-graduate seminar in child psychiatry Post-graduate	Judge Baker Center, Boston, Massachusetts 25 attendees
2004	"Disorders of Cerebral Development," Bresnan Child Neurology Course	Children's Hospital of Boston 200 attendees
2005	"Autism." Bresnan Child Neurology Course	Royal Sonesta Hotel (Massachusetts General Hospital organizer) 200 attendees
2008-2009	Neurodevelopmental disabilities as part of Pediatric Resident Ambulatory Care Rotation MGH Pediatric residents of all levels	Massachusetts General Hospital Monthly lecture
2007	"Autism: A brain disorder or a disorder that affects the brain?" Bresnan Child Neurology Course	Royal Sonesta Hotel (Massachusetts General Hospital organizer) 200 attendees
2009	"Autism: Research Update" Bresnan Child Neurology Course	Royal Sonesta Hotel (Massachusetts General Hospital organizer) 200 attendees
2011	"Autism: Research Update" Bresnan Child Neurology Course	Royal Sonesta Hotel (Massachusetts General Hospital organizer) 200 attendees
2013	"Autism: Research Update" Bresnan Child Neurology Course	Royal Sonesta Hotel (Massachusetts General Hospital organizer); 200 attendees
2015	"Autism: Research Update" Bresnan Child Neurology Course	Royal Sonesta Hotel (Massachusetts General Hospital organizer); 200 attendees
2016	"Whole Body Approaches to Understanding and Addressing Autism Spectrum Disorders", Autism Spectrum Disorders 2016, Harvard Medical School CME Course	Royal Sonesta Hotel (Massachusetts General Hospital organizer); 600 attendees

Laboratory and Other Research Supervisory and Training Responsibilities

2005-Present	Director of TRANSCEND Research Program, involving setting up the program; hiring, training and supervising staff; developing and documenting laboratory	TRANSCEND has been a full-time effort with the supervisory and training aspects being a significant part of the work. Supervision of infrastructure (e.g. IRBs,

	procedures	database management), data collection, data analysis.

Formally Supervised Trainees

1999-2001	Shelly Steele (degree)	Graduate student, UIC-Chicago She was exposed to whole brain volumetric analysis and contributed strongly to my lab organization.
1999-2000	Girim Sung B.S.	VP Finance company, applying for PhD She was MIT student who was exposed to multidisciplinary medical features contextualizing her neuroscience and molecular biology training.
2000-2002	Karen Bos M.D.	Harvard Medical School and Harvard School of Public Health She was a Radcliffe student fellow who gained experience with medical research, database organization and clinical resource development.
2001-2004	David A Ziegler PhD.	He was hired after two years of graduate school in psychology, neuroanatomy and statistics. He worked for three years and prepared several papers and many presentations. He then obtained a PhD 2004-2011 at MIT Brain & Cog Science, and is now a post-doctoral brain imaging fellow at UCSF He spent three years with me producing papers on the MRI morphometric data I had accumulated; he learned writing, presenting, grant preparation, bibliographic database management, data management and related skills.
2002-2004	Kathryn Devaney M.A.	School Counselor She served as a research assistant in my MRI infant siblings study.
2005-	Tal Kenet, PhD	Assistant Professor, Neurology, MGH She joined me direct from her postdoctoral fellowship with Dr. Michael Merzenich at UCSF, and has been instrumental in co-leading the TRANSCEND Research Program development effort.
2005-2006	Lisa McCoy Cremer B.A.	MSW and MPH She worked as a research assistant in our EEG program, gained valuable clinical experience, and moved on to social work school.
2006-2007	Suzanne Maness, M.S.	School psychologist, Riverside CA She was an outstanding contributor to the early development of our laboratory and served as a research coordinator, gaining experience with research management and neuroscience.
2006-2011 2016-	Nandita Shetty, MS	Neuroimaging MRI biomedical engineer, still in employ She was a biomedical engineer at the inception of my R01, ran the imaging acquisition and analysis, and was greatly proactive in the overall

		development of the research program, serving her ambition to go to business school in a joint imaging-business program. She returned to work with me remotely in the summer-fall of 2016 in building integrated clinical-research care services infrastructure.
2006-2008	Avi Ringer, BS	Graduate school molecular epidemiology He spent two years developing skills in biomarker research pertinent to neurodevelopmental disorders and contributed greatly to the design and grant proposal for our funded high-risk infant sibling study.
2006-2009	Emily Mott, BA	Infant research-normal development She served as recruiter, research coordinator and psychometrician and imaging acquisition assistant.
2007-2009	Alyssa Orinstein, BA	linical psychology at the University of Connecticut. In the TRANSCEND Research program she moved from recruiter to perform as a psychometrician and research coordinator, gaining great hands-on experience in a start-up research program that propelled her to admission to a highly competitive clinical neuropsychology PhD program.
2007-2008	Nikki Meribella, BA	Masters program in counseling She came to us with undergraduate research experience in EEG and worked in the earlier stages of our EEG research in data collection and analysis.
2009-	Jamie Fanelli, M.Ed.	Education background, psychometrician and research coordinator
2008-	Hari Bharadwaj, MS	Biomedical engineer and signal processing analyst He is collecting EEG data in our infant siblings study and analyzing the data, as well as contributing strongly to the development of our planned near infrared spectroscopy program.
2009-	Gillian V. Chapman PhD	Year training in autism research prior to her Clinical Psychology internship She has outstanding testing and interpersonal skills and came to our program to gain a year's experience with autism and imaging research.
2009-	Kanwaljit Singh MD, MPH	Research Fellow with TRANSCEND for both infant research program and school-aged research program He is a pediatrician aiming for a career in pediatric neurology who sought out a position in TRANSCEND due to its multidisciplinary approach to development, and has been doing outstanding work in biomaterials collection standard operating procedure development and statistical analysis of imaging and EEG data, as well as database development and maintenance.
2010-	Mark Westaway, MD	Non-Clinical Research Fellow, now physician. He is an experienced Australian physician who

		came to TRANSCEND to learn research techniques. He had a special interest in electrophysiological measures sensitive to change, which is consistent with the mission of the TRANSCEND Research Program. He left due to medical illness.
2010-	Nitzah Gebhard, BA	Research Coordinator and psychometrist with two years prior experience Her goal is doctoral training in clinical psychology focusing on autism.
2010-2016	Sara Bersche Golas, MA, MA	Research coordinator for the DoD-funded High-Risk Infant prospective multisystem study She has masters level training in experimental psychology and Arabic studies. She wishes to make a career in research. She was advanced to her present position after having joined the program as a temp coordinating the autonomic data collection. She has demonstrated remarkable abilities in coordinating data sets and human subjects. She moved on to a database management position but continued to work with us post-study funding until spring of 2016.
2010-2011	Molly Galdston, BA	Preparing for nurse practitioner training She worked as a research coordinator and psychometrist on both the infant and school-age children studies. Her experience in our infant sibling research study contributed to her deciding to become a nurse practitioner rather than a clinical psychologist.
2011	William LeBec	Was masters electrical engineering student at Ecole Polytechnique in France. Summer intern from Ecole Polytechnique in France who did a 90 day internship as part of his masters level electrical engineering training and worked on analyzing EEG data from the DoD At Risk Infant Sibling study.
2011	Lia Harrington	She was an undergraduate at Dartmouth University. Undergraduate summer intern with strong background in statistics who worked intensively in biomaterials acquisition and brain imaging statistical analysis.
2011	Meenakshi Mal, MD	Physician trained in India seeking further training in US. She is an Indian-trained physician who volunteered for three months to get experience in research to support her goal of doing a pediatrics residency program in the U.S.
2011-2012	Kaustubh Limaye, MD	Neurology Resident at University of Arkansas in Little Rock.

		He was a volunteer research fellow gaining experience in EEG and imaging research as he applied for neurology residency programs with the goal of being an epileptologist.
2011-2013	Robert Yuen, BS	Research assistant in the DoD High Risk Infant Siblings study. He joined TRANSCEND initially as a volunteer and then after outstanding performance in biomaterials sample processing, EEG and NIRS machine operation and data entry was hired in the DoD Infant Siblings study.
2012-2014	Shantanu Ghosh, Ph.D.	Signal processing engineering and brain imaging analysis with PhD in linguistics and strong interest in brain pathophysiology. Dr. Ghosh joined TRANSCEND to perform multimodal imaging analysis and plan future research studies'
2013-2016	Mohamad Alshikho, MD, MA	Dr. Alshikho joined our lab to learn about neurological and neurodevelopmental research. He is an internist trained in Syria who wishes to retrain as a neurologist and has joined my research program to learn how to perform interdisciplinary neuroscience research with a clinical orientation.
2011	Louisa Harrington	She is an undergraduate student from Dartmouth interested In autism and psychology.
2013 Summer	Lauren Purdom	Lauren worked in our laboratory during the summer between her sophomore and junior years at Lehigh University. Her job was to analyze magnetic resonance spectroscopy data.
2013-	Ann Z. Bauer	Ann wrote a public health/epidemiology dissertation on autism and acetaminophen at U Mass Lowell, and I was on her dissertation committee. I continue to mentor her in her research.
2013-2015	Margaret Ptak	Margaret is a graduate student at BU who will do her thesis using our infant siblings data and a practicum in bioinformatics building an autism research database as part of a lab collaboration.
2013-	Ya Wen, Ph.D.	Dr. Ya Wen has a PhD in Molecular Neuroscience from Hong Kong and two years' postdoc at Baylor. She is joining Dr. Herbert to work on meta-analyses related to metabolism, diet, genetics and brain relationships.
2014	Andrew Luo	Andrew is a high school student who interned in our lab and learned bibliographic searching and organizing tools.
2014-present	Jenny Foster, MS, BCBA	Psychologist at Center for Discovery Clinic within major residential facility in New York State, supervising her development of brain program

2015	Christine Lung	Medical student and student body president, did summer internship in Higher Synthesis Health Clinic
2015	Gillian Orlando	High school graduate taking year off before college, interested in special education, did fall internship in clinic
2015-	Donna Messinger, MS	Donna is a NeuroMovement practitioner who works in my clinic as well as in her own private practice. Her daughter was my patient in the Vincent Burnham Neurology Clinic. I am mentoring her in integrating her work into a broader neurology workflow.
2015-2016	Elizabeth DeBruin	Respiratory therapist taking bachelor's degree in psychology did internship in clinic
2016	Luisa Masclans	Harvard undergrad entering fourth year, as pre-med, did summer internship in clinic
2016-	Datis Kharrazian, DHSc	Researcher and educator, and functional neurology clinician, taking two-year MMSCI (Masters in Medical Science) whom I am mentoring and helping with research and IRB preparation as well as data preparation and presentation
2016-	Nandita Shetty, MS	Nandita, a biomedical engineer who worked in TTRANSCEND for 4 ½ years, left to pursue other interests including business graduate training in a Stanford run program in India, and then she built and sold a startup. She contacted me because she wanted to work in the health sector and she is now both helping and being mentored by me.

<u>Formal Teaching of Peers (e.g., CME and other continuing education courses)</u>

2006	Co-organizer of CME course at UC Davis-MIND Institute: Clinical Implications of Environmental Toxicology for Children's Neurodevelopment in Autism	November 2-3, 2006.
2007	Co-organizer of CME courses based at UC Davis-MIND Institute: Clinical Implications of Environmental Toxicology for Children's Neurodevelopment in Autism	July 2007Phoenix;, February 2008 UCSF.
2007	Connectivity in Autism, Kennedy Krieger Institute's Center for Autism and Related Disorders Annual CME Course	October 22, 2007
2007	"Understanding the Science of Autism Disorders," in "Autism Spectrum Disorders: From Childhood to Adulthood," Department of Psychiatry at Cambridge Health Alliance and Harvard Medical School	November 2, 2007.
2008	Co-organizer, CME course on Autism, Autism Society of America national conference	July 2008
2009	Co-organizer and presenter, CME course, "Autism as a Complex Crisis and Points of Intervention," Autism Society of America National Conference	July 2009
2009	"Autism Research Update," MGH Child Neurology CME course	September 29, 2009
	Massachusetts General Hospital	Boston
2009	"Imaging autism tissue and function," Martinos Center for	October 21, 2009

	Biomedical Imaging Advanced Neuroimaging course, Martinos Center for Biomedical Imaging	
2010	Convener and chair of Think Tank, Linking Brain Research to Clinical Applications, Autism One	, May 2010 Chicago
2011	Autism and the Brain UMDNJ Pediatric Neurology Grand Rounds	April, 2011, Newark, NJ
2011	Autism as a Whole-Body Systems Condition, Autism Research Institute Conference CME course	April, 2010 Atlanta
2011	Underlying pathophysiological processes in Autism Spectrum Disorders	May 2011 Chicago
2009	"Autism Research Update," MGH Child Neurology CME course Massachusetts General Hospital	September 29, 2009, Boston
2011	Autism as a Whole-Body Systems Condition, Autism Research Institute Conference CME course	October 2011, Las Vegas
2011	Autism Research Update, MGH Pediatric Neurology CME course	September 20, 2011, Boston
2011	Overview of Physiological issues Underlying Autism Spectrum Disorders, CME Course	November 2011, Barbados
2011	Autism and the Brain	Neurology, UMDNJ, Newark, NJ, April 2011
2012	Shifting models: Integrative systems approach to Autism.	MAPS CME, 3/2/2012
2012	Autism as a Whole-Body Systems Condition, Autism Research Institute Conference CME course	April 2012, Newark, New Jersey
2012	A pathophysiological approach to brain issues in Autism: More than development. CME course at AutismOne	May, 2012 Chicago IL
2012	Autism as a Whole-Body Systems Condition, Medical Academy of Pediatric Special Needs	September, 2012, Orlando, Florida
2012	Glial Cells, Advanced CME, Autism Research Institute	October, 2012, Anaheim, California
2012	Autism: From a Static Brain Defect to a Chronic Systemic Dynamic Encephalopathy	May 8, 2012. Neurology Grand Rounds, Tufts-NEMC, Boston2012
2012	The Autism Revolution: From Broken Brain to Chronic Treatable Systemic Condition	Marshall University Medical School, Huntington, W VA, Sept 21, 2012
2013	Autism Research Update	October, 2013, MGH Pedi Neuro CME course
2015	Autism Research Update	October, 2015, MGH Pedi Neuro CME course
2016	Whole Body Approaches to Understanding and Addressing Autism Spectrum Disorders	November 18-19, 2016 Harvard CME Course

Local Invited Presentations

2005	"Neurobiology of Autism: A Systems Approach." Massachusetts General Hospital seminar series: Autism: Genes, Brains, Babies and Beyond, November 2005.
2009	Autism: A Whole Body Systems Approach. Tufts-New England Medical Center, Pediatric Grand Rounds, April 2009.
2011	"Autism: Developmental, Chronic or Both?" Mass General Hospital-Charlestown,

	Pediatrics, February 2011	
2011	"Autism and Environmental Vulnerability: Whole Brain, Whole Body, Whole Planet", Groden Center Annual Conference, Providence, RI, March 2011.	
2012	Commentator, Autism Speaks Symposium, Boston Public Library, May 15, 2012	
2012	Autism: From a Static Brain Defect to a Chronic Dynamic Systems Encephalopathy, Neuroscience Grand Rounds, Tufts-New England Medical Center, May 31, 2012	
2012	Autism: From a Static Brain Defect to a Chronic Dynamic Systems Encephalopathy, Neuroscience Grand Rounds, Asian Medical Association, McLean Hospital, Belmont MA, August 26, 2012	
2012	Autism Whole Body Strategies, Newton Partnership, May, 2012	
2012	Keynote: Autism Chronic Treatable Features, American Chinese Medical Exchange, McLean Hospital, August 26, 2012	
2012	Autism Revolution, Autism Chinese Medical Exchange, Hyatt Hotel Cambridge, November 3, 2012	
2013	Radio interview for Patricia Raskin show on Providence RI radio station about whole-body approach to autism spectrum disorders	
2013-5	American-Chinese Medical Exchange Society – keynoting their tri-annual conferences	
2014-0228	Autism and Brain Health? The clinical utility of framing autism behaviors as emergent properties of disordered brain cellular and tissue health	Pediatric Neurology Noon Conference, MGH, Elizabeth Thiele Clinic-Lab
2014-0321	A Whole-Body Approach to Brain Health	MIT Media Lab
2015-0428	Reverse-Engineering Mechanisms of Recovery in Chronic Illness	World Medical Innovation Forum, Westin Copley Place, Partners Health Care

		Autismo - "El Autismo de Hoy"; San Jose, Costa Rica Medical Society
2015-0802	Autism is Actionable: Integrated, effective approaches can make a huge difference now	Keynote, Shenzhen Convention Center, Autism Conference
2015-0811	Non-invasive in vivo Brain Biomarkers: Utility in Assessments of Gut-Brain Axis problems and interventions in Neurodevelopmental Disorders with special reference to Autism	Nanjing University Medical School Psychiatry/Neurology joint presentation with Liping Zhao, PhD
2016-0426	How environmental toxins can alter brain development and degrade ongoing brain function	Toxic Contamination of Children, Conference at United Nations in honor of the 30th Anniversary of the Chernobyl Nuclear Meltdown
2017-0603	Missing in Plain View: Ongoing Progress and Recovery in Stroke with NeuroMovement (talk co-delivered with Anat Baniel, MS)	Institute for Functional Medicine Annual International Conference Topic: The Dynamic Brain. Los Angeles, CA

Report of Clinical Activities and Innovations

Current Licensure and Certification

1993-1996	MGH - Limited Licensure
1996-	Commonwealth of Massachusetts Board of Registration in Medicine Registration
1997-	Board Certified in Neurology, with Special Competence in Child Neurology Recertified 2007
2004-(year)	American Board of Psychiatry and Neurology, Subspecialty Certified in Neurodevelopmental Disabilities

Practice Activities

7/1996-7/2005	Major focus: neuropsychiatric disorders, neurodevelopmental disorders, epilepsy, headache. Complex consultations	Pediatric Neurology Clinic, McLean Hospital Department of Neurology	12hrs/week
7/1999-7/2006, 2006	Major focus: neuropsychiatric disorders, neurodevelopmental disorders, epilepsy, headache. Complex consultations	Pediatric Neurology Clinic, Massachusetts General Hospital	6hrs/week
9/2000-4/2006	Pediatric Neurology Attending Physician, Management of pediatric neurology inpatient service	Massachusetts General Hospital	15hrs/week
9/2005—12/2006	Pediatric Neurologist in Child Development Center, neurodevelopmental disorders, epilepsy, headache. Complex consultations	Cambridge Health Alliance, Cambridge Hospital, Harvard Medical School	12hrs/week
2014-15	Small pediatric neurology private practice	Higher Synthesis Health, Cambridge MA	4-8 hrs/week

2015-17	Expanded practice to include additional services and practitioners	Higher Synthesis Health, Cambridge MA	12-24 hours per week plus admin and research
2017-	Small pediatric neurology private practice	Higher Synthesis Health, Cambridge MA	4-8 hrs/week

Report of Education of Patients and Service to the Community

Activities

2005-2008	Executive Committee, NPART (New Paradigms in Autism Research and Treatment), Commonweal Institute, Bolinas, CA
2007-2009	Coordinator, Autism Recovery Documentation Project
2001-present	Frequent lectures to parent groups listed under invited lectures.

Educational Material for Patients and the Lay Community

	(selection of media appearances)
2006-	Personal website containing publications and links: www.marthaherbert.org
2011	Interviewed by Robert MacNeil on PBS in Part 3 of six part series on autism, http://www.pbs.org/newshour/bb/health/jan-june11/autism3causes_04-20.html, http://www.pbs.org/newshour/bb/health/jan-june11/herbertext_04-20.html
July 8,2011	Interviewed by Bruce Gellerman on NPR "Living on Earth" show about recent paper on autism having stronger environmental than genetic influences
2012	www.AutismRevolution.org , website for book, *The Autism Revolution* (Harvard Health Publications, 2012; see below under books)
2012	Website, www.autismWHYandHOW , a site for understanding the rationale and support for multiple points of view about the nature, causes and ways to help autism, a framework for civil discourse amongst these points of view, and a pertinent repository of scientific literature.
2012-	Blogs on above websites: WHY AREN'T WE THERE YET? Valuable but incomplete measures of brain changes in babies with autism HOUSEKEEPING AND HIGHER FUNCTIONS ARE MARRIED AND INSEPARABLE IN THE BRAIN Risk vs Cause: What's the difference between something causing autism versus increasing risk for autism? Obesity, Diabetes, and Autism Risk: Much That You Can Do Bigger than autism, Bigger than genes: A whole body approach to autism and what you can do Autism: 1 in 88 and what we can do New view of autism: Not locked in to genes, brain
2016	Interview on Morning Edition, WBUR, to discuss new findings reported in just published PLOS ONE paper on Pathway Networks in autism

2014-02	Full Potential Parenting	Summit
2014-05	Healthy Gut - interview	Healthy Gut Summit
2015-0110	Autism Intensive Summit	recorded in January for later broadcast
2015-0114	Autism Recovery Summit	recorded in January for later broadcast
2014-0804	Toxicity, Brain and Behavior: What should the Average Person Know	Web Summit by Deanna Minich
2015-0317	Whole Body Approach to Brain Health	Healing Our Children - Web Summit

Books, monographs, articles and presentations in other media

2006	Time to Get a Grip: Autism and Environment	Author and guest editor	Autism Advocate (magazine of Autism Society of America), December 2006
2008	Treatment Guided Research: Helping people now with humility, respect ad boldness	Author and editorial advisor	Autism Advocate (magazine of Autism Society of America), April, 2008
2012	The Autism Revolution: Whole-Body Strategies for Making Life All It Can Be	Book Author (with Karen Weintraub, writer)	Harvard Health Publications, and Random House – Ballantine Books, publication date 3/27/2012 (book completed April, 2012; peer review completed and book approved by Harvard Health Publications July 2011)
	Interviewed for a variety of films during past 15 years		
	Autism Now: Dr. Martha Herbert Extended Interview	PBS News Hour, Robin McNeil, April 2011	http://www.pbs.org/newshour/bb/health-jan-june11-herbertext_04-20/

The implications of non-linear biological oscillations on human electrophysiology for electrohypersensitivity (EHS) and multiple chemical sensitivity (MCS)

DOI 10.1515/reveh-2015-0007
Received May 6, 2015; accepted July 30, 2015; previously published online September 12, 2015

Abstract: The 'informational content' of Earth's electromagnetic signaling is like a set of operating instructions for human life. These environmental cues are dynamic and involve exquisitely low inputs (intensities) of critical frequencies with which all life on Earth evolved. Circadian and other temporal biological rhythms depend on these fluctuating electromagnetic inputs to direct gene expression, cell communication and metabolism, neural development, brainwave activity, neural synchrony, a diversity of immune functions, sleep and wake cycles, behavior and cognition. Oscillation is also a universal phenomenon, and biological systems of the heart, brain and gut are dependent on the cooperative actions of cells that function according to principles of non-linear, coupled biological oscillations for their synchrony. They are dependent on exquisitely timed cues from the environment at vanishingly small levels. Altered 'informational content' of environmental cues can swamp natural electromagnetic cues and result in dysregulation of normal biological rhythms that direct growth, development, metabolism and repair mechanisms. Pulsed electromagnetic fields (PEMF) and radiofrequency radiation (RFR) can have the devastating biological effects of disrupting homeostasis and desynchronizing normal biological rhythms that maintain health. Non-linear, weak field biological oscillations govern body electrophysiology, organize cell and tissue functions and maintain organ systems. Artificial bioelectrical interference can give false information (disruptive signaling) sufficient to affect critical pacemaker cells (of the heart, gut and brain) and desynchronize functions of these important cells that orchestrate function and maintain health. Chronic physiological stress undermines homeostasis whether it is chemically induced or electromagnetically induced (or both exposures are simultaneous contributors). This can eventually break down adaptive biological responses critical to health maintenance; and resilience can be compromised. Electrohypersensitivity can be caused by successive assaults on human bioelectrochemical dynamics from exogenous electromagnetic fields (EMF) and RFR or a single acute exposure. Once sensitized, further exposures are widely reported to cause reactivity to lower and lower intensities of EMF/RFR, at which point thousand-fold lower levels can cause adverse health impacts to the electrosensitive person. Electrohypersensitivity (EHS) can be a precursor to, or linked with, multiple chemical sensitivity (MCS) based on reports of individuals who first develop one condition, then rapidly develop the other. Similarity of chemical biomarkers is seen in both conditions [histamines, markers of oxidative stress, auto-antibodies, heat shock protein (HSP), melatonin markers and leakage of the blood-brain barrier]. Low intensity pulsed microwave activation of voltage-gated calcium channels (VGCCs) is postulated as a mechanism of action for non-thermal health effects.

Keywords: electrobiological rhythms; electrohypersensitivity; homeostasis; multiple chemical sensitivity; neuronal synchrony; voltage-gated calcium ion channel.

Introduction

Artificial electromagnetic exposures on Earth now join chemical exposures as a significant toxic burden that can chronically disrupt homeostasis, cell function and downstream electrophysiology and metabolic endpoints. Nonlinear biological oscillations require exquisite synchrony to perform nearly all basic body functions, and they can be disrupted by electromagnetic fields (EMF) and radiofrequency radiation (RFR), particularly when they are pulsed, and can result in serious health impacts (1–3).

Voltage-gated ion channels are one core function at the cellular level that keep living tissues operating properly and sustain normal growth and development (4–9). All this depends on the delicate balancing of electrophysiological conditions in the body that are cued by specific electromagnetic frequencies, intensities and their natural temporal cycling on Earth. Life on Earth has evolved with a specific set of electromagnetic signals that direct and regulate most, if not all, critical life processes. If the natural evolutionary set of instructions – the bioelectrophysiological envelope of life – is disrupted, the result will be a chronic disruption of core processes that sustain life – from living cells and their membrane regulation and communication, to living tissues, to the overall health and functioning of the organism (us).

We evolved as a human species with one to ten billion times lower microwave radiation exposures than are present today. The mid-1980s through 2012 saw huge increases in pulsed RFR emissions from wireless technologies. Life on earth evolved with no such exposures, thus no physiological defenses against these biologically discordant frequencies (unlike ultraviolet radiation, for example) (10). The 'informational' content' of Earth's electromagnetic signaling is like a set of operating instructions for human life. These environmental cues are dynamic, and involve exquisitely low inputs (intensities) of critical frequencies with which all life on Earth evolved. Circadian and other temporal biological rhythms depend on these fluctuating electromagnetic inputs to direct gene expression, cell communication and metabolism, neural development, brainwave activity and neural synchrony, a diversity of immune functions, sleep and wake cycles, behavior and cognition.

The pathophysiological consequences of exposure to EMF/RFR

How does EMF/RFR contribute to pathological electrical diseases and electromagnetic hypersensitivity (EHS) and might also contribute to the chronic medical condition of multiple chemical sensitivity (MCS)?

The brain is an information processing system that operates through networks of synchronized electrical oscillations or brain waves (1–3, 5, 6). EMF/RFR can disrupt normal neural synchrony leading to various impairments in function of the central nervous system (CNS). Chronic dysregulation of the CNS and autonomic nervous systems in turn can cause cascades of biological impacts leading to further disruption and health consequences. Exploring how EMF/RFR impacts electrophysiology, particularly neural function, may help to identify how pathophysiological and electrophysiological information processing interacts.

As non-linear, weak field biological oscillations are intrinsic modulators of body electrophysiology and act to organize functions in cells, tissues and organ systems; it is not surprising that artificial bioelectrical interference can disrupt the electrical activity of cells, including pacemaker cells of the heart, gut and brain and result in dis-integration of function. Nonthermal pulse-modulated RFR can significantly interact with bioelectrical signaling in the body (1, 2, 5, 6).

It follows that inadvertent exposures to myriad pulsed radiofrequency signals in daily life that are largely uncontrolled, unavoidable and involuntary may be likened to indiscriminate medical treatments with unpredictable health consequences (6, 9). Unless they are specifically designed for healing and applied in clinical settings under rigorous supervision, these daily exposures are most likely to harm rather than to heal.

The similarity of chemical biomarkers seen in both MCS and EHS suggest common pathways of interaction (histamines, markers of oxidative stress, auto-antibodies, HSP, melatonin markers and leakage of the blood-brain barrier). Belpomme (11) reports that their research group *"prospectively investigated clinically and biologically 1200 consecutive EHS and/or MCS-self reported cases, in an attempt to establish objective diagnosis criteria and to elucidate the pathophysiological aspects of these two disorders."* He concludes:

> *"Since inflammation appears to be a key process resulting from the EMF and/or chemical effects on tissues and histamine release is potentially a major trait of inflammation, we systematically measured histamine in the blood of patients. Importantly, 37%, 36.7% and 41.5% of the patients respectively in the above individualized groups showed a significant increase in histaminenua '>10 mol/L), meaning that a chronic inflammatory response can be detected in these patients. As the release of oxidants is part of the basic process of inflammation and they are a key contributor to damage and response, we also measured nitrotyrosine (NTT), a marker of both peroxynitrite (ONOO) production and opening of the blood brain barrier (BBB). NTT was increased in the blood (>0.90 µg/mL) in 29.7%, 26% and 28% of the cases in our three groups, respectively. Likewise protein S100B, another marker of BBB opening was found to be increased in the blood (>0.105 µg/L) in 14.7%, 19.7% and 10.7% of our cases, respectively. Circulating antibodies against O-myelin, Hsp 27 and/or Hsp 70 protein were also found to be increased in 43.1%, 25% and 52% of our cases, respectively, indicating that the EHS and MCS disorders are associated with some autoimmune response. Since most patients reported chronic insomnia and fatigue, we also determined the 24h urine*

melatonin/creatinin ratio and found it was decreased (<0.8) in all investigated cases." (11)

Altered electrophysiology, disruption of electromagnetic signaling, synchrony and sensory processing, mitochondrial dysfunction, immune system dysregulation, neuroinflammation and brain blood flow and behavior alterations are all adverse effects of pulsed EMF/RFR. These exposures can have the devastating effects of desynchronizing homeostasis and disrupting normal biological rhythms that maintain health. The altered 'informational content' from EMF/RFR can obliterate natural environmental cues and interfere with the information needed to regulate normal biological rhythms and direct growth, development, metabolism and repair mechanisms.

Chronic physiological stress undermines homeostasis and resistance to disease that can lead to persistently disrupted health status by eventually breaking down adaptive biological responses critical to health maintenance. Hypersensitivity can be caused by successive assaults on human bioelectrochemical dynamics (from exogenous EMF/RFR fields). As a result, electromagnetic hypersensitivity appears to be triggered by future exposures at lower and lower intensities of EMF/RFR (thousand-fold lower level can cause adverse health impacts to the EHS person).

Electromagnetic signaling, oscillation and synchrony are fundamental properties of living systems

While electrophysiological activity is an intrinsic property of the nervous system, electromagnetic signaling is a vital aspect of every cell and of molecular structure (3).

Prof. Ross Adey published some of the earliest scientific studies on the "cooperativity" actions of cells in communication. Studies showing us that the flux of calcium in brain tissue and immune cells is sensitive to ELF-modulated radiofrequency fields (RFR modulated by extremely low frequency signals) are actually telling us that some of the most fundamental properties of cells and thus of our existence can be modulated by EMF/RFR.

"All life on earth has evolved in a sea of natural low-frequency electromagnetic (EM) fields. They originate in terrestrial and extraterrestrial sources. The ever-growing use of electric power over the last century has sharply modified this natural environment in urban environments. Exposure to power-frequency fields far stronger than the natural environment is now universal in civilized society." (12)

"...in first detection of environmental EM fields in tissues, there appears to be a general consensus that the site of field action is at cell membranes. Strands of protein are strategically located on the surface of cells in tissue, where they act as detectors of electrical and chemical messages arriving at cell surfaces, transducing them and transmitting them to the cell interior. The structural basis for this transductive coupling by these protein strands is well known. Through them, cell membranes perform a triple role, in ***signal detection, signal amplification, and signal transduction to the cell interior.****"* (12)

Oscillation is also a universal phenomenon, and biological systems of the heart, brain and gut are dependent on the cooperative actions of cells that function according to principles of non-linear, coupled biological oscillations for their synchrony and are dependent on exquisitely timed cues from the environment at a vanishingly small level (1, 2, 13, 14). The key to synchronization is the joint actions of cells that co-operate electrically – linking populations of biological oscillators that couple together in large arrays and synchronize spontaneously according to the mathematics described for Josephson junctions (Brian Josephson won the 1993 Nobel prize for this concept).

Prof. Steven Strogatz, a mathematician at Cornell University has written about 'sync' as a fundamental organizing principle for biological systems (2, 13).

"Organisms are biochemically dynamic. They are continuously subjected to time-varying conditions in the form of both extrinsic driving from the environment and intrinsic rhythms generated by specialized cellular clocks within the organism itself. Relevant examples of the latter are the cardiac pacemaker located at the sinoatrial node in mammalian heSarts and the circadian clock residing at the suprachiasmatic nuclei in mammalian brains. These rhythm generators are composed of thousands of clock cells that are intrinsically diverse but nevertheless manage to function in a coherent oscillatory state. This is the case, for instance, of the circadian oscillations exhibited by the suprachiasmatic nuclei, the period of which is known to be determined by the mean period of the individual neurons making up the circadian clock. The mechanisms by which this collective behavior arises remain to be understood." (13)

Changes in brain and autonomic nervous system electrophysiology

The brain contains a population of oscillators with distributed natural frequencies that pull one another into synchrony (the circadian pacemaker cells). Strogatz has addressed the unifying mathematics of biological cycles and how external factors disrupt these cycles. Pacemaker cell disruption can affect key electrical functions of brain, gut and heart.

"Not just chemical reactions but synchronous biological oscillations in cells (pacemaker cells) can be disturbed and disrupted by artificial, exogenous environmental signals, which

can lead to desynchronization of neural activity that regulates critical functions (including metabolism) in the brain, gut and heart and circadian rhythms governing sleep and hormone cycles." (14)

Disturbance can become increasingly disruptive as more damage occurs and more systems are pushed into distress. One can think of the kindling model in which repeated induction of seizures leads to longer and more severe seizures and greater behavioral involvement. The combination of disruptive and stimulatory effects of biologically inappropriate EMF/RFR exposures could contribute to disruption of synchronized oscillation and cooperativity at myriad levels but particularly in the brain. This may contribute to the loss of coherence and complexity in the brain in autism, as well as dysregulation of multiple other bodily systems leading to dis-integration of synchronized activities critical to maintaining homeostasis.

Buzsaki in his book *Rhythms of the Brain (2006)* says *'rhythms can be altered by a wide variety of agents and that these perturbations must seriously alter brain performance."* (1)

Strogatz points out that there are many more ways of being desynchronized than of being synchronized (2). This disorganizing effect may apply to mitochondria, and the function of biological oscillators influencing energy production of cells.

"Organisation of mitochondrial metabolism is a quintessential example of a complex dissipative system which can display dynamic instabilities. Several findings have indicated that the conditions inducing instabilities are within the physiological range and that mild perturbations could elicit oscillations. Different mathematical models have been put forth in order to explain the genesis of oscillations in energy metabolism. One model considers mitochondria as an organised network of oscillators and indicates that communication between mitochondria involves mitochondrial reactive oxygen species (ROS) production acting as synchronisers of the energy status of the whole population of mitochondria. An alternative model proposes that extramitochondrial pH variations could lead to mitochondrial oscillations." (15)

Mitochondrial dysfunction may thus involve disruptions of normal oscillatory mitochondrial activity, which results from exposure to very low levels of electromagnetic radiation. EMF/RFR also has impacts at levels of brain function measurable by these techniques (3).

At various frequencies and durations of exposure, EMF/RFR has been noted to impact alpha and beta rhythms (16), to increase randomness (17, 18), to alter power and to modulate inter-hemispheric synchronization (19, 20), to alter electrical activity in brain slices (21) and to alter the patterns of coordination (spectral power coherence) across the major power bands (22). Bachman et al. (23) showed statistically significant changes in EEG rhythms and dynamics occurred in between 12% and 20% of healthy volunteers (23).

Immune dysfunction and allergic hypersensitivity reactions

Both human and animal studies of exposures to EMF and RFR report unintended consequences of new technologies that can be associated with large immunohistological changes in mast cells as well as other measures of immune dysfunction and dysregulation. Mast cells not only can degranulate and release irritating chemicals leading to allergic symptoms, they can also lead to skin and organ inflammation. They are also widely distributed in the body, including in the brain, gut and heart, which might relate to some of the symptoms commonly reported in relation to EMF/RFR exposure (such as headache, painful light sensitivity, leaky gut syndrome and cardiac rhythm and palpitation problems) (3).

"The body's immune defense system is now known to respond to very low-intensity exposures (24). Chronic exposure to factors that increase allergic and inflammatory responses on a continuing basis is likely to be harmful to health as the resultant chronic inflammatory responses can lead to cellular, tissue and organ damage over time. Many chronic diseases are related to chronic immune system dysfunction. Disturbance of the immune system by very low-intensity EMF exposure is discussed as a potential underlying cause for cellular damage and impaired healing (tissue repair), which could lead to disease and physiological impairment." (24, 25)

"EMF/RFR exposures are related to profound changes in immune status and function, with resulting reactivity and eventually hypersensitivity. A foundation is provided for understanding how chronic EMF/RFR exposure can compromise immune function and sensitize a person to even small exposures in the future (25). Johansson discusses alterations of immune function at environmental levels resulting in loss of memory and concentration, skin redness and inflammation, eczema, headache and fatigue. Mast cells that degranulate under EMF and RFR exposures and substances secreted by them (histamine, heparin and serotonin) may contribute to features of this sensitivity to EMFs (25). Seitz et al. reviewed extensive literature on electromagnetic hypersensitivity conditions reported to include sleep quality, dizziness, headache, skin rashes, memory and concentration impairments related to EMF and RFR (26). Johansson (25) also reports that benchmark indicators of immune system allergic and inflammatory reactions occur under exposure conditions of low-intensity non-ionizing radiation (immune cell alterations, mast cell degranulation histamine-positive mast cells in biopsies and immunoreactive

dendritic immune cells) (24, 25). In facial skin samples of electrohypersensitive persons, the most common finding is a profound increase in mast cells as monitored by various mast cell markers, such as histamine, chymase and tryptase." (27)

Alterations in molecular, cellular and systems physiological function, which occur in the brain as well as in the body, impact transduction into the electrical signaling activities of the brain and nervous system (3). Buchner and Eger (28) reported a significant elevation of the stress hormones adrenaline and noradrenaline during the first 6 months with a concomitant drop in dopamine in a German cell tower study. Chronic exposure to base station RF (whole-body) in humans showed increased stress hormones, dopamine levels substantially decreased and higher levels of adrenaline and nor-adrenaline; exposures produced chronic physiological stress in cells even after 1.5 years. These impacts were felt by the young, the old and the chronically ill, but not by healthy adults (28).

Pathological leakage of membrane barriers between the blood and brain, gut, testis, and possibly placenta is documented in the 2012 BioInitiative Report (3). Gut leakage and inflammatory conditions in intestines produced by pulsed RFR may also result in poor function of the gut under the influence of EMF/RFR; and the blood-brain barrier leakage of albumin can cause neuron death.

"Theoharides and colleagues have argued that environmental and stress related triggers might activate mast cells, causing inflammatory compromise and leading to gut-blood-brain barrier compromise, seizures and other ASC symptoms (29) and that this cascade of immune response and its consequences might also be triggered in the absence of infection by mitochondrial fragments that can be released from cells in response to stimulation by IgE/anti-IgE or by the proinflammatory peptide substance P." (30)

Salford et al. have reported pathological leakage of the blood-brain barrier at exceedingly low specific absorption rates (SARs) of 0.002 W/kg and 0.02 W/kg from exposure to cell phone radiation (31), far below international public safety standards.

Neurological damage, improper neural development in utero and altered fetal brain development leading to behavioral and learning difficulties in the young

As discussed by Herbert and Sage (3), there is both animal and human evidence of immune impacts of EMF/RFR. A relevant question is whether the impact of repeated or chronic exposure to EMF and RFR during pregnancy could this trigger similar immune responses (cytokine production) and stress protein responses, which in turn would have effects on the fetus. There are data that very low cell phone radiation exposures during both human and mouse pregnancies have resulted in altered fetal brain development leading to memory, learning, attention and behavioral problems (32). Aldad et al. (32) reports that simple in-utero exposure of pregnant mice to cell phone radiation far below FCC limits produces hyperactivity and impaired memory in the offspring, Divan et al. (33) report that children born of mothers who used cell phones during pregnancy develop more behavioral problems by the time they have reached school age than children whose mothers did not use cell phones during pregnancy. Children whose mothers used cell phones during pregnancy had 25% more emotional problems, 35% more hyperactivity, 49% more conduct problems and 34% more peer problems. The odds ratio for higher overall behavioral problems was 1.8 (1.45–2.23) in children with both prenatal and postnatal exposures to cell phones (33).

Kenet et al. demonstrated environmental vulnerability of sensory processing in the brain by the exposure of rat dams to noncoplanar polychlorinated biphenyls (PCBs) during gestation and for 3 subsequent weeks of nursing (34). The rat pups showed normal hearing sensitivity and brainstem auditory responses, but their tonotopic development of the primary auditory cortex was grossly distorted (35). This study may be particularly relevant for EMF/RFR exposures, as Pessah, a co-author on this paper, was cited earlier as documenting how the noncoplanar PCBs used in this experiment target calcium signaling as do EMF/RFR exposures – i.e. they both converge upon a common particularly critical cellular mechanism (36, 37).

Merzenich and Zhang (2008) reported that the auditory cortex in rat pups fails to develop normally if subjected to pulsed 'white noise' during a critical window of auditory cortex differentiation in the young. The rat pups are left with deficits in learning and behavior that mirror symptoms of autism and ASD in children. In Merzenich's words, *"Every time you have a pulse, you are exciting everything in the neural cortex – every neuron." "The pups cortices were devastated." "The rat pups, like autistic children, were predisposed to epilepsy."* (38)

The working theory is that 'some new environmental agent or exposure' might be generating non-stop brain-derived neurotropic factor (or BDNF) releases that cause a premature closure of this critical development window, when the brain strengthens connections between specific networks of neurons, for a specialized learning response to that particular stimulation. If pulsed 'white noise' can

so profoundly alter brain development in the young at critical learning windows where neural development is accelerated, then what other environmental factors that are pulsed signals might be relevant?

This work raised a question about whether pulsed radiofrequency from cell phone radiation could also negatively affect behavior, attention and learning and cause damage to key brain regions responsible for emotion, learning and behavior. Behavioral deficits were induced in adolescent rat pups exposed to 900 MHz whole-body cell phone frequency radiation for 1 h/day for 4 weeks at 146.60 mW/cm^2 using a GSM-type cell phone signal (39). In addition, all brain regions studied (amygdala, hippocampus, frontal cortex and cerebellum) showed increased lipid peroxidation, maximally elevated in the frontal cortex and amygdala as a result of 900 MHz RF exposure. The oxidant/anti-oxidant balance (and particularly glutathione anti-oxidant defense capacity) was significantly altered in these two brain regions that regulate emotionality in organisms. *"One of the reasons for behavioral alteration seen in rats after RF-EMR exposure is due to oxidative stress induced by RF-EMR in these brain regions...(t)he effect of RF-EMR induced oxidative stress is a concern due to the following reasons: 1) It could interfere with the learning and memory processes, 2) It may also accelerate various neurodegenerative diseases, 3) It might impair and oxidize DNA, lipids, sugars and proteins, and consequently result in dysfunction of these molecules within cells and finally bring on cell death in various organs, and 4) It could be a probable tumor promoter."* (39)

Maskey and Kim (40) substituted 835 MHz cell phone frequency radiation for 'white noise' on young mice. At 1.6 W/Kg SAR whole body exposure, 8 h/day for 3 months, they found a detrimental effect of RF exposure in the auditory neurons (40). It decreased both BDNF (required for normal auditory development, critical windows of learning and survival of auditory neurons) and decreased GNDF (which protects neurons from ischemic injury, excitotoxicity and aptosis). GNDF interestingly modulates intracellular calcium through calcium-binding proteins, and the observed decrease in GNDF may reflect RF exposure's pathway on auditory neurons.

Sleep disruption related to brain electrophysiology and disruption of circadian rhythms

As profiled by Herbert and Sage (3), sleep involves a profound change in brain electrophysiological activity, and EEG abnormalities including disrupted sleep architecture.

> *"Sleep symptoms include sleep onset delay, sleep duration and night wakings; sleep architecture can involve significantly less efficient sleep, less total sleep time, prolonged sleep latency and prolonged REM latency. Sleep disturbance symptoms or insomnia is commonly reported in people who are chronically exposed to low-level wireless antenna emissions. Mann and Rosch reported an 18% reduction in REM sleep, which is key to memory and learning functions in humans (41). EEG abnormalities have been associated with EMF/RFR exposure, including disrupted sleep architecture as well as changes in sleep spindles and in the coherence and correlation across sleep stages and power bands during sleep."* (42, 43)

Sleep disturbance symptoms are also common in both situations. Insomnia is widespread in people who are chronically exposed to low-level wireless antenna emissions. Mann and Rosch reported an 18% reduction in REM sleep, which is key to memory and learning functions in humans (41).

Yu et al. (2015) report that wakefulness is governed by GABA and histamine cotransmission.

> *"Histamine neurons form a globally projecting hub that integrates brain functions associated with wakefulness (Wada et al., 1991). Starting in the TMN, histaminergic axons course large distances throughout the brain, generating extrasynaptic pools of transmitter. We showed that selective pharmacogenetic stimulation of these histamine neurons in vivo behaviorally excites the animals, as would be expected (Haas et al., 2008; Lin et al., 1988; Monnier et al., 1967; Nicholson et al., 1991). But we also established that histaminergic neurons use vGAT to release GABA. Similar to histamine, the GABA released from histaminergic neurons functions in a paracrine manner, which would make these neurons an unexpected source of GABAergic volume transmission in the neocortex and striatum. As part of their integrative role in specifying behavioral state, we expect that these hypothalamic TMN 'GABA-histamine' neurons will contribute to tonic inhibition of many neural circuits simultaneously. Mice whose GABA-histamine neurons cannot release GABA are hyperactive, and they sleep less and do not catch up on this lost sleep. The sleepless phenotype' manifests during the night. Their behavior might be described as a form of mania (Kirshenbaum et al., 2011), which in humans would be considered as part of a bipolar disorder."* (44)

> *"In conclusion, we think it is no longer correct to refer to TMN neurons as 'histaminergic': the GABA arm of their activity is so striking that they might be referred to as 'GABA-histamine' neurons. We have demonstrated that the wide-ranging GABAhistamine axons of the hypothalamic TMN broadcast dual inhibitory-excitatory signals in the neocortex: an increased Gtonic generated by GABA release, and an increased synaptic drive generated by histamine. The two components may work together to regulate the amount of wakefulness. If this balance of GABA-histamine cotransmission changes unfavorably, mania-like behaviors could emerge."* (44)

Melatonin and serotonin disruption, chronic glutathione, GABA and glutamate imbalance

Melatonin is well-known for its role in regulation of circadian rhythms, but it also plays important metabolic and regulatory roles in relation to cellular protection, mitochondrial malfunction and glutathione synthesis (45, 46). It also helps prevent the breakdown of the mitochondrial membrane potential, decrease electron leakage and thereby reduce the formation of superoxide anions (47). Pharmacological doses of melatonin not only scavenge reactive oxygen and nitrogen species, but enhance levels of glutathione and the expression and activities of some glutathione-related enzymes (46, 48, 49). A low glutathione redox status can result in oxidative damage and inflammation (50). An ongoing imbalance in the glutathione/glutamate/GABA cycle where glutathione is reduced and glutamate/GABA are elevated is a chronic neurotoxicity pathway.

Co-carcinogenic effects of toxic chemicals and EMF/RFR

EMF/RFR and various toxicants can co-potentiate oxidative damage leading to DNA breakage (51–58). This well-supported evidence comes from more than 65 laboratory studies and suggests that there is synergistic damage from joint exposures of EMF/RFR and chemical toxins. That means exposure to both EMF/RFR and chemicals at or near the same time can make health impacts worse than either exposure alone. The resulting biological effects of each kind of exposure are similar and may point to an underlying association of EHS and MCS.

The role of voltage-gated calcium ion channels

A key site of interaction of EMF/RFR is the cell membrane, which contains ion channels for calcium, potassium, sodium and others in which operation is electrically controlled (i.e. voltage-gated). Ion channels within the membranes of cells convert electrical signaling into biochemical cascades that drive many key cellular processes in living tissues.

A 1988 paper by Berridge and Calione gave early clues to the importance of calcium oscillations as a cell-signaling key. They introduced the idea that calcium spikes might be a frequency-dependent digitized signal that depends on the frequency of the input (4).

> *"Many cells display oscillations in intracellular calcium resulting from the periodic release of calcium from intracellular reservoirs. Frequencies are varied, but most oscillations have periods ranging from 5 to 60 s. For any given cell, frequency can vary depending on external conditions, particularly the concentration of natural stimuli or calcium. This cytosolic calcium oscillator is particularly sensitive to those stimuli (neurotransmitters, hormones, growth factors) that hydrolyze phosphoinositides to give diacylglycerol and inositol 1,4,5-trisphosphate (Ins1,4,5P3). The ability of Ins1,4,5P3 to mobilize intracellular calcium is a significant feature of many of the proposed models that are used to explain oscillatory activity. Receptor-controlled oscillator models propose that there are complex feedback mechanisms that generate oscillations in the level of Ins1,4,5P3. Second messenger-controlled oscillator models demonstrate that the oscillator is a component of the calcium reservoir, which is induced to release calcium by a constant input of either Ins1,4,5P3 or calcium itself. In the latter case, the process of calcium-induced calcium release might be the basis of oscillatory activity in many cell types. The function of calcium oscillations is still unknown. Because oscillator frequency can vary with agonist concentration, calcium transients might be part of a frequency-encoded signaling system. When an external stimulus arrives at the cell surface the information is translated into a train of calcium spikes, i.e. the signal is digitized. Certain cells may then convey information by varying the frequency of this digital signal."* (4)

Two decades of work by Arthur Pilla (5, 6) document the effectiveness of non-thermal (very low-intensity) EMF/RFR in triggering major changes in voltage-gated calcium ion channel function. Pilla has developed an array of medical treatments using highly specific pulsed RFR exposures (or designer PEMF) that can be used therapeutically for bone and tissue repair, pain and inflammation reduction and other beneficial clinical uses. But they depend on very specific waveform configuration, frequency, amplitude of the electric field, burst duration, repetition rate and total exposure time of the microwave pulses. Such exposure levels are exquisitely minute, but very precise in signal delivery. Pilla showed that cells in culture, when exposed to a low intensity pulsed microwave field, produce an almost instantaneous Ca2+/calmodulin-dependent increase in nitric oxide (NO), occurring in <5 s providing strong evidence that the VGCCs are directly activated by low intensity EMF/RFR signals.

> *"There are numerous therapeutic effects of pulsed EMF and radiofrequency microwave radiation, and they are are well established to be non-thermal and operate through increased levels of [Ca2+]i and nitric oxide (NO) signaling."*(6)

"There is now sufficient evidence to support the proposal that CaM-dependent NO signaling is a primary PEMF transduction pathway." (6)

"PRF effects in living systems appear to occur within a window defined by a combination of pulse modulation parameters and amplitude of induced electric field." (6)

Because proper calcium metabolism is so essential for regulatory signaling in many cell functions, and aberrant calcium functioning is found as a causative or associated condition in many diseases, this evidence is strong support for the biological importance of pulsed fields, both in avoiding sickness and in delivering effective health care treatments.

"The results strongly support that PEMF signals can be configured to instantaneously modulate NO release in injured tissue.... (T)here is strong support that PEMF-mediated signaling is anti-inflammatory and can enhance angiogenesis.... (A)ctive studies are underway to assess the utility of the known anti-inflammatory activity of PRF for the treatment of traumatic brain injury, neurodegenerative diseases, cognitive disorders, degenerative joint disease, neural regeneration and cardiac and cerebral ischemia." (6).

A scientific review by Martin Pall (2015) on VGCC activation as a mechanism for non-thermal effects of microwave radiation provides further evidence that pulsed microwave radiation acts through VGCCs. Pall has proposed that pulsed non-thermal EMFs produce a wide variety of responses in the cell, via downstream effects of VGCC activation including elevated intracellular calcium [Ca2+] i, excessive calcium and nitric oxide signaling and excessive peroxynitrite, free radicals and oxidative stress (7–9).

"Downstream effects of VGCC activation include calcium signaling, elevated nitric oxide (NO), NO signaling, peroxynitrite, free radical formation, and oxidative stress. Downstream effects explain repeatedly reported biological responses to non-thermal exposures: oxidative stress; single and double strand breaks in cellular DNA; cancer; male and female infertility; lowered melatonin/sleep disruption; cardiac changes including tachycardia, arrhythmia, and sudden cardiac death; diverse neuropsychiatric effects including depression; and therapeutic effects." (9)

Disruption of the electrophysiology of voltage gated ion channels (calcium, potassium and others) can lead either directly or indirectly to many disease endpoints. Disruption of cell signaling and cell membrane function across living tissues can lead to disorganization of neural synchrony and sensory processing, as well as contribute to metabolic upsets and damage to tissues and organs through oxidative damage. Evidence is growing that disruption of electrical signaling and transduction is altered by pulsed microwave radiation and can alter key regulatory functions of voltage-gated calcium ion channels. If basic electrophysiology can be misdirected to throw off calcium balance in the cells, then many disease endpoints associated with chronic exposure to EMF/RFR may be related (EEG, EKG, pacemaker cells in brain, heart and gut).

Hypersensitivity – similarities in biological disruption for people with EHS and MCS

What happens when the basic biology of humans is upset in modern life by pulsed EMF/RFR? How is electrohypersensitivity related to or similar in symptoms to MCS? Many diseases and disruptions to normal healthy function have a **'similar suite of biological upsets'** that occur with exposures to chemicals and/or electromagnetic radiation. Joint exposures of chemicals and EMF/RFR can cause worse effects than either exposure alone, for example DNA damage. This 'suite' of similar biological consequences may be present in many chronic diseases and conditions that arise from persistent disruption of physical systems (immune, electrophysiological, neurological, metabolic, genetic stability, circadian, reproductive and developmental). Whether initial triggering exposures are chemical or pathologically electrical (or worse, they are both), the resulting physiological consequences on health disruption and behavior appear very similar. It is not particularly surprising that highly synchronized functions of inter-interconnected living tissues, once destabilized, can throw off normal, healthy functioning of other body systems. When forced to operate under suboptimal physiological conditions on a continuing basis, restoring the delicate balance of interacting cells and tissues once may be difficult. The damage caused by oxidative stress, poor functioning of cell membrane ion channels (calcium, potassium), off-kilter circadian rhythms and hormone cycling, dysfunctional membrane barriers, impaired mitochondria, buildup of cellular debris and over-burdened immune functions can lead to persistent low functioning. Perpetual upsets in physiological functioning may lead to symptoms similarly seen in MCS, Gulf War syndrome, Lyme disease, chronic fatigue syndrome and other chronic inflammatory and degenerative conditions. Similar dysfunction is also reported in those autism spectrum conditions. A long list of chronic diseases and conditions exhibit such symptoms with characteristic

disrupted homeostasis, inflammatory conditions and premature aging that share these characteristic biological upsets.

Suite of similar biological disruptions in pathological electrical diseases and MCS:

- Disruption of cell signaling and cell membrane function across living tissues.
- Disruption of electromagnetic signaling, neural synchrony and sensory processing.
- Disruption of electrophysiology of voltage gated ion channels (calcium, potassium and others.
- Electrophysiology changes in pacemaker cells (EEG, EKG, functions of brain, heart and gut).
- Changes in brain and autonomic nervous system electrophysiology.
- Pathological leakage of membrane barriers between the blood and the brain, the gut, the testis, the eyes and possibly the placenta. Gut leakage and inflammatory conditions in intestines (cilia) may result in poor function; blood-brain barrier leakage of albumin can cause neuron death.
- Neurological damage, improper neural development and chronic neuroinflammation.
- Sleep disruption and insomnia.
- Seizures.
- Genotoxicity.
- Oxidative damage.
- DNA repair failure.
- Chromatin condensation.
- Human stem cell DNA damage and repair failure.
- De novo mutations.
- Immune dysfunction and allergic hypersensitivity reactions.
- Inflammatory cytokine production.
- Melatonin and serotonin disruption.
- Mitochondrial disfunction.
- Glutathoine/glutamate/GABA balance altered equals a chronic neurotoxicity path.
- Metabolic diseases.
- Significant impairment of sperm motility and viability.
- Damage to follicle and nurse cells that support the oocyte.
- Chronic stress.
- Maladaptive behavioral changes.
- Anxiety and depression.
- Skin rashes, redness, flushing, blistering and pain sensitivity, headaches, tinnitus (ringing in the ears), sensitivity to light, computers and electronic devices, mood disorders and rages, nausea, fatigue, disabling joint pain, dizziness and vertigo, memory loss and confusion, 'brain fog', irritability and disorientation.

Conclusion

Compelling public health need to address growing prevalence of hypersensitivity diseases

- EHS should be established as a stand-alone medical condition that is on par with other medical conditions warranting disability status in the United States (protections under Americans with Disabilities Act, Department of Justice and health insurance regulations and codes).
- It is also imperative to evaluate joint actions of chemicals and EMF/RFR and their synergistic impacts on health and well-being, given the association of EHS and MCS, and to educate healthcare experts.
- Evidence strongly indicates that everyday levels of EMF and wireless pulsed RF are associated with increased risk of cancer and neurological diseases.
- 'Legal' levels of EMF/RFR in daily life (airplane and public transport, shopping, school attendance, work) already pose health risks and limit activities of those with EHS. Worse, medical implants can have their electrodes disabled by exposures now common on airplanes and when passing through security gates.
- We need to look for and act upon risk factors that are largely avoidable or preventable. Continued roll-out of wireless technologies is ill-advised as levels already exceed what is necessary to induce electrohypersensitivity in certain people.
- Life exposures to children at younger and younger ages will have many years more of cumulative exposure growing up with wireless technologies (to pulsed RFR). EHS in children may become a serious public health concern.
- Wireless learning devices and WiFi in schools, baby monitors, wireless baby clothing and pregnancy monitoring by wireless devices, and 'boutique 3D and 4D vanity ultrasound' should be avoided.
- New public safety limits are warranted, based on biologically relevant exposure levels causing biological disruption. The huge rise in chronic diseases makes it urgent for us to adopt biologically relevant public exposure standards. Standards must regulate pulsed RF in a fashion that does not include time-averaging, but recognizes that pulsed RF, even at very low intensities, is biologically active and harmful to health.
- Immediate, interim precautionary practices are needed with respect to pulsed electromagnetic radiation, including wired internet rather than wireless in homes, schools and institutional and workplace infrastructure.

SECRETARY'S BUREAU

Mr. Richard Tell
Chair, IEEE SCC28 (SC4)
Risk Assessment Work Group
Richard Tell Associates, Inc.
8309 Garnet Canyon Lane
Las Vegas, NV 89129-4897

Dear Mr. Tell:

The members of the Radiofrequency Interagency Work Group (RFIAWG) have identified certain issues that we believe need to be addressed to provide a strong and credible rationale to support RF exposure guidelines. I am writing on behalf of the RFIAWG members to share these ideas with you and other members of the IEEE SCC28, Subcommittee 4 Risk Assessment Work Group. Our input is in response to previous requests for greater participation on our part in the SCC28 deliberations on RF guidelines. The issues, and related comments and questions relevant to the revision of the IEEE RF guidelines, are given in the enclosure. No particular priority is ascribed to the order in which the issues are listed.

The views expressed in this correspondence are those of the members of the Radiofrequency Interagency Work Group and do not represent the official policy or position of the respective agencies.

The members of the RFIAWG appreciate your consideration of our comments and welcome further dialog on these issues. Feel free to contact me or any member of the RFIAWG directly. A list of the members of the RFIAWG is enclosed, with contact information for your use.

Sincerely yours,

W. Gregory Lotz

W. Gregory Lotz, Ph.D.

RF Guideline Issues

Identified by members of the federal RF Interagency Work Group, June 1999

Issue: Biological basis for local SAR limit

The C95.1 partial body (local) exposure limits are based on an assumed ratio of peak to whole body SAR; that is, they are dosimetrically, rather than biologically based. Instead of applying a dosimetric factor to the whole body SAR to obtain the local limits, an effort should be made to base local SAR limits on the differential sensitivity of tissues to electric fields and temperature increases. For example, it seems intuitive that the local limits for the brain and bone marrow should be lower than those for muscle, fat and fascia; this is not the case with the current limits which implicitly assume that all tissues are equally sensitive (except for eye and testicle). If no other data are available, differential tissue sensitivity to ionizing radiation should be considered.

If it is deemed necessary to incorporate dosimetric factors into the resulting tissue-specific SAR limits these should be based on up-to-date dosimetric methods such as finite-difference time-domain calculations utilizing MRI data and tissue-specific dielectric constants. For certain exposure conditions FDTD techniques and MRI data may allow better simulation of peak SAR values. Consideration should be given to the practical tissue volume for averaging SAR and whether this volume is relevant to potential effects on sensitive tissues and organs.

Issue: Selection of an adverse effect level

Should the thermal basis for exposure limits be reconsidered, or can the basis for an unacceptable/adverse effect still be defined in the same manner used for the 1991 IEEE guidelines? Since the adverse effect level for the 1991 guidelines was based on acute exposures, does the same approach apply for effects caused by chronic exposure to RF radiation, including exposures having a range of carrier frequencies, modulation characteristics, peak intensities, exposure duration, etc., that does not elevate tissue temperature on a macroscopic scale?

Selection criteria that could be considered in determining unacceptable/adverse effects include:

a) adverse effects on bodily functions/systems
b) minimal physiological consequences
c) measurable physiological effects, but no known consequences

If the adverse effect level is based on thermal effects in laboratory animals, the literature on human studies (relating dose rate to temperature elevation and temperature elevation to a physiological effect) should be used to determine if the human data could reduce uncertainties in determination of a

safety factor.

Issue: Acute and chronic exposures

There is a need to discuss and differentiate the criteria for guidelines for acute and chronic exposure conditions. The past approach of basing the exposure limits on acute effects data with an extrapolation to unlimited chronic exposure durations is problematic. There is an extensive data base on acute effects with animal data, human data (e.g. MRI information), and modeling to address thermal insult and associated adverse effects for acute exposure (e.g., less than one day). For lower level ("non-thermal"), chronic exposures, the effects of concern may be very different from those for acute exposure (e.g., epigenetic effects, tumor development, neurologic symptoms). It is possible that the IEEE RF radiation guidelines development process may conclude that the data for these chronic effects exist but are inconsistent, and therefore not useable for guideline development. If the chronic exposure data are not helpful in determining a recommended exposure level, then a separate rationale for extrapolating the results of acute exposure data may be needed. In either case (chronic effects data that are useful or not useful), a clear rationale needs to be developed to support the exposure guideline for chronic as well as acute exposure.

Issue: One tier vs two tier guidelines:

A one tier guideline must incorporate all exposure conditions and subject possibilities (e.g., acute or chronic exposure, healthy workers, chronically ill members of the general public, etc.). A two tier guideline, as now exists, has the potential to provide higher limits for a specific, defined population (e.g., healthy workers), and exposure conditions subject to controls, while providing a second limit that addresses greater uncertainties in the data available (about chronic exposure effects, about variations in the health of the subject population, etc.). A greater safety factor would have to be incorporated to deal with greater uncertainty in the scientific data available. Thus, a two-tier guideline offers more flexibility in dealing with scientific uncertainty, while a one-tier guideline would force a more conservative limit to cover all circumstances including the scientific uncertainties that exist.

Issue: Controlled vs. uncontrolled (applicability of two IEEE exposure tiers)

The current "controlled" and "uncontrolled" definitions are problematic, at least in the civilian sector, particularly since there are no procedures defined in the document to implement the "controlled" condition. The new guidelines should offer direction for the range of controls to be implemented and the training required for those who knowingly will be exposed (e.g. workers), along the lines of the existing ANSI laser safety standards. This essential element needs to be included for whatever limits are defined, be they one-tier or two-tier.

For example, the OSHA position is that the "uncontrolled" level is strictly an "action" level which

indicates that there is a sufficiently high exposure (compared to the vast majority of locations) to merit an assessment to determine what controls and training are necessary to ensure persons are not exposed above the "controlled" limit. Many similar "action" levels are part of OSHA and public health standards. Should this interpretation be incorporated into the IEEE standard as a means to determine the need to implement a safety plan? [The laser standard has a multi-tiered (Class I, II, III, IV) standard which similarly requires additional controls for more powerful lasers to limit the likelihood of an excess exposure, even though the health effect threshold is the same.]

On the other hand, if it is determined that certain populations (due to their health status or age) are more susceptible to RF exposures, then a multi-tiered standard, applicable only to those specific populations, may be considered.

The ANSI/IEEE standard establishes two exposure tiers for controlled and uncontrolled environments. The following statement is made in the rationale (Section 6, page 23): "The important distinction is not the population type, but the nature of the exposure environment." If that is the case, consideration should be given to providing a better explanation as to why persons in uncontrolled environments need to be protected to a greater extent than persons in controlled environments. An uncontrolled environment can become a controlled environment by simply restricting access (e.g., erecting fences) and by making individuals aware of their potential for exposure. After such actions are taken, this means that the persons who previously could only be exposed at the more restrictive uncontrolled levels could now be exposed inside the restricted area (e.g., inside the fence) at controlled levels.

What biologically-based factor changed for these people? Since the ostensible public health reason for providing greater protection for one group of persons has historically been based on biological considerations or comparable factors, it is not clear why the sentence quoted above is valid.

Issue: Uncertainty factors

The uncertainties in the data used to develop the guideline should be addressed. An accepted practice in establishing human exposure levels for agents that produce undesirable effects is the application of factors representing each area of uncertainty inherent in the available data that was used to identify the unacceptable effect level. Standard areas of uncertainty used in deriving acceptable human dose for agents that may produce adverse (but non-cancer) effects include

(1) extrapolation of acute effects data to chronic exposure conditions,
(2) uncertainty in extrapolating animal data to humans in prolonged exposure situations,
(3) variation in the susceptibility (response/sensitivity) among individuals,

(4) incomplete data bases,
(5) uncertainty in the selection of the effects basis, inability of any single study to adequately address all possible adverse outcomes.

If guidelines are intended to address nonthermal chronic exposures to intensity modulated RF radiation, then how could uncertainty factors be used; how would this use differ from the historical use of uncertainty factors in establishing RF radiation guidelines to limit exposure to acute or sub-chronic RF radiation to prevent heat-related effects?

There is a need to provide a clear rationale for the use of uncertainty factors.

Issue: Intensity or frequency modulated (pulsed or frequency modulated) RF radiation

Studies continue to be published describing biological responses to nonthermal ELF-modulated and pulse-modulated RF radiation exposures that are not produced by CW (unmodulated) RF radiation. These studies have resulted in concern that exposure guidelines based on thermal effects, and using information and concepts (time-averaged dosimetry, uncertainty factors) that mask any differences between intensity-modulated RF radiation exposure and CW exposure, do not directly address public exposures, and therefore may not adequately protect the public. The parameter used to describe dose/dose rate and used as the basis for exposure limits is time-averaged SAR; time-averaging erases the unique characteristics of an intensity-modulated RF radiation that may be responsible for producing an effect.

Are the results of research reporting biological effects caused by intensity-modulated, but not CW exposure to RF radiation sufficient to influence the development of RF exposure guidelines? If so, then how could this information be used in developing those guidelines? How could intensity modulation be incorporated into the concept of dose to retain unique characteristics that may be responsible for a relationship between exposure and the resulting effects?

Issue: Time averaging

Time averaging of exposures is essential in dealing with variable or intermittent exposure, e.g., that arising from being in a fixed location of a rotating antenna, or from moving through a fixed RF field. The 0.1 h approach historically used should be reassessed, but may serve this purpose adequately. Time averaging for other features of RF exposure is not necessarily desirable, however, and should be reevaluated specifically as it deals with modulation of the signal, contact and induced current limits, and prolonged, or chronic exposure. These specific conditions are discussed in a little more detail elsewhere.

If prolonged and chronic exposures are considered to be important, then there should be a

reconsideration of the time-averaging practices that are incorporated into existing exposure guidelines and used primarily to control exposure and energy deposition rates in acute/subchronic exposure situations.

Issue: Lack of peak (or ceiling) limits for induced and contact current

A recent change in the IEEE guidelines allows for 6 minute, rather than 1 second, time-weighted-averaging for induced current limits. This change increases the concern about the lack of a peak limit for induced and contact currents. Will the limits for localized exposure address this issue, i.e., for tissue along the current path?

Issue: Criteria for preventing hazards caused by transient discharges

The existing IEEE recommendation states that there were insufficient data to establish measurable criteria to prevent RF hazards caused by transient discharges. If specific quantitative criteria are still not available, can qualitative requirements be included in the standard to control this hazard (e.g., metal objects will be sufficiently insulated and/or grounded, and/or persons will utilize sufficient insulating protection, such as gloves, to prevent undesirable transient discharge.)?

ISSUE: Limits for exposure at microwave frequencies

Concerns have been expressed over the relaxation of limits for continuous exposures at microwave frequencies above 1500 MHz. The rationale provided in the current guideline (Section 6.8) references the fact that penetration depths at frequencies above 30 GHz are similar to those at visible and near infrared wavelengths and that the literature for skin burn thresholds for optical radiation "is expected to be applicable." The rationale then implies that the MPE limits at these high frequencies are consistent with the MPE limits specified in ANSI Z136.1-1986 for 300 GHz exposures. This is apparently the rationale for "ramping up" to the MPE limits for ***continuous*** exposure of 10 mW/cm^2 at frequencies above 3 GHz (controlled) or 15 GHz (uncontrolled). The rationale should be given as to why this ramp function has been established at relatively low microwave frequencies (i.e., 1500 MHz and above), rather than being implemented at higher frequencies that are truly quasi-optical. For example, one option could be two ramp functions, one beginning at 300 MHz, based on whole- or partial-body dosimetry considerations, and another at higher frequencies (say 30-100 GHz) to enable consistency with the laser standard. Such a revision should help reduce concern that the standard is not restrictive enough for continuous exposures at lower microwave frequencies where new wireless applications for consumers could make this an issue in the future.

Issue: Replication/Validation

Published peer-reviewed studies that have been independently replicated/validated should be used to establish the adverse effects level from which exposure guidelines are derived. The definition of "replicated/validated" should not be so restrictive to disallow the use of a set of reports that

are scientifically valid but are not an exact replication/validation of specific experimental procedures and results.

Peer-reviewed, published studies that may not be considered to be replicated/validated, but are well done and show potentially important health impacts provide important information regarding uncertainties in the data base used to set the adverse effect level (e.g., incomplete data base).

Issue: Important Health Effects Literature Areas:

Documentation should be provided that the literature review process included a comprehensive review of the following three areas:

1) long-term, low-level exposure studies (because of their importance to environmental and chronic occupational RFR exposure);
2) neurological/behavioral effects (because of their importance in defining the adverse effect level in existing RFR guidelines); and
3) micronucleus assay studies (because of their relevance to carcinogenesis).

Issue: Compatibility of RFR guidelines

Compatibility of national and international RFR guidelines remains a concern. It is important for the IEEE Committee to address this issue by identifying and discussing similarities and differences in a revised IEEE guideline and other RFR guidelines. Compatibility/noncompatibility issues could be discussed in the revised IEEE guideline or as a companion document distributed at the time the revised IEEE guideline is released to the public.

EDITORIAL

Negativity towards negative results: a discussion of the disconnect between scientific worth and scientific culture

Natalie Matosin[1,2,*], Elisabeth Frank[1,2], Martin Engel[1,2], Jeremy S. Lum[1,2] and Kelly A. Newell[1,2]

ABSTRACT

"What gets us into trouble is not what we don't know, it's what we know for sure that just ain't so." – Mark Twain.

Science is often romanticised as a flawless system of knowledge building, where scientists work together to systematically find answers. In reality, this is not always the case. Dissemination of results are straightforward when the findings are positive, but what happens when you obtain results that support the null hypothesis, or do not fit with the current scientific thinking? In this Editorial, we discuss the issues surrounding publication bias and the difficulty in communicating negative results. Negative findings are a valuable component of the scientific literature because they force us to critically evaluate and validate our current thinking, and fundamentally move us towards unabridged science.

KEY WORDS: Negative findings, Negative results, Null hypothesis

The impact of negative findings

Increasingly, there is pressure on scientists to choose investigative avenues that result in high-impact knowledge. This challenge has, in many cases, swayed scientists to pursue paths of investigation that are not necessarily logical or hypothesis-driven. Rather than approaching a research question in a systematic manner, it seems that scientists are encouraged to pursue non-linear lines of investigation in search of significance, and many that have the luxury are known to tuck away negative findings (the 'file-drawer' effect) and focus on their positive outcomes (Scargle, 1999). This behaviour likely stems from an ever-heightening hurdle that scientists need to jump: high publication output with a high citation rate in order to win competitive grants to drive their research, move up the rungs and pay the bills.

Published a few years ago in *PLoS ONE*, Daniele Fanelli states that "Papers are less likely to be published and to be cited if they report 'negative' results" (Fanelli, 2010). Because scientists are involuntarily finding themselves engaged in competition for positions and funding, many are choosing not to proceed with their non-significant findings (those that support the null hypothesis) that yield less scientific interest and fewer citations. Consequently, the amount of non-significant data reported is progressively declining (Fanelli, 2012). Although it could be argued that this is due to an increasing quality of science, it is more likely attributable to the selectiveness of 'high impact' journals that, in our opinion, might as well have a bold statement in the submission form: **negative results are not accepted**. However, there seems to be a gap between results that are positive and results that are high impact. Logically there is no connection, but it seems scientific culture assumes that they are analogous. Why aren't negative results considered to be of the same value?

Historically, the noblest aspect of science is its supposed transparency in presenting all sides of a story. In theory, scientific principles are always under reconsideration and, indeed, there are occasions (which we will subsequently discuss) where new evidence has refuted old hypotheses and impacted on current scientific thinking. This seems reasonable, but is perhaps easier said than done. One of the most prominent examples was provided by London-based research doctor Andrew Wakefield, who, together with 12 co-authors, published the radical finding that child vaccination (specifically the MMR vaccine) increases the incidence of autism (Wakefield et al., 1998). The now infamous paper, which appeared in *The Lancet*, triggered widespread panic that led to a decade-long decrease in child immunisation. In spite of the 13 studies with convincing negative results published between 1998 and the article retraction in 2010 (see table 1 of Gerber and Offit, 2009), support against Wakefield's claims failed to gain the same level of attention as the original study, evidenced by a rise in morbidity and mortality of preventable diseases, including measles, mumps and rubella, during this time (see Gerber and Offit, 2009).

The process of transitioning between paradigms of current scientific thinking particularly fascinated the famous American physicist and philosopher Thomas Kuhn. Kuhn's writings propose that once the body of evidence for the competing paradigm overtakes the evidence in support of the dominant paradigm, then scientists will easily switch allegiance (Kuhn, 1970). However, there are greater forces influencing this process, according to the theory that humans have an inbuilt need to support the status quo, and therefore have an innate difficulty in overriding preexisting beliefs (Jost and Hunyady, 2003). When faced with the challenges of opposing current views with new research, our own cognitive bias makes it difficult to muster up the strength to fight for the paradigm shift, especially because negative results are often associated with flawed or poorly designed studies, and thus might be viewed as a negative reflection on the scientist. Therefore, negative results are an inconvenient truth, and ignoring the inconsistent results would only be human.

Correcting the literature: an uphill battle

Although a search of recent literature will turn up periodic examples in which current research rejects previously published ideas, the difficulty that arises in attempting to do so, particularly on a large scale, is greatly ignored. Extreme difficulties in correcting the literature have been experienced by many, but discussed openly by few. Consultant cardiologist Dr Peter Wilmshurst was particularly proactive in discussing this topic and his own experiences.

Wilmshurst dedicated himself for two decades to disseminating his negative findings to reverse the aftermath of a drug trial regarding the heart-contractility drug amrinone. The original article, published in *The New England Journal of Medicine* (Benotti et al., 1978), stated that amrinone increased heart contractility in a small clinical trial. Wilmshurst's subsequent studies, by contrast, repeatedly showed that "although amrinone increased the strength of contraction of normal heart muscle, it did not affect contractility in patients with heart failure" (Wilmshurst, 2003). Interestingly, in spite of Wilmshurst's efforts to disseminate these findings and push for article retraction, he remains unsuccessful.

Australian cell biologist Professor David Vaux recently published an essay regarding his own attempts to refute research and retract his work from arguably the most influential scientific journal, *Nature* (Vaux, 2013). In 1995, Vaux was invited to peer-review a paper for the journal and was extremely excited by the results that proposed a mechanism to overcome the rejection of transplanted tissue (Bellgrau et al., 1995). This paradigm-changing data influenced him to both write a 'News and Views' piece, published in the same issue of *Nature* (Vaux, 1995), as well as directed his own laboratory's future research. However, over the next years, the Vaux lab repeatedly failed to replicate these experimental outcomes. Despite *Nature*'s policies to publish work that refutes data in their publications, Vaux's findings were ultimately rejected, and later received the same fate from *Nature Medicine*. Vaux writes, "Little did we know that instead of providing an answer to transplant rejection, these experiments would teach us a great deal about editorial practices and the difficulty of correcting errors once they appear in the literature" (Vaux, 2013). After 2 years, Vaux finally succeeded in publishing his negative findings in *PNAS* (Allison et al., 1997) and retracted his *Nature* 'News and Views' piece.

Science is, by its nature, a collaborative discipline, and one of the principal reasons why we should report negative results is so our colleagues do not waste their time and resources repeating our findings. Should Vaux not have so forcefully pushed for his negative findings to be published and for retraction of his commentary, there is no doubt that scientists would still be pursuing research in this direction, wasting valuable time and resources. Interestingly, shortly after Vaux was granted the retraction, *Nature Medicine* published a paper in support of the negative results despite originally rejecting Vaux's negative findings (Kang et al., 1997). Now, all the findings – positive and negative – have been disseminated and all in the field are entirely informed. Unfortunately, this is not always the case.

Examples from psychiatric research

At a recent conference, two colleagues discovered that they had both unsuccessfully attempted to alter depression-like behaviour in the CD1 mouse strain (a widely used animal model for toxicology studies) with a variety of classical antipsychotics. These findings were surprising in light of the many studies demonstrating efficacy of antipsychotic drugs in different experimental models. Realising that this had occurred in two separate labs, they considered that this might not have been a lack of experiments performed using CD1 mice, but rather a lack of publications on negative findings. They have since corroborated their findings with others. Because the results were unpublished, research groups had continued to follow the same lines of thought and the same paths of investigation, only to all fail in the same way, ultimately wasting time and resources. To our knowledge, these results remain unpublished.

Fundamentally, not publishing the inefficiency of antipsychotic drugs in this animal model could be detrimental to the progression of science; however, one can understand why it was not pursued. The time and effort required to construct the paper and survive the peer-review process is not outweighed by the benefits. Other than 'for the greater good of science', this information is not considered high-impact knowledge, and will not result in a highly cited paper. When time is money, and our research output is judged based on impact and citations, why waste the time? In our view, negative results are just as useful as positive findings, but, unfortunately, they do not attract the same citations (Fanelli, 2010).

Pessimism surrounding negative results is obviously a problem, but how are we going to reverse the anti-negative-finding culture? As proposed by Lieberman and Cunningham (Lieberman and Cunningham, 2009), "Perhaps a lab should have to correct for the total number of published results in a given year". The authors suggest that researchers should be obligated to retract their previous works throughout the progression of their career as they "...[find] that [their] previous tests in old papers are no longer significant in light of their success and, ironically, [their] contribution to the field" (Lieberman and Cunningham, 2009). The view of these authors is that the pressure for positive outcomes is simply putting the scientific community under unnecessary burden and decreases the overall research quality. Negative findings are fundamental to science: they encourage good scientific practice, teach us to critically analyse our pre-existing thoughts and direct new avenues of research. However, while the current scientific culture continues to favour positive findings, negative results will continue to face criticism.

This was the case within our own group when we attempted to disseminate 'negative' results. We focus on metabotropic glutamate receptors (mGluRs), which have been implicated in the pathology of schizophrenia and are proposed to be targets of antipsychotic intervention. Despite the large amount of interest and money being poured into the development of mGluR-based therapeutics to treat schizophrenia, the status of these receptors in the pathological state is largely unknown. Before our group embarked on this investigative path, it was unclear whether mGluR protein expression was affected in the pathological states that the novel therapeutics aimed to treat, so examination of mGluR protein expression was a crucial and linear line of investigation. Our findings showed that mGluR2/3 (Frank et al., 2011) and mGluR5 (Matosin et al., 2013) expression was not affected in the pathophysiology of schizophrenia in one of the largest post-mortem human cohorts to date. In the follow-up study, we showed that total mGluR2/3 and mGluR5 expression was unchanged in the cortex of 52 patients with schizophrenia across three independent cohorts compared with controls (our unpublished observations). If you approach these results from the perspective of uncovering the underlying cause of schizophrenia, then yes, these results have little impact. However, in light of the convincing preclinical studies that show promising therapeutic benefits of mGluR-based drugs in schizophrenia-relevant paradigms, our results have interesting translational consequences: if mGluR expression was overly reduced in the pathological state, then one would anticipate problems with the efficacy of these novel drugs *in vivo*. Although our findings were published in journals that recognise the value in reporting negative findings, we have found that members of the wider scientific community are less accepting. Indeed, we particularly faced resistance at scientific conferences when disseminating our evidence as we were criticised for overstating our findings. It makes one wonder, why is a negative finding viewed as such a bad thing? The notion of a negative finding does seem more philosophical than practical. A negative result is in response to a positive question. If you rephrased to a negative question, does that mean you have a positive finding? These negative findings were

integral to our group, positively directing our group's research and encouraging us to look beneath the surface, where we have since uncovered crucially relevant mechanisms.

Negating the negativity

The revolt against publication bias has sparked a movement in which some have attempted to reverse the pessimism towards negative results. For example, a group of journals have been specifically created to publish the 'rejects' (*Journal of Negative Results in Biomedicine*, *The All Results Journals*, *Journal of Articles in Support Of the Null Hypothesis*...and there are more), and new ways to provide access to negative data have emerged (e.g. https://pubpeer.com/). Negative findings are also increasingly represented in broad-scope journals such as *Disease Models & Mechanisms* and *PLoS ONE*. Even so, new journals launched with the specific scope of publishing negative findings often do not attract as many papers, demonstrating that it is the underlying scientific culture that requires change and not only the journal policies.

Publication bias is a common theme in the history of science, and it still remains an issue. This is encapsulated in a piece of commentary published in *Nature*: "...negative findings are still a low priority for publication, so we need to find ways to make publishing them more attractive" (O'Hara, 2011). Negative findings can have positive outcomes, and positive results do not equate to productive science. A reader commented online in response to the points raised by O'Hara: "Imagine a meticulously edited, online-only journal publishing negative results of the highest quality with controversial or paradigm-shifting impact. *Nature Negatives*" (O'Hara, 2011). Negative results are considered to be taboo, but they can still have extensive implications that are worthy of publication and, as such, real clinical relevance that can be translated to other related research fields.

So, although the current scientific culture assumes that negative results are not worthy of attention, here we present another perspective. Sharing negative results does not mean making a story out of dust, that the results are less significant (excuse the pun), or that the results should go unpublished. It means that the direction of scientific research should not be determined by the pressure to win the 'significance lottery', but rather systematic, hypothesis-driven attempts to fill holes in our knowledge. At the core, it is our duty as scientists to both: (1) publish all data, no matter what the outcome, because a negative finding is still an important finding; and (2) have a hypothesis to explain the finding. If the experiment has been performed to plan, the data has not been manipulated or pulled out of context and there is compiled evidence of a negative result, then it is our duty to provide an explanation as to why we are seeing what we are seeing. Only by truly rethinking the current scientific culture, which clearly favours positive findings, will negative results be esteemed for their entire value. Only then can we work towards an improved scientific paradigm.

United States Department of the Interior

OFFICE OF THE SECRETARY
WASHINGTON, D.C. 20240

FEB - 7 2014

TAKE PRIDE IN AMERICA

In Reply Refer To: (ER 14/0001) (ER 14/0004).

RECEIVED
APR 27 2018
PA PUBLIC UTILITY COMMISSION
SECRETARY'S BUREAU

Mr. Eli Veenendaal
National Telecommunications and Information Administration
U.S. Department of Commerce
1401 Constitution Avenue, N.W.
Washington, D.C. 20230

Dear Mr. Veenendaal:

The Department of the Interior (Department) has reviewed the above referenced proposal and submits the following comments and attachment for consideration. Because the First Responder Network Authority (FirstNet) is a newly created entity, we commend the U.S. Department of Commerce for its timely proposals for NEPA implementing procedures.

The Department believes that some of the proposed procedures are not consistent with Executive Order 13186 Responsibilities of Federal Agencies to Protect Migratory Birds, which specifically requires federal agencies to develop and use principles, standards, and practices that will lessen the amount of unintentional take reasonably attributed to agency actions. The Department, through the Fish and Wildlife Service (FWS), finds that the proposals lack provisions necessary to conserve migratory bird resources, including eagles. The proposals also do not reflect current information regarding the effects of communication towers to birds. Our comments are intended to further clarify specific issues and address provisions in the proposals.

The Department recommends revisions to the proposed procedures to better reflect the impacts to resources under our jurisdiction from communication towers. The placement and operation of communication towers, including un-guyed, unlit, monopole or lattice-designed structures, impact protected migratory birds in two significant ways. The first is by injury, crippling loss, and death from collisions with towers and their supporting guy-wire infrastructure, where present. The second significant issue associated with communication towers involves impacts from non-ionizing electromagnetic radiation emitted by them (See Attachment).

In addition to the 147 Birds of Conservation Concern (BCC) species, the FWS has listed an additional 92 species as endangered or threatened under the Endangered Species Act. Together with the bald and golden eagle, this represents 241 species of birds whose populations are in trouble or otherwise merit special protection, according to the varying criteria of these lists. The Department suggests that FirstNet consider preparing a programmatic environmental impact statement (see attachment) to determine and address cumulative impacts from authorizing FirstNet projects on those 241 species for which the incremental impact of tower mortality, when

EXHIBIT
C-12
AB 4/2/18
PENNSYLVANIA 800-631-6989

added to other past, present, and reasonably foreseeable future actions, is most likely significant, given their overall imperiled status. Notwithstanding the proposed implementing procedures, a programmatic NEPA document might be the most effective and efficient method for establishing best management practices for individual projects, reducing the burden to individual applicants, and addressing cumulative impacts.

Categorical Exclusions
The Department has identified 13 of the proposed categorical exclusions (A-6, A-7, A-8, A-9, A-10, A-11, A-12, A-13, A-14 A-15, A-16, A-17, and A-19) as having the potential to significantly affect wildlife and the biological environment. Given this potential, we want to underscore the importance of our comments on FirstNet's procedural guidance under Environmental Review and Consultation Requirements for NEPA Reviews and its list of extraordinary circumstances in Appendix D.

Environmental Review and Consultation Requirements for NEPA Reviews
To ensure there are no potentially significant impacts on birds from projects that may otherwise be categorically excluded, the Department recommends including the Migratory Bird Treaty Act and the Bald and Golden Eagle Protection Act to the list of requirements in this section.

Extraordinary Circumstances
To avoid potentially significant impacts on birds from projects that may otherwise be categorically excluded, the Department recommends including species covered under the Migratory Bird Treaty Act and the Bald and Golden Eagle Protection Act to the list of environmentally sensitive resources. Additionally, adding important resources to migratory birds such as sites in the Western Hemisphere Shorebird Reserve Network and Audubon Important Bird Areas to the paragraph on areas having special designation or recognition would help ensure their consideration when contemplating use of a categorical exclusion.

Developing the Purpose and Need
The Department recommends inclusion of language that would ensure consideration of all other authorities to which NEPA is supplemental as opposed to simply the FirstNet mission. As currently written, the procedures are limited to ensuring the purpose and need considers the FirstNet mission. If strictly applied, this approach would severely limit the range of reasonable alternatives, and likely preclude consideration of more environmentally benign locations or construction practices.

Environmental Review Process, Apply NEPA Early in the Process, Where Action is by Non-Federal Entity
The Department recommends that FirstNet be required to coordinate with federal agencies having jurisdiction by law or special expertise on construction and lighting of its network of towers.

Thank you for the opportunity to comment on the draft document. If you have any questions concerning the comments, please contact Diana Whittington, NEPA Migratory Bird lead, at (703) 358-2010. If you have any questions regarding Departmental NEPA procedures, contact Lisa Treichel, Office of Environmental Policy and Compliance at (202) 208-7116.

Sincerely,

Willie R. Taylor
Director, Office of Environmental Policy
and Compliance

Enclosure A

Background

The placement and operation of communication towers, including un-guyed, unlit, monopole or lattice-designed structures, impact protected migratory birds in two significant ways.

The first is by injury, crippling loss, and death from collisions with towers and their supporting guy-wire infrastructure, where present. Mass mortality events tend to occur during periods of peak spring and fall songbird bird migration when inclement weather events coincide with migration, and frequently where lights (either on the towers and/or on adjacent outbuildings) are also present. This situation has been well documented in the U.S. since 1948 in the published literature (Aronoff 1949, see Manville 2007a for a critique). The tallest communication towers tend to be the most problematic (Gehring *et al.* 2011). However, mid-range (~400-ft) towers as proposed by the First Responder Network Authority (FirstNet, a newly created entity under the Department of Commerce) can also significantly impact protected migratory birds, as can un-guyed and unlit lattice and monopole towers (Gehring *et al.* 2009, Manville 2007a, 2009, 2013a). Mass mortalities (more than several hundred birds per night) at unguyed, unlit monopole and lattice towers were documented in fall 2005 and 2011 in the Northeast and North Central U.S. (*e.g.*, Manville 2007a). It has been argued that communication towers including "short" towers do not impact migratory birds, including at the population level (*e.g.*, Arnold and Zink 2011), but recent findings have contradicted that assertion (Manville 2007a, 2013a, Longcore *et al.* 2012, 2013).

The second significant issue associated with communication towers involves impacts from non-ionizing electromagnetic radiation emitted by these structures. Radiation studies at cellular communication towers were begun circa 2000 in Europe and continue today on wild nesting birds. Study results have documented nest and site abandonment, plumage deterioration, locomotion problems, reduced survivorship, and death (*e.g.*, Balmori 2005, Balmori and Hallberg 2007, and Everaert and Bauwens 2007). Nesting migratory birds and their offspring have apparently been affected by the radiation from cellular phone towers in the 900 and 1800 MHz frequency ranges – 915 MHz is the standard cellular phone frequency used in the United States. However, the electromagnetic radiation standards used by the Federal Communications Commission (FCC) continue to be based on thermal heating, a criterion now nearly 30 years out of date and inapplicable today. This is primarily due to the lower levels of radiation output from microwave-powered communication devices such as cellular telephones and other sources of point-to-point communications; levels typically lower than from microwave ovens. The problem, however, appears to focus on very low levels of non-ionizing electromagnetic radiation. For example, in laboratory studies, T. Litovitz (personal communication) and DiCarlo *et al.* (2002) raised concerns about impacts of low-level, non-thermal electromagnetic radiation from the standard 915 MHz cell phone frequency on domestic chicken embryos – with some lethal results (Manville 2009, 2013a). Radiation at extremely low levels (0.0001 the level emitted by the average digital cellular telephone) caused heart attacks and the deaths of some chicken embryos subjected to hypoxic conditions in the laboratory while controls subjected to hypoxia were unaffected (DiCarlo *et al.* 2002). To date, no independent, third-party field studies have been conducted in North America on impacts of tower electromagnetic radiation on migratory birds. With the European field and U.S. laboratory evidence already available,

independent, third-party peer-reviewed studies need to be conducted in the U.S. to begin examing the effects from radiation on migratory birds and other trust species.

Discussion

Collision Deaths and Categorical Exclusions

Attempts to estimate bird-collision mortality at communication towers in the U.S. resulted in figures of 4-5 million bird deaths per year (Manville 2005, 2009). A meta-review of the published literature now suggests, based on statistically determined parameters, that mortality may be 6.8 million birds per year in Canada and the U.S.; the vast majority in the United States (Longcore *et al.* 2012). Up to 350 species of birds have been killed at communication towers (Manville 2007a, 2009). The Service's Division of Migratory Bird Management has updated its voluntary, 2000 communication tower guidelines to reflect some of the more recent research findings (Manville 2013b). However, the level of estimated mortality alone suggests at a minimum that FirstNet prepare an environmental assessment to estimate and assess the cumulative effects of tower mortality to protected migratory birds.

A second meta-review of the published mortality data from scientific studies conducted in the U.S. and Canada (Longcore *et al.* 2013) strongly correlates population effects to at least 13 species of Birds of Conservation Concern (BCC, USFWS 2008). These are mortalities to BCC species based solely on documented collisions with communication towers in the U.S. and Canada, ranging from estimated annual levels of mortality of 1 to 9% of their estimated total population. Among these where mortality at communication towers was estimated at over 2% annually are the Yellow Rail, Swainson's Warbler, Pied-billed Grebe, Bay-breasted Warbler, Golden-winged Warbler, Prairie Warbler, and Ovenbird. Longcore *et al.* (2013) emphasized that avian mortality associated with anthropogenic sources is almost always reported in the aggregate, *i.e.*, "number of birds killed," which cannot detect species-level effects necessary to make effective and meaningful conservation assessments, including determining cumulative effects. These new findings strongly suggest the need for at least an environmental assessment by FirstNet, or more likely, an environmental impact statement.

Radiation Impacts and Categorical Exclusions

There is a growing level of anecdotal evidence linking effects of non-thermal, non-ionizing electromagnetic radiation from communication towers on nesting and roosting wild birds and other wildlife in the U.S. Independent, third-party studies have yet to be conducted in the U.S. or Canada, although a peer-reviewed research protocol developed for the U.S. Forest Service by the Service's Division of Migratory Bird Management is available to study both collision and radiation impacts (Manville 2002).

As previously mentioned, Balmori (2005) found strong negative correlations between levels of tower-emitted microwave radiation and bird breeding, nesting, and roosting in the vicinity of electromagnetic fields in Spain. He documented nest and site abandonment, plumage deterioration, locomotion problems, reduced survivorship, and death in House Sparrows, White Storks, Rock Doves, Magpies, Collared Doves, and other species. Though these species had historically been documented to roost and nest in these areas, Balmori (2005) did not observe these symptoms prior to construction and operation of the cellular phone towers. Balmori and Hallberg (2007) and Everaert and Bauwens (2007) found similar strong negative correlations

among male House Sparrows. Under laboratory conditions, DiCarlo *et al.* (2002) raised troubling concerns about impacts of low-level, non-thermal electromagnetic radiation from the standard 915 MHz cell phone frequency on domestic chicken embryos – with some lethal results (Manville 2009). Given the findings of the studies mentioned above, field studies should be conducted in North America to validate potential impacts of communication tower radiation – both direct and indirect – to migratory birds and other trust wildlife species.

Dear Ms. Newton:

Thank you for your letter of January 31, 2002, to the Environmental Protection Agency Administrator Whitman, in which you express your concerns about non-thermal effects of radiofrequency (RF) radiation and the adequacy of the Federal Communications Commission's RF radiation exposure guidelines. The Administrator has asked us to critically examine the issues you bring to our attention, and we will be responding to you shortly.

We appreciate your interest in the matter of non-thermal RF exposure, possible health risks, and Federal government responsibility to protect human health.

Sincerely,

Frank Marcinowski, Director
Radiation Protection Division

Ms. Janet Newton
President
The EMR Network
P.O. Box 221
Marshfield, VT 05658

Dear Ms.Newton:

This is in reply to your letter of January 31, 2002, to the Environmental Protection Agency (EPA) Administrator Whitman, in which you express your concerns about the adequacy of the Federal Communications Commission's (FCC) radiofrequency (RF) radiation exposure guidelines and nonthermal effects of radiofrequency radiation. Another issue that you raise in your letter is the FCC's claim that EPA shares responsibility for recommending RF radiation protection guidelines to the FCC. I hope that my reply will clarify EPA's position with regard to these concerns. I believe that it is correct to say that there is uncertainty about whether or not current guidelines adequately treat nonthermal, prolonged exposures (exposures that may continue on an intermittent basis for many years). The explanation that follows is basically a summary of statements that have been made in other EPA documents and correspondence.

The guidelines currently used by the FCC were adopted by the FCC in 1996. The guidelines were recommended by EPA, with certain reservations, in a letter to Thomas P. Stanley, Chief Engineer, Office of Engineering and Technology, Federal Communications Commission, November 9, 1993, in response to the FCC's request for comments on their Notice of Proposed Rulemaking (NPRM), Guidelines for Evaluating the Environmental Effects of Radiofrequency Radiation (enclosed).

The FCC's current exposure guidelines, as well as those of the Institute of Electrical and Electronics Engineers (IEEE) and the International Commission on Non-ionizing Radiation Protection, are thermally based, and do not apply to chronic, nonthermal exposure situations. They are believed to protect against injury that may be caused by acute exposures that result in tissue heating or electric shock and burn. The hazard level (for frequencies generally at or greater than 3 MHz) is based on a specific absorption dose-rate, SAR, associated with an effect

Dear Ms.Newton:

This is in reply to your letter of January 31, 2002, to the Environmental Protection Agency (EPA) Administrator Whitman, in which you express your concerns about the adequacy of the Federal Communications Commission's (FCC) radiofrequency (RF) radiation exposure guidelines and nonthermal effects of radiofrequency radiation. Another issue that you raise in your letter is the FCC's claim that EPA shares responsibility for recommending RF radiation protection guidelines to the FCC. I hope that my reply will clarify EPA's position with regard to these concerns. I believe that it is correct to say that there is uncertainty about whether or not current guidelines adequately treat nonthermal, prolonged exposures (exposures that may continue on an intermittent basis for many years). The explanation that follows is basically a summary of statements that have been made in other EPA documents and correspondence.

The guidelines currently used by the FCC were adopted by the FCC in 1996. The guidelines were recommended by EPA, with certain reservations, in a letter to Thomas P. Stanley, Chief Engineer, Office of Engineering and Technology, Federal Communications Commission, November 9, 1993, in response to the FCC's request for comments on their Notice of Proposed Rulemaking (NPRM), Guidelines for Evaluating the Environmental Effects of Radiofrequency Radiation (enclosed).

The FCC's current exposure guidelines, as well as those of the Institute of Electrical and Electronics Engineers (IEEE) and the International Commission on Non-ionizing Radiation Protection, are thermally based, and do not apply to chronic, nonthermal exposure situations. They are believed to protect against injury that may be caused by acute exposures that result in tissue heating or electric shock and burn. The hazard level (for frequencies generally at or greater than 3 MHz) is based on a specific absorption dose-rate, SAR, associated with an effect

that results from an increase in body temperature. The FCC's exposure guideline is considered protective of effects arising from a thermal mechanism but not from all possible mechanisms. Therefore, the generalization by many that the guidelines protect human beings from harm by any or all mechanisms is not justified.

These guidelines are based on findings of an adverse effect level of 4 watts per kilogram (W/kg) body weight. This SAR was observed in laboratory research involving acute exposures that elevated the body temperature of animals, including nonhuman primates. The exposure guidelines did not consider information that addresses nonthermal, prolonged exposures, i.e., from research showing effects with implications for possible adversity in situations involving chronic/prolonged, low-level (nonthermal) exposures. Relatively few chronic, low-level exposure studies of laboratory animals and epidemiological studies of human populations have been reported and the majority of these studies do not show obvious adverse health effects. However, there are reports that suggest that potentially adverse health effects, such as cancer, may occur. Since EPA's comments were submitted to the FCC in 1993, the number of studies reporting effects associated with both acute and chronic low-level exposure to RF radiation has increased.

While there is general, although not unanimous, agreement that the database on low-level, long-term exposures is not sufficient to provide a basis for standards development, some contemporary guidelines state explicitly that their adverse-effect level is based on an increase in body temperature and do not claim that the exposure limits protect against both thermal and nonthermal effects. The FCC does not claim that their exposure guidelines provide protection for exposures to which the 4 W/kg SAR basis does not apply, i.e., exposures below the 4 W/kg threshold level that are chronic/prolonged and nonthermal. However, exposures that comply with the FCC's guidelines generally have been represented as "safe" by many of the RF system operators and service providers who must comply with them, even though there is uncertainty about possible risk from nonthermal, intermittent exposures that may continue for years.

The 4 W/kg SAR, a whole-body average, time-average dose-rate, is used to derive dose-rate and exposure limits for situations involving RF radiation exposure of a person's entire body from a relatively remote radiating source. Most people's greatest exposures result from the use of personal communications devices that expose the head. In summary, the current exposure guidelines used by the FCC are based on the effects resulting from whole-body heating, not exposure of and effect on critical organs including the brain and the eyes. In addition, the maximum permitted local SAR limit of 1.6 W/kg for critical organs of the body is related directly to the permitted whole body average SAR (0.08 W/kg), with no explanation given other than to limit heating.

I also have enclosed a letter written in June of 1999 to Mr. Richard Tell, Chair, IEEE SCC28 (SC4) Risk Assessment Work Group, in which the members of the Radiofrequency Interagency Work Group (RFIAWG) identified certain issues that they had determined needed to be addressed in order to provide a strong and credible rationale to support RF exposure guidelines.

Federal health and safety agencies have not yet developed policies concerning possible risk from long-term, nonthermal exposures. When developing exposure standards for other physical agents such as toxic substances, health risk uncertainties, with emphasis given to sensitive populations, are often considered. Incorporating information on exposure scenarios involving repeated short duration/nonthermal exposures that may continue over very long periods of time (years), with an exposed population that includes children, the elderly, and people with various debilitating physical and medical conditions, could be beneficial in delineating appropriate protective exposure guidelines.

I appreciate the opportunity to be of service and trust that the information provided is helpful. If you have further questions, my phone number is (202) 564-9235 and e-mail address is hankin.norbert@epa.gov.

Sincerely,

Norbert Hankin

PA PUBLIC UTILITY COMMISSION
SECRETARY'S BUREAU

The Honorable Mignon L. Clyburn
Acting Commissioner
Federal Communications Commission
445 12th Street SW
Washington, DC 20054

The Honorable Dr. Margaret A. Hamburg
Commissioner
U.S. Food and Drug Administration
10903 New Hampshire Avenue
Silver Spring, MD 20993

Dear Acting Chairwoman Clyburn and Commissioner Hamburg:

The American Academy of Pediatrics (AAP), a non-profit professional organization of 60,000 primary care pediatricians, pediatric medical sub-specialists, and pediatric surgical specialists dedicated to the health, safety and well-being of infants, children, adolescents, and young adults appreciates this opportunity to comment on the Proposed Rule "Reassessment of Exposure to Radiofrequency Electromagnetic Fields Limits and Policies" published in the Federal Register on June 4, 2013.

In the past few years, a number of American and international health and scientific bodies have contributed to the debate over cell phone radiation and its possible link to cancer. The International Agency for Research on Cancer (IARC), part of the United Nations' World Health Organization, said in June 2011 that a family of frequencies that includes mobile-phone emissions is "possibly carcinogenic to humans." The National Cancer Institute has stated that although studies have not demonstrated that RF energy from cell phones definitively causes cancer, more research is needed because cell phone technology and cell phone use are changing rapidly. These studies and others clearly demonstrate the need for further research into this area and highlight the importance of reassessing current policy to determine if it is adequately protective of human health.

As radiation standards are reassessed, the AAP urges the FCC to adopt radiation standards that:

- **Protect children's health and well-being**. Children are not little adults and are disproportionately impacted by all environmental exposures, including cell phone radiation. Current FCC standards do not account for the unique vulnerability and use patterns specific to pregnant women and children. It is essential that any new standard for cell phones or other wireless devices be based on

EXHIBIT

Complainant's
Exhibit No. 14

protecting the youngest and most vulnerable populations to ensure they are safeguarded throughout their lifetimes.

- **Reflect current use patterns.** The FCC has not assessed the standard for cell phone radiation since 1996. Approximately 44 million people had mobile phones when the standard was set; today, there are more than 300 million mobile phones in use in the United States. While the prevalence of wireless phones and other devices has skyrocketed, the behaviors around cell phone uses have changed as well. The number of mobile phone calls per day, the length of each call, and the amount of time people use mobile phones has increased, while cell phone and wireless technology has undergone substantial changes. Many children, adolescents and young adults, now use cell phones as their only phone line and they begin using wireless phones at much younger ages. Pregnant women may carry their phones for many hours per day in a pocket that keeps the phone close to their uterus. Children born today will experience a longer period of exposure to radio-frequency fields from cellular phone use than will adults, because they start using cellular phones at earlier ages and will have longer lifetime exposures. FCC regulations should reflect how people are using their phones today.

- **Provide meaningful consumer disclosure.** The FCC has noted that it does not provide consumers with sufficient information about the RF exposure profile of individual phones to allow consumers to make informed purchasing decisions. The current metric of RF exposure available to consumers, the Specific Absorption Rate, is not an accurate predictor of actual exposure. AAP is supportive of FCC developing standards that provide consumers with the information they need to make informed choices in selecting mobile phone purchases, and to help parents to better understand any potential risks for their children. To that end, we support the use of metrics that are specific to the exposure children will experience.

The AAP supports the reassessment of radiation standards for cell phones and other wireless products and the adoption of standards that are protective of children and reflect current use patterns. If you have questions, please contact Clara Filice in the AAP's Washington Office at 202/347-8600.

Sincerely,

Thomas K. McInerny MD

Founded in 1965 as a non-profit medical association, the American Academy of Environmental Medicine (AAEM) is an international organization of physician and scientists interested in the complex relationship between the environment and health.

AAEM physicians and physicians world-wide are treating patients who report adverse, debilitating health effects following the installation of smart meters, which emit electromagnetic frequencies (EMF) and radiofrequencies (RF).

The peer reviewed, scientific literature demonstrates the correlation between EMF/RF exposure and neurological, cardiac, and pulmonary disease as well as reproductive disorders, immune dysfunction, cancer and other health conditions. The evidence is irrefutable. Despite this research, claims have been made that studies correlating smart meter emissions with adverse health effects do not exist.

The AAEM has received a case series submitted by Dr. Federica Lamech, MBBS, *Self-Reporting of Symptom Development from Exposure to Wireless Smart Meters' Radiofrequency Fields in Victoria*. AAEM supports this research. It is a well documented 92 case series that is scientifically valid. It clearly demonstrates adverse health effects in the human population from smart meter emissions.

The symptoms reported in this case series closely correlate not only with the clinical findings of environmental physicians, but also with the scientific literature. Many of the symptoms reported including fatigue, headaches, heart palpitations, dizziness and other symptoms have been shown to be triggered by electromagnetic field exposure under double blind, placebo controlled conditions. Symptoms in this case series also correlate with the Austrian Medical Association's Guidelines for the Diagnosis and Treatment of EMF Related Health Problems.

It is critically important to note that the data in this case series indicates that the "vast majority of cases" were not electromagnetically hypersensitive until *after* installation of smart meters. Dr. Lamech concludes that smart meters "may have unique characteristics that lower people's threshold for symptom development".

This research is the first of its kind, clearly demonstrating the correlation between smart meters and adverse health effects.

Based on the findings of this case series, AAEM calls for:

- Further research regarding smart meter health effects
- Accommodation for health considerations regarding smart meters.
- Avoidance of smart meter EMF/RF emissions based on health considerations, including the option to maintain analog meters.
- A moratorium on smart meters and implementation of safer technology
- Physicians and health care providers to consider the role of EMF and RF in the disease process, diagnosis and treatment of patients.

Passed by the Board of Directors of the American Academy of Environmental Medicine October 23, 2013

Please note: Smart Meter case series research to be released upon publication

Electromagnetic and Radiofrequency Fields Effect on Human Health

For over 50 years, the American Academy of Environmental Medicine (AAEM) has been studying and treating the effects of the environment on human health. In the last 20 years, our physicians began seeing patients who reported that electric power lines, televisions and other electrical devices caused a wide variety of symptoms. By the mid 1990's, it became clear that patients were adversely affected by electromagnetic fields and becoming more electrically sensitive. In the last five years with the advent of wireless devices, there has been a massive increase in radiofrequency (RF) exposure from wireless devices as well as reports of hypersensitivity and diseases related to electromagnetic field and RF exposure. Multiple studies correlate RF exposure with diseases such as cancer, neurological disease, reproductive disorders, immune dysfunction, and electromagnetic hypersensitivity.

The electromagnetic wave spectrum is divided into ionizing radiation such as ultraviolet and X-rays and non-ionizing radiation such as radiofrequency (RF), which includes WiFi, cell phones, and Smart Meter wireless communication. It has long been recognized that ionizing radiation can have a negative impact on health. However, the effects of non-ionizing radiation on human health recently have been seen. Discussions and research of non-ionizing radiation effects centers around thermal and non-thermal effects. According to the FCC and other regulatory agencies, only thermal effects are relevant regarding health implications and consequently, exposure limits are based on thermal effects only.[1]

While it was practical to regulate thermal bioeffects, it was also stated that non-thermal effects are not well understood and no conclusive scientific evidence points to non-thermal based negative health effects.[1] Further arguments are made with respect to RF exposure from WiFi, cell towers and smart meters that due to distance, exposure to these wavelengths are negligible.[2] However, many in vitro, in vivo and epidemiological studies demonstrate that significant harmful biological effects occur from non-thermal RF exposure and satisfy Hill's criteria of causality.[3] Genetic damage, reproductive defects, cancer, neurological degeneration and nervous system dysfunction, immune system dysfunction, cognitive effects, protein and peptide damage, kidney damage, and developmental effects have all been reported in the peer-reviewed scientific literature.

EXHIBIT
C-16
AB 4/2/18
PENGAD 800-631-6989

Genotoxic effects from RF exposure, including studies of non-thermal levels of exposure, consistently and specifically show chromosomal instability, altered gene expression, gene mutations, DNA fragmentation and DNA structural breaks.[4-11] A statistically significant dose response effect was demonstrated by Maschevich et al. , who reported a linear increase in aneuploidy as a function of the Specific Absorption Rate(SAR) of RF exposure.[11] Genotoxic effects are documented to occur in neurons, blood lymphocytes, sperm, red blood cells, epithelial cells, hematopoietic tissue, lung cells and bone marrow. Adverse developmental effects due to non-thermal RF exposure have been shown with decreased litter size in mice from RF exposure well below safety standards.[12] The World Health Organization has classified RF emissions as a group 2 B carcinogen.[13] Cellular telephone use in rural areas was also shown to be associated with an increased risk for malignant brain tumors. [14]

The fact that RF exposure causes neurological damage has been documented repeatedly. Increased blood-brain barrier permeability and oxidative damage, which are associated with brain cancer and neurodegenerative diseases, have been found.[4,7,15-17] Nittby et al. demonstrated a statistically significant dose-response effect between non-thermal RF exposure and occurrence of albumin leak across the blood-brain barrier.[15] Changes associated with degenerative neurological diseases such as Alzheimer's, Parkinson's and Amyotrophic Lateral Sclerosis (ALS) have been reported.[4,10] Other neurological and cognitive disorders such as headaches, dizziness, tremors, decreased memory and attention, autonomic nervous system dysfunction, decreased reaction times, sleep disturbances and visual disruption have been reported to be statistically significant in multiple epidemiological studies with RF exposure occurring non-locally.[18-21]

Nephrotoxic effects from RF exposure also have been reported. A dose response effect was observed by Ingole and Ghosh in which RF exposure resulted in mild to extensive degenerative changes in chick embryo kidneys based on duration of RF exposure.[24] RF emissions have also been shown to cause isomeric changes in amino acids that can result in nephrotoxicity as well as hepatotoxicity.[25]

Electromagnetic field (EMF) hypersensitivity has been documented in controlled and double blind studies with exposure to various EMF frequencies. Rea et al. demonstrated that under double blind placebo controlled conditions, 100% of subjects showed reproducible reactions to that frequency to which they were most sensitive.[22] Pulsed electromagnetic frequencies were shown to consistently provoke neurological symptoms in a blinded subject while exposure to continuous frequencies did not.[23]

Although these studies clearly show causality and disprove the claim that health effects from RF exposure are uncertain, there is another mechanism that proves electromagnetic frequencies, including radiofrequencies, can negatively impact human health. Government agencies and industry set safety standards based on the narrow scope of Newtonian or "classical" physics reasoning that the effects of atoms and molecules are confined in space and time. This model supports the theory that a mechanical force acts on a physical object and thus, long-range exposure to EMF and RF cannot have an impact on health if no significant heating occurs. However, this is an incomplete model. A quantum physics model is necessary to fully understand and appreciate how and why EMF and RF fields are harmful to humans.[26,27] In quantum physics and quantum field theory, matter can behave as a particle or as a wave with wave-like properties.

Matter and electromagnetic fields encompass quantum fields that fluctuate in space and time. These interactions can have long-range effects which cannot be shielded, are non-linear and by their quantum nature have uncertainty. Living systems, including the human body, interact with the magnetic vector potential component of an electromagnetic field such as the field near a toroidal coil.[26,28,29] The magnetic vector potential is the coupling pathway between biological systems and electromagnetic fields.[26,27] Once a patient's specific threshold of intensity has been exceeded, it is the frequency which triggers the patient's reactions.

Long range EMF or RF forces can act over large distances setting a biological system oscillating in phase with the frequency of the electromagnetic field so it adapts with consequences to other body systems. This also may produce an electromagnetic frequency imprint into the living system that can be long lasting.[26,27,30] Research using objective instrumentation has shown that even passive resonant circuits can imprint a frequency into water and biological systems.[31] These quantum electrodynamic effects do exist and may explain the adverse health effects seen with EMF and RF exposure. These EMF and RF quantum field effects have not been adequately studied and are not fully understood regarding human health.

Because of the well documented studies showing adverse effects on health and the not fully understood quantum field effect, AAEM calls for exercising precaution with regard to EMF, RF and general frequency exposure. In an era when all society relies on the benefits of electronics, we must find ideas and technologies that do not disturb bodily function. It is clear that the human body uses electricity from the chemical bond to the nerve impulse and obviously this orderly sequence can be disturbed by an individual-specific electromagnetic frequency environment. Neighbors and whole communities are already exercising precaution, demanding abstention from wireless in their homes and businesses.

Furthermore, the AAEM asks for:

- An immediate caution on Smart Meter installation due to potentially harmful RF exposure.
- Accommodation for health considerations regarding EMF and RF exposure, including exposure to wireless Smart Meter technology.
- Independent studies to further understand the health effects from EMF and RF exposure.
- Recognition that electromagnetic hypersensitivity is a growing problem worldwide.
- Understanding and control of this electrical environmental bombardment for the protection of society.
- Consideration and independent research regarding the quantum effects of EMF and RF on human health.
- Use of safer technology, including for Smart Meters, such as hard-wiring, fiber optics or other non-harmful methods of data transmission.

Maryland Children's Environmental Health and Protection Advisory Council

Wifi Radiation in Schools in Maryland
Final Report

December 13, 2016

EXHIBIT
C-17
AS 4/24/18
PENGAD 800-631-6989

INTRODUCTION

The Maryland Children's Environmental Health and Protection Advisory Council (the Council) identifies environmental health issues that impact children and seeks to protect them from exposure to environmental hazards. Under Md. Code Ann., Health-General §13–1506, one of the responsibilities of CEHPAC is to:

(4) Gather and disseminate information to the public, including the research and medical communities, community–based organizations, schools, and State agencies, on how to reduce, treat, and eliminate children's exposures to environmental hazards to further the public's understanding of the environmental hazards that may potentially affect children; and

(5) Recommend uniform guidelines for State agencies to follow to help reduce and eliminate children's exposure to environmental hazards, especially in areas reasonably accessible to children...

In May, 2014, the Council received a request from a member of the public to consider the health and safety of wireless radiation (microwave radiation). The Council subsequently discussed the issue and heard from the public over a series of meetings, and invited input from the public. It also received a presentation on the topic from a resident physician in training in the Johns Hopkins Preventive Medicine Residency Program, and a literature review prepared by a graduate student enrolled in the University of Maryland School of Public Health. Throughout the process, the Council has heard from concerned citizens about the issue.

Based on this input, a work group of the Council (see Appendix A for Council and work group members) prepared an initial draft of this report, which was then reviewed by the Council. The work group set out to answer the following questions:

1. What exposures are linked to WiFi technology?
2. What health outcomes are linked to exposure?
3. Is the Federal Communications Commission radio-frequency energy exposure limit protective of children when it comes to WiFi exposures? Is it overprotective?
4. What are the policy options?

address adequately in this report. The Council has also heard concerns expressed regarding WiFi exposures and sources outside of schools, such as so-called "smart meters." This report does not address those issues.

BACKGROUND

What exposures are linked to WiFi techology?

"WiFi radiation" (WiFi), also referred to as radiofrequency radiation (RFR), is non-ionizing radiation typically in the microwave frequencies of approximately 900 megahertz (million cycles/second, or MHz) to approximately 5 gigahertz (1,000 million cycles per second, or GHz). WiFi is used primarily for cellular telephones, local area networks (LANs), and other communications technologies. The primary bands used for WiFi are generally 2.4 GHz and 5 GHz.

WiFi radiation exposures are regulated by several agencies. The U.S. Federal Communications Commission (FCC) issues radiation exposure guidelines as specific absorption rates (SARs) for fixed antennas, hand-held cellular telephones, and personal communications services (PCS) devices.[1] These guidelines were last issued by the FCC in 1996. The U.S. Occupational Safety and Health Administration (OSHA) has established occupational exposure limits for microwave radiation.[2] The U.S. Food and Drug Administration (FDA) does not have standards for cellular telephones, but can take regulatory action if these devices are shown to have adverse health impacts.[3]

[1] 47 Code of Federal Regulations § 1.1310, accessed 11/22/2016 at: http://www.ecfr.gov/cgi-bin/text-idx?SID=005917bcee652d12d9ad4d725bf3e4d9&mc=true&node=se47.1.1_11310&rgn=div8.

[2] See https://www.osha.gov/SLTC/radiofrequencyradiation/standards.html.

[3] See http://www.fda.gov/Radiation-EmittingProducts/RadiationEmittingProductsandProcedures/HomeBusinessandEntertainment/CellPhones/default.htm.

What Health Outcomes Are Linked to Exposure?

Some of the biological effects of WiFi radiation are well characterized. In particular, WiFi radiation is known to have thermal effects on tissues, due to the absorption of microwave RFR by water, which results in heating of the water. These thermal effects can be seen in a variety of tissues, and form the basis for most of the health standards that currently apply to WiFi radiation. There are also concerns about non-thermal effects, including cancer.

The Council's review included a wide variety of sources, including: WiFi Radiation in Schools

reconsider itsexposure standards, includingtheAmerican Academy of Pediatrics(2013).[8]

FINDINGS

Is the Federal Communications Commission radio-frequencyenergy exposure limit protective of children when it comes to WiFiexposures?

Regarding the third question, the Federal Communications Commission (FCC)guidance isdecadesold and some groups have called for it to be updated to reflectcurrent science and newer exposures, especially to children.The Council recommendsthatthe Maryland Departmentof Health andMental Hygiene ask the United StatesDepartment of HealthandHuman Services to**formally petition the FCC to revisit theexposure limit to ensure it is protective of children's health** and that it relies on current science.

What are the policy options?

There are a range ofpolicy approaches to address environmental exposures:fromadopting the precautionary principle to experimenting directly on humans. Below are some examples of policy approachesfrom around the world (more can be found athttp://www.parentsforsafetechnology.org/worldwide-countries-taking-action.html):

- In Massachusetts, the Ashland Public School Districtreduces wireless radiation exposures through a "bestpracticesfor mobile devices".
- France banned WiFiin nursery schools and ruled that routers in schoolsforchildren up to 11 should be turned off when not in use for pedagogic purposes.
- InVitoria City, Spaincitizens will be informed of the location ofwirelesstransmitters are in civic centers and municipal buildings.
- InIsrael, the Ministry Of Education issued guidelines limitingWiFiin schools including.
- Preschool through 2nd grade have banned the use of wireless networks.
- A hard wired direct cable connection is required if the teacher has acomputer in the class.Magneticfieldsbelow 4MG are being reduced.
- In third and fourth grade class internet is restricted to 3 hours per week.

[8] Letter of Thomas K. McInerney,MD, FAAP,August 29, 2013:Accessed November 26,2016 at:https://ecfsapi.fcc.gov/file/7520941318.pdf.WiFi Radiation in Schools December 13, 2016 Page 8

- Teach children to turn off WiFi when not in use.
- Consider placing routers as far away from students as possible.
- Share this document with teachers and parents.

• The General Assembly should consider funding education and research on electromagnetic radiation and health as schools add WiFi to classrooms.

• The Maryland Department of Health and Mental Hygiene should provide suggestions to the public on ways to reduce exposure: ○ Sit away from WiFi routers, especially when people are using it to access the internet.
- Turn off the wireless on your laptop when you are not using it.
- Turn off WiFi on smartphones and tablets when not surfing the web.
- Switch tablets to airplane mode to play games or watch videos stored on the device.

• This report should be posted on the Council website and shared with the: ○ United States Department of Health and Human Services
- Federal Communications Commission
- Maryland State Department of Education
- Maryland General Assembly

CONCLUSION

Many members of the public participated in Council meetings and contributed documentation relevant to these deliberations (Appendix B); we appreciate their input and dedication. While this report focused on WiFi radiation in schools, there are additional concerns about mobile phones and cell phone towers. CEHPAC plans to take a look at these broader issues over the next year. WiFi Radiation in Schools December 13, 2016

APPENDIX A: Members of the Children's Environmental Health and Protection Advisory Council Name

Appointed by the Governor, representing the following:

Abney, Dr. Diana	Maryland Association of County Officials
Bishai, Dr. David	Economist skilled in measuring the economic costs of illness and the benefits of prevention
Carrella, Veronika*	Parent or guardian whose child has been clinically diagnosed as having been exposed to
Diette, Dr. Gregory	Representative from an academic institution who has expertise in studying the impact of environmental exposures on childhood disease
Gitterman,Dr. Benjamin*	Licensed health care provider with expertise in the field of children's environmental health
Latshaw, Dr. Megan**	Epidemiologist with expertise in children's environmental health
Levy, Julian	Representative of private industry representing the regulated community
Matsui,Dr. Elizabeth	Licensed health care provider with expertise in the field of children's environmental health

How to Reduce Exposure to Radiofrequency Energy from Cell Phones

How can you reduce your exposure?

Keep your phone away from your body. Keeping your phone just a few feet away from you can make a big difference.

- ***When you talk on your cell phone, avoid holding it to your head—use the speakerphone or a headset instead.*** Wireless (Bluetooth) and wired headsets emit much less RF energy than cell phones.
- ***Send text messages instead of talking on the phone.***
- ***If you are streaming or if you are downloading or sending large files, try to keep the phone away from your head and body.***
- ***Carry your cell phone in a backpack, briefcase, or purse; NOT in a pocket, bra or belt holster.*** Because your phone's antenna tries to stay connected with a cell tower whenever it's on, it emits some RF energy even when you are not using it. It does not emit RF energy when it's in airplane mode. (Airplane mode turns off cellular, Wi-Fi, and Bluetooth.)

Reduce or avoid using your cell phone when it is sending out high levels of RF energy. This happens mainly when:

- ***You see only one or two bars displayed.*** Cell phones put out more RF energy to connect with cell towers when the signal is weak. If you must use your phone when the signal is weak, try to follow the other guidance on this page.
- ***You are in a fast-moving car, bus, or train.*** Your phone puts out more RF energy to maintain connections to avoid dropping calls as it switches connections from one cell tower to the next unless it is in airplane mode.
- ***You are streaming audio or video, or downloading or sending large files.*** To watch movies or listen to playlists on your phone, download them first, then switch to airplane mode while you watch

What about children?

Children may be more at risk for harm from exposure to RF energy because:

- RF energy can reach a larger area of a child's brain than an adult's brain.
- A child's brain and body grow and develop through the teen years. During this time, the body may be more easily affected by RF energy and the effect may be more harmful and longer lasting.
- A child who uses a cell phone will have many more years of exposure to RF energy in his or her lifetime than someone who started using a cell phone as an adult.

There is not a lot of research about the effects of cell phone RF energy on children or teenagers, but a few studies have shown that there may be hearing loss or ringing in the ears, headaches, and decreased general well-being.

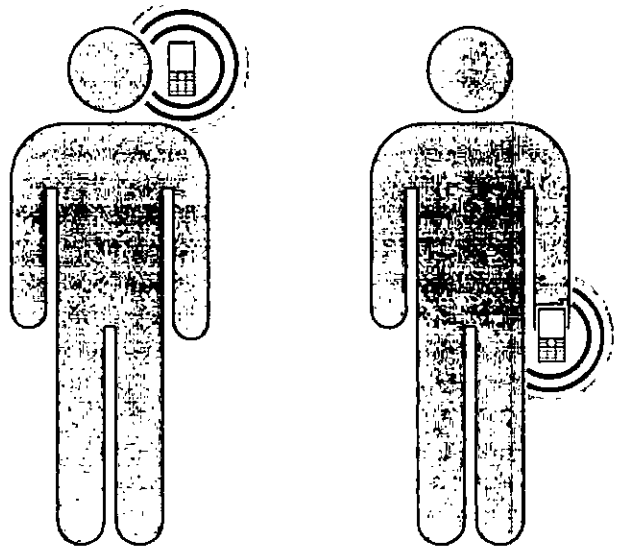
Complainant's
Exhibit No. 18



or listen.

Don't sleep with your phone in your bed or near your head. Unless the phone is off or in airplane mode, keep it at least a few feet away from your bed.

Take off the headset when you're not on a call. Headsets release small amounts of RF energy even when you are not using your phone.

Don't rely on a "radiation shield" or other products claiming to block RF energy, electromagnetic fields, or radiation from cell phones. According to the U.S. Federal Trade Commission, products that interfere with the phone's signal may force it to work harder and emit more RF energy in order to stay connected, possibly increasing your exposure.

You can limit exposure to Radio-frequency (RF) Energy from your cell phone.

PA PUBLIC UTILITY COMMISSION
SECRETARY'S BUREAU

Although studies continue to assess potential health effects of mobile phone use, the World Health Organization has classified RF Energy as a possible carcinogen.

This material was prepared solely by the City and County of San Francisco and must be provided to consumers under local law.

09/11

If you are concerned about potential health effects from cell phone RF Energy, the City of San Francisco recommends:

- **Limiting cell phone use by children** [1-3]
  Developing brains and thinner skulls lead to higher absorption in children.[4-8]
- **Using a headset, speakerphone or text instead** [9-11]
  Exposure decreases rapidly with increasing distance from the phone.[9,10]
- **Using belt clips and purses to keep distance between your phone and body** [12-14]
  Do not carry on your body to at least meet the distance specified in your phone's user manual.[12-14]
- **Avoiding cell phones in areas with weak signals (elevators, on transit, etc.)** [10]
  Using a cell phone in areas of good reception decreases exposure by allowing the phone to transmit at reduced power.[10]
- **Reducing the number and length of calls** [10]
  Turn off your cell phone when not in use.[9,10]

RESOLUTION NO. 3362

A RESOLUTION OF THE CITY COMMISSION OF THE CITY OF PEMBROKE PINES, FLORIDA, EXPRESSING THE CITY'S URGENT CONCERNS ARISING FROM RECENT MEDICAL SCIENCE REPORTS WHICH ADVISE OF THE POSSIBLE AND ADVERSE HEALTH EFFECTS DELIVERED UPON THOSE WHO USE CELL PHONES, INCLUDING, BUT NOT LIMITED TO, CANCER, AS A RESULT OF THE NON-IONIZED RADIATION EMITTED BY CELL PHONES; DIRECTING THE CITY CLERK TO FORWARD A COPY OF THIS RESOLUTION TO FLORIDA GOVERNOR RICK SCOTT, THE FLORIDA SENATE, THE FLORIDA HOUSE OF REPRESENTATIVES, THE FLORIDA LEAGUE OF CITIES, THE BROWARD COUNTY LEAGUE OF CITIES, THE BROWARD COUNTY BOARD OF COUNTY COMMISSIONERS, THE SCHOOL BOARD OF BROWARD COUNTY, AND EACH MUNICIPALITY WITHIN BROWARD COUNTY; PROVIDING FOR CONFLICTS; PROVIDING FOR SEVERABILITY; AND PROVIDING FOR AN EFFECTIVE DATE.

WHEREAS, cell phone use is pervasive in the City of Pembroke Pines; and

WHEREAS, the City of Pembroke Pines considers the health of its residents and children a priority; and

WHEREAS, cell phone users typically receive a 200-to-300-page user manual or user guide that is found in a cell phone's purchase box and which is viewable via the Internet; and

WHEREAS, cell phone user manuals and user guides state in various ways that the cell phone will emit a form of non-ionized radiation into the user's body; and

PROPOSED RESOLUTION NO. 2012-R-41

REVISION 1

RESOLUTION NO. 3362

WHEREAS, cell phone user manuals and user guides in various ways refer to non-ionized radiation as "Radio Frequency" and "Specified Absorption Rate"; and

WHEREAS, cell phone user manuals and user guides state in various ways that the cell phone user should always keep it centimeters or millimeters away from their heads and bodies so as to reduce their bodies' exposure to radiation; and

WHEREAS, said centimeters and millimeters are equivalent to one inch; and

WHEREAS, the majority cell phone users, particularly children and teenagers, are not keeping cell phones away from their heads and bodies; and

WHEREAS, there exists an ongoing scientific debate as to whether a person's being exposed to cell phone emitted radiation causes cancer; and

WHEREAS, there exists an ongoing scientific debate as to whether children and teenagers are more susceptible than adults to the possible ill effects of being exposed to cell phone emitted radiation; and

WHEREAS, on or about May 31, 2011, the International Agency for Research on Cancer, part of the World Health Organization, put out a report that asserts, inter alia, that the chance of a cell phone user becoming a cancer patient doubles once he or she reaches the ten-year mark of using a cell phones for at least 30 minutes per day; and

PROPOSED RESOLUTION NO. 2012-R-41

REVISION 1

RESOLUTION NO. 3362

WHEREAS, on or about March 15, 2012, the Yale School of Medicine published a report which states, inter alia, that Yale has concluded that prenatal exposures to cell phone radiation may affect brain development and behavior in offspring; and

WHEREAS, on or about June 15, 2012, the Federal Communications Commission's Chairman, Mr. Julius Genachowski, stated that FCC wants to open an inquiry into whether cell phone emissions standards need to be changed amid concerns that the emitted radiation could cause brain cancer; and

WHEREAS, on or about July 24, 2012, the Government Accountability Office published a 46-page report which, inter alia, urges the Federal Communications Commission to revise phone radiation standards which date back to 1998; and

WHEREAS, several city commissions within the United States of America have introduced resolutions designed to more adequately warn their residents about keeping cell phones away from their heads and bodies; and

WHEREAS, several states of the United States of America have introduced legislation designed to more adequately warn their residents about keeping cell phones away from their heads and bodies; and

PROPOSED RESOLUTION NO. 2012-R-41

REVISION 1

RESOLUTION NO. 3362

WHEREAS, several countries, such as France and Israel, have issued cell phone radiation advisories to all citizens about the risks associated with cell phones; and

WHEREAS, a cell phone user may reduce his or her exposure to cell phone radiation by keeping the cell phone at least one inch away from their bodies, using a wired headset, using a speakerphone, communicating by way of text messages, electronic mail, et cetera.

NOW, THEREFORE, BE IT RESOLVED BY THE CITY COMMISSION OF THE CITY OF PEMBROKE PINES, FLORIDA, AS FOLLOWS:

SECTION 1. The foregoing "WHEREAS" clauses are true and correct and hereby ratified and confirmed by the City Commission of the City of Pembroke Pines.

SECTION 2. The Pembroke Pines City Commission hereby expresses its concern regarding the amount of radiation that cell phones are emitting into users' bodies in light of the scientific debate that cell phone radiation exposure causes cancer.

SECTION 3. The Pembroke Pines City Commission strongly encourages everyone to carefully read through their cell phone user manuals and user guides and follow all instructions therein as to how to reduce the amount of radiation that will be emitted into their bodies.

PROPOSED RESOLUTION NO. 2012-R-41

REVISION 1

RESOLUTION NO. 3362

SECTION 4. The Pembroke Pines City Commission strongly encourages everyone, in addition to reading through their cell phone user manuals and user guides, to take all practical steps to keep themselves and their children well informed on the latest and ongoing scientific reports about the possible effects of cell phone radiation.

SECTION 5. The Pembroke Pines City Commission hereby resolves that additional scientific and medical research must be conducted by the public health community about the possible effects of cell phones' radiation upon adults, teenagers, and children.

SECTION 6. The Pembroke Pines City Commission hereby encourages that all local, state, and federal government agencies sworn to defend the public's health safety take all reasonable steps to vigilantly monitor and report publicly the information disclosed by ongoing scientific and medical research about the possible effects of cell phones' radiation upon adults, teenagers, and children.

SECTION 7. The City Clerk is hereby directed to transmit a copy of this resolution to Florida Governor Rick Scott, the Florida Senate, the Florida House of Representatives, the Florida League of Cities, the Broward League of Cities, the Broward County Board of County Commissioners, the School Board of Broward County, and each municipality within Broward County.

PROPOSED RESOLUTION NO. 2012-R-41

REVISION 1

RESOLUTION NO. 3362

SECTION 8. All Resolutions or parts of Resolutions in conflict herewith, be and the same are repealed to the extent of such conflict.

SECTION 9. If any clause, section or other part of this Resolution shall be held by any court of competent jurisdiction to be unconstitutional or invalid, such unconstitutional or invalid part shall be considered eliminated and will in no way affect the validity of the other provisions of this Resolution.

SECTION 10. This Resolution shall become effective immediately upon its passage and adoption.

PASSED AND ADOPTED BY THE CITY COMMISSION OF THE CITY OF PEMBROKE PINES, FLORIDA, THIS 20th DAY OF NOVEMBER, 2012.

CITY OF PEMBROKE PINES, FLORIDA

ATTEST: 11/27/12

SECRETARY'S BUREAU

TOWN OF JACKSON PROCLAMATION
DECLARING OCTOBER CELL PHONE SAFETY AWARENESS MONTH

WHEREAS, more people use cell phones today than ever before because of their convenience and portability; and,

WHEREAS, the Jackson Town Council considers the health and welfare of the citizens of the Town a priority; and

WHEREAS, some research links texting with cell phones to traffic accidents, and also links longer term use with increased risks of brain cancer, reproductive damage, and other illnesses; and,

WHEREAS, these longer term risks may be greater for children than adults because their skulls are thinner and their brains and bodies are smaller and faster growing; and,

WHEREAS, phones emit more radiation in weak signal areas as they attempt to connect to a tower; and,

WHEREAS, simple steps such as holding the phone farther away from your ear, turning off your phone when not in use, checking the specific absorption rate of your phone, and using a headset significantly reduces radiation absorption; and,

WHEREAS, recent studies have confirmed the risks of cell phone radiation such as Yale University's report that prenatal exposures affect brain development and behavior in offspring and the Government Accountability Office's review advising that cellphone tests and standards should be revised; and,

WHEREAS, Israel, France, and India have all developed policies to advise parents of risks of cell phones and to require that cell phones be sold with headsets; and,

WHEREAS, cell phones manufacturers provide fine print warnings to promote safer cell phone use; and,

WHEREAS, cell phones are important for communication and safety reasons, but all people, and especially parents of young children, should be aware of how to reduce risks from cell phone use.

NOW THEREFORE, I, Mark Barron, Mayor of the Town of Jackson do hereby declare the month of October, 2012 as **Cell Phone Awareness Month** and, in so doing, urge citizens to become aware of the risks associated with prolonged cell phone use and to take steps necessary to mitigate these risks to themselves and the children in their care.

DATED THIS 1st Day of October, 2012.

TOWN OF JACKSON

Parents For Safe Technology

Worldwide Precautionary Action

Around the world, countries are taking strong action to reduce wireless radiation on children.

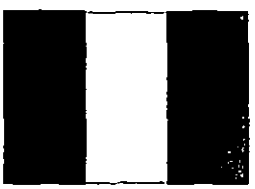
In addition the policies listed below, countries like Switzerland, Italy, France, Austria, Luxembourg, Bulgaria, Poland, Hungary, Israel, Russia and China have set RF exposure limits *100 to 10,000 times* ***less*** than the USA. They recognize that there can be non-thermal biological effects from wireless radiation.

Every great dream begins with a dreamer. Always remember, you have within you the strength, the patience, and the passion to reach for the stars to change the world.

-Harriet Tubman

[redacted]

France



National Legislation minimizing WiFi has been passed and the National Agency for Health, Food and Environmental Safety (ANSES) issued a report on the science in 2013.

- 2015 Law passed: WiFi banned from nursery schools, Wifi must be be turned off in elementary schools when not in use, Cellphone advertisements must recommend headsets to reduce exposure to brain.

- 2011 French Cell Phone Statute: Merchants must display SAR Radiation levels for different phone models, all phones must be sold with a headset, cell phone ads aimed at children younger than 14 are banned and phones made for children under 6 are banned.
- 2013 ANSES Report recommends hands free phones, SAR labeling, and "limiting the population's exposure to radiofrequencies... especially for children and intensive users, and controlling the overall exposure that results from relay antennas."
- The French National Library along with other libraries in Paris, and a number of universities have removed all Wi-Fi networks.
- Herouville-Saint-Clair has removed all Wi-Fi equipment installed in municipal buildings.

- 2011 French Cell Phone Statute: Merchants must display SAR Radiation levels for different phone models, all phones must be sold with a headset, cell phone ads aimed at children younger than 14 are banned and phones made for children under 6 are banned.
- 2013 ANSES Report recommends hands free phones, SAR labeling, and "limiting the population's exposure to radiofrequencies... especially for children and intensive users, and controlling the overall exposure that results from relay antennas."
- The French National Library along with other libraries in Paris, and a number of universities have removed all Wi-Fi networks.
- Herouville-Saint-Clair has removed all Wi-Fi equipment installed in municipal buildings.

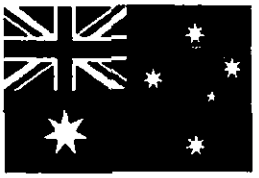
Belgium

Federal Public Health Regulations issued in 2013 due to Health Concerns for Children.

- Phones designed for children under 7 years old are prohibited from sale.
- Total Advertising Ban on cell phones aimed at children younger than 14.
- Mandatory Radiation SAR levels must be available for consumers at point of sale.
- Warning label on phones: "Think about your health – use your mobile phone moderately, make your calls wearing an earpiece and choose a set with a lower SAR value."
- Recommendations include use of hands-free methods to keep the phone away from the body such as text messaging and not making calls when the signal is weak, such as in elevator/vehicle.
- Ghent Municipality: Wireless internet is banned from spaces that cater to children between 0 and three: preschools and daycares to reduce exposure to microwave radiation.

Spain

- The Parliament of Navarra voted to urge removal of WIFI in schools and to apply the precautionary principle in relation to exposure limits to electromagnetic fields whose boundaries have become "obsolete".
- The Parliament voted to adopt a resolution which calls to implement the Parliamentary Assembly of the Council of Europe resolution 1815 of 2011, which recommends to "review the scientific basis for the standards of exposure to electromagnetic fields" and " set thresholds for levels of preventive long-term exposure in all indoor areas not exceeding 0.6 volts per meter ".
- The Vitoria City Council unanimously approved a precautionary approach with wireless: Citizens will be informed of the location of wireless transmitters are in civic centers and municipal buildings. It is recommended that children's spaces such as playgrounds and family libraries, will be free of WiFi or have decreased wifi and wifi free zones will be established in playgrounds and building entrances.



Israel

The Israeli Ministry Of Education has issued guidelines limiting WiFi and cell phone use in schools including.

- Preschool through 2nd grade have banned the use of wireless networks.
- A hard wired direct cable connection is required if the teacher has a computer in the class. Magnetic fields below 4MG are being reduced.
- The Israeli Supreme Court ordered the Israeli government to reply on ceasing Wifi installations
- In third and fourth grade class internet is restricted to 3 hours per week.
- The Education Ministry has instructed all schools to perform radiation tests.
- The Health Ministry has called for a halt to Wifi installations.
- See the governments official EMF information webpage Israeli National Information Center for Non-Ionizing Radiation
- Read the ISRAEL 2015 RF Safety Report detailing actions the government is

The Israeli Ministry of Health published Environmental Health in Israel 2014 which states that "Precautions should be strictly enforced with regard to children, who are more sensitive to developing cancer." and that "wireless communication networks in schools be reduced."

The Israeli Health Ministry recommends "sensible use of cellular and wireless technology, including: considering alternatives like landline telephones, use of a speaker while talking on a cellphone, and refraining from installing the base of wireless phones in a bedroom, work room, or children's room."

Australia

In 2013 the Australian Radiation Protection and Nuclear Safety Agency issued Fact Sheet 14: titled *How to Reduce Exposure from Mobile Phones and Other Wireless Devices* which states:

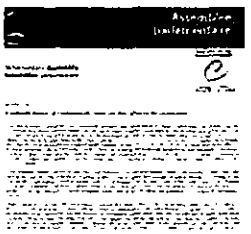
- Reduce the risk from WiFi devices by "keeping them at a distance, for example placing the wireless router away from where people spend time", and "reducing the amount of time you use them".
- "ARPANSA recommends that parents encourage their children to limit their exposure."

Australia has a very organized advocacy group working to redice wireless exposures on children. See the video to the left.

Italy

The Italian Supreme Court ruled a man's brain tumor was caused by his cell phone use in 2012. The National Institute for Workmen's Compensation must compensate a worker with head tumor due to cell use.

Please watch the documentary to the left about protests against radar installations in Sicily.



On June 10, 2015, the State Parliament of South Tyrol voted to allow the application of the precautionary principle mandating the state government to:

- **1. To replace existing wireless networks whenever possible** with networks that emit less radiation at schools, preschools, hospitals, nursing homes, and other public facilities.
- **2. Establish a working group** whose mandate it is to assess these new technologies and their exposure levels. With regard to wireless communication technologies, mobile Internet access, and public health, the working group shall clarify which technologies emit less radiation and provide sustainable technology options and
- **3. To start an education and awareness campaign** that informs about possible health risks, especially regarding the unborn, infants, children, and adolescents and that develops guidelines for a safer use of cell phones, smartphones, and Wi-Fi. Discussion at the Plenary Session, 10 June 2015 (in German) >>>///////Official Files, Resolutions (in German) >>>////////Previous Hearing at the Parliament of South Tyrol, 29 April 2015 (in German) >>>

CONSEIL DE L'EUROPE

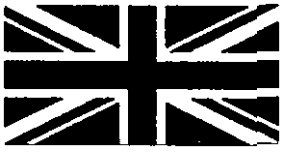
The Parliamentary Assembly of the Council of Europe

Resolution 1815 was issued in 2011 entitled:
The Potential Dangers of Electromagnetic Fields and Their Effect on the Environment.
A call to European governments to "take all reasonable measures" to reduce exposure to electromagnetic fields "particularly the exposure to children and young people who seem to be most at risk from head tumours." The Resolution calls for member states to:

- Implement "information campaigns about the risk of biological effects on the environment and human health, especially targeting children and young people of reproductive age. "
- "Reconsider the scientific basis for the present standards on exposure to electromagnetic fields set by the International Commission on Non-Ionising Radiation Protection, which have serious limitations, and apply ALARA principles, covering both thermal effects and the athermic or biological effects of electromagnetic emissions or radiation."
- "For children in general, and particularly in schools and classrooms, give preference to wired Internet connections, and strictly regulate the use of mobile phones by schoolchildren on school premises."

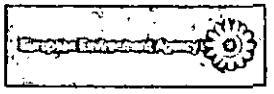
Switzerland

- The Governing Council of Thurgau Canton 2008 "The Governing Council recommends for schools to forgo the use of wireless networks when the structural makeup of a given school building allows for a wired network."



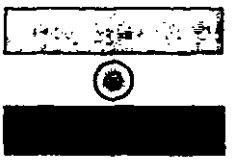
Germany

- The German Federal Ministry for Radiation Protection states,"supplementary precautionary measures such as wired cable alternatives are to be preferred to the WLAN system."
- Bavaria: The State Ministry of Education and Cultural Affairs: "For precautionary reasons the Federal Office for Radiation Protection recommends for schools that if a wireless network is used to place its components in suitable locations and to prefer the use of wired network solutions whenever possible." In 2007 Parliament recommendation to all schools to not install wireless LAN networks.
- Frankfurt: "In Frankfurt's schools there will be no wireless networks in the short or mid term. The Local Education Authority did not wish to conduct a "large scale human experiment," said Michael Damian, spokesperson of the Head of the School Department Jutta Ebeling.

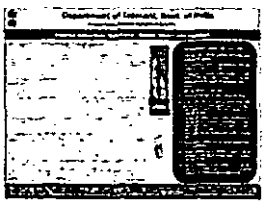


Austria

- "The official advice of the Public Health Department of the Salzburg Region is not to use WLAN and DECT in Schools or Kindergartens." -Gerd Oberfeld, MD.
- The Austrian Medical Society has issued cell phone safety guidelines (See picture to the left) stating that cell phones should be used for as short of a time as possible and that children under 16 should not use cell phones at all. They also state that wireless LAN leads to high microwave exposure.
- On March 2012, the Austrian Medical Association recognized and developed EHS treatment guidelines. Click HERE to download the Guidelines of the Austrian Medical Association for the diagnosis and treatment of EMF related health problems and illnesses (EMF syndrome)



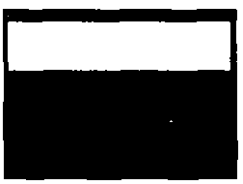
United Kingdom



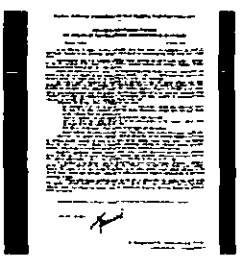
- The UK National Health Service issued guidelines specific Recommendations for children and cell phones as "children are thought to be at higher risk of health implications".
- "Children should only use mobile phones for essential purposes and keep all calls short. "
- For the public they have "recommendations to help lower any potential long-term risks" which include keeping calls short, keep phone away from the body on standby mode, only use it when the reception is strong and use a phone with an external antenna.

European Environment Agency:

- Professor Jacqueline McGlade, the EEA's executive director said, "Recent research and reviews on the long-term effects of radiations from mobile telecommunications suggest that it would be prudent for health authorities to recommend actions to reduce exposures, especially to vulnerable groups, such as children."
- The EEA issued a report "Mobile phone use and brain tumour risk: early warnings, early actions?" stating that "Precautionary actions now to reduce head exposures, as pointed out by the EEA in 2007, and many others since, would limit the size and seriousness of any brain tumour risk that may exist. "



India



- 2012 The Ministry of Communications and Information Technology issued EMF Guidelines with new Exposure Limits lowered to 1/10 of the ICNIRP level, SAR labeling on phones.
-
- Official guidelines for Cell Phone Use include: Headsets, Speakerphones, limiting cell use, increasing distance from devices, and choosing landlines.

- 2013: Supreme Court of India upheld the High Court of the State of Rajasthan decision to remove all cell towers from the vicinity of schools, hospitals and playgrounds because of radiation "hazardous to life."

- The Ministry of Communications and Information Technology has an EMF webpage
- Read the REPORT OF THE INTER-MINISTERIAL COMMITTEE ON EMF RADIATION.

- Zilla Parishad orders removal of all cellphone towers near schools citing exposure to "harmful radiation".
- Juli Chawla, former Miss India and Bollywood Actress became an voice for wireless safety after she found she was living across from cell base stations. Watch her excellent speech in the video to the left.
- Read a Document by Dr. Sharma, Sr. Deputy Director of the Indian Council of Medical Research on Indian Research Studies.

Russia

The Russian National Committee on Non-Ionizing Radiation Protection has repeatedly warned about electromagnetic radiation impacts on children and recommended WiFi not be used in schools. Download report HERE.

- "Thus, for the first time in the human history, children using mobile telecommunications along with the adult population are included into the health risk group due to the RF EMF exposure."
- "In children, the amount of so-called stem cells is larger than in adults and the stem cells were shown to be the most sensitive to RF EMF exposure."
- "It is reasonable to set limits on mobile telecommunications use by children and adolescents, including ban on all types of advertisement of mobile telecommunications for children."
- Decision of Russian National Committee on Non-Ionizing Radiation Protection 2008, "Children and Mobile Phones: The Health of the Following Generations is in Danger"

Cyprus

October 2015, The Cyprus National Committee on Environment and Child Health (ECH) announced it wants "to err on the side of caution", warning the public that using mobile devices could be potentially harmful to children.

- Stella Michaelidou, President of the ECH, states that society should respond by taking precautions because "Documentation of other potential and more serious biological side effects are on the tip of an emerging iceberg."
- This stance was documented in a recent news article that quotes Michaelidou stating that "multiple and frequent exposure to this kind of radiation, which falls below the acceptable levels of thermal effects, pose a health risk to a developing embryo." and children who use their mobile phone more frequently face a higher risk at having a weaker memory, attention deficit disorder, and similar issues.

United States

Legislation has been introduced at the state and national level. Some Communities have issued proclamations, resolutions and and started initiatives to inform the public of wireless health issues.

2015 California, Berkeley: Berkeley is the first city in the nation to require cell phone retailers to provide those who purchase a new phone an informational fact sheet which informs buyers to read the user manual to learn the cell phone's minimum separation distance from the body. Read all about this historic ordinance.

2014 New York: Wireless Router Labeling in all Suffolk Public buildings: 12/2014 The Suffolk County Legislature passed legislation to require all county buildings to post notices that wireless routers are in use such as, "Notice: Wireless technology in use." The resolution, sponsored by Legis. William Spencer (a physician), warns that every wireless device emits radio frequency radiation or microwave radiation. It notes that studies "that have looked at the effects of low-level RFR radiation on human cells and DNA have been inconclusive."

2014 Maryland, Greenbelt: The Greenbelt Maryland City Council voted unanimously on November 24, 2014 to alert citizens about the fine print warnings and possible health risks of cell phones and wireless devices, to send the FCC Chairman a letter urging the adoption of "radiation standards that will protect human health and safety." They also voted to oppose cell towers on school grounds.

2012 Wyoming: Jackson Hole issued a Proclamation of Cell Phone Safety which cites concern over long term health effects as well as the increased risk the radiation poses to children.

2012 Florida: Pembroke Pines, passed Resolution 3362 expressing the City's "Urgent Concerns" about Wireless Radiation and Health and which encourages citizens to read their manuals and presents information on how to reduce exposure by using a headset or speakerphone. Jimmy Gonzalez, an attorney who had developed brain cancer after heavy cell use, initially petitioned the Commission. Watch the Video of his powerful testimony here.

Canada

Health Canada offers "Practical Advice" on reducing exposure to wireless radiation.

- Recommendations: 1. Limit the length of cell phone calls, 2. Replace cell phone calls with text, use "hands-free" devices and 3. Encourage children under the age of 18 to limit their cell phone usage
- 2015: National Bill C-648 Introduced into the House Of Commons,"An Act Respecting the Prevention of Potential Health Risks From Radiofrequency Electromagnetic Radiation" would require manufacturers of all wireless devices to place specific health warning labels clearly on packaging, or face daily penalties /fines and/or imprisonment.

Finland

The Radiation and Nuclear Safety Authority issued 2009 recommendations for children which include: favoring text messages, parents limiting duration and amount of calls, the use of hands free devices, avoiding calls in a low reception area and keeping the phone away from the body.

"With children, we have reason to be especially careful, because there is not enough research on children's mobile phone use", according to STUK research director Sisko Salomaa.

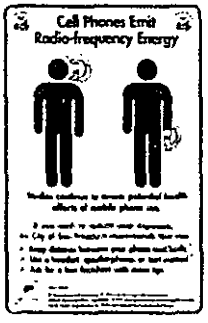
Namibia

Read Namibia's atomic energy review that states pretty clearly that current so called "safety" standards DO NOT protect citizens from long term health effects.

ICNIRP guidelines do not gurantee adequate protection against the long term effects of exposure, such as increased risk of cancer.

-Republic of Namibia- The Atomic Energy Review.

2010 California, San Francisco: Cell Phone Radiation (How to Reduce Exposures) Webpage launched. San Francisco developed a poster, factsheet and display stickers.



2010 California: Burlingame California City Council voted to include cell phone safety guidelines in their Healthy Living in Burlingame initiative (WHO classification and consumer precautions).

2010 Maine, Portland :Mayor Mavodenes, Jr. declared October "Cell Phone Awareness Month"

Proposed Legislation

2012 The Cell Phone Right to Know Act H.R. 6358 was introduced receiving strong support from many organizations including the American Academy of Pediatrics. (AAP Letter here.) This legislation called for labels on mobile devices at point of sale, a comprehensive national research program to study whether exposure to wireless devices causes adverse biological effects directed by NIEHS and the EPA and exposure level regulation.

2014 The Maine LD 1013 "The Wireless Information Act" passed the State Senate and House but then failed to pass the second vote. The Bill requires manufacturer's information on radio-frequency exposure be visible on the outside of the cell phone's product packaging.

2014 Hawaii Senate Bill SB 2571 was introduced calling for a warning label encouraging consumers to follow the enclosed product safety guidelines to reduce exposure to radiation that may be hazardous to their health.

The San Francisco Cell Phone Right to Know Ordinance was signed in 2011 requiring cell phone retailers to distribute an educational sheet created by the San Francisco Department of Environment that explains radiofrequency emissions from cell phones and how consumers can minimize their exposure. The CTIA sued the city and settled with the City to block implementation of the Ordinance in exchange for a waiver of attorneys' fees. The City Cell Phone Radiation Webpage remains online. San Francisco developed a poster, factsheet and display stickers.

SB 932 California, HM 32, New Mexico, HB 1408 Pennsylvania, and SB 679 Oregon.

Read a Recent Review of International Policy

Redmayne M. International policy and advisory response regarding children's exposure to radio frequency electromagnetic fields (RF-EMF). Electromagn Biol Med. 2015 Jun 19:1-9.

- Over 20 countries and municipalities have issued precautionary advice to the public concerning wireless exposures. This review of policy and advice regarding children's RF-EMF exposure shows a wide variety of approaches which I have categorized and tabulated ranging from ICNIRP/IEEE guidelines and "no extra precautions needed" to precautionary or scientific much lower maxima and extensive advice to minimize RF-EMF exposure, ban advertising/sale to children, and add exposure information to packaging.
- The wide range of policy approaches can be confusing for parents/carers of children. Some consensus among advisory organizations would be helpful acknowledging that, despite extensive research, the highly complex nature of both RF-EMF and the human body, and frequent technological updates, means simple assurance of
- "Therefore, m s recommended. "

PA PUBLIC UTILITY COMMISSIO
SECRETARY'S BUREAU

EMFscientist.org

To: His Excellency Antonio Guterres, Secretary-General of the United Nations;
Honorable Dr. Tedros Adhanom, Director-General of the World Health Organization;
Honorable Erik Solheim, Executive Director of the U.N. Environment Programme;
U.N. Member Nations

International Appeal:

Scientists call for Protection from Non-ionizing Electromagnetic Field Exposure

We are scientists engaged in the study of biological and health effects of non-ionizing electromagnetic fields (EMF). Based upon peer-reviewed, published research, we have serious concerns regarding the ubiquitous and increasing exposure to EMF generated by electric and wireless devices. These include–but are not limited to–radiofrequency radiation (RFR) emitting devices, such as cellular and cordless phones and their base stations, Wi-Fi, broadcast antennas, smart meters, and baby monitors as well as electric devices and infra-structures used in the delivery of electricity that generate extremely-low frequency electromagnetic field (ELF EMF).

Scientific basis for our common concerns

Numerous recent scientific publications have shown that EMF affects living organisms at levels well below most international and national guidelines. Effects include increased cancer risk, cellular stress, increase in harmful free radicals, genetic damages, structural and functional changes of the reproductive system, learning and memory deficits, neurological disorders, and negative impacts on general well-being in humans. Damage goes well beyond the human race, as there is growing evidence of harmful effects to both plant and animal life.

These findings justify our appeal to the United Nations (UN) and, all member States in the world, to encourage the World Health Organization (WHO) to exert strong leadership in fostering the development of more protective EMF guidelines, encouraging precautionary measures, and educating the public about health risks, particularly risk to children and fetal development. By not taking action, the WHO is failing to fulfill its role as the preeminent international public health agency.

Inadequate non-ionizing EMF international guidelines

The various agencies setting safety standards have failed to impose sufficient guidelines to protect the general public, particularly children who are more vulnerable to the effects of EMF. The International

EXHIBIT

AB 4/2/18
FENGAD 800-631-6989

Commission on Non-Ionizing Radiation Protection (ICNIRP) established in 1998 the "Guidelines For Limiting Exposure To Time-Varying Electric, Magnetic, and Electromagnetic Fields (up to 300 GHz)"[1]. These guidelines are accepted by the WHO and numerous countries around the world. The WHO is calling for all nations to adopt the ICNIRP guidelines to encourage international harmonization of standards. In 2009, the ICNIRP released a statement saying that it was reaffirming its 1998 guidelines, as in their opinion, the scientific literature published since that time "has provided no evidence of any adverse effects below the basic restrictions and does not necessitate an immediate revision of its guidance on limiting exposure to high frequency electromagnetic fields[2]. ICNIRP continues to the present day to make these assertions, in spite of growing scientific evidence to the contrary. It is our opinion that, because the ICNIRP guidelines do not cover long-term exposure and low-intensity effects, they are insufficient to protect public health.

The WHO adopted the International Agency for Research on Cancer (IARC) classification of extremely low frequency electromagnetic field (ELF EMF) in 2002[3] and radiofrequency radiation (RFR) in 2011[4]. This classification states that EMF is a *possible human carcinogen (Group 2B).* Despite both IARC findings, the WHO continues to maintain that there is insufficient evidence to justify lowering these quantitative exposure limits.

Since there is controversy about a rationale for setting standards to avoid adverse health effects, we recommend that the United Nations Environmental Programme (UNEP) convene and fund an independent multidisciplinary committee to explore the pros and cons of alternatives to current practices that could substantially lower human exposures to RF and ELF fields. The deliberations of this group should be conducted in a transparent and impartial way. Although it is essential that industry be involved and cooperate in this process, industry should not be allowed to bias its processes or conclusions. This group should provide their analysis to the UN and the WHO to guide precautionary action.

Collectively we also request that:

1. children and pregnant women be protected;
2. guidelines and regulatory standards be strengthened;
3. manufacturers be encouraged to develop safer technology;
4. utilities responsible for the generation, transmission, distribution, and monitoring of electricity maintain adequate power quality and ensure proper electrical wiring to minimize harmful ground current;
5. the public be fully informed about the potential health risks from electromagnetic energy and taught harm reduction strategies;
6. medical professionals be educated about the biological effects of electromagnetic energy and be provided training on treatment of patients with electromagnetic sensitivity;
7. governments fund training and research on electromagnetic fields and health that is independent of industry and mandate industry cooperation with researchers;
8. media disclose experts' financial relationships with industry when citing their opinions regarding health and safety aspects of EMF-emitting technologies; and
9. white-zones (radiation-free areas) be established.

Appendix – Survey of Consumer Attitudes

Endnotes

Chapter One: The Corrupted Network

Renee Sharp seemed proud to discuss her spring 2014 meeting with the Federal Communications Commission.

As research director for the non-profit Environmental Working Group, Sharp doesn't get many chances to visit with the FCC. But on this occasion she was able to express her concerns that lax FCC standards on radiation from wireless technologies were especially hazardous for children.

The FCC, however, should have little trouble dismissing those concerns.

Arguing that current standards are more than sufficient and that children are at no elevated risk from microwave radiation, wireless industry lobbyists don't generally have to set up appointments months in advance. They are at the FCC's door night and day.

Indeed, a former executive with the Cellular Telecommunications Industry Association (CTIA), the industry's main lobbying group, has boasted that the CTIA meets with FCC officials "500 times a year."[1]

Sharp does not seem surprised. "There's no question that the government has been under the influence of industry. The FCC is a captured agency," she said.[2]

Captured agency.

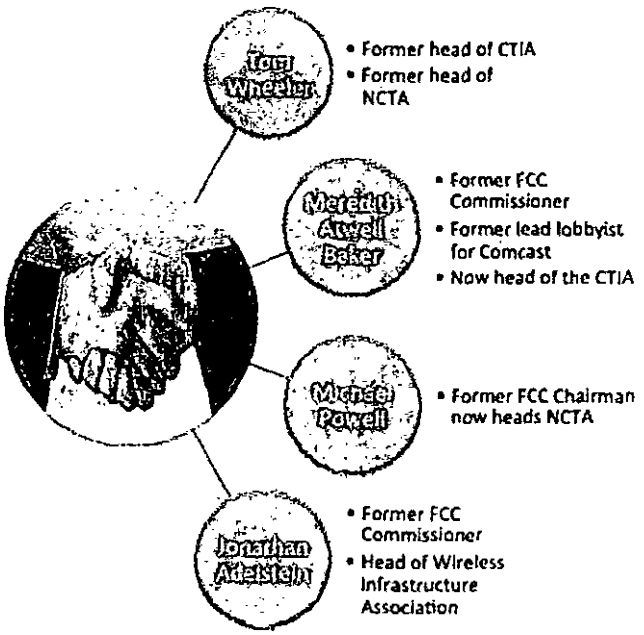
That's a term that comes up time and time again with the FCC. Captured agencies are essentially controlled by the industries they are supposed to regulate. A detailed look at FCC actions—and non-actions—shows that over the years the FCC has granted the wireless industry pretty much what it has wanted. Until very recently it has also granted cable what it wants. More broadly, the FCC has again and again echoed the lobbying points of major technology interests.

Money—and lots of it—has played a part. The National Cable and Telecommunications Association (NCTA) and CTIA have annually been among Washington's top lobbying spenders. CTIA alone lobbied on at least 35 different Congressional bills through the first half of 2014. Wireless market leaders AT&T and Verizon work through CTIA. But they also do their own lobbying, spending nearly $15 million through June of 2014, according to data from the Center for Responsive Politics (CRP). In all, CTIA, Verizon, AT&T, T-Mobile USA, and Sprint spent roughly $45 million lobbying in 2013. Overall, the Communications/Electronics sector is one of Washington's super heavyweight lobbyists, spending nearly $800 million in 2013-2014, according to CRP data.

But direct lobbying by industry is just one of many worms in a rotting apple. The FCC sits at the core of a network that has allowed powerful moneyed interests with limitless access a variety of ways to shape its policies, often at the expense of fundamental public interests.

As a result, consumer safety, health, and privacy, along with consumer wallets, have all been overlooked, sacrificed, or raided due to unchecked industry influence. The cable industry has consolidated into giant local monopolies that control pricing while leaving consumers little choice over content selection. Though the FCC has only partial responsibility, federal regulators have allowed the Internet to grow into a vast hunting grounds for criminals and commercial interests: the go-to destination for the surrender of personal information, privacy and identity. Most insidious of all, the wireless industry has been allowed to grow unchecked and virtually unregulated, with fundamental questions on public health impact routinely ignored.

Industry controls the FCC through a soup-to-nuts stranglehold that extends from its well-placed campaign spending in Congress through its control of the FCC's Congressional oversight committees to its persistent agency lobbying. "If you're on a committee that regulates industry you'll be a major target for industry," said Twaun Samuel, chief of staff for Congresswoman Maxine Waters.[3] Samuel several years ago helped write a bill aimed at slowing the revolving door. But with Congress getting its marching orders from industry, the bill never gained any traction.



Industry control, in the case of wireless health issues, extends beyond Congress and regulators to basic scientific research. And in an obvious echo of the hardball tactics of the tobacco industry, the wireless industry has backed up its economic and political power by stonewalling on public relations and bullying potential threats into submission with its huge standing army of lawyers. In this way, a coddled wireless industry intimidated and silenced the City of San Francisco, while running roughshod over local opponents of its expansionary infrastructure.

On a personal level, the entire system is greased by the free flow of executive leadership between the FCC and the industries it presumably oversees. Currently presiding over the FCC is Tom Wheeler, a man who has led the two most powerful industry lobbying groups: CTIA and NCTA. It is Wheeler who once supervised a $25 million industry-funded research effort on wireless health effects. But when handpicked research leader George Carlo concluded that wireless radiation did raise the risk of brain tumors, Wheeler's CTIA allegedly rushed to muffle the message. "You do the science. I'll take care of the politics," Carlo recalls Wheeler saying.[4]

Wheeler over time has proved a masterful politician. President Obama overlooked Wheeler's lobbyist past to nominate him as FCC chairman in 2013. He had, after all, raised more than $700,000 for Obama's presidential campaigns. Wheeler had little trouble earning confirmation from a Senate whose Democrats toed the Presidential line and whose Republicans understood Wheeler was as industry-friendly a nominee as they could get. And while Wheeler, at the behest of his Presidential sponsor, has taken on cable giants with his plans for net neutrality and shown some openness on other issues, he has dug in his heels on wireless.

Newly ensconced as chairman of the agency he once blitzed with partisan pitches, Wheeler sees familiar faces heading the industry lobbying groups that ceaselessly petition the FCC. At CTIA, which now calls itself CTIA - The Wireless Association, former FCC commissioner Meredith Atwell Baker is in charge.

Wireless and Cable Industries Have the FCC Covered

And while cell phone manufacturers like Apple and Samsung, along with wireless service behemoths like Verizon and AT&T, are prominent CTIA members, the infrastructure of 300,000 or more cellular base stations and antenna sites has its own lobbying group: PCIA, the Wireless Infrastructure Association. The President and CEO of PCIA is Jonathan Adelstein, another former FCC commissioner. Meanwhile, the cable industry's NCTA employs former FCC chairman Michael Powell as its president and CEO. Cozy, isn't it?

FCC commissioners in 2014 received invitations to the Wireless Foundation's May 19th Achievement Awards Dinner. Sounds harmless, but for the fact that the chief honoree at the dinner was none other than former wireless lobbyist but current FCC Chairman Tom Wheeler. Is this the man who will act to look impartially at the growing body of evidence pointing to health and safety issues?

The revolving door also reinforces the clout at another node on the industry-controlled influence network. Members of congressional oversight committees are prime targets of

industry. The cable industry, for example, knows that key legislation must move through the Communications and Technology Subcommittee of the House Energy and Commerce Committee. Little wonder then that subcommittee chairman Greg Walden was the second leading recipient (after Speaker John Boehner) of cable industry contributions in the last six years (through June 30, 2014). In all, Walden, an Oregon Republican, has taken over $108,000 from cable and satellite production and distribution companies.[5] But he is not alone. Six of the top ten recipients of cable and satellite contributions sit on the industry's House oversight committee. The same is true of senators on the cable oversight committee. Committee members were six of the ten top recipients of campaign cash from the industry.[6]

Cable & Satellite Campaign Contributions

Top House Recipients Funded

Recipient	Amount
John A. Boehner	$135,425
Greg Walden	$108,750
Bob Goodlatte	$93,200
John Conyers Jr.	$84,000
Mike Coffman	$82,137
Fred Upton	$73,500
Lee Terry	$65,916
Henry A. Waxman	$65,000
Cory Gardner	$64,500
Anna G. Eshoo	$60,500

Cellular Industry Campaign Contributions

Top House Recipients Funded

Recipient	Amount
Henry A. Waxman	**$41,500**
Scott H. Peters	$40,300
Greg Walden	**$35,750**
Fred Upton	**$32,250**
Bob Goodlatte	$31,250
Lee Terry	**$29,600**
Anna G. Eshoo	**$27,000**
Doris O. Matsui	**$25,500**
John Shimkus	**$24,000**
Peter J. Roskam	$21,100

Cable & Satellite Campaign Contributions

Top Senate Recipients Funded

Recipient	Amount
Edward J. Markey	**$320,500**
Kirsten E. Gillibrand	$194,125
Mitch McConnell	$177,125
Harry Reid	$175,600
Charles E. Schumer	$175,450
Mark L. Pryor	**$172,950**
Michael F. Bennet	$159,000
Richard Blumenthal	**$148,800**
Claire McCaskill	**$138,185**
Mark Udall	$136,625

Cellular Industry Campaign Contributions

Top Senate Recipients Funded

Recipient	Amount
Edward J. Markey	**$155,150**
Mark R. Warner	$74,800
Harry Reid	$73,600
Mark L. Pryor	**$71,900**
Roy Blunt	**$57,400**
John McCain	$56,261
Charles E. Schumer	$53,300
Roger F. Wicker	$51,300
Barbara Boxer	$49,578
Kelly Ayotte	$43,333

The compromised FCC network goes well beyond the revolving door and congressional oversight committees. The Washington social scene is one where money sets the tone and throws the parties. A look at the recent calendar of one current FCC commissioner shows it would take very disciplined and almost saintly behavior on the part of government officials to resist the lure of lavishly catered dinners and cocktail events. To paraphrase iconic investigative journalist I.F. Stone, if you're going to work in Washington, bring your chastity belt.

All that free liquor, food and conviviality translates into the lobbyist's ultimate goal: access. "They have disproportionate access," notes former FCC commissioner Michael Copps. "When you are in a town where most people you see socially are in industry, you don't have to ascribe malevolent behavior to it," he added.[7]

Not malevolent in motive. But the results can be toxic. And blame does not lie solely at the feet of current commissioners. The FCC's problems predate Tom Wheeler and go back a long way.

Indeed, former Chairman Newton Minow, enduringly famous for his 1961 description of television as a "vast wasteland," recalls that industry manipulation of regulators was an issue even back then. "When I arrived, the FCC and the communications industry were both regarded as cesspools. Part of my job was to try to clean it up."[8]

More than 50 years later, the mess continues to pile up.

Chapter Two: Just Don't Bring Up Health

Perhaps the best example of how the FCC is tangled in a chain of corruption is the cell tower and antenna infrastructure that lies at the heart of the phenomenally successful wireless industry.

It all begins with passage of the Telecommunications Act of 1996, legislation once described by South Dakota Republican senator Larry Pressler as "the most lobbied bill in history." Late lobbying won the wireless industry enormous concessions from lawmakers, many of them major recipients of industry hard and soft dollar contributions. Congressional staffers who helped lobbyists write the new law did not go unrewarded. Thirteen of fifteen staffers later became lobbyists themselves.[9]

Section 332(c)(7)(B)(iv) of the Act remarkably—and that adverb seems inescapably best here—wrests zoning authority from local governments. Specifically, they cannot cite health concerns about the effects of tower radiation to deny tower licenses so long as the towers comply with FCC regulations.

Congress Silences Public

Section 332(c)(7)(B)(iv) of the Communications Act provides:

> **No State or local government or instrumentality thereof may regulate the placement, construction, and modification of personal wireless service facilities on the basis of the environmental effects of radio frequency emissions to the extent that such facilities comply with the Commission's regulations concerning such emissions.**

In preempting local zoning authority—along with the public's right to guard its own safety and health— Congress unleashed an orgy of infrastructure build-out. Emboldened by the government green light and the vast consumer appetite for wireless technology, industry has had a free hand in installing more than 300,000 sites. Church steeples, schoolyards, school rooftops, even trees can house these facilities.

Is there any reason to believe that the relatively low level radiofrequency emissions of these facilities constitute a public health threat? Certainly, cell phones themselves, held close to the head, have been the focus of most concern on RF emissions. Since the impact of RF diminishes with distance, industry advocates and many scientists dismiss the possibility that such structures pose health risks.

But it's not really that simple. A troubling body of evidence suggests exposure to even low emission levels at typical cellular frequencies between 300 MHz and 3 GHz can have a wide range of negative effects.

In a 2010 review of research on the biological effects of exposure to radiation from cell tower base stations, B. Blake Levitt and Henry Lai found that "some research does exist to warrant caution in infrastructure siting."[10] They summarized the results on one 2002 study that compared the health of 530 people living at various distances within 300 meters of cell towers with a control group living more than 300 meters away. "Results indicated increased symptoms and complaints the closer a person lived to a tower. At <10 m, symptoms included nausea, loss of appetite, visual disruptions, and difficulties in moving. Significant differences were observed up through 100 m for irritability, depressive tendencies, concentration difficulties, memory loss, dizziness, and lower libido."[11]

A 2007 study conducted in Egypt found similar results. Levitt and Lai report, "Headaches, memory changes, dizziness, tremors, depressive symptoms, and sleep disturbance were significantly higher among exposed inhabitants than controls."[12]

Beyond epidemiological studies, research on a wide range of living things raises further red flags. A 2013 study by the Indian scientists S. Sivani and D. Sudarsanam reports: "Based on current available literature, it is justified to conclude that RF-EMF [electro magnetic fields] radiation exposure can change neurotransmitter functions, blood-brain barrier, morphology, electrophysiology, cellular metabolism, calcium efflux, and gene and protein expression in certain types of cells even at lower intensities."[13]

The article goes on to detail the effects of mobile tower emissions on a wide range of living organisms: "Tops of trees tend to dry up when they directly face the cell tower antennas. . . . A study by the Centre for Environment and Vocational Studies of Punjab University noted that embryos of 50 eggs of house sparrows were damaged after being exposed to mobile tower radiation for 5-30 minutes. . . . In a study on cows and calves on the effects of exposure from mobile phone base stations, it was noted that 32% of calves developed nuclear cataracts, 3.6% severely."[14]

Does any of this constitute the conclusive evidence that would mandate much tighter control of the wireless infrastructure? Not in the estimation of industry and its captured agency. Citing other studies—often industry-funded—that fail to establish health effects, the wireless industry has dismissed such concerns. The FCC has typically echoed that position.

Keep in mind that light regulation has been one factor in the extraordinary growth of wireless—CTIA says exactly that in a Web post that credits the Clinton Administrations light regulatory touch.

July 25, 2013

CTIA BLOG

CTIA is an international nonprofit trade association that has represented the wireless communications industry since 1984.

But our position as the world's leader was no accident. It started with the Clinton Administration that had the foresight to place a "light regulatory touch" on the wireless industry, which was in its infancy at the time. That light touch has continued through multiple Administrations.

Obviously, cellular technology is wildly popular because it offers many benefits to consumers. But even allowing for that popularity and for the incomplete state of science, don't some of these findings raise enough concern to warrant some backtracking on the ham-fisted federal preemption of local zoning rights?

In reality, since the passage of the 1996 law, the very opposite has occurred. Again and again both Congress and the FCC have opted to stiffen—rather than loosen—federal preemption over local zoning authority. In 2009, for example, the wireless industry convinced the FCC to impose a "shot clock" that requires action within 90 days on many zoning applications. "My sense is that it was an industry request," said Robert Weller, who headed up the FCC's Office of Engineering and Technology when the shot clock was considered and imposed.[15]

And just last November, the FCC voted to further curb the rights of local zoning officials to control the expansion of antenna sites Again and again, Congress and the FCC have extended the wireless industry carte blanche to build out infrastructure no matter the consequences to local communities.

The question that hangs over all this: would consumers' embrace of cell phones and Wi-Fi be quite so ardent if the wireless industry, enabled by its Washington errand boys, hadn't so consistently stonewalled on evidence and substituted legal intimidation for honest inquiry? (See Appendix for online study of consumer attitudes on wireless health and safety.)

Document searches under the Freedom of Information Act reveal the central role of Tom Wheeler and the FCC in the tower siting issue. As both lobbyist and FCC chairman, Wheeler has proved himself a good friend of the wireless industry.

In January of 1997, CTIA chieftain Wheeler wrote FCC Wireless Telecommunications Bureau Chief Michele C. Farquhar citing several municipal efforts to assert control over siting. Wheeler, for example, asserted that one New England state had enacted a law requiring its Public Service Commissioner to issue a report on health risks posed by wireless facilities.[16] He

questions whether such a study—and regulations based on its results—would infringe on FCC preemption authority.

FCC bureau chief Farquhar hastily reassured Wheeler that no such study could be consulted in zoning decisions. "Therefore, based on the facts as you have presented them, that portion of the statute that directs the State Commissioner to recommend regulations based upon the study's findings would appear to be preempted,"[17] the FCC official wrote to Wheeler. She emphasized that the state had the right to do the study. It just couldn't deny a siting application based on anything it might learn.

The FCC in 1997 sent the message it has implicitly endorsed and conveyed ever since: study health effects all you want. It doesn't matter what you find. The build-out of wireless cannot be blocked or slowed by health issues.

Now let's fast forward to see Wheeler on the other side of the revolving door, interacting as FCC chairman with a former FCC commissioner who is now an industry lobbyist.

A March 14, 2014 letter[18] reveals the chummy relationship between Wheeler and former commissioner Jonathan Adelstein, now head of PCIA, the cellular infrastructure lobbying group. It also references FCC Chairman Wheeler seeking policy counsel from lobbyist Adelstein:

Wheeler Still Willing to Help

Subject: How to Spur Wireless Broadband Deployment

Tom – It was great to see you the other night at the FCBA event, and wonderful to see how much fun you're having (if that's the right word). I know I enjoyed my time there (thanks to your help with Daschle in getting me that role in the first place!).

Thanks for asking how we think the FCC can help spur wireless broadband deployment. The infrastructure proceeding perfectly tees up many of the top issues the FCC needs to address. As you requested, I've summarized briefly in the attached letter some of the key steps you can take now.

"Tom – It was great to see you the other night at the FCBA event, and wonderful to see how much fun you're having (if that's the right word). I know I enjoyed my time there (thanks to your help with Daschle in getting me that role in the first place!)."

"Thanks for asking how we think the FCC can help spur wireless broadband deployment," the wireless lobbyist writes to the ex-wireless lobbyist, now running the FCC.

Adelstein's first recommendation for FCC action: "*Amend its rules to categorically exclude DAS and small deployments* [Ed. note: these are compact tower add-ons currently being widely deployed] *from environmental and historic review.*" Adelstein outlined other suggestions for further limiting local antenna zoning authority and the FCC soon did its part. Late last year, the agency proposed new rules that largely (though not entirely) complied with the antenna industry's wish list.

James R. Hobson is an attorney who has represented municipalities in zoning issues involving the FCC. He is also a former FCC official, who is now of counsel at Best, Best and Krieger, a Washington-based municipal law practice. "The FCC has been the ally of industry," says Hobson. Lobbyist pressure at the FCC was intense even back in the 70s, when he was a bureau chief there. "When I was at the FCC, a lot of my day was taken up with appointments with industry lobbyists." He says of the CTIA that Wheeler once headed: "Their reason for being is promoting the wireless industry. And they've been successful at it."[19]

The FCC's deferential compliance has allowed industry to regularly bypass and if necessary steamroll local authorities. Violation of the FCC-imposed "shot clock," for example, allows the wireless license applicant to sue.

The FCC's service to the industry it is supposed to regulate is evidently appreciated. The CTIA web site, typically overflowing with self-congratulation, spreads the praise around in acknowledging the enabling contributions of a cooperative FCC. In one brief summation of its own glorious accomplishments, CTIA twice uses the word "thankfully" in describing favorable FCC actions.

In advancing the industry agenda, the FCC can claim that it is merely reflecting the will of Congress. But the agency may not be doing even that.

Remember the key clause in the 96 Telecom Act that disallowed denial of zoning permits based on health concerns? Well, federal preemption is granted to pretty much any wireless outfit on just one simple condition: its installations must comply with FCC radiation emission standards. In view of this generous carte blanche to move radiation equipment into neighborhoods, schoolyards and home rooftops, one would think the FCC would at the very least diligently enforce its own emission standards. But that does not appear to be the case.

Indeed, one RF engineer who has worked on more than 3,000 rooftop sites found vast evidence of non-compliance. Marvin Wessel estimates that "10 to 20% exceed allowed radiation standards."[20] With 30,000 rooftop antenna sites across the U.S. that would mean that as many as 6,000 are emitting radiation in violation of FCC standards. Often, these emissions can be 600% or more of allowed exposure levels, according to Wessel.

Antenna standards allow for higher exposure to workers. In the case of rooftop sites, such workers could be roofers, painters, testers and installers of heating and air conditioning

equipment, to cite just a few examples. But many sites, according to Wessel, emit radiation at much higher levels than those permitted in occupational standards. This is especially true of sites where service providers keep adding new antenna units to expand their coverage. "Some of these new sites will exceed ten times the allowable occupational radiation level," said Wessel.[21] Essentially, he adds, this means that nobody should be stepping on the roof.

"The FCC is not enforcing its own standard," noted Janet Newton, who runs the EMF Policy Institute, a Vermont-based non-profit. That group several years ago filed 101 complaints on specific rooftop sites where radiation emissions exceeded allowable levels. "We did this as an exercise to hold the FCC's feet to the fire," she said. But the 101 complaints resulted in few responsive actions, according to Newton.[22]

Former FCC official Bob Weller confirms the lax—perhaps negligible is the more appropriate word—FCC activity in enforcing antenna standards. "To my knowledge, the enforcement bureau has never done a targeted inspection effort around RF exposure," he said.[23] Budget cuts at the agency have hurt, limiting the FCC's ability to perform field inspections, he added. But enforcement, he adds, would do wonders to insure industry compliance with its limited regulatory compliance requirements. "If there were targeted enforcement and fines issued the industry would pay greater attention to ensuring compliance and self-regulation," he allowed.

Insurance is where the rubber hits the road on risk. So it is interesting to note that the rating agency A.M. Best, which advises insurers on risk, in 2013 topped its list of "emerging technology-based risks" with RF Radiation:

> *"The risks associated with long-term use of cell phones, although much studied over the past 10 years, remain unclear. Dangers to the estimated 250,000 workers per year who come in close contact with cell phone antennas, however, are now more clearly established. Thermal effects of the cellular antennas, which act at close range essentially as open microwave ovens can include eye damage, sterility and cognitive impairments. While workers of cellular companies are well trained on the potential dangers, other workers exposed to the antennas are often unaware of the health risks. The continued exponential growth of cellular towers will significantly increase exposure of these workers and others coming into close contact with high-energy cell phone antenna radiation,"* A.M. Best wrote.[24]

So what has the FCC done to tighten enforcement? Apparently, not very much. Though it does follow up on many of the complaints filed against sites alleged to be in violation of standards it takes punitive actions very rarely. (The FCC did not provide answers to written questions on details of its tower enforcement policies.)

The best ally of industry and the FCC on this (and other) issues may be public ignorance.

An online poll conducted for this project asked 202 respondents to rate the likelihood of a series of statements.[25] Most of the statements were subject to dispute. Cell phones raise the risk of certain health effects and brain cancer, two said. There is no proof that cell phones are harmful, another declared. But among the six statements there was one statement of indisputable fact: "The U.S. Congress forbids local communities from considering health effects when deciding whether to issue zoning permits for wireless antennae," the statement said.

Though this is a stone cold fact that the wireless industry, the FCC and the courts have all turned into hard and inescapable reality for local authorities, just 1.5% of all poll respondents replied that it was "definitely true."

Public ignorance didn't take much cultivation by the wireless industry on the issue of local zoning. And maybe it doesn't matter much, considering the enormous popularity of wireless devices. But let's see how public ignorance has been cultivated and secured—with the FCC's passive support—on the potentially more disruptive issue of mobile phone health effects.

Chapter Three: Wireless Bullies and the Tobacco Analogy

Issues of cable and net neutrality have recently attracted wide public attention (more on that in Chapter Six). Still, the bet here remains that future judgment of the FCC will hinge on its handling of wireless health and safety issues.

And while the tower siting issue is an egregious example of an industry-dominated political process run amuck, the stronger health risks appear to reside in the phones themselves. This is an issue that has flared up several times in recent years. Each time, industry has managed to beat back such concerns. But it's worth noting that the scientific roots of concern have not disappeared. If anything, they've thickened as new research substantiates older concerns.

The story of an FCC passively echoing an industry determined to play hardball with its critics is worth a further look. The CTIA's own website acknowledges the helpful hand of government's "light regulatory touch" in allowing the industry to grow.[26]

Former congressman Dennis Kucinich ventures one explanation for the wireless industry's success in dodging regulation: "The industry has grown so fast its growth has overtaken any health concerns that may have gained attention in a slow growth environment. The proliferation of technology has overwhelmed all institutions that would have attempted safety testing and standards," Kucinich said.[27]

But the core questions remain: Is there really credible evidence that cell phones emit harmful radiation that can cause human health problems and disease? Has the FCC done an adequate job in protecting consumers from health risks? Or has it simply aped industry stonewalling on health and safety issues?

Before wading into these questions, some perspective is in order.

First, there's simply no denying the usefulness and immense popularity of wireless technology. People depend on it for safety, information, entertainment and communication. It doesn't take a keen social observer to know that wireless has thoroughly insinuated itself into daily life and culture.

The unanswered question, though, is whether consumers would embrace the technology quite so fervently if health and safety information was not spun, filtered and clouded by a variety of industry tactics.

To gain some insight into this question, we conducted an online survey of 202 respondents, nearly all of whom own cell phones, on Amazon's Mechanical Turk Web platform (see Appendix). One striking set of findings: many respondents claim they would change behavior—reduce wireless use, restore landline service, protect their children—if claims on health dangers of wireless are true.

It is not the purpose of this reporter to establish that heavy cell phone usage is dangerous. This remains an extremely controversial scientific issue with new findings and revised scientific conclusions repeatedly popping up. Just months ago, a German scientist who had been outspoken in denouncing the view that cell phones pose health risks reversed course. In an April 2015 publication, Alexander Lerchl reported results confirming previous research on the tumor-promoting effects of electromagnetic fields well below human exposure limits for mobile phones. "Our findings may help to understand the repeatedly reported increased incidences of brain tumors in heavy users of mobile phones," the Lerchl team concluded.[28] And in May 2015, more than 200 scientists boasting over 2,000 publications on wireless effects called on global institutions to address the health risks posed by this technology.

But the National Cancer Institute still contends that no cell phone dangers have been established. A representative of NCI was the sole known dissenter among the 30 members of the World Health Organization's International Agency for Research on Cancer (IARC) when it voted to declare wireless RF "possibly carcinogenic."[29] If leading scientists still can't agree, I will not presume to reach a scientific conclusion on my own.

PRESS RELEASE
N° 208

31 May 2011

IARC CLASSIFIES RADIOFREQUENCY ELECTROMAGNETIC FIELDS AS POSSIBLY CARCINOGENIC TO HUMANS

Lyon, France, May 31, 2011 -- The WHO/International Agency for Research on Cancer (IARC) has classified radiofrequency electromagnetic fields as **possibly carcinogenic to humans (Group 2B)**, based on an increased risk for **glioma**, a malignant type of brain cancer, associated with wireless phone use.

But let's at least look at some of the incriminating clues that health and biology research has revealed to date. And let's look at the responses of both industry and the FCC.

The most widely cited evidence implicating wireless phones concerns gliomas, a very serious type of brain tumor. The evidence of elevated risk for such tumors among heavy cell phone users comes from several sources.

Gliomas account for roughly half of all malignant brain tumors, which are relatively rare. The annual incidence of primary malignant brain tumors in the U.S. is only 8.2 per 100,000 people, according to the International Radio Surgery Association.

Still, when projected over the entire U.S. population, the public health impact is potentially very significant.

Assuming roughly four new glioma cases annually in the U.S. per 100,000 people, yields over 13,000 new cases per year over a total U.S. population of 330 million. Even a doubling of that rate would mean 13,000 new gliomas, often deadly, per year. A tripling, as some studies have found, could mean as many as 26,000 more new cases annually. Indeed, the respected online site Medscape in January 2015 reported results of Swedish research under the headline: *Risk for Glioma Triples With Long-Term Cell Phone Use.*[30]

And here's some eye-opening quantitative perspective: the wars in Iraq and Afghanistan, waged now for more than a decade each, have together resulted in roughly 7,000 U.S. deaths.

Preliminary—though still inconclusive—research has suggested other potential negative health effects. Swedish, Danish and Israeli scientists have all found elevated risk of salivary gland tumors. One Israeli studied suggested elevated thyroid cancer risk. Some research has found that men who carry their phones in their pockets may suffer sperm count damage. One small study even suggests that young women who carry wireless devices in their bras are unusually vulnerable to breast cancer.

And while industry and government have never accepted that some portion of the population is unusually sensitive to electromagnetic fields, many people continue to complain of a broad range of symptoms that include general weakness, headaches, nausea and dizziness from exposure to wireless.

Some have suggested that the health situation with wireless is analogous to that of tobacco before court decisions finally forced Big Tobacco to admit guilt and pay up. In some ways, the analogy is unfair. Wireless research is not as conclusively incriminating as tobacco research was. And the identified health risks with wireless, significant as they are, still pale compared with those of tobacco.

But let's not dismiss the analogy outright. There is actually a very significant sense in which the tobacco-wireless analogy is uncannily valid.

People tend to forget that the tobacco industry—like the wireless industry—also adopted a policy of tone-deaf denial. As recently as 1998, even as evidence of tobacco toxicity grew overwhelming, cigarette maker Phillip Morris was writing newspaper advertorials insisting there was no proof smoking caused cancer.

It seems significant that the responses of wireless and its captured agency—the FCC—feature the same obtuse refusal to examine the evidence. The wireless industry reaction features stonewalling public relations and hyper aggressive legal action. It can also involve undermining the credibility and cutting off the funding for researchers who do not endorse cellular safety. It is these hardball tactics that look a lot like 20th century Big Tobacco tactics. It is these hardball tactics—along with consistently supportive FCC policies—that heighten suspicion the wireless industry does indeed have something to hide.

Begin with some simple facts issuing from meta-analysis of cellular research. Dr. Henry Lai, emeritus professor of bioengineering at the University of Washington, has reviewed hundreds of published scientific papers on the subject. He wanted to see how many studies demonstrated that non-ionizing radiation produces biological effects beyond the heating of tissue. This is critical since the FCC emission standards protect only against heating. The assumption behind these standards is that there are no biological effects beyond heating.

But Dr. Lai found that just over half—actually 56%—of 326 studies identified biological effects. And the results were far more striking when Dr. Lai divided the studies between those that were industry-funded and those that were independently funded. Industry-funded research identified biological effects in just 28% of studies. But fully 67% of non-industry funded studies found biological effects (Insert Slide—Cell Phone Biological Studies).

A study conducted by Swiss and British scientists also looked at how funding sources affected scientific conclusions on the possible health effects of cell phone usage. They found that of studies privately funded, publicly funded and funded with mixed sponsorship, industry-funded studies were "least likely to report a statistically significant result."[31] "The interpretation of results from studies of health effects of radiofrequency radiation should take sponsorship into account," the scientists concluded.[32]

So how does the FCC handle a scientific split that seems to suggest bias in industry-sponsored research?

In a posting on its Web site that reads like it was written by wireless lobbyists, the FCC chooses strikingly patronizing language to slight and trivialize the many scientists and health and safety experts who've found cause for concern. In a two page Web post titled "Wireless Devices and Health Concerns," the FCC four times refers to either "some health and safety interest groups," "some parties," or "some consumers" before in each case rebutting their presumably groundless concerns about wireless risk.[33] Additionally, the FCC site references the World Health Organization as among those organizations who've found that "the weight of scientific

evidence" has not linked exposure to radiofrequency from mobile devices with "any known health problems."

Yes, it's true that the World Health organization remains bitterly divided on the subject. But it's also true that a 30 member unit of the WHO called the International Agency for Research on Cancer (IARC) was near unanimous in pronouncing cell phones "possibly carcinogenic" in 2011. How can the FCC omit any reference to such a pronouncement? Even if it finds reason to side with pro-industry scientists, shouldn't this government agency also mention that cell phones are currently in the same potential carcinogen class as lead paint?

Now let's look a bit more closely at the troublesome but presumably clueless crowd of "some parties" that the FCC so cavalierly hastens to dismiss? Let's begin with **Lennart Hardell**, professor of Oncology and Cancer Epidemiology at the University Hospital in Oreboro, Sweden.

Until recently it was impossible to gain any real sense of brain tumor risk from wireless since brain tumors often take 20 or more years to develop. But the cohort of long-term users has been growing. In a study published in the International Journal of Oncology in 2013, Dr. Hardell and Dr. Michael Carlberg found that the risk of glioma—the most deadly type of brain cancer—rose with cell phone usage. The risk was highest among heavy cell phone users and those who began to use cell phones before the age of 20.[34]

Indeed, those who used their phones at least 1640 hours (which would be roughly 30 minutes a day for nine years) had nearly three times the glioma incidence. Drs. Hardell and Carlberg also found that gliomas tend to be more deadly among heavy wireless callers.[35]

Perhaps of greatest long-term relevance, glioma risk was found to be four times higher among those who began to use mobile phones as teenagers or earlier. These findings, along with the established fact that it generally takes decades for tumors induced by environmental agents to appear, suggest that the worst consequences of omnipresent wireless devices have yet to be seen.

In a 2013 paper published in *Reviews on Environmental Health*, Drs. Hardell and Carlberg argued that the 2011 finding of the IARC that identified cell phones as a "possibly carcinogenic" needs to be revised. The conclusion on radiofrequency electromagnetic fields from cell phones should now be "cell phones are not just a possible carcinogen." They can now be "regarded as carcinogenic to humans" and the direct cause of gliomas (as well as acoustic neuromas, a less serious type of tumor).[36] Of course, these views are not universally accepted.

The usual spin among industry supporters when presented with research that produces troubling results is along the lines of: "We might pay attention if the results are duplicated." In fact, the Hardell results were echoed in the French CERENAT study, reported in May of 2014. The CERENAT study also found higher risk among heavy users, defined as those using their phones at least 896 hours (just 30 minutes a day for five years). "These additional data support

previous findings concerning a possible association between heavy mobile phone use and brain tumors," the study concluded.[37]

Cell phones are not the only wireless suspects. Asked what he would do if he had policy-making authority, Dr. Hardell swiftly replied that he would "ban wireless use in schools and pre-schools. You don't need Wi-Fi," he noted.[38] This is especially interesting in view of the FCC's sharply hiked spending to promote and extend Wi-Fi usage, as well as its consistent refusal to set more stringent standards for children (more on all this later). But for now let's further fill out the roster of the FCC's unnamed "some parties."

Martin Blank is a Special Lecturer in Physiology and Cellular Biophysics at Columbia University. Unlike Dr. Hardell, who looks at broad epidemiological effects over time, Dr. Blank sees cause for concern in research showing there is biological response at the cellular level to the type of radiation emitted by wireless devices. "The biology tells you unequivocally that the cell treats radiation as a potentially damaging influence," Dr. Blank said in a late 2014 interview.[39]

"The biology tells you it's dangerous at a low level," he added. Though some results have been difficult to replicate, researchers have identified a wide range of cellular responses including genetic damage and penetration of the blood brain barrier. Dr. Blank specifically cited the "cellular stress response" in which cells exposed to radiation start to make proteins.

It is still not clear whether biological responses at the cellular level translate into human health effects. But the research seems to invalidate the basic premise of FCC standards that the only biological effect of the type of radiation produced by wireless devices is tissue heating at very high power levels. But the standards-setting agencies "ignore the biology," according to Dr. Blank. He describes the FCC as being "in industry's pocket."[40]

Sweden's Lund University is annually ranked among the top 100 universities in the world. **Leif Salford** has been chairman of the Department of Neurosurgery at Lund since 1996. He is also a former president of the European Association for Neuro-Oncology. In the spring of 2000, Professor Salford told me that wireless usage constituted "the world's largest biological experiment ever."[41]

He has conducted numerous experiments exposing rats to cellular-type radiation. Individual experiments have shown the radiation to penetrate the blood-brain barrier, essential to protecting the brain from bloodstream toxins. Professor Salford also found that rats exposed to radiation suffered loss of brain cells. "A rat's brain is very much the same as a human's. They have the same blood-brain barrier and neurons. We have good reason to believe that what happens in rat's brains also happens in humans," he told the BBC in 2003. Dr. Salford has also speculated that mobile radiation could trigger Alzheimer's disease in some cases but emphasized that much more research would be needed to establish any such causal relationship. Does this man deserve to be dismissed as one of a nameless and discredited group of "some parties?"

And what about the **American Academy of Pediatrics (AAP),** which represents 60,000 American doctors who care for children? In a December 12, 2012 letter to former Ohio Congressman Dennis Kucinich, AAP President Dr. Thomas McInerny writes: "Children are disproportionately affected by environmental exposures, including cell phone radiation. The differences in bone density and the amount of fluid in a child's brain compared to an adult's brain could allow children to absorb greater quantities of RF energy deeper into their brains than adults."[42]

In a subsequent letter to FCC officials dated August 29, 2013, Dr. McInerny points out that "children, however, are not little adults and are disproportionately impacted by all environmental exposures, including cell phone radiation." Current FCC exposure standards, set back in 1996, "do not account for the unique vulnerability and use patterns specific to pregnant women and children," he wrote. (Insert slide: A Plea from Pediatricians). Does an organization representing 60,000 practitioners who care for children deserve to be brushed off along with "some health and safety interest groups?"

So what is the FCC doing in response to what at the very least is a troubling chain of clues to cellular danger? As it has done with wireless infrastructure, the FCC has to this point largely relied on industry "self-regulation." Though it set standards for device radiation emissions back in 1996, the agency doesn't generally test devices itself. Despite its responsibility for the safety of cell phones, the FCC relies on manufacturers' good-faith efforts to test them. Critics contend that this has allowed manufacturers undue latitude in testing their devices.

Critics further contend that current standards, in place since cell phones were barely in use, are far too lax and do not reflect the heavy usage patterns that have evolved. Worse still, industry is allowed to test its own devices using an imprecise system that makes no special provision for protecting children and pregnant women. One 2012 study noted that the procedure widely used by manufacturers to test their phones "substantially underestimates" the amount of RF energy absorbed by 97% of the population, "especially children." A child's head can absorb over two times as much RF energy. Other persons with smaller heads, including women, are also more vulnerable. The authors recommend an alternative computer simulation technique that would provide greater insight into the impact of cellular radiation on children and on to the specific RF absorption rates of different tissues, which vary greatly.[43]

Acting on recommendations of the General Accounting Office, the FCC is now reconsidering its standards for wireless testing and allowed emissions. On the surface, this may seem to represent an effort to tighten standards to promote consumer health and safety. But many believe the FCC's eventual new standard will actually be weaker, intensifying any health risk from industry's self-reported emission levels. "They're under great pressure from industry to loosen the criteria," notes Joel Moskowitz, director of the Center for Family and Community Health at UC Berkeley's School of Public Health.[44] One fear is that the FCC could measure the allowed radiation absorption level (SAR) over a wider sample of tissue, effectively loosening the

standard allowable energy absorption. One FCC official, who asked that his name not be used, contended that a decision had not yet been made to loosen the standard.

But to this point, there is little evidence the FCC is listening to anyone beyond its familiar friends in the wireless industry. Carl Blackman, a scientist at the Environmental Protection agency until retiring in 2014, notes that the FCC does rely to some degree on an inter-agency governmental group for advice on health matters. The group includes, for example, representatives from the EPA and the FDA.

Blackman served on that advisory group and he says that it has been divided. Though some government advisers to the FCC find evidence of wireless health risks convincing, others remain skeptical, said Blackman. Root of the skepticism: even though numerous researchers have found biological and health effects, the mechanism for action by non-ionizing radiation on the human body has still not been identified. "I don't think there's enough of a consensus within the Radio Frequency Inter-agency Working Group for them to come out with stricter standards," he says.[45]

But political pressures also figure mightily in all this. The EPA, notably, was once a hub of research on RF effects, employing as many as 35 scientists. However, the research program was cut off in the late 80s during the Regan presidency. Blackman says he was personally "forbidden" to study health effects by his "supervisory structure."[46] He termed it "a political decision" but recognized that if he wanted to continue to work at the EPA he would have to do research in another area.

Blackman is cautious in imputing motives to the high government officials who wanted his work at EPA stopped. But he does say that political pressure has been a factor at both the EPA and FCC: "The FCC people were quite responsive to the biological point of view. But there are also pressures on the FCC from industry." The FCC, he suggests, may not just be looking at the scientific evidence "The FCC's position—like the EPA's—is influenced by political considerations as well."[47]

Still, the FCC has ultimate regulatory responsibility and cannot indefinitely pass the buck on an issue of fundamental public health. Remarkably, it has not changed course despite the IARC classification of cell phones as possibly carcinogenic, despite the recent studies showing triple the glioma risk for heavy users, despite the floodtide of research showing biological effects, and despite even the recent defection of core industry booster Alex Lerchl. It is the refusal of both industry and the FCC to even acknowledge this cascade of warning signs that seems most incriminating.

Of course, industry behavior goes well beyond pushing for the FCC's willful ignorance and inaction. Industry behavior also includes self-serving public relations and hyper aggressive legal action. It can also involve undermining the credibility of and cutting off the funding for researchers who do not endorse cellular safety. It is these hardball tactics that recall 20th century Big Tobacco tactics. It is these tactics that heighten suspicion that the wireless industry does

indeed have a dirty secret. And it is those tactics that intensify the spotlight on an FCC that so timidly follows the script of the fabulously wealthy, bullying, billion-dollar beneficiaries of wireless.

Chapter Four: You Don't Need Wires To Tie People Up

So let's look a little more deeply at some of the actions of an industry group that boasts of 500 meetings a year with the FCC. Lobbying is one thing. Intimidation is another. CTIA has shown its skill at—and willingness to use—both.

Outright legal bullying is a favored tactic. The City of San Francisco passed an ordinance in 2010 that required cell phone manufacturers to display more prominently information on the emissions from their devices. This information was already disclosed—but often buried—in operator manuals and on manufacturer websites. The idea was to ensure that consumers saw information already mandated and provided.

Seeing this as a threat to its floodtide of business, the industry sued the City of San Francisco. The City, fearing a prolonged legal fight with an industry that generates hundreds of billions of dollars in annual revenue, backed down.

On May 12, 2015, Berkeley, California's City Council unanimously passed a similar ordinance. Joel Moskowitz, director of the Center for Family and Community Health at the University of California-Berkeley's School of Public Health, has been involved in the effort. Berkeley, he says, didn't want to run into the same legal threats that paralyzed San Francisco. So it tried to draft the most inoffensive and mild language possible. The proposed Cell Phone Right to Know ordinance: "To assure safety, the Federal Government requires that cell phones meet radio frequency (RF) exposure guidelines. If you carry or use your phone in a pants or shirt pocket or tucked into a bra when the phone is ON and connected to a wireless network, you may exceed the federal guidelines for exposure to RF radiation. This potential risk is greater for children. Refer to the instructions in your phone or user manual for information about how to use your phone safely."[48]

Sounds pretty inoffensive, no? Not to the CTIA, which indicated that it was prepared to sue, according to Berkeley City Attorney Zach Cowan.[49] (On June 8th, CTIA did indeed sue the City of Berkeley.)

Well, from the industry point of view, why not throw around your weight? Smash mouth legal tactics have been highly successful thus far as industry has managed to throttle several efforts to implicate manufacturers in cases where heavy users suffered brain tumors.

But one current case has advanced in district court in Washington to the point where the judge allowed plaintiffs to present expert witness testimony. The industry response: file a legal action seeking to invalidate long-held court methods for qualifying expert witnesses.

This is a very rich industry that does not hesitate to outspend and bully challengers into submission. Meanwhile, amidst the legal smoke and medical confusion, the industry has

managed to make the entire world dependent on its products. Even tobacco never had so many hooked users.

Such sustained success in the face of medical doubt has required industry to keep a lid on critics and detractors. Many scientists who've found real or potential risk from the sort of microwave radiation emanating from wireless devices have learned there is a price to be paid for standing up to the industry juggernaut. A few prominent examples:

--

In 1994, University of Washington researchers Henry Lai and N.P. Singh found that rats exposed to microwave radiation suffered DNA damage to their brain cells. This was a scary finding since DNA damage can lead to mutations and possibly cancer.

The reaction from industry was swift. Motorola was at that time the U.S. market leader in cell phones. In a memorandum obtained by the journal Microwave News, Motorola PR honcho Norm Sandler outlined how the company could "downplay the significance of the Lai study." One step: "We have developed a list of independent experts in this field and are in the process of recruiting individuals willing and able to reassure the public on these matters," Sandler wrote. After outlining such measures, he concluded that Motorola had "sufficiently war-gamed" the issue. The practices of lining up industry-friendly testimony and "war-gaming" researchers who come up with unfavorable results have been persistent themes with this industry.

Motorola "War-Games" Bad News

Motorola, Microwaves and DNA Breaks: "War-Gaming" the Lai-Singh Experiments

"We have developed a list of independent experts in this field and are in the process of recruiting individuals willing and able to reassure the public on these matters."

"I think we have sufficiently war-gamed the Lai-Singh issue..."

--

After Lai's results were published, Motorola decided to sponsor further research on microwaves and DNA damage. Oftentimes, lab results cannot be reproduced by other

researchers, particularly if experiments are tweaked and performed a bit differently. Non-confirming studies raise doubt, of course, on the original work.

Motorola lined up Jerry Phillips, a scientist at the Veteran's Administration Medical Center in Loma Linda, California, and Phillips tested the effect of radiation at different frequencies from those tested by Lai and Singh. Nevertheless, Phillips found that at some levels of exposure, DNA damage increased, while at other levels it decreased. Such findings were "consistent" with the sorts of effects produced by chemical agents, Phillips said in an interview.[50] In some cases, the radiation may have activated DNA repair mechanisms, reducing the overall microwave effect. But what was important, Phillips explained, is that there were *any* biological effects at all. The wireless industry has long contended—and the FCC has agreed—that there is no evidence that non-ionizing radiation at the frequencies and power levels used by cell phones is biologically active.

Understanding the potential impact of "biological effect" findings, Motorola again turned to damage control, said Phillips. He recalls receiving a phone call from a Motorola R&D executive. "I don't think you've done enough research,'" Phillips recalls being told. The study wasn't ready for publication, according to the Motorola executive. Phillips was offered more money to do further research without publishing the results of what he'd done.

But Phillips felt he'd done enough. Despite warnings for his own boss to "give Motorola what it wants," Phillips went ahead and published his findings in 1998. Since then, Phillips' industry funding has dried up. Meanwhile, as many other researchers report, government funding to do independent research on microwave radiation has dried up, leaving the field at least in the U.S. to industry-funded scientists. "There is no money to do the research," Said Phillips. "It's not going to come from government because government is controlled by industry."[51]

--

Om P. Gandhi is Professor of Electrical and Computer Engineering at the University of Utah and a leading expert in dosimetry—measurement of non-ionizing radiation absorbed by the human body. Even before cell phones were in wide use, Professor Gandhi had concluded that children absorb more emitted microwave radiation. "The concentration of absorbed energy is 50 to 80% greater," he explained.[52]

These conclusions were not acceptable to Professor Gandhi's industrial sponsors. In 1998, he recalls, an executive from a cell phone manufacturer—which he did not want to identify—told him directly that if he did not discontinue his research on children his funding would be cut off. Professor Gandhi recalled replying: "I will not stop. I am a tenured professor at the University of Utah and I will not reject my academic freedom." Professor Gandhi also recalled some of his thought process: "I wasn't going to order my students to alter their results so that I can get funding." His industry sponsors cancelled his contract and asked for a return of funds.

Professor Gandhi believes that some cell phone users require extra protection because their heads are smaller and more absorptive. "Children, as well as women and other individuals with smaller heads absorb more concentrated energy because of the proximity of the radiating antenna to the brain tissue," he said. And yet the FCC has not acted to provide special protection for these groups. Asked why not, Professor Gandhi conceded that he doesn't know. He does note, however, that recent standards-setting has been dominated by industry representatives.[53]

--

While the mobile industry refuses to admit to even the possibility that there is danger in RF radiation, giant insurance companies see things differently. Several insurers have in recent years issued reports highlighting product liability risk with cell phones. This is important because it is evidence that where money is on the line professionals outside the industry see the risk of legal liability.

Legal exposure could be one reason—perhaps the central one—the industry continues to stonewall. Should legal liability be established, one key question will be how much wireless executives knew—and at what point in time. Meanwhile, the combination of public relations denials, legal intimidation and the selective application of pressure on research follows a familiar pattern. "The industry is basically using the tobacco industry playbook," UC Berkeley's Moskowitz said in a recent radio interview.[54]

That playbook has thus far been highly successful in warding off attention, regulation and legal incrimination.

Chapter Five: $270 Billion . . . and Looking for Handouts

The FCC's network of corruption doesn't just shield industry from needed scrutiny and regulation on matters of public health and safety. Sometimes it just puts its hand directly into the public pocket and redistributes that cash to industry supplicants.

Such is arguably the case with the Universal Service Fund. Originally established to extend telephone service to rural and urban areas that industry would find difficult or uneconomical to wire, the USF is now shifting from subsidizing landline phone service to subsidizing the extension of broadband Internet. USF monies also support the Lifeline program, which subsidizes cell phone service to low-income consumers, and the E-Rate program, which subsidizes Internet infrastructure and service to schools and libraries.

Since 1998, more than $110 billion has been allocated to Universal Service programs, notes Charles Davidson, director of the Advanced Communications Law & Policy Institute at New York Law School. The FCC has allocated over $40 billion to the E-Rate program alone.

Who pays the freight for these high-cost programs? You do.

Technically, landline and wireless phone companies are assessed for the Universal Service fund's expenditures. But the FCC also allows those companies to pass on such charges to their subscribers, which they do. Both landline and wireless subscribers pay a monthly Universal Service charge that is tacked on to their phone bills. That charge has been rising and recently amounted to a 16% surcharge on interstate calls.

Consumers who pay for these programs might be interested to learn that both the E-Rate and Lifeline programs have been riddled with fraud. Government watchdogs have repeatedly found the programs to be inefficient and prone to inflated and fraudulent claims. But the programs have been a windfall for tech and telecom industry beneficiaries. Wherever the FCC presides, it seems, these industries reap a windfall.

The General Accounting Office (GAO) has issued several reports citing fraud, waste and mismanagement, along with inadequate FCC oversight of the subsidy program. Bribery, kickbacks and false documentation can perhaps be expected in a handout program mandated by Congress and only indirectly supervised by the FCC.

But the scope of fraud has been impressive. The most striking corruption has marred the E-Rate program, which subsidizes Internet hardware, software and service for schools and libraries, and the Lifeline cell phone subsidies.

In recent years, several school districts have paid fines to settle fraud cases involving bribery, kickbacks, non-competitive bidding of contracts and false documentation in the E-Rate

program. More eye opening perhaps are the settlements of fraud claims by tech giants like IBM, Hewlett Packard and AT&T. The HP case, for example, involved some colorful bribery allegations, including gifts of yachts and Super Bowl tickets. HP settled for $16 million. An HP official and a Dallas Independent School District official both received jail sentences.

The Lifeline program has also been riddled with fraud. A Wall Street Journal investigation of the five top corporate beneficiaries of Lifeline showed that 41% of more than 6 million subsidy claimants "couldn't demonstrate their eligibility or didn't respond to requests for certification."[55] AT&T, Verizon, and Sprint Nextel were three of the major Lifeline beneficiaries.

The FCC has initiated several efforts to clean up USF programs and seems honestly determined to bring greater accountability and efficiency to its subsidy efforts. Nevertheless, problems with fraud persist, as reported recently by the FCC's own top investigator.

Congress established the FCC's Office of Inspector General in 1989 to "provide objective and independent investigations, audits and reviews of the FCC's programs and operations." Here's what the FCC's internal investigative unit said in a September 30, 2014 report to Congress about its Office of Investigation (OI): "*The bulk of the work of OI involves investigating and supporting civil and criminal investigations/prosecutions of fraud in the FCC's federal universal service program.*"[56]

Office of Inspector General

OFFICE OF INVESTIGATION

The bulk of the work of OI involves investigating and supporting civil and criminal investigations/prosecutions of fraud in the FCC's federal universal service program.

Fraud—as pervasive and troubling as it has been—is just one of the problems with the programs of universal service. It may not even be the fundamental problem. More fundamental issues concern the very aim, logic and efficiency of programs to extend broadband and wireless technology at public expense. Though the aims of extending service to distant impoverished areas seem worthy on the surface, there are many reasons to think the major beneficiaries of these programs are the technology companies that win the contracts.

Lobbyists have long swarmed over the FCC looking to get an ever-growing piece of the USF honeypot. An FCC report on meetings with registered lobbyists details a 2010 meeting with representatives of the International Society for Technology in Education and other education lobbyists. Topics discussed, according to the FCC report, included "the need to raise the E-Rate's annual cap."[57]

The CTIA, leaving no stone unturned in its efforts to pump up member revenues, last year responded to a House hearing on the USF by grousing that "current USF-supported programs skew heavily toward support of wireline services. . . . The concentration of USF monies to support wireline services is inconsistent with technological neutrality principles and demonstrated consumer preferences," CTIA wrote..[58] An industry that generates hundreds of billions of dollars in equipment and service revenues annually bellies up for a bigger slice of the $8 billion a year USF.

The grousing has paid off. The FCC recently announced that it will raise spending on E-Rate from what had been a cap of $2.4 billion a year to $3.9 billion. A significant portion of new outlays will go to Wi-Fi—yet another wireless industry victory at the FCC. But the CTIA is by no means the only industry group pressing the FCC.

Leading the roster of active lobbyists on E-Rate issues is the Software and Information Industry Association. Beginning in 2006, SIAA led all lobbyists with 54 mentions of E-Rate in its filings, according to the Center for Responsive Politics. SIAA board members include executives from tech heavyweights Google, Oracle and Adobe Systems.

Tech business leaders—many of them direct beneficiaries of FCC programs—made a direct pitch to FCC Chairman Wheeler last year to hike E-Rate funding. "The FCC must act boldly to modernize the E-Rate program to provide the capital needed to upgrade our K-12 broadband connectivity and Wi-Fi infrastructure within the next five years," the executives wrote.[59]

There were dozens of corporate executive signees to this letter, including the CEOs of many Fortune 500 giants. But let's just consider the participation of three: top executives of Microsoft, Google and HP all joined the call to expand E-Rate subsidies. Consider the simple fact that these three tech giants alone had revenues of $270 billion—more than a quarter of a trillion dollars—in a recent four-quarter period. Together, they produced nearly $40 billion in net income. And yet their top executives still thought it necessary to dun the FCC—and really, they were surreptitiously hitting up the public—for ramped-up spending on what was then a $2.4 billion a year program.

Is that greed? Arrogance? Or is it simply behavior conditioned by success in repeatedly getting what they want at the public trough? Almost never mentioned in these pleas for higher subsidies is the fact that ordinary American phone subscribers are the ones footing the bill for the E-Rate program—not the FCC or the telecom industry.

Much of the added spending, as noted, will go towards the installation of wireless networks. And yet Wi-Fi does not have a clean bill of health. When Lennart Hardell, professor of Oncology and Cancer Epidemiology at the University Hospital in Orebro, Sweden, was asked what he would do if given policy authority over wireless health issues, he replied swiftly that he would "ban wireless use in schools and pre-school." Noting that there are wired alternatives, Professor Hardell flatly stated: "You don't need Wi-Fi."[60] And yet the FCC, prodded by an industry ever on the lookout for incremental growth opportunities, is ignoring the health of youngsters to promote expanded Wi-Fi subsidies in schools across the U.S.

And what about the merit of the program itself? Overlooking the fraud and lobbying and Wi-Fi safety issues for a moment, shouldn't schools and libraries across the country be equipped with the best electronic gear, accessing the Internet at the fastest speeds? Doesn't the government owe that to its younger citizens, especially those disadvantaged by the long-referenced digital divide?

Well, maybe. But answers to these questions hinge on even more fundamental question: Do students actually learn more or better with access to the latest high-speed electronic gadgetry?

It would be foolish to argue that nobody benefits from access to high-speed Internet. But the benefits are nowhere near as broad or rich as corporate beneficiaries claim. Some researchers, for example, have concluded that computers don't seem to have positive educational impact—they may even have negative impact—when introduced into the home or freely distributed to kids from low income backgrounds.

Duke University researchers Jacob Vigdor and Helen Ladd studied the introduction of computers into North Carolina homes. They found that the academic performance of youngsters given computers actually declined. "*The introduction of home computer technology is associated with modest but statistically significant and persistent negative impacts on student math and reading test scores,*" the authors wrote in a National Bureau of Economic Research Working Paper.[61] The impact was actually most negative on the poorer students.

A study in the Journal of International Affairs examined the impact of the global One Laptop Per Child Program (OLPC), which has distributed millions of computers to children around the world. Researchers Mark Warschauer and Morgan Ames conclude: "*The analysis reveals that provision of individual laptops is a utopian vision for the children in the poorest countries, whose educational and social futures could be more effectively improved if the same investments were instead made on more proven and sustainable interventions. Middle- and high-income countries may have a stronger rationale for providing individual laptops to children, but will still want to eschew OLPC's technocratic vision. In summary, OLPC represents the latest in a long line of technologically utopian schemes that have unsuccessfully attempted to solve complex social problems with overly simplistic solutions.*"[62]

JOURNAL OF INTERNATIONAL AFFAIRS

Can One Laptop Per Child Save the World's Poor?

"...In summary, One Laptop Per Child represents the latest in a long line of technologically utopian development schemes that have unsuccessfully attempted to solve complex social problems with overly simplistic solutions."

Access to computers in the home may not work educational magic. But what about computers in the classroom? Don't they have educational value there?

The anecdotal evidence is mixed at best. Consider how students in Los Angeles, newly equipped with flashy iPads at a mind-boggling taxpayer cost of more than $1 billion, went about using the new tools to improve their educational performance. "Instead of solving math problems or doing English homework, as administrators envisioned, more than 300 Los Angeles Unified School District students promptly cracked the security setting and started tweeting, posting to Facebook and playing video games."[63]

But let's cut through the self-serving corporate claims and the troubling anecdotes to hear from someone who actually has had extensive and unique field experience. Kentaro Toyama was co-founder of Microsoft's research lab in India. Over more than five years he oversaw at least a dozen projects that sought to address educational problems with the introduction of computer technology. His conclusion: "The value of technology has been over-hyped and over-sold."

The most important factor in improving schools, says Toyama, now the W.K Kellogg Associate Professor of Community Information at the University of Michigan, is good teachers. Without good, well-trained teachers, adequate budgets and solid school administration, technology does little good. "Technology by itself never has any kind of positive impact," he said.[64]

The only schools in his experience that benefited from increased technology investment were those where "the teachers were very good, the budgets adequate." The richer schools, in essence. But as both Vigdor and Warschauer found, the introduction of technology has by itself little if any positive effect. For a public conditioned to believe in the virtues of new technology, such testimony is a bracing dose of cold reality.

But what about cost? Doesn't technology in the schools more efficiently replace alternative investments? Cost reductions are often the most persuasive argument for technology, Toyama agrees. But even these have been overstated. The costs of introducing new technology run far beyond initial hardware and software investments, said Toyama. In reality, the total costs of ownership—including maintenance, training, and repair—typically run to five or ten times the initial cost, according to Toyama. He said of the investment in technology for cost benefits: "I would say that in the long run—and even in the medium run and the short-run—that's probably the worst and most misguided conclusion to come to."[65]

He adds: "The inescapable conclusion is that significant investments in computers, mobile phones and other electronic gadgets in education are neither necessary nor warranted for most school systems. In particular, the attempt to use technology to fix underperforming class rooms . . . is futile. And for all but wealthy, well-run schools, one-to-one computer programs cannot be recommended in good conscience."[66]

But that doesn't keep industry lobbyists from recommending them. And it hasn't kept the FCC for spending scores of billions subsidizing technology to the very groups least likely to benefit from it.

Unmoved by the arguments of researchers and educators like Vigdor, Warschauer, and Toyama, the FCC keeps moving to increase technology subsidies. Ignoring research that disputes the value of technology in closing the so-called "digital divide," the FCC has even pioneered a new slogan: "the Wi-Fi gap."

In announcing that it was lifting E-Rate's annual budget from $2.4 billion to $3.9 billion and stepping up investment in wireless networking, FCC chairman Wheeler exulted that "10 million students are going to experience new and better opportunities."[67] The impact on consumer pocketbooks (and potentially on youngsters' health from daily Wi-Fi exposure) were not mentioned.

The two Republican members of the FCC did at least recognize the pocketbook impact. "It always seems easier for some people to take more money from the American people via higher taxes and fees rather than do the hard work," said Commissioner Michael O'Reilly.[68]

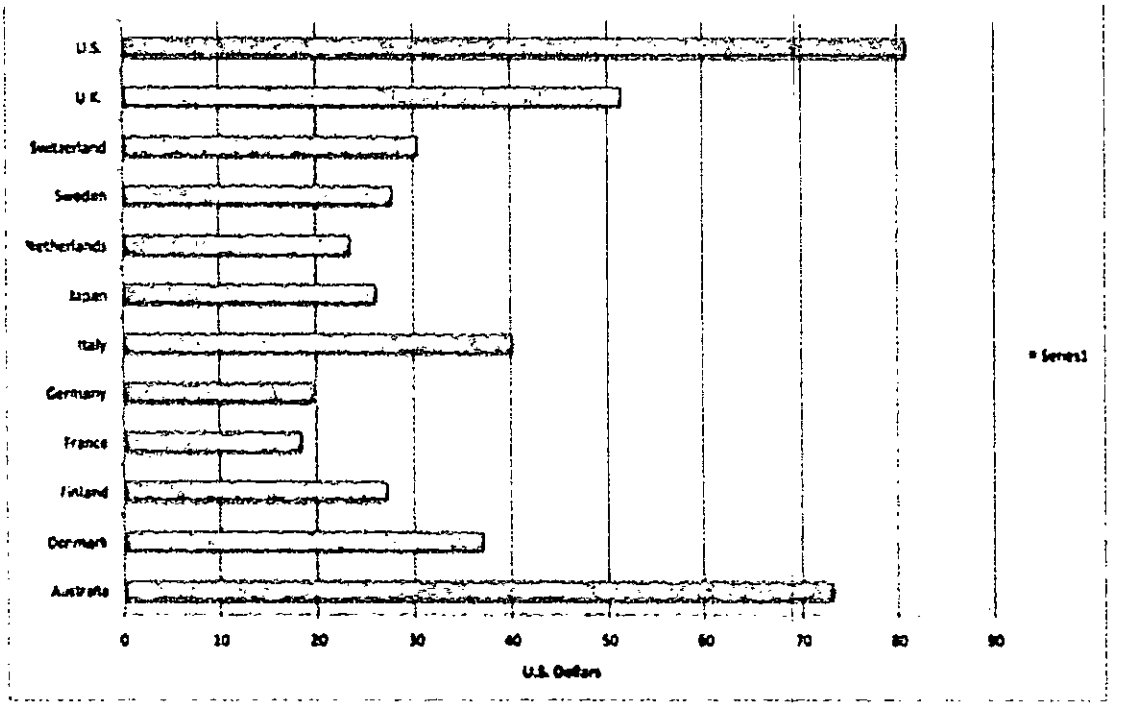
The subsidized provision of high-speed Internet service is yet another pet project of the FCC. Julius Genachowski, chairman from 2009 to 2013, championed the transition of the USF from landline phone service to broadband. Universal broadband Internet connections would begin to absorb the monies collected from consumers to extend basic phone service.

As with government subsidies for cell phone service, classroom technology, and Wi-Fi, there are basic questions about the wisdom of subsidizing broadband. Charles Davidson and Michael Santorelli of the New York Law School found that spending billions to extend broadband is a flawed approach since there are many largely ignored reasons people choose not to adopt

broadband. "Everybody is pushing broadband non-stop," noted Davidson, director of the Law School's Advanced Communications Law and Policy Institute. "I think the FCC is focused on the wrong set of issues," he said.[69]

Already, he explained, over 98% of Americans have access to wired or wireless broadband. The issue is not one of supply. It's one of demand. Many people—for a variety of reasons—don't really care about broadband, he contends. Price is one issue. Also powerful factors—but given almost no attention—are privacy and security concerns. "In our view, they should be focused on barriers to meaningful broadband utilization: privacy and security," said Davidson.[70]

But consumer privacy (more on this subject in Chapter Seven) has no well-funded lobby with limitless access to the FCC.



Chapter Six: The Cable Connection

The network has also been active in diluting FCC control of the cable television industry. Over the years, cable has devolved into major de facto local monopolies. Comcast and Time Warner Cable, whose merger proposal was dropped in April, are dominant forces in both cable television and broadband Internet subscriptions. Somehow, though, they have managed to steer clear of one another in specific markets, giving each pricing power where it faces little local competition.

It's interesting that cable companies annually rank in consumer polls among the "most hated" or "most disliked" American corporations. Indeed, Comcast and Time Warner Cable often top the "most hated" list.[71] Why would these companies—providers of the TV programming that has so expanded consumer options in recent decades—be so widely scorned? After all, the U.S. has been a leader in developing both cable technology and diverse television programming.

The problem is that it hasn't been anything close to a leader in bringing down subscriber prices. Industry consultants typically measure pricing by the metric of average revenue per subscriber. Industry trackers at IHS compared the price of U.S. pay television (which includes satellite services) to those in more than 60 other countries. U.S. prices were the highest, with only Australia even coming close. The average revenue per subscriber in the U.S. in 2013 was $81. But in France it was just $18.55. In Germany it was $19.68. In Japan it was just over $26.

Pay TV Monthly Revenue Per Person:

And U.S. cable prices have risen in recent years at rates three or more times the rate of inflation. This has been going on for some time. From 1995 to 2013 cable rates increased at a 6.1% annual clip. The Consumer Price Index, by contrast, rose by just 2.4% annually. Former FCC commissioner Michael Copps says the FCC shares a major part of the blame. "The FCC is as culpable for allowing that as much as the companies for imposing it," he said.[72]

One area where the FCC has contributed to the problem is in its traditional rubber-stamping of merger agreements. The proposed Comcast/Time Warner Cable deal has been shelved, largely because of Justice Department reservations. But a long run of earlier FCC-sanctioned deals allowed Comcast and Time Warner Cable to grow to the market dominance—and attendant pricing power—they currently command.

Lofty monthly cable bills pinch consumers. But it's more than that. Subscribers paying $80 a month are often paying for a lot of channels they don't watch and don't want. The FCC has never required cable operators to charge for what consumers actually want to watch. Kevin Martin, who chaired the FCC from 2005 to 2009, pushed to "debundle" programming in hopes of lowering bills. But the issue was never resolved. Only recently have viable competitive alternatives to cable's "bundled" packages become available. The satellite service Dish, for example, months ago introduced its Sling offering that enables consumers to opt for smaller and cheaper packages.

In fairness to cable operators, it should be pointed that programmers often require operators to take unwanted or fledgling channels along with their stars. New York cable operator Cablevision Systems filed suit against Viacom in 2013, charging that in order to get popular channels like MTV and Nickelodeon it was also forced to take low-rated channels like Nicktoons and VH1 Soul. But the simple truth is that no matter who is to blame, the cable consumer pays high prices, typically for some programming he doesn't want. As it often does when powerful interests pursue dubious practices, the FCC has for the most part idly stood by.

Still, the FCC isn't entirely to blame. Some factors in the growth of the cable giants cannot be laid at its doorstep. Local municipalities often granted monopoly or duopoly status in granting franchises to cable network builders. With the huge capital investments required to cable metropolitan areas, this once seemed to make sense.

And over the years, the cable giants have used a variety of tactics to weaken what little local competition they may have had. Active lobbyists on the local level, the cable giants have managed to convince a growing number of states to outlaw municipal systems that could threaten private corporate incumbents. The FCC for many years declined to tangle with the states in this matter, partly due to the opposition of Republican commissioners. But the Wheeler-led Commission did vote recently to override state laws that limit the build-out of municipal cable systems.

Still, many years of industry subservience will be difficult to swiftly undo. One linchpin merger shows how FCC decision-making has been thoroughly undermined by the revolving door, lobbying, and carefully targeted campaign contributions. All conspired in Comcast's pivotal 2011 buyout of NBC Universal, a deal which reinforced Comcast's domination of both cable and broadband access. This deal also set the stage for the recent headline-grabbing acrimony over the issue of net neutrality.

In 2011, mighty Comcast proposed to acquire NBC Universal. A series of mergers including the 1986 acquisition of Group W assets and the 2002 acquisition of AT&T's cable assets had already vaulted Comcast into cable market leadership. In bidding for NBC Universal, a huge step towards vertical integration, Comcast was once again raising the stakes. NBC Universal would give Comcast a treasure trove of programming, including valued sports content like NFL football and the Olympics.

Suddenly, the issue was not just cable subscriber base size—where Comcast had already bought its way to dominance. NBC Universal would also allow Comcast to consolidate its growing power as a broadband Internet provider. And with NBC Universal's programming assets, Comcast would gain new leverage when negotiating prices to carry the competing programming content of rivals. This would prompt a new round of debate over net neutrality. Couldn't a programming-rich Comcast slow down rival services—or charge them more to carry their programming?

To short-circuit any potential opposition to the merger, Comcast assembled a superstar cast of lobbyists. As Susan Crawford reports in her 2013 book, "Comcast hired almost eighty former government employees to help lobby for approval of the merger, including several former chiefs of staff for key legislators on congressional antitrust committees, former FCC staffers and Antitrust Division lawyers, and at least four former members of Congress.[73] Such "profligate hiring," Crawford observes, pretty much silenced the opposition to the deal. If Comcast had already retained one member of a lobbying firm, the firm could not under conflict of interest rules object to the deal. And Comcast had locked up key lobbying shops. Money was both weapon and silencer.

Of course, Comcast had always been a big spender on lobbying, with outlays exceeding $12 million every year since 2008. Lobbying costs peaked in 2011 at $19.6 million, according to the Center for Responsive Politics.

For its part, the FCC had a long history of approving most media mergers. So it was hardly a great surprise when the agency, after exacting some relatively minor concessions from Comcast, rubber-stamped the deal. Comcast would thus broaden its footprint as local monopoly distributor of cable. And with its new programming assets, it would enhance its leverage in negotiating deals to carry its rivals' programming. It would also fortify its position of growing strength as broadband Internet gatekeeper.

The most telling footnote to the deal would come just four months later. FCC Commissioner Meredith Atwell Baker, who voted to approve the merger in January 2011, left the FCC to become a top-tier Comcast lobbyist in May. It was the ultimate—and perhaps most telling—glide of the revolving door.

Baker's was a high-profile defection. But it was neither the first nor the last. Comcast had successfully convinced other FCC officials to take their expertise and government contacts to the cable giant. Comcast has long been a master at spinning the revolving door to its own advantage. "Comcast has been very good at hiring everyone who is very smart," said Crawford.[74]

Approval of the NBC Universal deal was another in the long string of FCC merger approvals that made Comcast a nationwide monopolist that could dictate both pricing and viewer programming choice.

But the deal may have had another unintended consequence. It set the stage for Comcast's subsequent battles on net neutrality. "Those mergers gave additional oomph to the issue of net neutrality," noted former commissioner Copps. Speaking specifically of Comcast's buyout of NBC Universal, IHS senior analyst Eric Brannon agreed. "That merger laid the grounds for net neutrality."

In allowing Comcast to acquire major programming assets, the deal would sharpen questions about the power of gatekeepers like Comcast to control the flow of traffic from rival Web services. So in bowing to lobbyist pressure, the FCC would bring on itself a whole new set of pressures by focusing public attention on the issue of net neutrality.

With activists rounding up comments from the public and hip TV personalities like HBO's John Oliver also beating the drums, net neutrality quickly grew into a popular issue that won the support of President Obama, and by proxy, his hand-picked appointee Tom Wheeler. When the FCC ruled in February of 2015 that it would seek Title II authority to regulate the Internet and presumably block any favoritism by broadband gatekeepers, it seemed to finally cast its lot with the public against steamrolling corporate interests

The issue had simmered for years but reached full boil when movie purveyor Netflix, which had argued that its service was slowed down by Comcast, signed a side deal ensuring better download speeds for its wares. This triggered an outburst of public concern that Comcast was now in position to operate "fast" and "slow" lanes, depending on whether a rival programmer could afford to ensure that Comcast provide adequate download speed.

With nearly 4 million comments—many supplied or encouraged by public interest groups—filed to the FCC, net neutrality was a bankable political issue. And there's no question, net neutrality attracted public interest because it gave cable viewers—long furious at the treatment by the monopolists who send them monthly bills—issues of both viewing pleasure and economics.

But it also fed into the longstanding sentimental but increasingly unrealistic view of the Internet as the last bastion of intellectual freedom. Internet romanticists have long seen the Web as a place that somehow deserves special rules for breaking the stranglehold of traditional media and offering exciting new communications, information retrieval and shopping efficiencies.

Yes, the Internet is a modern marvel. This is beyond dispute. But some of the favors it has won from government over the years have had unfortunate unintended consequences.

In the 1990s, for example, net access providers were repeatedly exempted as an "infant industry" from paying access charges to the Baby Bells even though they had to connect users through local phone networks. The long distance companies were then paying as much as $30 billion a year for the privilege. But the Internet was exempted.

As the late 90s approached, the Internet was no longer an infant industry. Still, the exemption from access charges was extended. That exemption essentially allowed AOL in the late 90s to offer unlimited unmetered online time, a key factor in boosting usage and siphoning advertisers from print media. Why buy an ad in print that might get viewed with the transitory flip of a page when you can get round-the-clock attention online?[75] FCC decisions to grant the Internet access-charge exemptions arguably accelerated the decline of print media and much of the quality journalism print advertising could once support.

Meanwhile, retailers on the Internet were making inroads into brick and mortar retail business with the help of a Supreme Court-sanctioned exemption from collecting sales tax.[76] This judicial coddling of the Internet was the death knell for many smaller mom and pop local businesses, already challenged to match online pricing. And that's not all. The special favors continue virtually every year, as Congress proposes and/or passes legislation to extend special tax exemptions to Internet services.

Well, maybe tax breaks aren't such a bad idea for such an innovative and transformational emerging technology. For all its faults, the Internet—gateway to all goods, repository of all things, wizardly guide to all knowledge, enabler of universal self-expression—is undeniably cool.

But let's not deny that the combination of tax advantages and deregulation was toxic. Allow an industry to emerge with advantages over useful existing industries that largely play by the rules—well, maybe that can be rationalized. But then fail to hold the upstart industry to the same rules, allowing it more leeway to trample fundamental rights because it has the technical capacity to do so. Well, then you have a cruel Faustian bargain.

With the see-no-evil deregulatory gospel loosing all constraints, the Web would devolve into a playground for corporate snoops and criminals. For all its wonders, the Internet comes at a cost: the loss of control over personal data, the surrender of personal privacy, sometimes even the confiscation of identity.

Perhaps the most favorable consequence of net neutrality—and one that has gotten surprisingly little attention—is that it could set the stage for privacy reform. (More on this in Chapter Seven). The FCC can now choose to exercise its Title II powers to enforce privacy standards over broadband Internet. Privacy is one area where the FCC has done a pretty good job in the past.

Worth remembering, though, is that the hard-fought public victory over Net Neutrality may be transitory. AT&T and others have threatened to go to court to upend the FCC rules. And there's a fair chance a Republican Congress will legislate against Title II.

Meanwhile, though, one supreme irony has begun to unfold in the marketplace.

Modern-day laissez fair ideologues love to invoke the wisdom of markets as represented by the "mysterious hand" of Adam Smith. Unfortunately, in the absence of effective regulation, the putatively wise "mysterious hand" generally seems to work its magic for those with huge financial resources and the political access it buys.

In the current cable situation, however, the mysterious hand may actually be working in consumer-friendly ways. Years of regulation that favored the cable companies have now backfired as the market reacts to monopolistic pricing and content control.

Whereas cable giants have commanded premium monthly subscriber prices to deliver packages of largely unwatched channels, the market is now beginning to burst with new "debundled" options that are whittling away at cable's vast subscriber base.

Satellite service Direct TV, as noted, now offers its streaming video Sling TV package of popular networks that includes live sports and news. Amazon, Apple, CBS, HBO, Netflix, Sony, and others offer a variety of streaming video options that allow viewers to cut the cable cord. Suddenly, consumers have the cherry-picking capability that bundled—and expensive—cable packages have never allowed.

In this case, at least, the unintended consequences of the FCC's pro-industry policies may be producing an unexpected pro-consumer twist.

Chapter Seven: What about Privacy?

Has any issue gotten as much lip service—and as little meaningful action?

For all the various congressional bills, corporate self-regulatory schemes and presidential Privacy Bill of Rights proposals, the simple truth remains that no personal information is safe on the Internet. Data brokers have built a multi-billion dollar business exchanging information used to build profiles of Net users. Your shopping and surfing habits, your health history, your banking data, your network of social ties, perhaps even your tax filings are all potentially exposed online. Both legal and criminal enterprises amass this information. And it doesn't go away.

At any given moment people you don't know somehow know where you are. They may very well know when you made your last bank deposit, when you had your last asthma attack or menstrual period. Corporations encourage and pay for every bit of information they can use or sell. Creepy? Perhaps, but as Jeff Chester, president of the Center for Digital Democracy points out: "The basic business model that drives online is advertising."[77]

The FCC largely escapes blame on this one. It is the Federal Trade Commission that has had primary responsibility for protecting Internet privacy. The FCC does have some limited authority, which, some critics say, could have been exercised more vigorously. But for the most part the FCC is not to blame for the rampant online abuse of personal privacy and identity.

The FCC does however have privacy authority over the phone, cable and satellite industries. Until recently, at least, the FCC has kept privacy issues at bay among the companies in these industries. "The FCC has generally taken privacy very seriously," noted Harold Feld, a senior vice president at the non-profit Public Knowledge.[78]

But dynamics now in place suggest that privacy may be the next great testing ground for the FCC. A new chance, perhaps, to champion public interest. Even before the opportunity for privacy enforcement under Title II regulatory powers, the FCC faces new challenges from phone companies, now itching to monetize their vast consumer data stashes the way Net companies have. The commonly used term is "Google envy."

"Until now, ISPs (Internet Service Providers) have mostly not gotten into hot water on privacy—but that's changing," observed Jonathan Mayer, a fellow at the Center for Internet and Society.[79] Verizon and AT&T, major providers of mobile Internet access, have each introduced "super cookies" that track consumer behavior even if they try to delete older, less powerful, forms of cookies. AT&T is actually charging its customers an extra $30 a month *not* to be tracked.

Showdowns loom.

In adopting Title II to enforce net neutrality, the FCC has made broadband Internet access a telecom service subject to regulation as a "common carrier." This reclassification means that the FCC could choose to invoke privacy authority under Title II's Section 222. That section, previously applied to phone and cable companies, mandates the protection of consumer information. Such information—called CPNI for Customer Proprietary Network Information—has kept phone companies from selling data on whom you call, from where you call and how long you spend on the phone. Consumers may have taken such protection for granted on their phone calls. But they have no such protection on their Internet activity—which, as noted, has been a multi-billion dollar safe house hideaway for corporate and criminal abusers of personal privacy.

Now, though, the FCC could put broadband Internet communications under Section 222 protection. To Scott Cleland, a telecom industry consultant who has often been ahead of the analytic pack, this would be a momentous decision.

When the smoke clears—and it hasn't yet—the FCC could make consumer identifiers like IP addresses the equivalent of phone numbers. Suddenly, the Internet companies that have trafficked in all that personal data would be subject to the same controls as the phone and cable companies.

Cleland argues that the risk for privacy abuses extends beyond broadband access providers like Comcast and Verizon to Internet giants like Google and Facebook that have until now flourished with all that personal data. "They are at risk and they are going to live under the uncertainty their business model could be ruled illegal by the FCC," Cleland said.[80]

Much has been written about the legal challenges broadband access providers intend to mount against the FCC's new rules. But Cleland argues that a very different type of legal action could engulf companies that have benefited from the use and sale of private data. Trial lawyers, he argues, will see opportunity in rounding up massive class action suits of Internet users whose privacy has been violated. What sorts of privacy abusers face legal action? Anyone who has "collected CPNI via some type of cookie," according to Cleland.

"Right now, edge providers like Google, Facebook and Twitter are at risk of being sued by trial lawyers," he said.[81]

Sounds great for consumers who care about privacy on the Internet and how it has been abused. But the FCC, Cleland was reminded, has never been a consumer advocate. "Bingo," replied Cleland. That's what makes the FCC's potential move into privacy protection so important and so surprising, he suggests.

There are other signs that the FCC under Tom Wheeler might actually become more consumer-friendly on the issue of data privacy. While Wheeler has brought some former associates from lobbying groups to the FCC, he has also peppered his staff with respected

privacy advocates. Indeed, he named Gigi Sohn, longtime president of the non-profit Public Knowledge, as Counsellor to the Chairman in April.

Another appointee with a privacy background is Travis LeBlanc, head of the FCC's Enforcement Bureau. In previous employment in California's Office of the Attorney General, LeBlanc was active in enforcing online privacy. LeBlanc has stated an interest in privacy and has already taken action against two firms that exposed personal information—including social security numbers—on unprotected Internet servers.

But many aspects of LeBlanc's approach to regulating Internet privacy under Title II remain unclear. Unfortunately, the FCC declined repeated requests to make LeBlanc available for an interview. (It also declined to answer written questions on its enforcement intentions in both privacy and cell tower infrastructure emissions.)

It remains to be seen if LeBlanc and his superiors at the FCC are really willing to take on privacy enforcement. Such a stance would require great courage as the entire Internet infrastructure is built around privacy abuse. It is also questionable whether the FCC would have the courage to challenge Google—a rare corporate ally in the battles over Net Neutrality.

Chapter Eight: Dependencies Power the Network of Corruption

As a captured agency, the FCC is a prime example of institutional corruption. Officials in such institutions do not need to receive envelopes bulging with cash. But even their most well-intentioned efforts are often overwhelmed by a system that favors powerful private influences, typically at the expense of public interest.

Where there is institutional corruption, there are often underlying dependencies that undermine the autonomy and integrity of that institution. Such is the case with the FCC and its broader network of institutional corruption.

As noted earlier, the FCC is a single node on a corrupt network that embraces Congress, congressional oversight committees and Washington social life. The network ties the public sector to the private through a frictionless revolving door—really no door at all.

Temptation is everywhere in Washington, where moneyed lobbyists and industry representatives throw the best parties and dinners. Money also allows industry to control other important factors, like the research agenda. All of this works together to industry's advantage because—as with other instances of institutional corruption—there are compromising dependencies. Policy makers, political candidates and legislators, as well as scientific researchers are all compromised by their dependence on industry money.

Dependency #1 – So much of the trouble here comes back to the core issue of campaign finance. Cable, cellular and educational tech interests know where to target their funds for maximum policy impact. And the contributions work, seemingly buying the silence of key committee congressmen—even those with past records as progressives. Key recipients of industry dollars include Massachusetts Senator Ed Markey and, until he retired, California Democrat Henry Waxman. Though they have intermittently raised their voices on such issues as data privacy and cellular health and safety, neither has shown any great inclination to follow through and take up what would have to be a long and tough fight on these issues.

Dependency #2 – Democrats might be expected to challenge industry now and then. They traditionally have done so, after all. But this is the post-*Citizens United* era where the Supreme Court has turned government into a giant auction house.

Bid the highest price and you walk home with the prize—your personal congressman, legislative loophole, even an entire political party.

Such is the case with technology industries and the Democrats. The communications/electronics industry is the third largest industry group in both lobbying and campaign contributions, according to the Center for Responsive Politics. In just 2013 and 2014, this industry sector spent well over $750 million on lobbying.[82]

Only the finance/insurance/real estate and health industries outspend the tech sector on lobbying. But those industry groups lean Republican. Over 62% of the finance/insurance/real estate campaign contributions go to the GOP. Health contributions lean Republican 57% to 43%. But the technology group leans sharply to Democrats, who got 60% of contributions in the 2013-2014 election cycle.[83] The two next largest industry groups—energy/natural resources and agribusiness—also lean heavily Republican. So of the top five industry groups whose money fuels and often tilts elections four are strongly Republican. The Democrats need the tech industry—and they show that dependence with consistent support, rarely raising such public interest issues as wireless health and safety and Internet privacy.

Dependency #3 – Spectrum auctions give the wireless industry a money-making aura. In recent Congressional testimony, an FCC official reminded legislators that the FCC has over the years been a budget-balancing revenue-making force.[84] Indeed, the auctions of electromagnetic spectrum, used by all wireless communications companies to send their signals, have yielded nearly $100 billion in recent years. The most recent auction to wireless providers produced the unexpectedly high total of $43 billion. No matter that the sale of spectrum is contributing to a pea soup of electromagnetic "smog" whose health consequences are largely unknown. The government needs money and Congress shows its appreciation with consistently pro-wireless policies.

Dependency #4 – Science is often the catalyst for meaningful regulation. But what happens when scientists are dependent on industry for research funding? Under pressure from budget cutters and deregulators, government funding for research on RF health effects has dried up. The EPA, which once had 35 investigators in the area, has long since abandoned its efforts.[85] Numerous scientists have told me there's simply no independent research funding in the U.S. They are left with a simple choice: work on industry-sponsored research or abandon the field.

Chapter Nine: A Modest Agenda for the FCC

Nobody is proposing that cell phones be banned. Nor does anyone propose the elimination of the Universal Service program or other radical reforms. But there are some steps—and most are modest—that the FCC can take now to right some of the wrongs that result from long years of inordinate industry access and influence:

1. Acknowledge that there may be health risks in wireless communications. Take down the dismissive language. Maturely and independently discuss the research and ongoing debate on the safety of this technology.

2. In recognition of this scientific uncertainty, adopt a precautionary view on use of wireless technology. Require prominent point-of-sale notices suggesting that users who want to reduce health risks can adopt a variety of measures, including headphones, more limited usage and storage away from at-risk body parts.

3. Back off the promotion of Wi-Fi. As Professor Lennart Hardell has noted, there are wired alternatives that do not expose children to wireless risk.

4. Petition Congress for the budgetary additions needed to expand testing of emissions on antenna sites. It was Congress after all that gave industry carte blanche for tower expansion so long as they comply with FCC standards. But there is evidence of vast non-compliance and Congress needs to ensure that tower infrastructure is operating within the law.

5. Acknowledge that children and pregnant women may be more vulnerable to the effects of RF emissions and require special protection.

6. Promote cable debundling as a way to lighten consumer cable bills, especially for those customers who don't care about high-cost sports programming.

7. Apply more rigorous analysis to properly assess the value of technology in education. Evidence continues to pile up that technology in education is not as valuable as tech companies claim. Pay less attention to tech CEOs—pay more attention to the researchers who've actually studied the impact of trendy technology fixes on learning

8. Take over enforcement of personal privacy rights on the Internet. Of all the basic suggestions here, this would require the most courage as it would involve challenging many of the entrenched powers of the Internet.

Chapter Ten: Stray Thoughts

Some concluding thoughts:

Why do so many of the most dubious FCC policies involve technology?

In large part, of course, because the FCC has authority over communications and that is a sector that has been radically transformed—along with so many others—by technology.

Let's be clear, though. The problem is not technology, which unarguably brings countless benefits to modern life. The problem is with the over-extension of claims for technology's usefulness and the worshipful adulation of technology even where it has fearful consequences. Most fundamentally, the problem is the willingness in Washington—for reasons of both venality and naïveté—to give technology a free pass.

Personally, I don't believe that just because something can be done it should heedlessly be allowed. Murder, rape and Ponzi schemes are all doable—but subject to prohibition and regulation. Government regulators have the responsibility to examine the consequences of new technologies and act to at least contain some of the worst. Beyond legislators and regulators, public outrage and the courts can also play a role—but these can be muffled indefinitely by misinformation and bullying.

There are precedents for industries (belatedly perhaps) acting to offset the most onerous consequences of their products. In responding to a mix of litigation, public demand and regulatory requirement, the auto industry, for example, has in the last 50 years substantially improved the safety and environmental footprint of its products.

Padded instrument panels, seat belts, air bags, and crumple zones have all addressed safety issues. Environmental concerns have been addressed with tightened emissions and fuel consumption standards. The response to new safety challenges is ongoing. Before side air bags were widely deployed, sedan drivers side-swiped by much larger SUVs were at vastly disproportionate risk of death and dismemberment.[86] But the deployment of side air bags has "substantially" reduced the risk of collision deaths.[87] Overall, auto fatality rates per 100,000 persons have dropped by nearly 60% in the U.S. since 1966.[88] Today, automakers continue to work on advanced safety features like collision avoidance.

It can be argued that most of these safety improvements came decades after autos were in wide usage and only in response to outrage at Ralph Nader's 1965 revelations on the auto industry.[89] No matter the catalysts. The simple truth remains that the auto industry—and its regulators—have for the last half-century been addressing safety and environmental issues.

But with the overwhelming application of money and influence, information and communications technologies have almost totally escaped political scrutiny, regulatory control, and legal discipline.

Should the Internet have been allowed to develop into an ultra-efficient tool for lifting personal information that includes financial records, health histories and social security numbers? Should wireless communications be blindly promoted even as new clues keep suggesting there may be toxic effects? Should local zoning authorities and American citizens be stripped of the right to protect their own health? Should education be digitized and imposed just because technology companies want to develop a new market and lock in a younger customer base?

All these questions can perhaps be rolled up in one: do we all just play dead for the corporate lobbyists and spinners who promote the unexamined and unregulated application of their products?

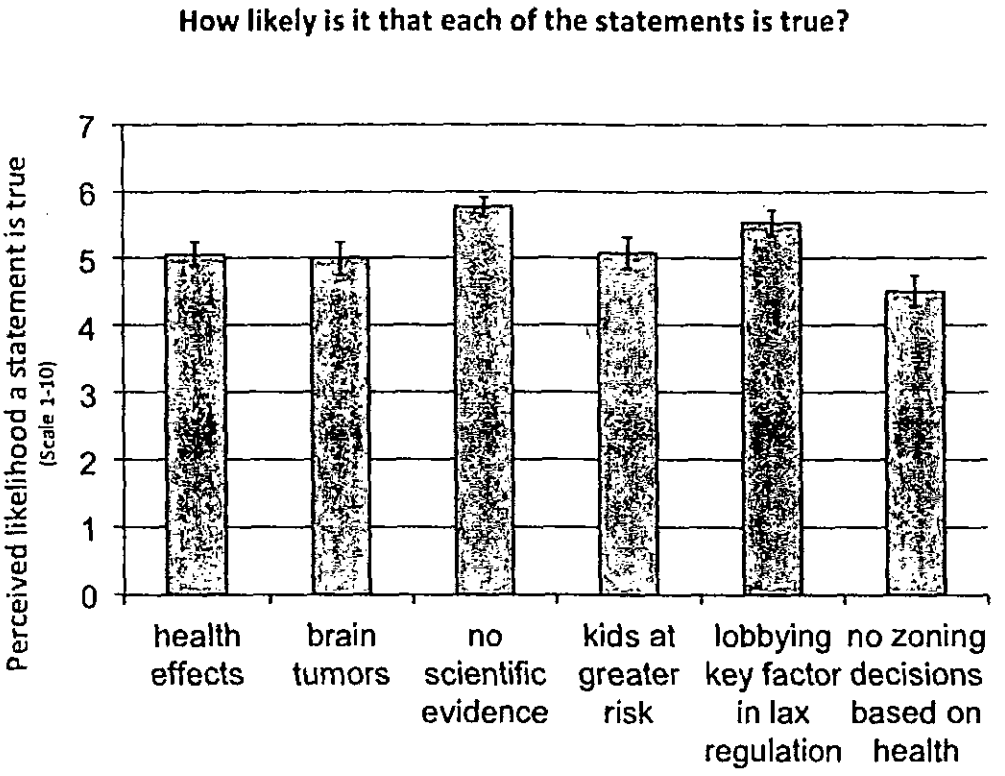
Finally, a word about the structure of the FCC. With five commissioners—no more than three from the same party—the structure seems to make some kind of sense.

But in practice, it works out poorly. The identification of commissioners by party tends to bring out the worst in both Republicans and Democrats. Instead of examining issues with clear-sighted independence, the commissioners seem to retreat into the worst caricatures of their parties. The Republicans spout free market and deregulatory ideology that is most often a transparent cover for support of business interests. The Democrats seems satisfied if they can implement their pet spending programs—extension of broadband wireless to depressed urban and rural schools, cell phone subsidies for low income clients. The result is a Commission that fulminates about ideology and spends heavily to subsidize powerful interests.

Perhaps one solution would be to expand the Commission to seven by adding two public interest Commissioners. The public interest only rarely prevails at the FCC. So it would represent vast improvement if both Republican and Democrat commissioners had to vie for support of public interest representatives in order to forge a majority. The public interest, in other words, would sometimes carry the swing votes.

It's very hard to believe, though, that Congress would ever approve such a plan. It simply represents too much of a threat to the entrenched political power of the two parties. Why would they ever agree to a plan that dilutes that power?

It's also worth noting that the public interest is not always easy to define. Sometimes there are arguably conflicting definitions. Still, an FCC with public interest commissioners is an idea worth consideration. It would at least require party apologists to defend how they so consistently champion the moneyed interests that have purchased disproportionate access and power in Washington.



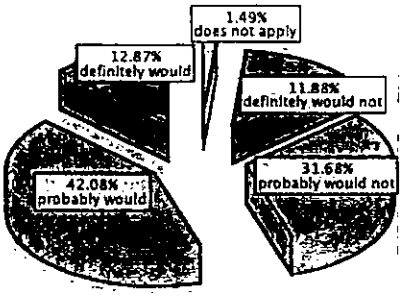
Appendix—Survey of Consumer Attitudes

What does the public believe about the science and politics of wireless health research? Under what conditions would people change wireless usage patterns? Is the FCC currently trusted to protect public health? How would confirmation of health risks affect trust in the FCC?

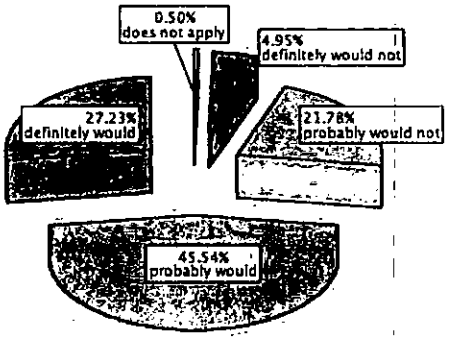
These are some of the questions Ann-Christin Posten[90] and Norm Alster[91] hoped to answer with an April 2015 online survey of 202 respondents. Participants were recruited through Amazon's Mechanical Turk online platform. All were U.S. residents and had achieved qualifying approval rates in prior Mechanical Turk surveys.

Participants were asked how likely they believed the following statements to be true:

> Statement 1. Prolonged and heavy cell phone use can have a variety of damaging effects on health.
>
> Statement 2. Prolonged and heavy cell phone use triples the risk of brain tumors.
>
> Statement 3. There is no scientific evidence that proves that wireless phone usage can lead to cancer or a variety of other problems.
>
> Statement 4. Children and pregnant women are especially vulnerable to radiation from wireless phones, cell towers and Wi-Fi
>
> Statement 5. Lobbying and campaign contributions have been key factors in keeping the government from acknowledging wireless hazards and adopting more stringent regulation.
>
> Statement 6. The U.S. Congress forbids local communities from considering health concerns when deciding whether to issue zoning permits for wireless antennae.

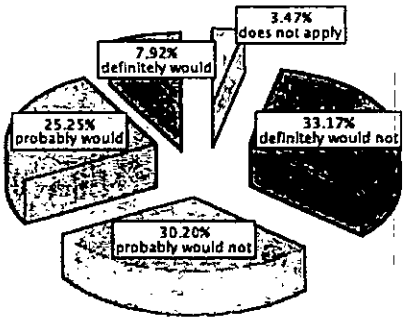


Two findings seem especially interesting:

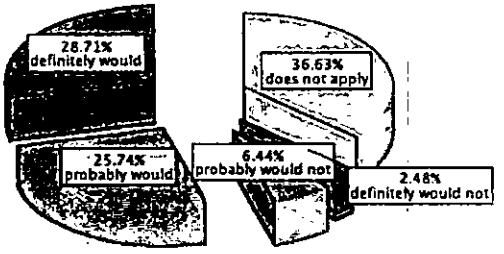


1. Statement 3 received a higher credibility rating than Statements 1 and 2. The different credibility levels are statistically significant. Respondents are more likely to trust in wireless safety than to believe there are general or specific health risks.

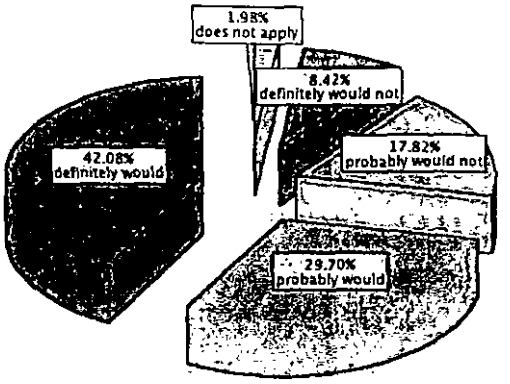
2. The only statement that is a matter of uncontested fact is Statement 6 on the outlawing of opposition to antenna sites on health grounds. (All other statements have been both proclaimed and denied.) And yet Statement 6 was least likely to be believed. Just 1.5% of respondents recognized this as an "absolutely true" statement. Over 14% thought this statement was "not true at all." Answers to this question would seem to reflect public ignorance on the political background to wireless health issues.



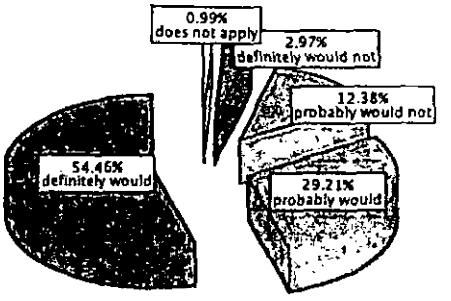
Participants were also asked how they would change behavior if claims of wireless health risks were established as true:



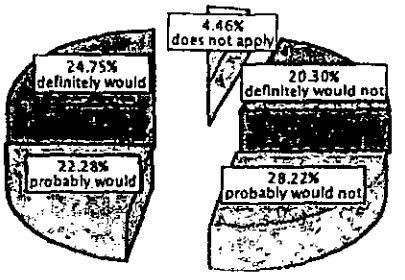
If statement 1 was true,
I would start using headphones.



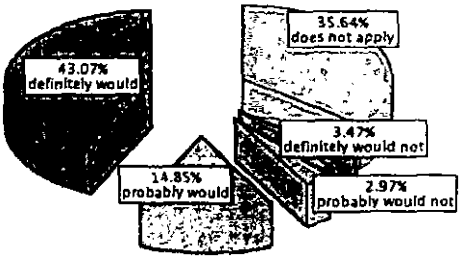
If statement 1 was true,
I would restrict the amount of time
I spend on the phone.



If statement 1 was true,
I would start up a new land line
account for home use.



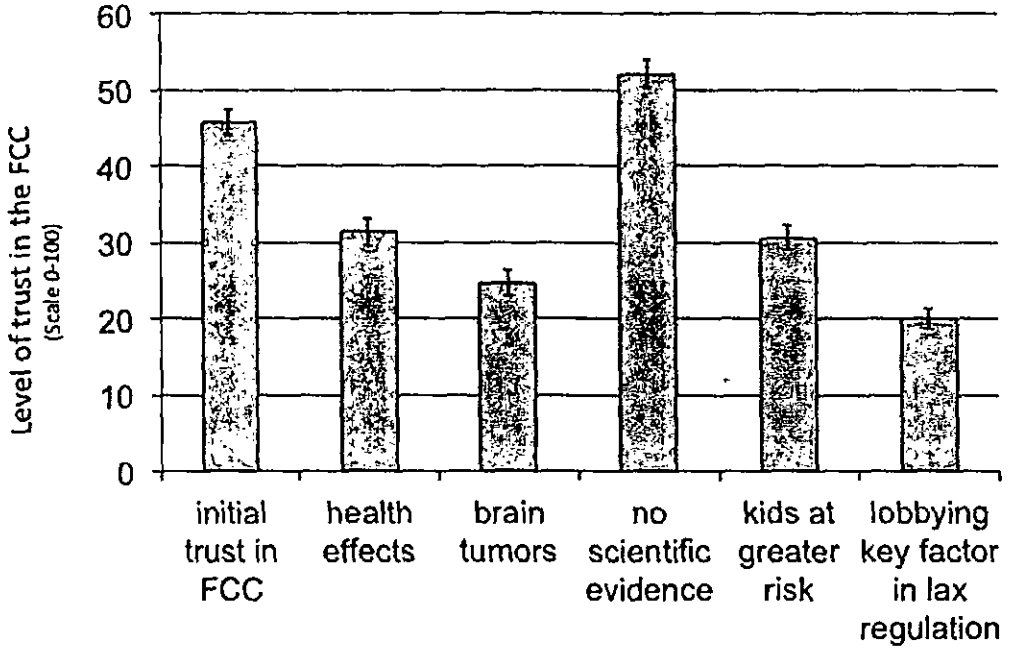
If statement 1 was true,
I would restrict my children's cell phone use.



If statement 2 was true,
I would start using headphones.

If statement 2 was true,
I would restrict the amount of time
I spend on the phone.

If statement 2 was true,
I would start up a new land line
account for home use.



If statement 2 was true,
I would restrict my children's cell phone use.

The greatest impact on behavior came when respondents were asked to assume it is true that prolonged and heavy cell phone use triples the risk of brain tumors. More than half said they would "definitely" restrict the amount of time spent on the phone. Just over 43% would "definitely" restrict their children's phone use. Perhaps most surprisingly, close to 25% would "definitely" start up a new landline phone account. (This last response suggests it may be foolishly premature for the phone giants to exit the landline business just yet.)

The inclination of consumers to change behavior should negative health effects be confirmed suggests the stakes are enormous for all companies that derive revenue from wireless usage.

This survey points to—but cannot answer—some critical questions: Do wireless companies better protect themselves legally by continuing to deny the validity of all troublesome research? Or should they instead be positioning themselves to maintain consumer trust? Perhaps there is greater financial wisdom in listening to the lawyers right now and denying all chance of harm. If so, however, why would anyone seriously concerned about health listen to the industry—or to its captured agency? That's a question the FCC will eventually need to answer.

Trust could eventually become a central issue. Respondents were initially asked to describe their level of trust in the wireless industry and in the FCC as its regulator. Not surprisingly, establishment of any of the presumed health risks—or confirmation of inordinate industry pressure—resulted in statistically significant diminution of trust in both the industry and the FCC.

On a scale of 1 to 100, the FCC had a mean baseline trust level of 45.66. But if the tripling of brain tumor risk is established as definitely true, that number falls all the way to 24.68. If "lobbying and campaign contributions" have been "key factors" in keeping the government from acknowledging wireless hazards, the trust level in the FCC plummets to 20.02. All results were statistically significant.

It's clear that at this point confirmation of health dangers—or even of behind-the-scenes political pressures—from wireless will substantially diminish public trust in the FCC. Skeptics might argue that this gives the FCC motive to continue to downplay and dismiss further evidence of biological and human health effects. Those of a more optimistic bent might see in these findings reason to encourage an FCC concerned about public trust to shake itself loose from special interests.

UW Scientist Henry Lai Makes Waves in the Cell Phone Industry

UW scientist Dr. Henry Lai never set out to link cell phones to cancer, but his work—and efforts

BY:
Naomi Ishisaka
| FROM THE PRINT EDITION |
January 2011

A greeting card on bioengineering professor Henry Lai's office wall at the University of Washington contains this quotation from Ralph Waldo Emerson: "Do not go where the path may lead; go instead where there is no path and leave a trail."

This philosophy could well sum up Lai's work on the effects of low-level radiation on DNA, as well as what he believes should be the guiding principle of science: independent investigation and research leading to discovery for the public good. Yet the soft-spoken scientist's steadfast belief in that principle has placed his research at the center of a persistent global controversy and created powerful enemies that tried to get him fired and essentially succeeded in drying up the source of funding for the type of research he was doing.

Lai admits that he was naive. He came to the UW in 1972 and earned a doctorate in psychology. Two decades later, as a bioengineering researcher, he studied esoteric scientific topics in relative obscurity. He and a fellow researcher, Narendra "N.P." Singh, were looking at the effects of nonionizing microwave radiation—the same type of radiation emitted by cell phones—on the DNA of rats. They used a level of radiation considered safe by government standards and found that the DNA in the brain cells of the rats was damaged—or broken—by exposure to the radiation. Ironically, cell phones weren't even on Lai's mind when he performed the initial studies. Funded initially by the Office of Naval Research, Lai was investigating how radar, which emits radio-frequency radiation, affects the health of operators. "We did not really pay attention to the importance of this thing," he recalls. But during his research, cell phone giant Motorola Inc. indicated that someone had told the company about Lai's unpublished results. Motorola asked to meet with him in his lab and at a meeting in Copenhagen.

After Lai and Singh's research finding an effect on DNA was published in 1995, Lai learned of a full-scale effort to discredit his work. In an internal company memo leaked to Microwave News,

PENGAD 800-631-6989
AB 4/2/18

a publication that examines health and environmental effects of electromagnetic radiation, Motorola described its plan to "war-game" and undermine Lai's research. After initially accepting industry funding for continued research from the Wireless Technology Research (WTR) program (created to manage $25 million in research funds), Lai and Singh wrote an open letter to Microwave News questioning restrictions placed on their research by the funders. After that, the head of WTR sent a memo asking then-UW president Richard McCormick to fire Lai and Singh. McCormick refused, but the dustup sent a clear message to Lai and his colleagues.

"This shocked me," Lai says, "the letter trying to discredit me, the 'war games' memo. As a scientist doing research, I was not expecting to be involved in a political situation. It opened my eyes on how games are played in the world of business."

Thus was launched an epic battle over research and truth. If Lai and Singh were correct about the potential impact on brain cells from radio-frequency radiation, there could be billions of dollars on the line for the cell phone industry in potential liability, leading to significant design changes and lost market expansion.

To the layperson, the science behind Lai's work, which was largely funded by the National Institutes of Health, and industry-funded research to contradict it is mind-numbingly complex. Virtually every assertion of risk has a counterassertion of no risk. For every independent study showing damage to DNA and memory, there is a study showing the opposite.

Lai, 61, says this phenomenon could be a direct result of the way science is now funded around the world. "[The U.S. was on] the cutting edge of this whole area for the last 30 years. [But] right now, we're the Third World country. We're not doing research at all," Lai says. With government funding all but nonexistent, the bulk of scientific research is funded by private industry. "The mechanism is funding," Lai says. "You don't bite the hand that feeds you. The pressure is very impressive. The massive Interphone study, coordinated by the International Agency for Research on Cancer and released in May 2010, exemplifies these challenges.

Purported to be the definitive word on cell phone radiation and brain tumors, Interphone involved 13 countries (all outside the U.S.), $25 million, and thousands of tumor patients and controls. Conducted over 10 years, the widely anticipated study was supposed to at last provide clarity on the risks of cell phone use. Yet, once again, the science was divided. The day after the study's release, headlines read, "No answer, just fuzz, from cell phone study," and, "One conclusion emerges from Interphone study: Controversy will continue."

Why, after so much money and time, were the data so mixed? Louis Slesin, editor of Microwave News, says there were a number of problems with Interphone. "When we started interviewing the protagonists," he says, "we realized there was a lot of conflict going on. It was a bitter struggle. It tells you the interpretation of the data is not clear cut in any way."

For the purposes of the Interphone study, a person who used a cell phone 30 minutes a day for more than 10 years was considered to be subjected to heavy exposure. Today, that level of cell phone use (900 minutes a month) is average. The people defined as the most heavily exposed in the Interphone study now represent the average user.

To illustrate that point, Elisabeth Cardis, head of the Interphone study, was quoted as saying, "In my personal opinion, I think we have a number of elements that suggest a possible increased risk among the heaviest users, and because the heaviest users in our study are considered the low users today, I think that's something of concern. Until stronger conclusions can be drawn one way or another, it may be reasonable to reduce one's exposure."

Lai's frustration with the increasing body of contradictory research led him to do an analysis in 2006 of the available studies on cell phone radiation between 1990 and 2006, and where their funding came from. What he found was that 50 percent of the 326 studies showed a biological effect from radio-frequency radiation and 50 percent did not. But when he filtered the studies into two stacks—those funded by the wireless industry and those funded independently—Lai discovered industry-funded studies were 30 percent likely to find an effect, as opposed to 70 percent of the independent studies.

Lai says that, while his findings highlight the crucial role industry funding plays in scientific research, the 50-50 split alone should be cause for concern. "Even if you accept all the industry studies, you still end up with 50-50," he says. "How could 50 percent all be garbage? People always start with the statement 'Hundreds of studies have been done on this topic, and no effect has been found,' but this is a very misleading statement. [The statements] come out from the cell phone industry, and people just use it, like the American Cancer Society. People haven't even gone in to look at the real studies and look at the effects that people have reported. This really worries me, because people come out and say things without the facts."

Slesin agrees and says Lai's work is important for the research that does show effects from radiation. "[Lai] is one of the most widely cited scientists in this field," Slesin says.

The American Cancer Society did not reply to requests for an interview. Its official position on the risks of cell phone use states: "Radio frequency (RF) waves given off by cell phones don't have enough energy to damage DNA directly. Because of this, many scientists believe that cell phones aren't able to cause cancer. Most studies done in the lab have supported this theory, finding that RF waves do not cause DNA damage."

CTIA-The Wireless Association, the cell phone industry trade organization, also declined to comment for this story, but its website states: "To date, global health organizations believe that the available scientific evidence does not show that any health problems are associated with using wireless phones. Many studies of low-level RF exposure, such as that which occurs with wireless devices, have not discovered any negative biological effects."

Dr. Beth Mueller, an epidemiologist at the Fred Hutchinson Cancer Research Center in Seattle, acknowledges that there is not strong evidence linking cell phones to brain tumors. But Mueller warns that the research is difficult and that much more study is needed. "I think [cell phone radiation] would be important to study. There are no studies I know of on the possible impact on children and I think it's something that many people–including some people here at the Hutch–want to see evaluated. I'm concerned because children are using [cell phones] a lot. It's something that should be looked at, definitely."

Katy Rock would agree. The Kirkland resident is an athletic 31-year-old who began having headaches in her late teens. "Headaches became an unwelcome fact of life for me in college," she says, "at first always after running around on the soccer or lacrosse field. So I assumed for years that it was due to dehydration/nutrition problems or just being out of shape. Eventually, they got worse. I started having them with no explainable cause."

It wasn't until a she had a seizure in 2007 that Rock discovered something was terribly wrong. The next day, she underwent an emergency double craniotomy to remove a tumor the size of a small lemon from her right frontal lobe and two tumors the size of large grapes from her right temporal lobe. A biopsy showed the cancerous tumors had been growing for about 10 years. A year of chemotherapy followed.

Rock was an early adopter of cell phones. Given a phone as a gift during college in 1997, she recalls using it about two to three hours a week (about 630 minutes a month). Her usage increased in later years with a job that required her to be on call. She is right-handed, and her tumors were on the right side.

Rock, who recently completed her first 5K run in support of Seattle Children's Hospital's Pediatric Brain Tumor Research Guild, would not be surprised to find a link between cell phones and brain tumors. "When I was in college, I used to charge my cell phone at night, and the charger cord ran over a leaf of my philodendron plant," she says. "Over time, the strip on the leaf where the cord touched turned brown. The small amount of power running through the cord was enough to kill some cells of the otherwise healthy plant."

While Rock's tale is merely metaphorical, its suggestive import is not lost on Devra Davis, Ph.D., a huge admirer of Lai's work to raise awareness about the potential hazards of cell phone radiation. Davis is a longtime toxicologist, public health expert and founder of the Wyoming-based Environmental Health Trust, a group that provides basic research and training on environmental health hazards. Davis' most recent book, released last October, is Disconnect: The Truth About Cell Phone Radiation. Davis calls Lai a "hero" for his groundbreaking work. "[Lai] has made a tremendous impact on the field in many aspects. Not just on the field of DNA, but on the brain, on receptors. In a fair and just world he would be a serious candidate for the Nobel Prize, because he did foundational research on the way the body responds to electromagnetic and radiofrequency radiation and because he persisted in the face of many challenges. He's been outstanding and indomitable in the face of opposition that would have overwhelmed most people."

In her book, Davis describes a disconnect between the general public's largely unquestioning acceptance of cell phone radiation and the large body of evidence suggesting cause for concern. With Lai's work as her foundation, Davis demonstrates a pattern of the cell phone industry's scientific manipulation spanning decades. Davis is particularly concerned because the rate of cell phone use by children is skyrocketing—with three out of four 12-year-olds and half of 10-years-olds in the U.S. now possessing a cell phone. Even more troubling: Lennart Hardell, Ph.D., a researcher in Sweden, found that those who began using cell phones in their teens (such as Rock) had four to five times the number of malignant tumors by their late 20s as those who did not use cell phones as teenagers.

While Davis would argue that there is a proven, causal link between cell phones and tumors, Lai does not. What he does say is that there is enough reason for concern, and that a "precautionary principle" should be embraced, as France has done in warning against cell phone use by children, and as San Francisco has done in mandating information on "specific absorption rates" of radiation on cell phone packaging.

"European countries generally believe you need some kind of precautionary approach," says Lai, who does not own—or use—a cell phone. "What else can we do? Obviously, we don't know the answer at all. But, then, there is a cause for concern. We need to take some kind of precautionary action." For now, however, Lai will continue to do research on the drug artemisinin—long used by Chinese herbalists—for applications in cancer treatment, because there is no longer any independent funding available for his research on the effects of nonionizing radiation.

Meanwhile, Davis, who uses a cell phone but only with a headset or as a speakerphone (she never keeps it close to her body), hopes that by the time the public realizes the importance of the path Lai has been on, it won't be too late. In Disconnect, she wonders how our grandchildren will answer these questions: "Did we do the right thing and act to protect them? Or did we harm them needlessly, irresponsibly and permanently, blinded by the addictive delights of our technological age?"

Electromagnetic Fields and Cancer: The Cost of Doing Nothing

RECEIVED
APR 27 2018
PA PUBLIC UTILITY COMMISSION
SECRETARY'S BUREAU

President's Cancer Panel January 27, 2009

David O. Carpenter, M.D.

Director, Institute for Health and the Environment, University at Albany, and Professor of Environmental Health Sciences, School of Public Health University at Albany, 5 University Place. A217, Rensselaer, New York, NY 12144-3429,U.S.A.

Abstract. Everyone is exposed to electromagnetic fields (EMFs) from electricity (extremely low frequency, ELF), communication frequencies, and wireless devices (radiofrequency, RF). Concern of health hazards from EMFs has increased as the use of cell phones and other wireless devices has grown in all segments of society, especially among children. While there has been strong evidence for an association between leukemia and residential or occupational exposure to ELF EMFs for many years, the standards in existence are not sufficiently stringent to protect from an increased risk of cancer. For RF EMFs, standards are set at levels designed to avoid tissue heating, in spite of convincing evidence of adverse biological effects at intensities too low to cause significant heating. Recent studies demonstrate elevations in rates of brain cancer and acoustic neuroma only on the side of the head where individuals used their cell phone. Individuals who begin exposure at younger ages are more vulnerable. These data indicate that the existing standards for radiofrequency exposure are not adequate. While there are many unanswered questions, the cost of doing nothing will result in an increasing number of people, many of them young, developing cancer.

INTRODUCTION

It has been known for many years that high frequency EMFs (X-rays, gamma rays, cosmic rays) have sufficient energy to directly break chemical bonds, causing damage to molecules ranging from water to DNA, leading to increased risk of cancer and birth defects /1/. Thus these forms of EMF are "ionizing". There is less consensus as to whether lower energy forms of EMFs, such as radiofrequency and ELF, can cause disease. In spite of strong documentation that exposure to non-ionizing EMFs is associated with an elevated risk of cancer, most national and international bodies have discounted this evidence, based on the belief that lower energy EMFs cannot possibly have adverse biological effects. This particular point of view is held by many in the physics and engineering communities, individuals not known for their knowledge of biology or medicine /2/. There are legitimate concerns as to what mechanisms might explain the association between exposure and cancer. The purpose of this presentation is to provide an overview of the issues, explore both the associations between exposure and disease and the mechanisms that might explain them, and to propose biologically-based standards of exposure which, although difficult to achieve, would be more protective of human health. While there are a variety of diseases of possible concern, this review will focus on only cancer.

HEALTH EFFECTS OF ELF EMFS

There has been evidence that residential exposure to elevated magnetic fields results in an increased risk for childhood leukemia since the pioneering 1979 studies of Wertheimer and Leeper

2010 Freund Publishing House Limited

EXHIBIT
PENGAD 800-631-6989
C-27
AS 4/20/18

/3/. Most subsequent studies have confirmed elevated risks of leukemia /4/, and several meta-analyses have shown significantly elevated odds ratios (ORs) whether exposure was determined through use of wire codes or measured magnetic fields /5/. In addition there is evidence that leukemia is elevated in adults employed in occupations that involve elevated exposure to EMFs from electricity /6/. Meta-analyses of occupational exposure have also reported elevated risks for leukemia, with less strong evidence for associations with other kinds of cancer /7/. A meta-analysis has also reported a significant elevation in rates of brain cancer among adults working in "electrical" occupations /8/. Thus the association between ELF exposure and cancer, especially leukemia, is very well documented in both children and adults and has been replicated in multiple investigations.

HUMAN DISEASE FROM EXPOSURE TO RF EMFS

Until recently there has been relatively little attention to RF exposures and human health. Older studies have reported elevations in both leukemia and brain tumors among individuals with occupational exposures to RF (see www.bioinitiative.org for references), but the results were not very consistent across studies. Recent reports have found elevated rates of leukemia among children who live near AM radio transmitter sites /12/. This is the same cancer elevated with exposure to power-line frequency EMFs, suggesting that leukemia is the cancer most likely to show elevated risk with whole body exposure to EMFs of any frequency. With the advent of enormous increases in the use of cell phones, we now have a situation in which a very large segment of society is regularly exposed to high levels of RF. In addition, the whole population has increased exposure through the placement of cell phone towers, wireless buildings and even wireless cities. The strongest evidence for hazards has come from Europe, especially Scandinavia, where cell phones were initially manufactured and have been in wide use for a longer period of time than in other parts of the world. Long-term use of a cell phone is associated with an elevated risk of ipsilateral brain tumors and acoustic neuromas. A meta-analysis by Hardell et al. /13/, based on four studies, reported an OR of 2.0 (95% CL = 1.2-3.4) for glioma among adults who have used a cell phone for ten years or more, but only on the side of the head where the phone was used. There was also an OR of 2.4 (95% CL = 1.1-5.3) for acoustic neuroma among long-term users. Risks for meningioma were elevated, but not significantly so. Kundi /14/ has reported on 33 epidemiological studies, and finds that the combined ORs from these studies show an OR of 1.5 (95% CL = 1.2-1.8) for glioma. There was also a non-significant elevation in ORs for acoustic neuroma but no relationship with meningioma. Hopefully, additional information will come from the pooled results of the INTERPHONE study, a 13-nation investigation coordinated by the World Health Organization (WHO), which should be available in the near future. The Israeli component of this study has also found an elevated risk of ipsilateral parotid gland cancer with long-term cell phone use /15/. There is reason for particular concern about risks to children exposed to RF. Hardell et al. /16/ studied relative risk based on the age when a person began to use a cell phone. For use of either analog or cordless phones when assessed at >1 or >5 year latency, he found that individuals whose use began while they were in their 20s has higher ORs for brain cancer than those whose use began use at an older age. Later Hardell reported at a meeting in London last September that children who began use of a cell phone prior to the age of 20 had an OR of developing glioma of 5.2 (95% CL = 2.2-12) after only one+ year of cell phone use, while for all ages the OR was 1.4 (95% CL = 1.1-1.7).

The same relative relationship was seen with use of a cordless phone, where use before the age of 20 years gave an OR of 4.4 (95% CL = 1.9-10), whereas for all ages the OR was 1.4 (95% CL = 1.1-1.8). These studies support the conclusion that use of cordless phones also increases risk, and that children are more vulnerable to risk of brain cancer than adults. The elevated risk to children poses a major concern given the current extensive use of cell phones by even young children.

WHY HAVE THESE RESULTS NOT BEEN REFLECTED IN NEW STANDARDS OF EXPOSURE?

In spite of this consistency in observations relating to ELF EMFs and leukemia, and the developing evidence for a relationship between cell phone use and elevated risk of brain cancer and acoustic neuroma, there has been a general failure of governments and international advisory bodies to accept the reported relationships as being cause and effect, and to follow through with standards designed to reduce exposure. This is a consequence of two major scientific problems, public support of wireless technologies and the political power of the industry. No single mechanism has been identified to be the basis for the development of cancer following exposure to EMFs. In addition, animal studies have not consistently demonstrated cancer as a result of exposure to ELF EMFs. This dilemma is captured well by a statement from the 2007 WHO report /17/: "*Resolving the conflict between epidemiological data (which show an association between ELF magnetic field exposure and an increased risk of childhood leukemia) and experimental and mechanistic data (which do not support this association) is the highest research priority in this field.*" The central question in this issue is whether the statement that the experimental and mechanistic data "do not support this association" is correct. There is the widespread but mistaken belief that all carcinogens act by causing direct DNA damage, as is the case with ionizing radiation. However, many proven human carcinogens do not cause direct DNA damage. These agents are identified as "non-mutagenic carcinogens" by the US Environmental Protection Agency and include such well-documented carcinogens as arsenic /18/ and dioxin /19/. Exact mechanisms are not known to explain the carcinogenicity of either. Thus the fact that ELF and RF EMFs are "non-ionizing" does not mean they are not carcinogens. Both ELF and RF EMFs are known to induce genes /20/, generate reactive oxygen species /21/, trigger formation of heat shock proteins /20,22/ and cause indirect DNA damage /21,23/, any one of which might lead to cancer (see www.bioinitiative.org for additional references and detailed discussion). Thus the argument that mechanistic data does not support a relationship between EMF exposure and cancer is simply wrong. The other argument for discounting the human health information is that animal models have not consistently demonstrated cancer as an outcome. While this is the case for most rodent laboratory studies, Reif et al. /24/ have demonstrated that dogs living in homes with very high wire codes (comparable to those associated with elevated risk of childhood cancer) showed a significant 6.8-fold elevated risk of developing lymphoma. EMFs differ significantly from chemical carcinogens, and it is not clear exactly what field parameters would be comparable to those levels resulting in cancer in humans. It is important to note that the US Supreme Court in the case of Daubert vs. Merrell Dow Pharmaceuticals /25/ effectively ruled that animal studies were not relevant to human health, and that the only admissible evidence must be from human studies. While this is certainly not a justifiable conclusion, in the case of EMFs we have strong evidence for a relationship between exposure and cancer in humans, but much weaker evidence from animal studies. For all of the above reasons lack of strong

evidence for cancer in animals is not a sufficient reason to disregard that strong evidence for a relationship between both ELF and RF exposure and cancer in humans.

PROPOSED EMF STANDARDS THAT ARE BASED ON STUDIES OF HUMAN HEALTH AFTER EXPOSURE

The Bioinitiative Report (www.bioinitiative.org) presents recommendations for standards of EMF exposure that are based on the epidemiological evidence in human populations. For ELF EMFs the proposed standard is 1 mG (0.1 μT), to be compared with the current International Commission on Non-ionizing Radiation Protection standard of 1,000 mG (100 μT). For RF radiation the proposed standard is 0.1 $\mu W/cm^2$, to be compared with the US Federal Communications Commission standard of 583 $\mu W/cm^2$ for 875 MHz cell phone frequency, and 1,000 $\mu W/cm^2$ in the frequency range of 1,800-1,950 MHz. The differences between these numbers show the magnitude of the problem. There is no question that a sudden imposition of standards so drastically different from those existing would impose hardship. However, there is also no question that the human studies clearly indicate that the existing standards are not protective of human health. The benefits to society derived from electricity and wireless communications are significant, and certainly none of us is willing to return to the pre-electric age. However it is imperative that society at least acknowledge the disparities between current standards and current evidence of risk of cancer. Rigid and sudden imposition of the standards we propose is unrealistic, but these levels are appropriate goals that could at least be approached by a combination of development of new technology and changes in behaviors.

THE COSTS OF BEING WRONG

At present we do not know precisely to what degree the risk of cancer is increased by exposure to EMFs. Human studies are difficult under any circumstances, but those difficulties are even greater when studying the effects of EMFs. Levels of exposure for each of us vary over the course of every day as we move through our environment and use appliances, cell phones and other wireless devices. This makes exposure assessment extremely difficult. Given the long latency for development of cancer, one would expect that the actual risk of EMF-induced cancer is significantly greater than that indicated by studies with inadequate exposure assessment. There is considerable evidence that children are more vulnerable to many environmental insults than are adults /26/. The reality is that children are using cell phones at increasing rates and for long durations. Therefore, if the risks are real, and especially if children are more susceptible, we may be facing an epidemic of brain and other cancers. The concern is increased because to date, there has been little warning advising restrictions on use of cell phones, especially by children. While questions regarding mechanisms are not all answered, the evidence for a relationship between EMF exposure and cancer is sufficiently strong so as to demand action. The alternative may be significant increases in certain cancers, especially leukemia and brain cancer. It is not clear whether there is increased risk of other kinds of cancer following exposure because there has not been a study of, for example, the health hazards of wearing a cell phone on your belt and pelvic cancers. Fortunately, the rates of leukemia and brain cancer are not high, at least not at present.

There have recently been significant improvements in treatment of leukemia, especially among children. Kundi /14/ has hypothesized that use of cell phones may increase the rates of brain cancer by as much as 50%. Even if this is true, this

certainly does not mean that every exposed person will develop brain cancer. However an increase in brain cancer of 50% would still have a significant impact, not only on the individuals affected but also on society, especially given that much of this increase is likely to occur among young people. It is not appropriate to deny the well-documented relationship between EMF exposure and cancer only because the mechanistic details are uncertain. The evidence that we have at present is too convincing to be ignored. Our national and international standards are obsolete, and ignore evidence reported by many different investigators. The lack of certainty with regard to mechanisms and animal models is no reason to ignore studies of human health.

We need the electric and communications industries to be proactive in developing products that can be used with reduced exposures. We need governments and international organizations to set standards that are based on the evidence of hazard, not on a hypothesis that is not credible based on the evidence from animal, cellular and human studies. Most importantly, we need individuals to understand that personal decisions will significantly impact the level to which they are exposed to both ELF and RF EMFs.

Radiofrequency Levels: *Units in* mW/m^2

No Concern:	Slight Concern:	Severe Concern:	Extreme Concern:
less than 0.0001	0.0001 – 0.0100	0.0100 – 1.0000	Over 1.0000

Biological effects have been observed down to very low exposure levels!

**1 mW/m^2 = 0.1 $\mu W/cm^2$*

Power Density (mW/m^2)*	Reported Biological Effects from Radiofrequency Radiation at Low-Intensity Exposure (All At Exposure Levels the FCC tells us are "safe")
0.000000000001	Super-low intensity RFR effects at MW resonant frequencies resulted in changes in genes; problems with chromatin conformation (DNA)
0.00000000005	Changed growth rates in yeast cells
0.0034	Chronic exposure to mobile phone pulsed RF significantly reduced sperm count
0.005	RFR decreased cell proliferation at 960 MHz GSM 217 Hz for 30-min exposure
0.006 - 0.128	Fatigue, depressive tendency, sleeping disorders, concentration difficulties, and cardiovascular problems reported with exposure to GSM 900/1800 MHz cell phone signal at base station level exposures.
0.03 - 0.2	In children and adolescents (8-17 yrs.) short-term exposure caused headache, irritation, concentration difficulties in school.
0.03 to 0.5	In children and adolescents (8-17 yrs.) short-term exposure caused conduct problems in school (behavioral problems)
0.05	In adults (30-60 yrs.) chronic exposure caused sleep disturbances, (but not significantly increased across the entire population)
0.05 - 0.4	Adults exposed to short-term cell phone radiation reported headaches, concentration difficulties (differences not significant, but elevated)
0.06 - 0.1	Chronic exposure to base station RF (whole-body) in humans showed increased stress hormones; dopamine levels substantially decreased; higher levels of adrenaline and nor-adrenaline; dose response seen; produced chronic physiological stress in cells even after 1.5 years.
[illegible]1 - 1.1	RFR from cell towers caused fatigue, headaches, sleeping problems
[illegible]- 0.5	Adults (18-91 yrs.) with short-term exposure to GSM cell phone radiation reported headache, neurological problems, and sleep and concentration problems.
0.05 - 0.4	Adults exposed to short-term cell phone radiation reported headaches, concentration difficulties (differences not significant, but elevated)
0.15 – 2.1	Adults exposed to short-term GSM 900 radiation reported changes in mental state (e.g., calmness) but limitations of study on language descriptors prevented refined word choices (stupefied, zoned-out)
0.5 - 1	RFR linked to adverse neurological, cardio symptoms and cancer risk
0.5 - 1	RFR related to headache, concentration and sleeping problems, fatigue
0.7 - 1	Sperm head abnormalities in mice exposed for 6-months to base station level RF/MW. Sperm head abnormalities occurred in 39% to 46% exposed mice (only 2% in controls) abnormalities was also found to be dose dependent. The implications of the pin-head and banana-shaped sperm head. The occurrence of sperm head observed increase occurrence of sperm head abnormalities on the reproductive health of humans living in close proximity to GSM base stations were discussed."
1	EEG brain waves are altered when exposed to cell phone signal
1.3	RFR from 3G cell towers decreased cognition, well-being
1.6	Motor function, memory and attention of school children affected (Latvia)
3.8	RFR affected calcium metabolism in heart cells
1.68 - 10.53	Irreversible infertility in mice after 5 generations of exposure to RFR from an 'antenna park'
2 - 80	RFR caused a two-fold increase in leukemia in children
2 - 80	RFR decreased survival in children with leukemia
2.1 - 12.8	Adolescents and adults exposed only 45 min to UMTS cell phone radiation reported increases in headaches.
[illegible]	Significant degeneration of seminiferous epithelium in mice at 2.45 GHz, 30-40 min.
[illegible]10	Wi-Fi level laptop exposure for 4-hr resulted in decrease in sperm viability, DNA fragmentation with

	sperm samples placed in petri dishes under a laptop connected via WI-FI to the network.
8 - 100	RFR caused emotional behavior changes, free-radical damage by super-weak MWs
0	RFR induced pathological leakage of the blood-brain barrier
0	RFR caused significant effect on immune function in mice
10	RFR affected function of the immune system
10	Short-term (50 min) exposure in electrosensitive patients, caused loss of well-being after GSM and especially UMTS cell phone radiation exposure
12.5	RFR exposure affected kidney development in rats (in-utero exposure)
13 - 57	RFR associated with a doubling of leukemia in adults
15	RFR reduced memory function in rats
20	RFR induced double-strand DNA damage in rat brain cells
20 - 40	Direct effect of RFR on ion channels in cells/opening of acetylcholine channels
20 - 40	Altered cell membranes; acetylcholine-induced ion channel disruption
24	Interference with medical devices at least up to 1000 MHz
25	RFR affected calcium concentrations in heart muscle cells
40	RFR caused changes in hippocampus (brain memory and learning)
40 - 100	Visual reaction time in children is slowed/lower memory function in tests
40 - 150	Memory impairment, slowed motor skills and retarded learning in children
50	RFR caused drop in NK lymphocytes (immune function decreased)
52.5	20 minutes of RFR at cell tower frequencies induced cell stress response
50 - 100	RFR caused impaired nervous system activity
60	RFR induced DNA damage in cells
87.5	RFR at 900 MHz for 2-12 hours caused DNA breaks in leukemia cells
100	Significant differences in visual reaction time and reduced memory function
00	Changes in behavior (avoidance) after 0.5 hour exposure to pulsed RFR
0 - 250	Changes in the hippocampus of the brain
100 - 1000	Increased risk in radar operators of cancer; very short latency period; dose response to exposure lev RFR reported.
125	RFR caused calcium efflux in cells - can affect many critical cell functions
135	RFR affected human lymphocytes - induced stress response in cells
200	Increase in serum cortisol (a stress hormone)
282	RFR increased free radical production in rat cells
375	Immune system effects - elevation of PFC count (antibody producing cells)
450	Pulsed RFR affected serum testosterone levels in mice
500	Cell phone RFR caused a pathological leakage of the blood-brain barrier in 1 hour
500	An 18% reduction in REM sleep (important to memory and learning functions)
600	RFR caused structural changes in cells of mouse embryos
600	Pulsed RFR affected immune function in white blood cells
600	Cortex of the brain was activated by 15 minutes of 902 MHz cell phone
650	RFR affected genes related to cancer
925	RFR caused genetic changes in human white blood cells
1000	Changes in immune function
1000	A 26% drop in insulin
1000	A 24.3% drop in testosterone after 6 hours of CW RFR exposure
1200	A pathological leakage in the blood-brain barrier with 915 MHz cell RF
5000	Intestinal epithelial cells exposed to 2.45 GHz pulsed at 16 Hz showed changes in intercellular calcium.
5000	A 24.6% drop in testosterone and 23.2% drop in insulin after 12 hrs. of pulsed RFR exposure.

wirelessaction@outlook.com

Government regulations do not protect us!

wer Density /m²)	Standard/Regulation
6000	Limit for uncontrolled public exposure to 800-900 MHz (ANSI, IEEE, FCC)
	PCS STANDARD for public exposure (as of September 1,1997)
0000	PCS STANDARD for occupational exposure (as of September 1, 1997)

The BioInitiative Report [2012] recommends exposure no higher than 1mW/m² – 10,000 times lower than current US FCC standards (10,000 mW/m²)

Ambient background levels of RF radiation

0.03	Background RF levels in US cities and suburbs in the 1990s
0.5	Median ambient power density in cities in Sweden (30-2000 MHz)
1 - 100	Ambient power density within 100-200' of cell site in US (data from 2000)

How Much Radiation Are You Being Exposed To?

**The Cornet ED88T meter used is only capable of measuring exposure levels up to 1827 mW/m² – therefore, readings of 1827 indicate that the meter was maxed out and actual RF levels were likely much higher.*

Because computers connected via Ethernet cable (most desktops PCs), corded landline telephones, and incandescent light-bulbs do not emit any microwave radiation, they were not measured. Devices in Airplane Mode also generally do not emit any microwave radiation. Notice how much radiation levels decrease as distance increases.

		Max Power Density (mW/m²)

APPENDIX
Exhibit List

Docket No, C-2017-2620710

Exhibit	Description
1	Direct Testimony Letter and Exhibit List submitted by David O. Carpenter, M.D. as an expert witness on behalf of Richard N. Myers. Complainant's Book 3 also contains Dr. Carpenter's Testimony Letter and Exhibits
2	Curriculum Vitae of Dr. David O. Carpenter
3	**Bioinitiative 2012 Report**: A Rationale for Biologically-based Public Exposure Standards for Electromagnetic Fields (ELF and RF)
4	U.S. Navy's Naval Medical Research Institute: ***"Bibliography of Reported Phenomena ('Effects') and Clinical Manifestations Attributed to Microwave and Radio-Frequency Radiation. Project MF12.524.015-0004B, Report No. 2 dated 4 October, 1971, Second Printing, with Revisions, Corrections, and Additions: 20 April 1972"***
5	List of 155 Reviews on Non-thermal Effects of Microwave/Intermediate Frequency EMFs by Martin Pall
6	Testimony Letter and Research paper by Martha R. Herbert, M.D. entitled ***"Autism and EMF? Plausibility of a pathophysiological link Part I and Part II"*** *Published in the Official Journal of the International Society for Pathophysiology*
7	Curriculum Vitae of Dr. Martha R. Herbert
8	Research paper: ***"The implications of non-linear biological oscillations on human Electrophysiology for electrohypersenstitvity (EHS) and multiple chemical sensitivity (MCS)"***
9	Department of Health and Human Services letter to Chair, IEEE SCC28 dated June 17, 1999
10	**Negativity Towards Negative Results**: an Editorial on the disconnect between scientific worth and scientific culture
11	WHO/IARC Classifies Radiofrequency Electromagnetic Fields as Possibly Carcinogenic to Humans
12	United States Department of the Interior Letter, Office of the Secretary to Mr. Eli Veenendaal of the National Telecommunications and Information Administration, U.S. Department of Commerce dated February 7, 2014

Exhibit	Description
13	United States Environmental Protection Agency letter to Ms. Janet Newton, President, the EMR Network dated March 8, 2002
14	American Academy of Pediatrics letter to FCC and FDA dated August 29, 2013 urging reassessment of current RF radiation standards
15	American Academy of Environmental Medicine Statement on Wireless Smart Meter Case Studies
16	American Academy of Environmental Medicine Statement on Electromagnetic and Radiofrequency Fields Effect on Human Health
17	Maryland's Children's Environmental Health and Protection Advisory Council
18	California Department of Public Health Issues Warning About Cell Phone Use
19	The City and County of San Francisco recommendations to reduce RF energy from cell phones
20	The City of Pembroke Pines, FL
21	The City of Jackson Hole, WY
22	Worldwide Precautionary Action published by Parents For Safe Technology
23	International Appeal: Scientists call for Protection from Non-ionizing Electromagnetic Field Exposure

ADDRESSING:

WHY I REQUEST EXEMPTION FROM SMART METER INSTALLATION

INTRODUCTION

My Name: Richard N. Myers

Address: 1123 Elm Avenue, Lancaster, PA 17603

Telephone: 717-393-613

Q. **PLEASE EXPLAIN WHAT YOU ARE REQUESTING**

A I request to be exempt from having a smart meter installed in my home.

Q. **PLEASE EXPLAIN WHY YOU ARE REQUESTING EXEMPTION**

A. I am a 73 year old male and for health reasons I want to minimize my exposure to the non-thermal RF radiation emitted by PPL smart meters.

Q. **WHAT IS YOUR BACKGROUND?**

A. I graduated from the University of Louisville on a full NROTC scholarship with a a BA in history and minor in Naval Science. I am retired from 35 years of Naval Service and spent 20 years on active duty as a Naval Officer. This included 10 years of sea duty

ADDRESSING:

WHY I REQUEST EXEMPTION FROM SMART METER INSTALLATION

INTRODUCTION

My Name: Richard N. Myers

Address: 1123 Elm Avenue, Lancaster, PA 17603

Telephone: 717-393-613

Q. **PLEASE EXPLAIN WHAT YOU ARE REQUESTING**

A I request to be exempt from having a smart meter installed in my home.

Q. **PLEASE EXPLAIN WHY YOU ARE REQUESTING EXEMPTION**

A. I am a 73 year old male and for health reasons I want to minimize my exposure to the non-thermal RF radiation emitted by PPL smart meters.

Q. **WHAT IS YOUR BACKGROUND?**

A. I graduated from the University of Louisville on a full NROTC scholarship with a a BA in history and minor in Naval Science. I am retired from 35 years of Naval Service and spent 20 years on active duty as a Naval Officer. This included 10 years of sea duty

and two tours in Vietnam. Following active duty I worked 15 years as a Federal employee specializing in operations and program management for a Washington, DC naval command that operated a fleet of civilian manned vessels with specialized DOD missions.

Q. PLEASE EXPLAIN YOUR OBJECTIONS TO THE PPL SMART METER

A. I have 12 objections. First, PPL has not provided me with scientific research or evidence showing that the non-thermal RF radiation PPL's smart meter emits into my home is safe.

a. Instead, PPL claims their smart meters comply with FCC Guidelines. However, FCC's thermal Guidelines are widely recognized by researchers and other government authorities as being incomplete and woefully obsolete. FCC adopted those Guidelines in 1996 and they were largely based on IEE C95.1 Guidelines of 1991 and with industry input. They take no account of the thousands of peer reviewed studies before 1996 and after which report adverse health effects from non-thermal RF radiation.

b. In a letter to me dated September 17, 2017, Counsel for PPL wrote: "It is denied that smart meters pose any health or safety concerns." However, unlike the pharmaceutical industry which rightfully is required to test and prove their products are safe for humans, PPL conveniently shifts the burden of proof on me that their smart meter technology is safe.

c. The PPL website reads: "We are not aware of any studies that have found any health risks caused by this type of smart meter in homes and businesses." See last sentence in the screen shot below from their website [1]

[1] https://www.ppleclectric.com/reliability/new-electric-meters/what -you-need-to-know.aspx

d. I couldn't disagree more with PPL statements in 1 (b) and 1 (c) above. Again, where is the science? I wish to make the following points:

1) We are bioelectrical beings having by some estimates 85-86 billion brain cells and up to 500 trillion synapses which pass electrical and chemical signals between these billions of cells.[2] How does PPL or FCC know that the non-thermal RF radiation from their smart meters does not adversely effect infinitesimally small brain cells and synapses and their electrical signals?

2) Unlike a cell phone which I can turn off, PPL informs me their smart meter would pulse non-thermal radiation into my home approximately 1,720 time per day, 365 days a year. Why should PPL be allowed to transmit RF radiation into my home when a flood of research reports adverse health effects from chronic exposure to non-thermal RF radiation?

A. 2 FFC's RF radiation Guidelines do not adequately protect public health according to countless researchers, numerous Federal, State and municipal officials, and foreign countries. Specifically:

a. FCC Guidelines consider acute 30 minute thermal effects only. But the latency period for cancers and other illnesses is not 30 minutes. The Guidelines ignore whole body non-thermal effects

[2] https://en.wikipedia.org/wiki/Neuron

which are known to occur at the cellular level. FCC used a mannequin head modeled for a 210 lb male to simulate and measure human tissue heating. (How does that work for the thinner skull of an infant or fetus?) Heating skin tissue is not my concern. My concern is what adverse health effects will smart meter non-thermal radiation have on my cells, the very building blocks of life.

b. FCC Guidelines ignore the whole body exposure from the ubiquitous RF radiation emitted by cell phone towers, cell phones, wi-fi, lap tops, tablets, security systems, baby monitors, smart meters, smart meter banks, and other wireless technologies in the last 20 years. However convenient wireless technologies may be, they have immersed us in a sea of man-made RF radiation vastly greater than existed when the Guidelines were adopted in 1996 and are unprecedented in human history.

c. FCC Guidelines do not take into account the cumulative effect of non-thermal radiation over a period of years.

d. FCC Guidelines do not take into account the latency period for cancers and other chronic diseases to develop.

e. FCC Guidelines do not take into account the effect non-thermal radiation has on the most vulnerable people in our society: pregnant women and their fetuses, infants, children, children on the Autism spectrum, cancer victims, cancer survivors, the chronically ill, and the elderly for which a different standard may apply.

f. FCC Guidelines do not take into account that non-thermal RF radiation is absorbed differently by various parts of the bodies (e.g. fetuses, female breast tissue, testes, sperm, eyes).

g. FCC Guidelines do not take into account the potential non-thermal effects may have on the genetic heritage of future generations, animals and plants.

h. FCC Guidelines not take into account the increased RF radiation a person receives when placing cell phones to their ear, in their clothing, placing laptops and tablets on their laps, wearing wireless headsets.

i. FCC Guidelines do not take into account that smart meters pulse non-thermal RF radiation energy into a person's home 24/7/365, unlike cell phones which a user can turn off. If any of my statements in 2a through 2i above are incorrect, request PPL please explain and cite a reference for the hearing record.

A. **3. There is a massive amount of research in the scientific literature that attribute adverse health effects from non-thermal RF radiation. Specifically:**

a. I request **Exhibit 1** consisting of the Direct Testimony of my expert witness Dr. David O. Carpenter plus his six (6) Exhibits be entered into the record as expert testimony. Dr. Carpenter is Professor of Environment Health Sciences and Director for the Institute for Health and the Environment, University at Albany. Dr. Carpenter graduated magna cum laude from Harvard, cum laude from Harvard Medical School, is an author/co-author of over 400 peer-reviewed publications, and has written six books. Dr. Carpenter's expertise has qualified him as a subject matter expert in previous legal matters. His CV is provided as **Exhibit 2**.

b. Between 2007 and 2012 roughly 1800 new scientific studies on the effects of non-thermal RF radiation have been published, according to the Bionitiative Report 2012, **Exhibit 3.** The report is a compendium of the science, public health, public policy and response to the growing health issue of RF radiation. The number of such studies continues to increase every year.

c. **Exhibit 4** is a U.S. Navy research report by the Naval Medical Research Institute entitled ***Bibilography of Reported Biological Phenomena ('Effects') and Clinical Manifestations Attributed to Microwave and Radio-Frequency Radiation."*** It lists 2,311 research studies published on biological responses to RF radiation. I request **Exhibit 4** be entered into the hearing record as evidence.

d. **Exhibit 5** lists 155 other studies attributing various adverse health effects from non-thermal RF radiation, some of which were published before 2007. I request Exhibit 5 be entered as evidence into the hearing record. Since it is impossible to bring the authors of research in **Exhibits 3, 4** and **5** to the hearing for cross examination, my request to the PUC Commissioners is to acknowledge that a large number of peer-reviewed scientific research studies do in fact exist and that research raises legitimate question about the safety of non-thermal RF radiation for humans, and all life forms for that matter.

e. I request **Exhibit 6** containing the Testimony letter and study by Dr. Martha R. Herbert entitled **"Autism and EMF? Plausibility of a pathophysiological link, Parts 1 and 2"** be entered into the record as expert testimony. Dr. Herbert is a neuroscientist and a recognized expert in brain development research. Her CV is provided as **Exhibit 7**.

f. The number of studies identified in **Exhibits 3, 4, 5** and **6** total 4,264.

g. The adverse health effects from RF radiation exposure as shown in **Exhibits 3, 4, 5, 6, 26, 27** and **28** include (but are not limited to) the following:

Breast cancer

Brain cancer (gliomas)

Brain tumors

Leukemia

Note: The people most vulnerable to non-thermal radiation injuries have been reported to be cancer patients, cancer survivors, fetuses, infants, pre-school children, in-school children, and the elderly,

Leakage of the blood-brain barrier

Electromagnetic hypersensitivity (EHS)

Induced multiple chemical sensitivity (MCS)

Cataracts

Endocrine problems

Reduced salivary flow

Autism

Tinnitus

Disruption of normal biological rhythms

Male reproductive problems: sperm death, decrease sperm count, decrease sperm motility

Female reproductive problems, miscarriages

DNA damage

Genetic damage

Cognitive impairment: memory, concentration, learning

Headaches

Fatigue

Nervous system disorders

Disruption of sleep and wake cycles

Insomnia

Heart – irregular or rapid heart beat

Thyroid and adrenal problems

Altered immune function

h. I do not wish to put my health at risk due to exposure to smart meter non-thermal RF radiation.

i . I cite in **Exhibit 8** one study in particular for its relevance to PPL smart meter pulsing: **"The implications of non-linear biological oscillations on human electrophysiology for electrohypersensitivity (EHS) and multiple chemical sensitivity".** Quoting from the study:

> **"Pulsed" electromagnetic fields and radiofrequency radiation (RFR) can have the devastating biological *effect of disrupting homeostasis and desynchronizing* normal biological rhythms that maintain health."**

4. Similar to the tobacco industry which denied smoking caused cancer for many years, the wireless technology industry downplays the health risks of non-thermal RF radiation, denies or suppresses evidence, and benefits from public inattention or confusion. For example:

a. RF radiation research has been largely funded by the military, government agencies[3] and the telecommunications industry, each having their own agendas. Their subject matter experts have often been quick to discredit independent research that challenges the safety of FCC's 1996 Guidelines. But being blind to other research is not science. **Exhibit 9** is a letter from the Department of Health and Human Services (DHHS) to the Chairman, IEEE SCC28 (SC4) Risk Assessment Work Group which stresses the need NOT to dismiss studies from independent researchers. Quoting from page 7:

> **"Published peer-reviewed studies that have been independently replicated/validated should be used to establish the adverse effects levels from which exposure guidelines are derived. The definition of "replicated/validated" should not be so restrictive to disallow**

[3] FCC Bulletin OET 56

the use of a set of reports that are scientifically valid but are not an exact replication/validation of specific experimental procedures."

"Peer-reviewed, published studies that may not be considered to be replicated/validated, but are well done and show potentially important health impacts provide important information regarding uncertainties in the data base used to set the adverse effect level (e.g., incomplete data base)."

If the DHHS states that there can be uncertainties in the data base used to set the adverse effect level of non-thermal RF radiation, then the PA PUC must conclude the legitimacy of this statement.

b. The reasons given by industry researchers and spokespersons for discrediting independent researchers have become well known and repetitious. Typical criticisms and my responses are listed below.

Criticism: The mechanism of action was never identified.

My response: Knowing the mechanism of action can take years to be identified or may never be identifed. We don't know the mechanism of action for many diseases such as cancers and Alzheimers, nor for Tylenol and certain psychiatric drugs. But that doesn't stop scientists or medical professionals from making good use of the information they do have.

Criticism: Not a reflection of current scientific knowledge.

My response: Not true. There are thousands of research studies in the USA and throughout the world which attribute biological and adverse effects from exposure to RF radiation. **Exhibits 3, 4, 5, 6, 8, 27, 28**

Criticism: The conclusions are very different from national and international views on the subject.

My response: Not true. There are thousands of research studies in the USA and throughout the world which attribute biological or adverse health effects from exposure to RF radiation. See **Exhibits 3, 4, 5, 6, 8, 27, 28**

Criticism: The evidence was not conclusive.

My response: Misleading. It's not uncommon for research studies not to be conclusive. That is the nature of scientific inquiry. But when new research studies support earlier findings, then those new studies become more important.

Criticism: The study could not be replicated

My response: Just because a study does not replicate an earlier study does not invalidate the earlier study. Human biology and cellular processes are incredibly complex. There are many variables that can interfere with duplicating an earlier observation. For example: the difference in the RFexposure that the study participant has accumulated over time compared to another participant, the health and immune strength of different participants, the cell membrane strength or thickness of tissues for different participants, body mass index (BMI), uncontrolled exposure to other triggers, the differences in age, gender and race of subjects.

Criticism: Further study is needed.

My response: The need for further study underscores the need for the PUC to adopt a precautionary principle as prudent public policy.

c. Ignoring or dismissing scientific studies that challenge the current view is counter-productive to filling gaps in knowledge. Consider the points below in an article authored by a team of researchers -. ***Exhibit 10:***

> **"Science is often romanticised as a flawless system of knowledge building, where scientists work together to systematically find answers. In reality, this is not always the case. Dissemination of results are straightforward when the findings are positive, but what happens when you obtain results that support the null hypothesis, or do not fit with the current scientific thinking?"**
>
> **"Negative findings are a valuable component of the scientific literature because they force us to critically evaluate and validate our current thinking, and fundamentally move us towards unabridged science."**
>
> **"Papers are less likely to be published and cited if they report negative results."**

A. 5. The World Health Organization has classified non-thermal RF radiation as a Class 2B Carcinogen - the same level as lead and DDT. Exhibit 11. What right does PPL and Pennsylvania officials have to subject 12 million Pennsylvanians to chronic exposure to a Class 2B carcinogen? Why would anyone do that?

A. **6. In the United States an ever increasing number of Federal, state and municipal officials, agencies and professional organizations have concluded that FCC's 1996 thermal Guidelines are obsolete and do not adequately protect the public. Some examples are listed below. To avoid redundancy I refrain from listing more that I have.**

a. United States Department of Interior – **Exhibit 12**

b. United States Environmental Protection Agency – **Exhibit 13**

c. The Amercan Academy of Pediatrics – a 60,000 member organization - **Exhibit 14**

d. American Academy of Environmental Medicine Statement on Wireless Smart Meter Case Studies – **Exhibit 15**

e. American Academy of Environmental Medicine Statement on Electromagnetic and Radiofrequency Fields Effect on Human Health – **Exhibit 16**

f. Maryland's Children's Environmental Health and Protection Advisory Council - **Exhibit 17**

g. California Department of Public Health Issues Warning About Cell Phone Use – **Exhibit 18**

h. The City and County of San Francisco, CA – **Exhibit 19**

i. The City of Pembroke Pines, FL – **Exhibit 20**

j. The City of Jackson Hole, WY – **Exhibit 21**

A **7. Sixteen (16) nations have ruled that the thermal RF radiation levels set by the National Council of Radiation Protection (NCRP), the International Commission on Non-Ionizing Radiation Protection (ICNIRP), and FCC are obsolete, do not adequately protect the public, and are taking actions to mitigate public risk. The countries are:**

France, Belgium, Spain, Israel, Australia, Italy, Switzerland, Germany, Austria, United Kingdom, India, Russia, Canada, Finland, Nambia and Cyprus - **Exhibits 3, 22**

Also taking precautionary measures are the European Environmental Agency, the Parliamentary Assembly of the Council of Europe representing 800 million Europeans, and the Supreme Court of India. **Exhibit 22, Exhibit 3**

A. 8. An International Appeal by 246 Leading Scientists as recently as November 9, 2017 petitioned the United Nations, the United Nations Environmental Program (UNEP), and the World Health Organization to exert strong leadership to implement protective measures against EMF-RF emissions and to educate the public about EMF-RF health risks. Exhibit 23

Clearly, the FCC Guidelines do not constitute "CONSENSUS SCIENCE". Non-thermal RF radiation is indeed an unsettled subject. A common complaint is that FCC and other key organizations like ANSI, IEEE and ICNIRP staff their standards committees with a majority of industry loyalists and exclude independent researchers[4]. How can decades old research using only narrow test criteria of acute, short term thermal effects negate thousands of subsequent and ever increasing numbers of peer-reviewed research studies and findings? I submit it cannot.

A. 9. It's been reported (and known for years) that the FCC has been largely "captured" by telecommunications giants, the very industry it is supposed to regulate. This is documented in the book **"Captured Agency: How the Federal Communications Commission is Dominated by the Industries it Presumably Regulates"**. The author is Norman Alster and it is published by Harvard University Safra Center for Ethics. **Exhibit 24.** Quoting from the book:

a. The communications/Electronic sector spent nearly $800 million lobbying Washington officials in 2013-2014.

[4] Bionitiative 2012, Section One, p.5

b. Verizon, T-Mobile USA, Sprint, Cellular Telecommunication Industry Association (CTIA) spent roughly $45 million lobbying in 2013.

c. Industry donations to key Senate and House lawmakers - $3,626,0 in campaign donations in the six year period ending in 2014.

d. The revolving door that exists between FCC Commissioners and executives of the wireless industry with resulting conflicts of interest:

- Outgoing FCC Commissioner Wheeler was previously head of CTIA
- Former FCC Commissioner Baker is now head of the CTIA
- Former FCC Commissioner Adelstein is now Head of the Wireless
- Infrastructure Association
- Former FCC Chairman Powell now heads National Cable and Telecommunications Association (NCTA)

e. There are a number of instances where scientific research which reports adverse health effects from RF radiation has been suppressed by industry. For example:

1) Dr. Henry Lai, Emiritus Professor of Bioengineering at University of Washington and his colleague Dr. N. P Sing discovered RF radiation caused DNA damage to rats. But their findings were suppressed when industry promptly launched a war-gaming campaign to discredit their research and even asked the President of the University of Washington to fire Dr. Lai. **Exhibit 24, page 27, Exhibit 25**

2) Scientist Jerry Phillips did follow up research and found DNA damage as well. Whereupon his industry funded research was cut off. **Exhibit 24, page 28.**

3) A research scientist named George Carlo who was hand picked by industry also concluded that wireless radiation increased the risk of brain cancer, whereupon his funding was cut off. **Exhibit 24, page 5.**

f. With RF radiation research being largely funded by the military, Federal agencies, [5]and the telecommunications industry, independent scientists and researchers fend for themselves to obtain funding, or conduct research without funding. Papers are less likely to be published if they report "negative results". However, in one of just many surveys 70% of non-industry studies reported harmful effects beyond skin heating, and only a third of industry studies showed harmful effects from non-thermal RF radiation. **Exhibit 26**

Further attesting to the obsolecences of FFC's 1996 Guidelines, Dr. Lai did a meta-analysis of 326 studies and discovered that 56% of those studies identified biological effects. 28% of those studies were industry funded. 67% of non-industry studies found biological effects. **Exhibit 3, page 20.**

g. Stonewalling. In 2013 FCC began a project to update safe RF radiation exposure limits, including completing work begun as far back as 2003[6]. Where are those revisions? If FCC thought its RF thermal radiation Guidelines were safe, why then did FCC undertake the steps to update safe RF radiation exposure limits in the first place

A. **10. HB2200/ACT129 is seriously flawed legislation.**

a. Would Governor Wolf and the General Assembly knowingly enact legislation that puts the health of 12 million Pennsylvanians at risk? I submit they would not had they been informed of the massive evidence linking adverse health effects to non-thermal RF radiation.

b. Wording in the bill as to whether smart meter installations were mandatory or optional was vague and misleading to many . Quoting from HB2200/Act 129:

> **"Electric distribution companies shall furnish smart meter technology as follows:**
>
> **(i) Upon request from a customer that agrees to pay the cost of the**

[5] FCC Bulletin OET 56

[6] https://www.fcc.gov/general/radio-frequency-safety-0

smart meter at the time of the request

(ii) In new building construction

(iii) In accordance with a depreciation schedule not to exceed years"

c. Smart meter proponents provided lawmakers, the President pro tempore, and Speaker with false or confusing statements in discussions leading up to the final vote on HB2200. Here are four examples from the Senate and House Legislative Journals[7]

Senator Boscola to President pro tempore and fellow lawmakers: "We also made sure that smart meters would not be mandated for every single taxpayer."

Senator Fumo to President pro tempore and fellow lawmakers:
"In addition, we did not mandate smart meters, but we made them optional."

Senator Tomlinson to President pro tempore and fellow lawmakers:
"It is not mandated, but it allows for the deployment of smart meters through a depreciation process, through new home construction process, and through the depreciation of years, and for anyone who wants to purchase a smart meter which they feel will help them manage their electric load better."

Representative Freeman to the Speaker:
"Keep in mind that opting in to this program is an optional opportunity for customers , and they would not be able to selectively pick certain customers to be blacked out versus

[7] Senate Legislative Journal Oct 8, 2008, p 2677/2629,2626,
House Legislative Journal Feb, 2008, p. 389

others."

d. Since the General Assembly would not knowingly enact legislation that would endanger public health and since the record is clear that there was confusion in the passage of HB2200, the PUC should err on the side of public safety and adopt the precautionary principle approach as many nations have found necessary to do.

A. **11. The potential for a Pennsylvania health crisis.**

a. Dismissing thousands of scientific studies which attribute adverse health effects from non-thermal RF radiation, ignoring the plea by 246 international EMF scientists for the United Nations to take action **(Exhibit 23)**, and disregarding the fact that non-thermal RF radiation is a Class B carcinogen, has the potential for a health crisis of epic proportions. Ignoring decades of independent research is an unacceptable approach to public health policy.

b. The financial impact on Pennsylvania residents and the state's healthcare system and budget could be devastating. Lawsuits alone against PPL and other utility companies could dwarf the 23.6 billion punitive damage claim against R.J. Reynolds tobacco in 1996[8].

A. **12. There would be minimal financial impact to PPL if individuals with health problems or concerns were permitted to opt out. Federal law does not mandate smart meter installation and other states allow the public to opt-out[9]. In those states some utility companies impose a modest surcharge to cover the expense of manual reading.**

Q. WHAT ARE YOUR REQUESTS?

[8] http://www.nydailynews.com/news/national/reynolds-tobacco-hit-23-6-billion-ruling-lawsuit-article-1.1873481

[9] Florida, Maryland, Michigan, for example

A. **I urge the Pennsylvania Utility Commission to:**

1. Acknowledge the massive and ever increasing amount of peer reviewed scientific research I identified in my Exhibits (over 4,000 studies) and which attribute biological and/or adverse health effects from chronic exposure to non-thermal RF radiation, and acknowledge that a scientific consensus does not exist about the safety of non-thermal RF radiation.

2. Exempt me from having a smart meter installed in my home and allow me instead to keep the traditional analog meter.

3. Adopt the **"Precautionary Principle"** as public policy with regards to smart meters based on the ever growing body of scientific evidence and the precautionary approach many other countries are now taking to protect public safety.

This is a very serious public health matter. Smart meter public health policy should not be based on a single narrow premise such as "the absence of a known mechanism". It should be based on broader criteria including scientifically valid independent research and weighing the potential harm to large numbers of people, especially children and the vulnerable in our population. I submit the PUC has the authority and responsibility to do so under the following:

a. Pennsylvania Statutes Title 66 Pa.C.S.A. Public Utilities §01. Character of serviceand facilities which requires public utilities to provide **safe** service to consumers.

Quoting from the statute[10]

[10] https://law.justia.com/codes/pennsylvania/2010/title-66/chapter-15/1501/

"Every public utility shall furnish and maintain adequate, efficient, safe and reasonable service and facilities, and shall make all such repairs, damages, alterations, substitutions, extensions, and improvements in or to such service and facilities as shall be necessary or proper for the accommodation, convenience, and safety of its patrons, employees, and the public."

b. The Mission Statement of the Pennsylvania Utility Commission requires it to ensure safe utility services are provided to the public and is quoted below:

"Mission Statement: The Pennsylvania Public Utility Commission balances the needs of consumers and utilities; ensures safe and reliable utility service at reasonable rates; protects the public interest; educates consumers to make independent and informed utility choices; furthers economic development; and fosters new technologies and competitive markets in an environmentally sound manner."

PUC's failure to live up to its statutory responsibilities could subject the PUC and Pennsylvania to expensive litigation and liability.

4. Contact the Consumer Protection and Licensure Committee and the House Consumer Affairs Committee and urge them to promptly release smart meter opt-out bills for vote by the General Assembly. Currently the smart meter opt-out bills stalled in Committee are HB 1564, HB 1566, and SB 441.

6. PA PUC be prepared to establish a tracking program and data base to monitor consumer complaints if there appears to be a rapid rise in health complaints AFTER installation of smart meters. Possible adverse health effects reported in the scientific literature include electromagnetic hypesensitivity (EHS), insomnia, restlessness, heart palpitations, headaches, depression, anxiety, lack of concentration, impaired memory, autism, and other abnormalities that health experts may direct. If complaints of health problems rise and are associated with the roll out of smart meters then urge a moratorium of further smart meter installations.

8. **For Pennsylvania Power and Light Utilities Corporation**

1. In view of the scientific studies I provided in my Exhibits request PPL please update your website which states that PPL is not aware of any studies which have found any health risks caused by the use of this type of meter 16in homes or businesses.

Respectfully submitted:

Richard Myers
